font-variant CSS property

The **`font-variant`** CSS shorthand property allows you to set all the font variants for a font.

You can also set the `<font-variant-css2>` values of `font-variant` defined in CSS Level 2.1, (that is, `normal` or `small-caps`), by using the `font` shorthand.

Try it

```
font-variant: normal;
```

```
font-variant: no-common-ligatures proportional-nums;
```

```
font-variant: common-ligatures tabular-nums;
```

```
font-variant: small-caps slashed-zero;
```

```
<section id="default-example">
  <div id="example-element">
    <p>Difficult waffles</p>
    <table>
      <tbody>
        <tr>
          <td><span class="tabular">0O</span></td>
        </tr>
        <tr>
          <td><span class="tabular">3.14</span></td>
        </tr>
        <tr>
          <td><span class="tabular">2.71</span></td>
        </tr>
      </tbody>
    </table>
  </div>
</section>
```

```
@font-face {
  font-family: "Fira Sans";
  src:
    local("FiraSans-Regular"),
    url("/shared-assets/fonts/FiraSans-Regular.woff2") format("woff2");
  font-weight: normal;
  font-style: normal;
}

section {
  font-family: "Fira Sans", sans-serif;
  margin-top: 10px;
  font-size: 1.5em;
}

#example-element table {
  margin-left: auto;
  margin-right: auto;
}

.tabular {
  border: 1px solid;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `font-variant-alternates`
- `font-variant-caps`
- `font-variant-east-asian`
- `font-variant-emoji`
- `font-variant-ligatures`
- `font-variant-numeric`
- `font-variant-position`

Syntax

```
font-variant: small-caps;
font-variant: common-ligatures small-caps;

/* Global values */
font-variant: inherit;
font-variant: initial;
font-variant: revert;
font-variant: revert-layer;
font-variant: unset;
```

Values

This property is specified as a space-separated list of the following values:

`normal`

Specifies a normal font face. Each longhand property has an initial value of `normal`.

`none`

Sets the value of the `font-variant-ligatures` as `none` and the values of the other longhand properties as `normal`, their initial value.

`<common-lig-values>`, `<discretionary-lig-values>`, `<historical-lig-values>`, `<contextual-alt-values>`

Specifies the keywords related to the `font-variant-ligatures` longhand property. The possible values are `common-ligatures`, `no-common-ligatures`, `discretionary-ligatures`, `no-discretionary-ligatures`, `historical-ligatures`, `no-historical-ligatures`, `contextual`, and `no-contextual`.

`stylistic()`, `historical-forms`, `styleset()`, `character-variant()`, `swash()`, `ornaments()`, `annotation()`

Specifies the keywords and functions related to the `font-variant-ligatures` longhand property.

`small-caps`, `all-small-caps`, `petite-caps`, `all-petite-caps`, `unicase`, `titling-caps`

Specifies the keywords and functions related to the `font-variant-caps` longhand property. The `small-caps` value is the only non-`normal` font variant valid within the `font` shorthand property.

`<numeric-figure-values>`, `<numeric-spacing-values>`, `<numeric-fraction-values>`, `ordinal`, `slashed-zero`

Specifies the keywords related to the `font-variant-numeric` longhand property. The possible values are `lining-nums`, `oldstyle-nums`, `proportional-nums`, `tabular-nums`, `diagonal-fractions`, `stacked-fractions`, `ordinal`, and `slashed-zero`.

`<east-asian-variant-values>`, `<east-asian-width-values>`, `ruby`

Specifies the keywords related to the `font-variant-east-asian` longhand property. The possible values are `jis78`, `jis83`, `jis90`, `jis04`, `simplified`, `traditional`, `full-width`, `proportional-width`, and `ruby`.

`sub`, `super`

Specifies the keywords and functions related to the `font-variant-position` longhand property.

`text`, `emoji`, `unicode`

Specifies the keywords and functions related to the `font-variant-emoji` longhand property.

Formal definition

Initial value	`normal`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
font-variant =
  normal                                                |
  none                                                  |
  [ [ <common-lig-values> || <discretionary-lig-values> || <historical-lig-values> || <contextual-alt-values> ] || [ small-caps | all-small-caps | petite-caps | all-petite-caps | unicase | titling-caps ]
|| [ stylistic( <font-feature-value-name> ) || historical-forms || styleset( <font-feature-value-name># ) || character-variant( <font-feature-value-name># ) || swash( <font-feature-value-name> ) ||
ornaments( <font-feature-value-name> ) || annotation( <font-feature-value-name> ) ] || [ <numeric-figure-values> || <numeric-spacing-values> || <numeric-fraction-values> || ordinal || slashed-zero ] || [
<east-asian-variant-values> || <east-asian-width-values> || ruby ] || [ sub | super ] || [ text | emoji | unicode ] ]

<common-lig-values> =
  common-ligatures     |
  no-common-ligatures

<discretionary-lig-values> =
  discretionary-ligatures     |
  no-discretionary-ligatures

<historical-lig-values> =
  historical-ligatures     |
  no-historical-ligatures

<contextual-alt-values> =
  contextual     |
  no-contextual
```

```
<font-feature-value-name> =
  <ident>

<numeric-figure-values> =
  lining-nums    |
  oldstyle-nums

<numeric-spacing-values> =
  proportional-nums  |
  tabular-nums

<numeric-fraction-values> =
  diagonal-fractions  |
  stacked-fractions

<east-asian-variant-values> =
  jis78       |
  jis83       |
  jis90       |
  jis04       |
  simplified  |
  traditional

<east-asian-width-values> =
  full-width          |
  proportional-width
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting the small-caps font variant

HTML

```
<p class="normal">Firefox rocks!</p>
<p class="small">Firefox rocks!</p>
```

CSS

```
p.normal {
  font-variant: normal;
}
p.small {
  font-variant: small-caps;
}
```

font-variant-alternates CSS property

The **`font-variant-alternates`** CSS property controls the usage of alternate glyphs. These alternate glyphs may be referenced by alternative names defined in `@font-feature-values`.

The `@font-feature-values` at-rule can be used to associate, for a given font face, a human-readable name with a numeric index that controls a particular OpenType font feature. For features that select alternative glyphs (`stylistic`, `styleset`, `character-variant`, `swash`, `ornament` or `annotation`), the `font-variant-alternates` property can then reference the human-readable name in order to apply the associated feature.

This allows CSS rules to enable alternative glyphs without needing to know the specific index values that a particular font uses to control them.

Syntax

```
/* Keyword values */
font-variant-alternates: normal;
font-variant-alternates: historical-forms;

/* Functional notation values */
font-variant-alternates: stylistic(user-defined-ident);
font-variant-alternates: styleset(user-defined-ident);
font-variant-alternates: character-variant(user-defined-ident);
font-variant-alternates: swash(user-defined-ident);
font-variant-alternates: ornaments(user-defined-ident);
font-variant-alternates: annotation(user-defined-ident);
font-variant-alternates: swash(ident1) annotation(ident2);

/* Global values */
font-variant-alternates: inherit;
font-variant-alternates: initial;
font-variant-alternates: revert;
font-variant-alternates: revert-layer;
font-variant-alternates: unset;
```

Values

This property is specified as `normal` or as a space-separated list of the following values:

`normal`

> This keyword deactivates alternate glyphs.

`historical-forms`

> This keyword enables historical forms — glyphs that were common in the past but not today. It corresponds to the OpenType value `hist`.

`stylistic()`

This function enables stylistic alternates for individual characters. The parameter is a font-specific name mapped to a number. It corresponds to the OpenType value `salt`, like `salt 2`.

`styleset()`

This function enables stylistic alternatives for sets of characters. The parameter is a font-specific name mapped to a number. It corresponds to the OpenType value `ssXY`, like `ss02`.

`character-variant()`

This function enables specific stylistic alternatives for characters. It is similar to `styleset()`, but doesn't create coherent glyphs for a set of characters; individual characters will have independent and not necessarily coherent styles. The parameter is a font-specific name mapped to a number. It corresponds to the OpenType value `cvXY`, like `cv02`.

`swash()`

This function enables swash glyphs. The parameter is a font-specific name mapped to a number. It corresponds to the OpenType values `swsh` and `cswh`, like `swsh 2` and `cswh 2`.

`ornaments()`

This function enables ornaments, like fleurons and other dingbat glyphs. The parameter is a font-specific name mapped to a number. It corresponds to the OpenType value `ornm`, like `ornm 2`.

> **Note:** In order to preserve text semantics, font designers should include ornaments that don't match Unicode dingbat characters as ornamental variants of the bullet character (U+2022). Be aware that some existing fonts don't follow this advice.

`annotation()`

This function enables annotations, like circled digits or inverted characters. The parameter is a font-specific name mapped to a number. It corresponds to the OpenType value `nalt`, like `nalt 2`.

Formal definition

Initial value	`normal`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
font-variant-alternates =
  normal                                                |
  [ stylistic( <font-feature-value-name> ) || historical-forms || styleset( <font-feature-value-name># ) || character-variant( <font-feature-value-name># ) || swash( <font-feature-value-name> ) ||
ornaments( <font-feature-value-name> ) || annotation( <font-feature-value-name> ) ]

<font-feature-value-name> =
  <ident>
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Enabling swash glyphs

In this example, we use the `@font-feature-values` at-rule to define a name for the `swash` feature of the MonteCarlo font. The rule maps the name `"fancy"` to the index value `1`.

We can then use that name inside `font-variant-alternates` to switch on swashes for that font. This is the equivalent of a line like `font-feature-settings: "swsh" 1`, except that the CSS applying the feature does not need to include, or even know, the index value needed for this particular font.

HTML

```
<p>A Fancy Swash</p>
<p class="variant">A Fancy Swash</p>
```

CSS

```
@font-face {
  font-family: "MonteCarlo";
  src: url("/shared-assets/fonts/monte-carlo/monte-carlo-regular.woff2");
}

@font-feature-values "MonteCarlo" {
  @swash {
    fancy: 1;
  }
}

p {
  font-family: "MonteCarlo", cursive;
  font-size: 3rem;
  margin: 0.7rem 3rem;
}

.variant {
  font-variant-alternates: swash(fancy);
}
```

font-variant-caps CSS property

The **`font-variant-caps`** CSS property controls the use of alternate glyphs used for small or petite capitals or for titling.

Try it

```
font-variant-caps: normal;
```

```
font-variant-caps: small-caps;
```

```
font-variant-caps: all-small-caps;
```

```
<section id="default-example">
  <div id="example-element">
    <p>Difficult waffles</p>
  </div>
</section>
```

```
@font-face {
  font-family: "Fira Sans";
  src:
    local("FiraSans-Regular"),
    url("/shared-assets/fonts/FiraSans-Regular.woff2") format("woff2");
  font-weight: normal;
  font-style: normal;
}

section {
  font-family: "Fira Sans", sans-serif;
  margin-top: 10px;
  font-size: 1.5em;
}
```

Syntax

```
/* Keyword values */
font-variant-caps: normal;
font-variant-caps: small-caps;
font-variant-caps: all-small-caps;
font-variant-caps: petite-caps;
font-variant-caps: all-petite-caps;
font-variant-caps: unicase;
font-variant-caps: titling-caps;

/* Global values */
font-variant-caps: inherit;
font-variant-caps: initial;
font-variant-caps: revert;
font-variant-caps: revert-layer;
font-variant-caps: unset;
```

Values

This property is specified as one of the following keyword values:

`normal`

Deactivates of the use of alternate glyphs.

`small-caps`

Enables display of small capitals (OpenType feature: `smcp`). Small-caps glyphs typically use the form of uppercase letters but are displayed using the same size as lowercase letters.

`all-small-caps`

Enables display of small capitals for both upper and lowercase letters (OpenType features: `c2sc`, `smcp`).

`petite-caps`

Enables display of petite capitals (OpenType feature: `pcap`).

`all-petite-caps`

Enables display of petite capitals for both upper and lowercase letters (OpenType features: `c2pc`, `pcap`).

`unicase`

Enables display of mixture of small capitals for uppercase letters with normal lowercase letters (OpenType feature: `unic`).

`titling-caps`

Enables display of titling capitals (OpenType feature: `titl`). Uppercase letter glyphs are often designed for use with lowercase letters. When used in all uppercase titling sequences they can appear too strong. Titling capitals are designed specifically for this situation.

Description

The `font-variant-caps` property controls the use of alternate glyphs used for small or petite capitals or for titling.

When a given font includes capital letter glyphs of multiple different sizes, this property selects the most appropriate ones. If petite capital glyphs are not available, they are rendered using small capital glyphs. If these are not present, the browser synthesizes them from the uppercase glyphs.

The value is a single keyword. For each value, if the font doesn't support the OpenType value, then it synthesizes the glyphs. Fonts sometimes include special glyphs for various caseless characters (such as punctuation marks) to better match the capitalized characters around them. However, small capital glyphs are never synthesized for caseless characters.

Language-specific rules

This property accounts for language-specific case mapping rules. For example:

- In Turkic languages, such as Turkish (tr), Azerbaijani (az), Crimean Tatar (crh), Volga Tatar (tt), and Bashkir (ba), there are two kinds of `i` (one with the dot, one without) and two case pairings: `i`/`İ` and `ı`/`I`.
- In German (de), the `ß` may become `ẞ` (U+1E9E) in uppercase.

- In Greek (el), vowels lose their accent when the whole word is in uppercase (ά/Α), except for the disjunctive eta (ή/Η). Also, diphthongs with an accent on the first vowel lose the accent and gain a diacritic on the second vowel (άι/Αΐ).

Accessibility

Large sections of text set with a `font-variant` value of `all-small-caps` or `all-petite-caps` may be difficult for people with cognitive concerns such as Dyslexia to read.

- MDN Understanding WCAG, Guideline 1.4 explanations
- W3C Understanding WCAG 2.2

Formal definition

Initial value	`normal`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
font-variant-caps =
  normal           |
  small-caps       |
  all-small-caps   |
  petite-caps      |
  all-petite-caps  |
  unicase          |
  titling-caps
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting the small-caps font variant

HTML

```
<p class="small-caps">Firefox rocks, small caps!</p>
<p class="normal">Firefox rocks, normal caps!</p>
```

CSS

```
.small-caps {
  font-variant-caps: small-caps;
  font-style: italic;
}
.normal {
  font-variant-caps: normal;
  font-style: italic;
}
```

Result

font-variant-east-asian CSS property

The **`font-variant-east-asian`** CSS property controls the use of alternate glyphs for East Asian scripts, like Japanese and Chinese.

Try it

```
font-variant-east-asian: normal;
```

```
font-variant-east-asian: ruby;
```

```
font-variant-east-asian: jis78;
```

```
font-variant-east-asian: proportional-width;
```

```
<section id="default-example">
  <div id="example-element">
    <p>
      JIS78とJIS83以降では、檜と桧、籠と篭など、一部の文字の入れ替えが行われている。また、「唖然」や「躯体」などの書体が変更されている。
    </p>
  </div>
</section>
```

```
section {
  font-family:
    "YuGothic Medium", "YuGothic", "Yu Gothic Medium", "Yu Gothic", sans-serif;
  margin-top: 10px;
  font-size: 1.5em;
}
```

Syntax

```
font-variant-east-asian: normal;
font-variant-east-asian: ruby;
font-variant-east-asian: jis78; /* <east-asian-variant-values> */
font-variant-east-asian: jis83; /* <east-asian-variant-values> */
font-variant-east-asian: jis90; /* <east-asian-variant-values> */
font-variant-east-asian: jis04; /* <east-asian-variant-values> */
font-variant-east-asian: simplified; /* <east-asian-variant-values> */
font-variant-east-asian: traditional; /* <east-asian-variant-values> */
font-variant-east-asian: full-width; /* <east-asian-width-values> */
font-variant-east-asian: proportional-width; /* <east-asian-width-values> */
font-variant-east-asian: ruby full-width jis83;

/* Global values */
font-variant-east-asian: inherit;
font-variant-east-asian: initial;
font-variant-east-asian: revert;
font-variant-east-asian: revert-layer;
font-variant-east-asian: unset;
```

Values

This property is specified either as `normal` or `ruby` or as a space-separated list of the following values:

`normal`

> This keyword leads to the deactivation of the use of such alternate glyphs.

`ruby`

> This keyword forces the use of special glyphs for ruby characters. As these are usually smaller, font creators often designs specific forms, usually slightly bolder to improve the contrast. This keyword corresponds to the OpenType values `ruby`.

`<east-asian-variant-values>`

> These values specify a set of logographic glyph variants which should be used for display. Possible values are:

Keyword	Standard defining the glyphs	OpenType equivalent
`jis78`	JIS X 0208:1978	`jp78`
`jis83`	JIS X 0208:1983	`jp83`
`jis90`	JIS X 0208:1990	`jp90`
`jis04`	JIS X 0213:2004	`jp04`
`simplified`	None, use the simplified Chinese glyphs	`smpl`
`traditional`	None, use the traditional Chinese glyphs	`trad`

`<east-asian-width-values>`

> These values control the sizing of figures used for East Asian characters. Two values are possible:
>
> - `proportional-width` activating the set of East Asian characters which vary in width. It corresponds to the OpenType values `pwid`.
> - `full-width` activating the set of East Asian characters which are all of the same, roughly square, width metric. It corresponds to the OpenType values `fwid`.

Formal definition

Initial value	`normal`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
font-variant-east-asian =
  normal                                          |
  [ <east-asian-variant-values> || <east-asian-width-values> || ruby ]

<east-asian-variant-values> =
  jis78       |
  jis83       |
  jis90       |
  jis04       |
  simplified  |
  traditional

<east-asian-width-values> =
  full-width          |
  proportional-width
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting East Asian glyph variants

This example require font "Yu Gothic" installed in your OS, other fonts may not support OpenType features.

HTML

```
<table>
  <thead></thead>
  <tbody>
    <tr>
      <th>normal/jis78:</th>
      <td>麹町</td>
```

```
      <td class="jis78">麹町</td>
    </tr>
    <tr>
      <th>normal/ruby:</th>
      <td>しんかんせん</td>
      <td class="ruby">しんかんせん</td>
    </tr>
    <tr>
      <th>normal/traditional:</th>
      <td>大学</td>
      <td class="traditional">大学</td>
    </tr>
  </tbody>
</table>
```

CSS

```
tbody {
  border: 0;
}

td {
  font-family: "Yu Gothic", fantasy;
  font-size: 20px;
}
th {
  color: grey;
  padding-right: 10px;
}

.ruby {
  font-variant-east-asian: ruby;
}

.jis78 {
  font-variant-east-asian: jis78;
}

.traditional {
  font-variant-east-asian: traditional;
}
```

Result

- font-variant-ligatures
- font-variant-numeric
- font-variant-position

font-variant-emoji CSS property

The **font-variant-emoji** CSS property specifies the default presentation style for displaying emojis.

Traditionally, this was done by appending a *Variation Selector*, U+FE0E for text and U+FE0F for emoji, to the emoji code point. Only emojis listed as contributing to a Unicode emoji presentation sequence are affected by this property.

Syntax

```
/* Keyword values */
font-variant-emoji: normal;
font-variant-emoji: text;
font-variant-emoji: emoji;
font-variant-emoji: unicode;

/* Global values */
font-variant-emoji: inherit;
font-variant-emoji: initial;
font-variant-emoji: revert;
font-variant-emoji: revert-layer;
font-variant-emoji: unset;
```

Values

This property is specified as one of the following keyword values:

normal

Allows a browser to choose how to display the emoji. This often follows the operating system setting.

text

Renders the emoji as if it were using the unicode text variation selector (U+FE0E).

emoji

Renders the emoji as if it were using the unicode emoji variation selector (U+FE0F).

unicode

Renders the emoji in accordance with the Emoji presentation properties. If the U+FE0E or U+FE0F variation selector is present, then it will override this value setting.

Formal definition

Initial value	normal

Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
font-variant-emoji =
  normal   |
  text     |
  emoji    |
  unicode
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Accessibility

While the use of emojis may seem fun, you should consider their impact on accessibility, specifically for users with visual and cognitive impairments. Consider the following factors while using emojis:

- Display on screen-readers: Screen-readers will read out the alt text of an emoji. Keep this in mind to consider the position of an emoji in the content. Repeated and overuse of emojis will have a detrimental effect on screen-reader users. It is better to use emojis than emoticons; emoticons will be read out as punctuation characters.
- Contrast with background: When using emojis, consider their colors and how that will work with the background color, especially if you have background colors that can change, such as light/dark modes.
- Intent of use: Do not use emojis to replace words because your understanding of the emoji meaning may differ from that of the users'. Also consider that emojis might have different meanings in different cultures and geographies. Our recommendation is to preferably limit usage to commonly known emojis.

Examples

Changing the way an emoji is displayed

This example shows how you can render an emoji in its `text` or `emoji` presentation.

HTML

```
<p class="no-support">
  Your Browser does not support <code>font-variant-emoji</code>. This image
  shows how it is rendered with support.
</p>
<img
  class="no-support"
  src="./font-variant-emoji-example.jpg"
  alt="a telephone emoji show as text, black and white next to a telephone emoji shown as emoji full color and graphical representation" />
```

```

font-variant-ligatures CSS property

The **`font-variant-ligatures`** CSS property controls which ligatures and contextual forms are used in the textual content of the elements it applies to. This leads to more harmonized forms in the resulting text.

Try it

```
font-variant-ligatures: normal;
```

```
font-variant-ligatures: no-common-ligatures;
```

```
font-variant-ligatures: common-ligatures;
```

```
<section id="default-example">
  <div id="example-element">
    <p>Difficult waffles</p>
  </div>
</section>
```

```
@font-face {
  font-family: "Fira Sans";
  src:
    local("FiraSans-Regular"),
    url("/shared-assets/fonts/FiraSans-Regular.woff2") format("woff2");
  font-weight: normal;
  font-style: normal;
}

section {
  font-family: "Fira Sans", sans-serif;
  margin-top: 10px;
  font-size: 1.5em;
}
```

Syntax

```
/* Keyword values */
font-variant-ligatures: normal;
font-variant-ligatures: none;
font-variant-ligatures: common-ligatures; /* <common-lig-values> */
font-variant-ligatures: no-common-ligatures; /* <common-lig-values> */
font-variant-ligatures: discretionary-ligatures; /* <discretionary-lig-values> */
font-variant-ligatures: no-discretionary-ligatures; /* <discretionary-lig-values> */
font-variant-ligatures: historical-ligatures; /* <historical-lig-values> */
font-variant-ligatures: no-historical-ligatures; /* <historical-lig-values> */
font-variant-ligatures: contextual; /* <contextual-alt-values> */
font-variant-ligatures: no-contextual; /* <contextual-alt-values> */

/* Two keyword values */
font-variant-ligatures: no-contextual common-ligatures;

/* Four keyword values */
font-variant-ligatures: common-ligatures no-discretionary-ligatures
  historical-ligatures contextual;

/* Global values */
font-variant-ligatures: inherit;
font-variant-ligatures: initial;
font-variant-ligatures: revert;
font-variant-ligatures: revert-layer;
font-variant-ligatures: unset;
```

Values

This property is specified as a single keyword or as a space-separated list of the following values:

`normal`

This keyword activates the usual ligatures and contextual forms needed for correct rendering. The ligatures and forms activated depend on the font, language, and kind of script. This is the default value.

`none`

This keyword specifies that all ligatures and contextual forms are disabled, even common ones.

`<common-lig-values>`

These values control the most common ligatures, like for `fi`, `ffi`, `th`, or similar. They correspond to the OpenType values `liga` and `clig`. Two values are possible:

- `common-ligatures` activating these ligatures. Note that the keyword `normal` activates these ligatures.
- `no-common-ligatures` deactivating these ligatures.

`<discretionary-lig-values>`

These values control specific ligatures, specific to the font and defined by the type designer. They correspond to the OpenType values `dlig`. Two values are possible:

- `discretionary-ligatures` activating these ligatures.
- `no-discretionary-ligatures` deactivating the ligatures. Note that the keyword `normal` usually deactivates these ligatures.

`<historical-lig-values>`

These values control the ligatures used historically, in old books, like the German tz digraph being displayed as ʧ. They correspond to the OpenType values `hlig`. Two values are possible:

- `historical-ligatures` activating these ligatures.
- `no-historical-ligatures` deactivating the ligatures. Note that the keyword `normal` usually deactivates these ligatures.

`<contextual-alt-values>`

These values control whether letters adapt to their context—that is, whether they adapt to the surrounding letters. These values correspond to the OpenType values `calt`. Two values are possible:

- `contextual` specifies that the contextual alternates are to be used. Note that the keyword `normal` usually activates these ligatures too.

- `no-contextual` prevents their use.

Formal definition

Initial value	`normal`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
font-variant-ligatures =
  normal                                          |
  none                                            |
  [ <common-lig-values> || <discretionary-lig-values> || <historical-lig-values> || <contextual-alt-values> ]

<common-lig-values> =
  common-ligatures     |
  no-common-ligatures

<discretionary-lig-values> =
  discretionary-ligatures     |
  no-discretionary-ligatures

<historical-lig-values> =
  historical-ligatures     |
  no-historical-ligatures

<contextual-alt-values> =
  contextual     |
  no-contextual
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting font ligatures and contextual forms

HTML

```
<link href="//fonts.googleapis.com/css?family=Lora" rel="stylesheet" />
<p class="normal">
  normal<br />
  if fi ff tf ft jf fj
</p>
<p class="none">
  none<br />
  if fi ff tf ft jf fj
</p>
<p class="common-ligatures">
  common-ligatures<br />
  if fi ff tf ft jf fj
</p>
<p class="no-common-ligatures">
  no-common-ligatures<br />
  if fi ff tf ft jf fj
</p>
<p class="discretionary-ligatures">
  discretionary-ligatures<br />
  if fi ff tf ft jf fj
</p>
<p class="no-discretionary-ligatures">
  no-discretionary-ligatures<br />
  if fi ff tf ft jf fj
</p>
<p class="historical-ligatures">
  historical-ligatures<br />
  if fi ff tf ft jf fj
</p>
<p class="no-historical-ligatures">
  no-historical-ligatures<br />
  if fi ff tf ft jf fj
</p>
<p class="contextual">
  contextual<br />
  if fi ff tf ft jf fj
</p>
<p class="no-contextual">
  no-contextual<br />
  if fi ff tf ft jf fj
</p>
```

CSS

```
p {
  font-family: "Lora", serif;
}
.normal {
  font-variant-ligatures: normal;
}

.none {
  font-variant-ligatures: none;
}

.common-ligatures {
  font-variant-ligatures: common-ligatures;
}
```

```
.no-common-ligatures {
  font-variant-ligatures: no-common-ligatures;
}

.discretionary-ligatures {
  font-variant-ligatures: discretionary-ligatures;
}

.no-discretionary-ligatures {
  font-variant-ligatures: no-discretionary-ligatures;
}

.historical-ligatures {
  font-variant-ligatures: historical-ligatures;
}

.no-historical-ligatures {
  font-variant-ligatures: no-historical-ligatures;
}

.contextual {
  font-variant-ligatures: contextual;
}

.no-contextual {
  font-variant-ligatures: no-contextual;
}
```

font-variant-numeric CSS property

The **font-variant-numeric** CSS property controls the usage of alternate glyphs for numbers, fractions, and ordinal markers.

Try it

```
font-variant-numeric: normal;
```

```
font-variant-numeric: ordinal;
```

```
font-variant-numeric: slashed-zero;
```

```
font-variant-numeric: tabular-nums;
```

```
font-variant-numeric: oldstyle-nums;
```

```
font-variant-numeric: lining-nums;
```

```
font-variant-numeric: proportional-nums;
```

```
font-variant-numeric: diagonal-fractions;
```

```
<section id="default-example">
  <div id="example-element">
    <table>
      <tbody>
        <tr>
          <td><span class="tabular">0</span></td>
        </tr>
        <tr>
          <td><span class="tabular">3.54</span></td>
        </tr>
        <tr>
          <td><span class="tabular">1.71</span></td>
        </tr>
        <tr>
          <td><span class="tabular">1st</span></td>
        </tr>
        <tr>
          <td><span class="tabular">3/4</span></td>
        </tr>
      </tbody>
    </table>
  </div>
</section>
```

```
@font-face {
  font-family: "Source Sans Pro";
  src:
    local("SourceSansPro-Regular"),
    url("/shared-assets/fonts/SourceSansPro-Regular.otf") format("opentype");
  font-weight: normal;
  font-style: normal;
}

section {
  font-family: "Source Sans Pro", sans-serif;
```

```
  margin-top: 10px;
  font-size: 1.5em;
}

#example-element table {
  margin-left: auto;
  margin-right: auto;
}

.tabular {
  border: 1px solid;
}
```

Syntax

```
font-variant-numeric: normal;
font-variant-numeric: ordinal;
font-variant-numeric: slashed-zero;
font-variant-numeric: lining-nums; /* <numeric-figure-values> */
font-variant-numeric: oldstyle-nums; /* <numeric-figure-values> */
font-variant-numeric: proportional-nums; /* <numeric-spacing-values> */
font-variant-numeric: tabular-nums; /* <numeric-spacing-values> */
font-variant-numeric: diagonal-fractions; /* <numeric-fraction-values> */
font-variant-numeric: stacked-fractions; /* <numeric-fraction-values> */
font-variant-numeric: oldstyle-nums stacked-fractions;

/* Global values */
font-variant-numeric: inherit;
font-variant-numeric: initial;
font-variant-numeric: revert;
font-variant-numeric: revert-layer;
font-variant-numeric: unset;
```

Values

This property is specified either as `normal` or a space-separated list of the following values:

`normal`

This keyword leads to the deactivation of the use of such alternate glyphs.

`ordinal`

This keyword forces the use of special glyphs for the ordinal markers, like 1st, 2nd, 3rd, 4th in English or a 1a in Italian. It corresponds to the OpenType values `ordn`.

`slashed-zero`

This keyword forces the use of a 0 with a slash; this is useful when a clear distinction between O and 0 is needed. It corresponds to the OpenType values `zero`.

`<numeric-figure-values>`

These values control the figures used for numbers. Two values are possible:

- `lining-nums` activating the set of figures where numbers are all lying on the baseline. It corresponds to the OpenType values `lnum`.
- `oldstyle-nums` activating the set of figures where some numbers, like 3, 4, 7, 9 have descenders. It corresponds to the OpenType values `onum`.

`<numeric-spacing-values>`

These values controls the sizing of figures used for numbers. Two values are possible:

- `proportional-nums` activating the set of figures where numbers are not all of the same size. It corresponds to the OpenType values `pnum`.
- `tabular-nums` activating the set of figures where numbers are all of the same size, allowing them to be easily aligned like in tables. It corresponds to the OpenType values `tnum`.

`<numeric-fraction-values>`

These values controls the glyphs used to display fractions. Two values are possible:

- `diagonal-fractions` activating the set of figures where the numerator and denominator are made smaller and separated by a slash. It corresponds to the OpenType values `frac`.
- `stacked-fractions` activating the set of figures where the numerator and denominator are made smaller, stacked and separated by a horizontal line. It corresponds to the OpenType values `afrc`.

Formal definition

Initial value	`normal`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
font-variant-numeric =
  normal                                          |
  [ <numeric-figure-values> || <numeric-spacing-values> || <numeric-fraction-values> || ordinal || slashed-zero ]

<numeric-figure-values> =
  lining-nums    |
  oldstyle-nums

<numeric-spacing-values> =
  proportional-nums  |
  tabular-nums

<numeric-fraction-values> =
  diagonal-fractions  |
  stacked-fractions
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting ordinal numeric forms

Click "Play" in the code blocks below to edit the example in the MDN Playground:

```
<p class="ordinal">1st, 2nd, 3rd, 4th, 5th</p>
```

```
@font-face {
  font-family: "Source Sans Pro";
  src: url("https://mdn.github.io/shared-assets/fonts/SourceSansPro-Regular.otf")
    format("opentype");
  font-weight: normal;
  font-style: normal;
}

.ordinal {
  font-family: "Source Sans Pro", sans-serif;
  font-size: 2rem;
  font-variant-numeric: ordinal;
}
```

- font-variant-caps
- font-variant-east-asian
- font-variant-emoji
- font-variant-ligatures
- font-variant-position

font-variant-position CSS property

The **font-variant-position** CSS property controls the use of alternate, smaller glyphs that are positioned as superscript or subscript.

The glyphs are positioned relative to the baseline of the font, which remains unchanged. These glyphs are typically used in <sub> and <sup> elements.

When the usage of these alternate glyphs is activated, if one character in the run doesn't have such a typographically-enhanced glyph, the whole set of characters of the run is rendered using a fallback method, synthesizing these glyphs.

These alternate glyphs share the same em-box and the same baseline as the rest of the font. They are merely graphically enhanced, and have no effect on the line-height and other box characteristics.

Syntax

```
/* Keyword values */
font-variant-position: normal;
font-variant-position: sub;
font-variant-position: super;

/* Global values */
font-variant-position: inherit;
font-variant-position: initial;
font-variant-position: revert;
font-variant-position: revert-layer;
font-variant-position: unset;
```

Values

This property is specified as one of the following keyword values:

`normal`

Deactivates alternate superscript and subscript glyphs.

`sub`

Activates subscript alternate glyphs. If, in a given run, one such glyph is not available for a character, all the characters in the run are rendered using synthesized glyphs.

`super`

Activates superscript alternate glyphs. If, in a given run, one such glyph is not available for a character, all the characters in the run are rendered using synthesized glyphs.

Formal definition

Initial value	`normal`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
font-variant-position =
  normal  |
  sub     |
  super
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting superscript and subscript forms

HTML

```
<p class="normal">Normal!</p>
<p class="super">Super!</p>
<p class="sub">Sub!</p>
```

CSS

```
p {
  display: inline;
}

.normal {
  font-variant-position: normal;
}

.super {
  font-variant-position: super;
}

.sub {
  font-variant-position: sub;
}
```

- font-variant-numeric

font-variation-settings CSS property

The **font-variation-settings** CSS property provides low-level control over variable font characteristics by letting you specify the four letter axis names of the characteristics you want to vary along with their values.

Try it

```
font-variation-settings: "wght" 50;
```

```
font-variation-settings: "wght" 850;
```

```
font-variation-settings: "wdth" 25;
```

```
font-variation-settings: "wdth" 75;
```

```
<section id="default-example">
  <p id="example-element">
    ...it would not be wonderful to meet a Megalosaurus, forty feet long or so,
    waddling like an elephantine lizard up Holborn Hill.
  </p>
</section>
```

```
@font-face {
  src: url("/shared-assets/fonts/variable-fonts/AmstelvarAlpha-VF.woff2");
  font-family: "Amstelvar";
  font-style: normal;
}

p {
  font-size: 1.5rem;
  font-family: "Amstelvar", serif;
}
```

Syntax

```
/* Use the default settings */
font-variation-settings: normal;

/* Set values for variable font axis names */
font-variation-settings: "xhgt" 0.7;

/* Global values */
font-variation-settings: inherit;
font-variation-settings: initial;
font-variation-settings: revert;
font-variation-settings: revert-layer;
font-variation-settings: unset;
```

Values

This property is specified as `normal` or a comma-separated list of string-number value pairs:

`normal`

Text is laid out using default settings.

`<string> <number>`

When rendering text, the list of variable font axis names is passed to the text layout engine to enable or disable font features. Each setting is always one or more pairs consisting of a `<string>` of 4 ASCII characters followed by a `<number>` indicating the axis value to set. If the `<string>` has more or fewer characters or contains characters outside the U+20 - U+7E code point range, the whole property is invalid. The `<number>` can be fractional or negative, depending on the value range available in your font, as defined by the font designer.

Description

This property is a low-level mechanism designed to set variable font features where no other way to enable or access those features exist. You should only use it when no basic properties exist to set those features (e.g., `font-weight`, `font-style`).

Font characteristics set using `font-variation-settings` will always override those set using the corresponding basic font properties, e.g., `font-weight`, no matter where they appear in the cascade. In some browsers, this is currently only true when the `@font-face` declaration includes a `font-weight` range.

Registered and custom axes

Variable font axes come in two types: **registered** and **custom**.

Registered axes are the most commonly encountered — common enough that the authors of the specification felt they were worth standardizing. Note that this doesn't mean that the author has to include all of these in their font.

Here are the registered axes along with their corresponding CSS properties:

Axis Tag	CSS Property
"wght"	`font-weight`
"wdth"	`font-stretch`
"slnt" (slant)	`font-style`: `oblique + angle`
"ital"	`font-style`: `italic`
"opsz"	`font-optical-sizing`

Custom axes can be anything the font designer wants to vary in their font, for example ascender or descender heights, the size of serifs, or anything else they can imagine. Any axis can be used as long as it is given a unique 4-character axis. Some will end up becoming more common, and may even become registered over time.

> **Note:** Registered axis tags are identified using lower-case tags, whereas custom axes should be given upper-case tags. Note that font designers aren't forced to follow this practice in any way, and some won't. The important takeaway here is that axis tags are case-sensitive.

To use variable fonts on your operating system, you need to make sure that it is up to date. For example Linux OSes need the latest Linux FreeType version, and macOS before 10.13 does not support variable fonts. If your operating system is not up to date, you will not be able to use variable fonts in web pages or the Firefox Developer Tools.

Formal definition

Initial value	`normal`
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	a transform

Formal syntax

```
font-variation-settings =
  normal                        |
  [ <opentype-tag> <number> ]#

<opentype-tag> =
  <string>
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

You can find a number of other variable font examples in our Variable fonts guide.

Controlling variable font weight (wght)

Click "Play" in the code blocks below to edit the example in the MDN Playground. Edit the CSS to play with different font weight values. See what happens when you specify a value outside the weight range.

```
<div>
  <p class="p1">Weight</p>
  <span>(font-weight: 625)</span>
</div>
<div>
  <p class="p2">Weight</p>
  <span>(font-variation-settings: "wght" 625)</span>
</div>
<div class="adjustable">
  <p class="p3">Weight</p>
  (font-variation-settings: "wght" <span id="angle-text">625</span>)<br />
  <label for="text-axis">Adjust Weight: </label>
  <input
    type="range"
    id="text-axis"
    name="text-axis"
    min="300"
    max="900"
    value="625" />
</div>
```

```
@font-face {
  font-family: "Amstelvar VF";
  src: url("https://mdn.github.io/shared-assets/fonts/variable-fonts/AmstelvarAlpha-VF.woff2")
    format("woff2-variations");
  font-weight: 300 900;
  font-stretch: 35% 100%;
  font-style: normal;
```

```
  font-display: swap;
}

p {
  font:
    1.2em "Amstelvar VF",
    "Georgia",
    serif;
  font-size: 4rem;
  margin: 1rem;
  display: inline-block;
}

.adjustable {
  border: 1px dashed;
  --text-axis: 625;
}
```

```
/* weight range is 300 to 900 */
.p1 {
  font-weight: 625;
}

/* weight range is 300 to 900 */
.p2 {
  font-variation-settings: "wght" 625;
}

/* Adjust with slider & custom property */
.p3 {
  font-variation-settings: "wght" var(--text-axis);
}
```

```
const angle = document.querySelector("#text-axis");
const text = document.querySelector("#angle-text");
const adjustable = document.querySelector(".adjustable");

angle.addEventListener("input", (e) => {
  const angle = e.target.value;
  text.innerText = angle;
  adjustable.style.setProperty("--text-axis", angle);
});
```

Controlling variable font slant (slnt)

Click "Play" in the code blocks below to edit the example in the MDN Playground. Edit the CSS to play with different font slant/oblique values.

```
<div>
  <p class="p1">Slant</p>
  <span>(font-style: oblique 14deg)</span>
</div>
<div>
  <p class="p2">Slant</p>
  <span>(font-variation-settings: 'slnt' 12)</span>
</div>
<div class="adjustable">
  <p class="p3">Slant</p>
  (font-variation-settings: 'slnt' <span id="angle-text">5</span>)<br />
  <label for="text-axis">Adjust Weight: </label>
  <input
    type="range"
    id="text-axis"
    name="text-axis"
    min="0"
    max="12"
    value="5" />
</div>
```

```
@font-face {
  font-family: "Roboto VF";
  src: url("https://mdn.github.io/shared-assets/fonts/variable-fonts/Roboto-VF.woff2")
    format("woff2-variations");
  font-weight: 100 900;
  font-stretch: 75% 100%;
  font-style: oblique 0deg 12deg;
  font-display: swap;
}

p {
  font:
    1.2em "Roboto VF",
    "Helvetica",
    sans-serif;
  font-size: 4rem;
  margin: 1rem;
  display: inline-block;
}

.adjustable {
  border: 1px dashed;
  --text-axis: 5;
}
```

```
/* slant range is from 0deg to 12deg */
.p1 {
  font-style: oblique 14deg;
}

/* slant range is from 0 to 12 */
.p2 {
  font-variation-settings: "slnt" 12;
```

```
}

/* Adjust with slider & custom property */
.p3 {
  font-variation-settings: "slnt" var(--text-axis);
}
```

```
const angle = document.querySelector("#text-axis");
const text = document.querySelector("#angle-text");
const adjustable = document.querySelector(".adjustable");

angle.addEventListener("input", (e) => {
  const angle = e.target.value;
  text.innerText = angle;
  adjustable.style.setProperty("--text-axis", angle);
});
```

- Variable fonts on v-fonts.com

font-weight CSS property

The **`font-weight`** CSS property sets the weight (or boldness) of the font. The weights available depend on the `font-family` that is currently set.

Try it

```
font-weight: normal;
```

```
font-weight: bold;
```

```
font-weight: lighter;
```

```
font-weight: bolder;
```

```
font-weight: 100;
```

```
font-weight: 900;
```

```
<section id="default-example">
  <p id="example-element">
    London. Michaelmas term lately over, and the Lord Chancellor sitting in
    Lincoln's Inn Hall. Implacable November weather. As much mud in the streets
    as if the waters had but newly retired from the face of the earth, and it
    would not be wonderful to meet a Megalosaurus, forty feet long or so,
    waddling like an elephantine lizard up Holborn Hill.
  </p>
</section>
```

```
section {
  font-size: 1.2em;
}
```

Syntax

```
/* <font-weight-absolute> keyword values */
font-weight: normal;
font-weight: bold;

/* <font-weight-absolute> numeric values [1,1000] */
font-weight: 100;
font-weight: 200;
font-weight: 300;
font-weight: 400; /* normal */
font-weight: 500;
font-weight: 600;
font-weight: 700; /* bold */
font-weight: 800;
font-weight: 900;

/* Keyword values relative to the parent */
font-weight: lighter;
font-weight: bolder;

/* Global values */
font-weight: inherit;
font-weight: initial;
font-weight: revert;
font-weight: revert-layer;
font-weight: unset;
```

Values

This property is specified as a single value from the following list:

`normal`

Normal font weight. Same as `400`.

`bold`

Bold font weight. Same as `700`.

`<number>`

A `<number>` value between 1 and 1000, both values included. Higher numbers represent weights that are bolder than (or as bold as) lower numbers. This allows fine-grain control for variable fonts. For non-variable fonts, if the exact specified weight is unavailable, a fallback weight algorithm is used — numeric values that are divisible by 100 correspond to common weight names, as described in the Common weight name mapping section below.

`lighter`

One relative font weight lighter than the parent element. Note that only four font weights are considered for relative weight calculation; see the Meaning of relative weights section below.

`bolder`

One relative font weight heavier than the parent element. Note that only four font weights are considered for relative weight calculation; see the Meaning of relative weights section below.

Fallback weights

If the exact weight given is unavailable, then the following rule is used to determine the weight actually rendered:

- If the target weight given is between `400` and `500` inclusive:
  - Look for available weights between the target and `500`, in ascending order.
  - If no match is found, look for available weights less than the target, in descending order.
  - If no match is found, look for available weights greater than `500`, in ascending order.
- If a weight less than `400` is given, look for available weights less than the target, in descending order. If no match is found, look for available weights greater than the target, in ascending order.
- If a weight greater than `500` is given, look for available weights greater than the target, in ascending order. If no match is found, look for available weights less than the target, in descending order.

> **Note:** The fallback weight algorithm is only used for rendering. The computed value of the property is still the specified value.

Meaning of relative weights

When `lighter` or `bolder` is specified, the below chart shows how the absolute font weight of the element is determined.

Note that when using relative weights, only four font weights are considered — thin (100), normal (400), bold (700), and heavy (900). If a font family has more weights available, they are ignored for the purposes of relative weight calculation.

Inherited value	`bolder`	`lighter`
100	400	100
200	400	100
300	400	100
400	700	100
500	700	100
600	900	400
700	900	400
800	900	700
900	900	700

Common weight name mapping

The numerical values `100` to `900` roughly correspond to the following common weight names (see the OpenType specification):

Value	Common weight name
100	Thin (Hairline)
200	Extra Light (Ultra Light)
300	Light
400	Normal (Regular)
500	Medium
600	Semi Bold (Demi Bold)
700	Bold
800	Extra Bold (Ultra Bold)
900	Black (Heavy)
950	Extra Black (Ultra Black)

Variable fonts

While many fonts have a particular weight corresponding to one of the numbers in Common weight name mapping, most variable fonts support a range of weights providing much finer granularity, giving designers and developers more control over the chosen weight.

For TrueType or OpenType variable fonts, the "wght" variation is used to implement varying widths.

This demo loads with `font-weight: 500;` set. Change the value of the `font-weight` property in the `.sample` selector to see the weight of the text change (e.g., 200, 700). Click "Play" in the code blocks below to edit the example in the MDN Playground:

```
<p class="sample">
  ...it would not be wonderful to meet a Megalosaurus, forty feet long or so,
  waddling like an elephantine lizard up Holborn Hill.
</p>
```

```
@font-face {
  src: url("https://mdn.github.io/shared-assets/fonts/variable-fonts/MutatorSans.ttf");
  font-family: "MutatorSans";
  font-style: normal;
  font-weight: 1 1000;
}
```

```
.sample {
  text-transform: uppercase;
  font-weight: 500;
  font-size: 1.5rem;
  font-family: "MutatorSans", sans-serif;
}
```

Accessibility

People experiencing low vision conditions may have difficulty reading text set with a `font-weight` value of `100` (Thin/Hairline) or `200` (Extra Light), especially if the font has a low contrast color ratio.

- MDN Understanding WCAG, Guideline 1.4 explanations
- Understanding Success Criterion 1.4.8 | W3C Understanding WCAG 2.0

Formal definition

Initial value	`normal`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	the keyword or the numerical value as specified, with `bolder` and `lighter` transformed to the real value
Animation type	by computed value type

Formal syntax

```
font-weight =
  <font-weight-absolute>  |
  bolder                  |
  lighter

<font-weight-absolute> =
  normal             |
  bold               |
  <number [1,1000]>
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting font weights

HTML

```
<p>
  Alice was beginning to get very tired of sitting by her sister on the bank,
  and of having nothing to do: once or twice she had peeped into the book her
  sister was reading, but it had no pictures or conversations in it, "and what
  is the use of a book," thought Alice "without pictures or conversations?"
</p>

<div>
  I'm heavy<br />
  <span>I'm lighter</span>
</div>
```

CSS

```
/* Set paragraph text to be bold. */
p {
  font-weight: bold;
}

/* Set div text to two steps heavier than
   normal but less than a standard bold. */
div {
  font-weight: 600;
}

/* Set span text to be one step lighter
   than its parent. */
span {
  font-weight: lighter;
}
```

font-width CSS property

> **Note:** The `font-width` property is the modern replacement for `font-stretch`, which is a legacy alias. While `font-width` is the specification's preferred name, `font-stretch` currently has broader browser support. Check the fallback example and browser compatibility table for details.

The **`font-width`** CSS property selects a normal, condensed, or expanded face from a font.

Try it

```
font-width: condensed;
```

```
font-width: expanded;
```

```
font-width: ultra-expanded;
```

```
font-width: 50%;
```

```
font-width: 100%;
```

```
font-width: 150%;
```

```
<section class="default-example" id="default-example">
  <p class="transition-all" id="example-element">
    London. Michaelmas term lately over, and the Lord Chancellor sitting in
    Lincoln's Inn Hall. Implacable November weather. As much mud in the streets
    as if the waters had but newly retired from the face of the earth, and it
    would not be wonderful to meet a Megalosaurus, forty feet long or so,
    waddling like an elephantine lizard up Holborn Hill.
  </p>
</section>
```

```
@font-face {
  src: url("/shared-assets/fonts/LeagueMono-VF.ttf") format("truetype");
  font-family: "League";
  font-style: normal;
  font-weight: normal;
}

section {
  font-size: 1.2em;
  font-family: "League", sans-serif;
}
```

Syntax

```
/* Keyword values */
font-width: normal;
font-width: ultra-condensed;
font-width: extra-condensed;
font-width: condensed;
font-width: semi-condensed;
font-width: semi-expanded;
font-width: expanded;
font-width: extra-expanded;
font-width: ultra-expanded;

/* Percentage values */
font-width: 50%;
font-width: 100%;
font-width: 200%;

/* Global values */
font-width: inherit;
font-width: initial;
font-width: revert;
font-width: revert-layer;
font-width: unset;
```

Values

This property is specified as a single value from the following list:

`normal`

Specifies a normally condensed font face.

`semi-condensed`, `condensed`, `extra-condensed`, `ultra-condensed`

Specifies a more condensed font face than normal, with `ultra-condensed` being the most condensed.

`semi-expanded`, `expanded`, `extra-expanded`, `ultra-expanded`

Specifies a more expanded font face than normal, with `ultra-expanded` being the most expanded.

`<percentage>`

A `<percentage>` value between 50% and 200% (inclusive). Negative values are not allowed for this property.

Keyword to numeric mapping

The table below shows the mapping between the keyword values and numeric percentages:

Keyword	Percentage
`ultra-condensed`	50%
`extra-condensed`	62.5%
`condensed`	75%
`semi-condensed`	87.5%
`normal`	100%
`semi-expanded`	112.5%
`expanded`	125%
`extra-expanded`	150%
`ultra-expanded`	200%

Description

Some font families offer additional faces in which the characters are narrower than the normal face (*condensed* faces) or wider than the normal face (*expanded* faces).

You can use `font-width` to select a condensed or expanded face from such fonts. If the font you are using does not offer condensed or expanded faces, this property has no effect.

Font face selection

The face selected for a given value of `font-width` depends on the faces supported by the font in question. If the font does not provide a face that exactly matches the given value, then values less than 100% map to a condensed face, and values greater than or equal to 100% map to an expanded face.

The table below demonstrates the effect of setting different percentage values of `font-width` on two different fonts:

```
@font-face {
  font-family: "Inconsolata";
  src: url("https://fonts.gstatic.com/s/inconsolata/v31/QldduNThLqRwH-OJ1UHjlKENVzlm-WkL3GZQmAwPyya15.woff2")
    format("woff2");
}

@font-face {
  font-family: "Anek Malayalam";
  src: url("https://fonts.gstatic.com/s/anekmalayalam/v4/6qLUKZActRTs_mZAJUZWWkhke0nYa-f6__Azq3-gP1W7db9_.woff2")
    format("woff2");
}

body {
  font-family: system-ui;
}

table {
  border-collapse: collapse;
  width: 100%;
}

tbody th {
  text-align: right;
}

th,
td {
  padding: 0.25rem;
  font-weight: normal;
  text-align: center;
}

td {
  border: solid;
  border-width: 1px;
  font-size: 5rem;
}

.inconsolata {
  font-family: "Inconsolata", sans-serif;
}

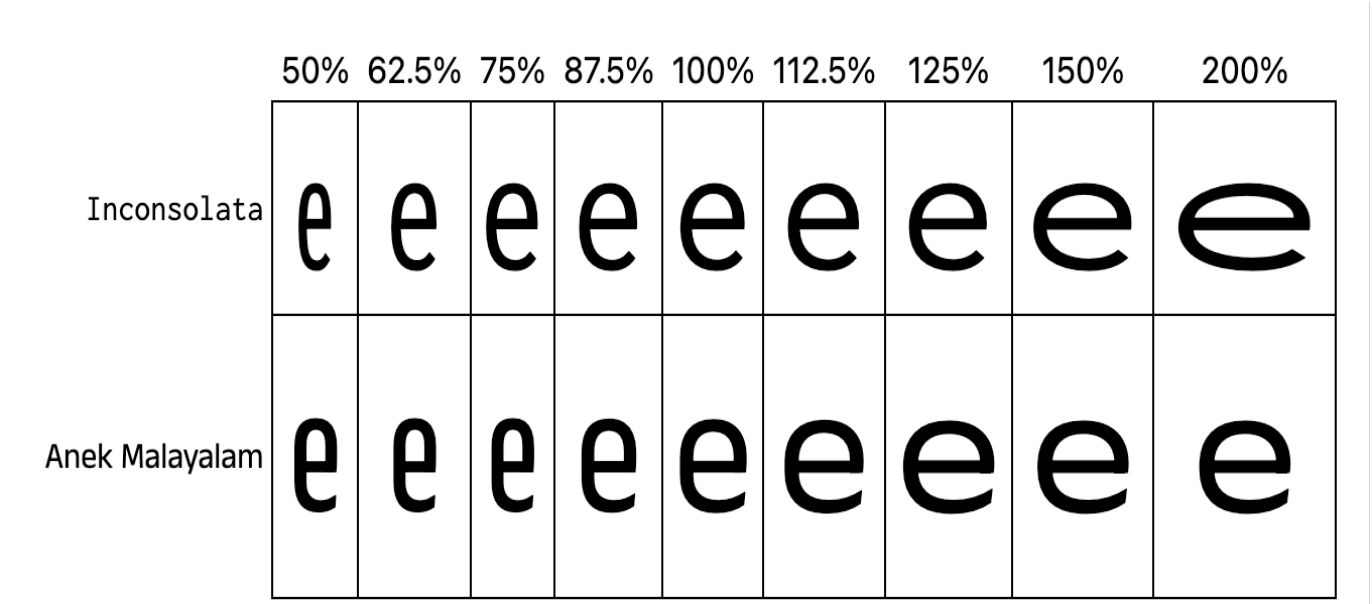
.anek-malayalam {
  font-family: "Anek Malayalam", sans-serif;
}

td:nth-child(2) {
  font-width: 50%;
}
td:nth-child(3) {
  font-width: 62.5%;
}
td:nth-child(4) {
  font-width: 75%;
}
td:nth-child(5) {
  font-width: 87.5%;
}
td:nth-child(6) {
  font-width: 100%;
}
td:nth-child(7) {
  font-width: 112.5%;
}
td:nth-child(8) {
  font-width: 125%;
}
td:nth-child(9) {
  font-width: 150%;
}
td:nth-child(10) {
  font-width: 200%;
}
```

```
<table>
  <thead>
    <tr>
      <th scope="row"></th>
      <th scope="col">50%</th>
      <th scope="col">62.5%</th>
      <th scope="col">75%</th>
      <th scope="col">87.5%</th>
      <th scope="col">100%</th>
      <th scope="col">112.5%</th>
      <th scope="col">125%</th>
      <th scope="col">150%</th>
      <th scope="col">200%</th>
    </tr>
  </thead>
  <tbody>
    <tr class="inconsolata">
      <th scope="row">Inconsolata</th>
      <td>e</td>
```

```
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
    </tr>
    <tr class="anek-malayalam">
      <th scope="row">Anek Malayalam</th>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
    </tr>
  </tbody>
</table>
```

The following screenshot shows how the above table is rendered, in case your browser doesn't support the `font-width` property:



- Inconsolata is a variable font that offers a continuous range of widths from 50% to 200%.
- Anek Malayalam is a variable google font that supports widths from 75% to 125%. Values below and above this range select the closest matching font.

Formal definition

Initial value	`normal`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	percentage
Animation type	by computed value type

Formal syntax

```
font-width =
  normal             |
  <percentage [0,∞]> |
  ultra-condensed    |
  extra-condensed    |
  condensed          |
  semi-condensed     |
  semi-expanded      |
  expanded           |
  extra-expanded     |
  ultra-expanded
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting font width percentages

```
<p class="condensed">an elephantine lizard</p>
<p class="normal">an elephantine lizard</p>
<p class="expanded">an elephantine lizard</p>
```

```
@font-face {
  src: url("/shared-assets/fonts/LeagueMono-VF.ttf") format("truetype");
  font-family: "LeagueMonoVariable";
  font-style: normal;
```

```
}

p {
  font:
    1.5rem "LeagueMonoVariable",
    sans-serif;
}

.condensed {
  font-width: 50%;
}

.normal {
  font-width: 100%;
}

.expanded {
  font-width: 200%;
}
```

Providing a font-stretch fallback

Because `font-width` does not yet have broad browser support, you may want to include the legacy `font-stretch` property as a fallback. Place `font-stretch` before `font-width` so that supporting browsers use the modern property:

```
p {
  font-stretch: condensed; /* for browsers that don't support font-width */
  font-width: condensed;
}
```

> **Note:** You can automate this fallback pattern using the postcss-preset-env plugin for PostCSS, which includes the postcss-font-width-property transform to convert `font-width` properties to `font-stretch` automatically.

- CSS fonts module

forced-color-adjust CSS property

The **`forced-color-adjust`** CSS property allows authors to opt certain elements out of forced colors mode. This then restores the control of those values to CSS.

Syntax

```
forced-color-adjust: auto;
forced-color-adjust: none;
forced-color-adjust: preserve-parent-color;

/* Global values */
forced-color-adjust: inherit;
forced-color-adjust: initial;
forced-color-adjust: revert;
forced-color-adjust: revert-layer;
forced-color-adjust: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

> The element's colors are adjusted by the user agent in forced colors mode. This is the default value.

`none`

> The element's colors are not automatically adjusted by the user agent in forced colors mode.

`preserve-parent-color`

> In forced colors mode, if the `color` property inherits from its parent (i.e., there is no cascaded value or the cascaded value is `currentColor`, `inherit`, or another keyword that inherits from the parent), then it computes to the used color of its parent's `color` property. In all other cases, it behaves the same as `none`.

Usage notes

This property should only be used to makes changes that will support a user's color and contrast requirements. For example, if you become aware that the color optimizations made by the user agent result in a poor experience when in a high contrast or dark mode. Using this property would enable tweaking of the result in that mode to provide a better experience. **It should not be used to prevent user choices being respected**.

Formal definition

Initial value	`auto`
Applies to	all elements and text
Inherited	yes
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
forced-color-adjust =
  auto                  |
  none                  |
  preserve-parent-color
```

This syntax reflects the latest standard as per CSS Color Adjustment Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Preserving colors

In the example below the first box will use the color scheme that the user has set. For example in Windows High Contrast mode black scheme it will have a black background and white text. The second box will preserve the site colors set on the `.box` class.

By using the `forced-colors` media feature, you could add any other optimizations for forced color mode alongside the `forced-color-adjust` property.

CSS

```
.box {
  border: 5px solid grey;
  background-color: #cccccc;
  width: 300px;
  margin: 20px;
  padding: 10px;
}

@media (forced-colors: active) {
  .forced {
    forced-color-adjust: none;
  }
}
```

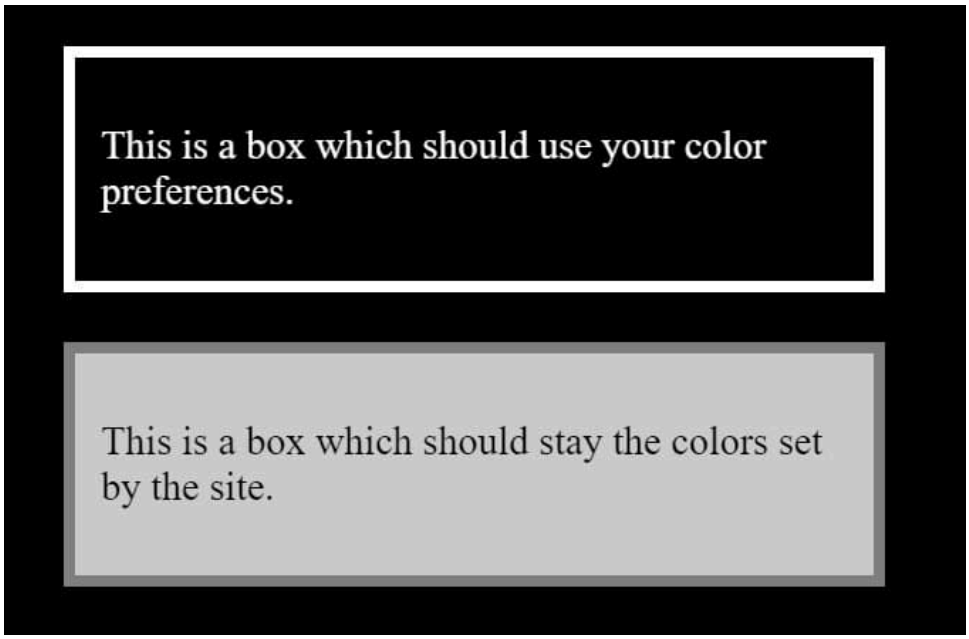
HTML

```
<div class="box">
  <p>This is a box which should use your color preferences.</p>
</div>

<div class="box forced">
  <p>This is a box which should stay the colors set by the site.</p>
</div>
```

Result

The following screenshot shows the image above in Windows High Contrast Mode:



See also

- Styling for Windows high contrast with standards for forced colors.
- `print-color-adjust`

frame-sizing CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`frame-sizing`** CSS property can be used to set an `<iframe>` element's horizontal or vertical size to equal the layout size of its embedded document in the same dimension, but only if the embedded document has opted in to sharing its size information.

Syntax

```
/* Keyword values */
frame-sizing: auto;
frame-sizing: content-width;
frame-sizing: content-height;
```

```
frame-sizing: content-inline-size;
frame-sizing: content-block-size;

/* Global values */
frame-sizing: inherit;
frame-sizing: initial;
frame-sizing: revert;
frame-sizing: revert-layer;
frame-sizing: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

The initial value. The `<iframe>` element's size is not affected by the layout size of its embedded document.

`content-width`

The `<iframe>` element's `width` is set to the layout width of its embedded document.

`content-height`

The `<iframe>` element's `height` is set to the layout height of its embedded document.

`content-inline-size`

The `<iframe>` element's `inline-size` is set to the layout size of its embedded document in the inline direction.

`content-block-size`

The `<iframe>` element's `block-size` is set to the layout size of its embedded document in the block direction.

Description

For security and privacy reasons, `<iframe>` elements do not by default expose any information to the parent document about the size of the content in the document they are embedding.

To enable responsive sizing of `<iframe>` elements based on their content, the `<meta name="responsive-embedded-sizing">` tag can be included in an embedded document to opt it in to sharing its size information with the parent document. The `frame-sizing` property can then be set on the `<iframe>` to cause it to adopt the same horizontal or vertical size as the embedded document's actual content size (termed the **internal layout intrinsic size** in the spec, but abbreviated to "layout size" in our documentation). The document content will then fit seamlessly into the embedding `<iframe>`, avoiding unnecessary scrollbars.

The `frame-sizing` property can take values of `content-width` or `content-height` to cause the `<iframe>` element's `width` or `height` to adopt the embedded document's layout width or layout height, respectively.

There are also logical equivalents available — `frame-sizing` can take values of `content-inline-size` or `content-block-size` to cause the `<iframe>` element's `inline-size` or `block-size` to adopt the embedded document's inline size or block size, respectively. The block or inline direction is determined by the `<iframe>` element's `writing-mode`, not that of the embedded document's content.

To resize the `<iframe>` dynamically as the embedded document changes layout size, you can call the `Window.requestResize()` method from the embedded document to make it report an updated size.

Formal definition

Initial value	`auto`
Applies to	replaced elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
frame-sizing =
  auto                |
  content-width       |
  content-height      |
  content-block-size  |
  content-inline-size
```

This syntax reflects the latest standard as per CSS Box Sizing Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates usage of the `frame-sizing` property.

We have two documents, the main `index.html` document, and the embedded `frame.html` document.

The main `index.html`

The `index.html` document's HTML contains a heading and an `<iframe>`, into which is embedded the `frame.html` document:

```
<h1>Responsive iframes — basic example</h1>

<iframe src="frame.html"></iframe>
```

In the `index.html` CSS, we give the `<iframe>` a `frame-sizing` value of `content-block-size`. Because the `<iframe>` has a horizontal `writing-mode`, its `height` will be set to the embedded document's layout height.

```
iframe {
  frame-sizing: content-block-size;
  border: 2px solid gray;
}
```

The embedded `frame.html`

The `frame.html` document contains a heading and some paragraphs. More significantly, however, it includes the `<meta name="responsive-embedded-sizing" />` tag, which opts it in to sharing its content layout size with the parent document.

```
<head>
  ...
```

```
  <meta name="responsive-embedded-sizing" />

  ...
</head>
<body>
  <h1>This is my frame</h1>
  <p>This is the content of my discontent.</p>
  <p>This is some more content.</p>
</body>
```

Result

Open our basic responsive `<iframe>` sizing demo in a separate tab to see it in action (see the source code).

Even though no explicit `height` has been set on the `<iframe>`, it is sized to the right height to exactly contain its embedded document, with no scroll bars.

- CSS box sizing module
- `<meta name="responsive-embedded-sizing">`
- `Window.requestResize()`

gap CSS property

The **gap** CSS shorthand property sets the gaps (also called gutters) between rows and columns on multi-column, flex, and grid containers.

Try it

```
gap: 0;
```

```
gap: 10%;
```

```
gap: 1em;
```

```
gap: 10px 20px;
```

```
gap: calc(20px + 10%);
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">
      <div>One</div>
      <div>Two</div>
      <div>Three</div>
      <div>Four</div>
      <div>Five</div>
    </div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-template-columns: 1fr 1fr;
  width: 200px;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `row-gap`
- `column-gap`

Syntax

```
/* One value */
gap: normal;
gap: 20px;
gap: 1em;
gap: 3vmin;
gap: 0.5cm;
gap: 16%;
gap: 100%;
gap: thick;
gap: calc(10% + 20px);

/* Two values */
gap: 20px 10px;
gap: 1em 0.5em;
gap: 3vmin 2vmax;
gap: 0.5cm 2mm;
gap: 16% 100%;
gap: 21px 82%;
gap: normal thin;
gap: thin thick;
gap: calc(20px + 10%) calc(10% - 5px);
gap: calc(20px + 10%) medium;

/* Global values */
gap: inherit;
gap: initial;
gap: revert;
```

```
gap: revert-layer;
gap: unset;
```

Values

This property is specified as one or two values from the following list:

`normal`

Sets the gap to `1em` in multi-column layouts and to `0` in all other contexts. This is the default value.

`<line-width>`

Sets the size of the gap using the keywords `thin`, `medium`, or `thick`, or a positive `<length>` value.

`<length-percentage>`

Sets the gap to a non-negative `<length>` or `<percentage>` value.

Description

The `gap` property defines gaps between columns and rows, with the effect of the definition depending on whether the container is a grid container, a flexbox container, or a multi-column layout container. See Defining CSS gaps for more information about gaps by layout type.

The shorthand accepts one or two values. A single value sets both the `row-gap` and the `column-gap`. Two values set `row-gap` first, then `column-gap`. The default value is `normal` for both sub-properties; but if you declare only one value, it applies to both.

Percentage gap values are always calculated against the content box size of the container element. The behavior is well-defined and consistent across layout modes when the container size is definite.

The generated gaps create empty spaces that have the width or height of the gap's specified size, much like an empty item or track. The visible space between elements may differ from the provided `gap` value because margins, padding, and distributed alignment may increase the separation between elements beyond what is determined by `gap`.

Gaps may contain visible separators as gap decorations. If there are decorative rules between the columns, rows, or both, they will appear in the middle of their gap, but have no effect on the gaps' size. These decorative lines can be added to the otherwise "empty space" by using the `rule` shorthand.

In grid layouts

In CSS grid layout, the `gap` property defines the space between rows and columns. If two values are included, the first value defines the gutter between rows, and the second defines the gutter between columns.

Percentage values are calculated against the content box size of the container element. Cyclic percentage sizes resolve against zero for determining intrinsic size contributions but resolve against the grid container's content box when laying out the contents. Two examples below demonstrate percentage gap values with explicit container size and implicit container size in the examples section.

The effect of positive `gap` values is as though the grid lines acquired thickness: the grid track between two grid lines is the space between the gutters that represent them. If a grid item spans multiple rows or columns, for the purpose of track sizing, the gutter is treated as an extra, empty, fixed-size track of the specified size, added to the dimension in the spanning direction. For example, if `gap: 10px` is set on a 3x3 grid of 100px by 100px boxes, if a grid item spans two vertical columns, its width would be `210px`. If it spans all three, it has a width of `320px`.

The space between grid rows and columns may be larger than the value of the `gap` property due to space added between tracks by the `justify-content` and `align-content` properties.

Gutters only appear between tracks of the implicit grid. If a grid is fragmented between tracks, no gutter spacing is added between those tracks. There is no gutter before the first track or after the last track, and if a track is collapsed, it will have no gutter.

Early versions of the CSS grid specification called this property `grid-gap`. To maintain compatibility with legacy websites, browsers accept `grid-gap` as an alias for `gap`.

In flexbox

With flex containers, the `gap` property defines the space between both flex items and flex lines. Whether the first value is the gap between flex items or between flex lines depends on the direction. Flex items are laid out in either rows or columns depending on the value of the `flex-direction` property. For rows (`row` (the default) or `row-reverse`), the first value defines the gap between flex lines, and the second value defines the gap between items within each line. If only one value is included, that value is used for both dimensions.

For columns (`column` or `column-reverse`), the first value defines the gap between flex items within a flex line, and the second value defines the gaps between each flex line. Again, if only one value is included, that value is used for both dimensions.

In multi column layouts

In CSS multi-column layout, the property defines the gutter between columns and rows of columns. The first value defines the gap between adjacent column boxes, while the second value defines the size of the gutter between rows of column boxes, if multiple rows were established by the `column-height` property.

Formal definition

Initial value	as each of the properties of the shorthand: • `row-gap`: `normal` • `column-gap`: `normal`
Applies to	multi-column elements, flex containers, grid containers
Inherited	no
Computed value	as each of the properties of the shorthand: • `row-gap`: as specified, with <length>s made absolute, and normal computing to zero except on multi-column elements • `column-gap`: as specified, with <length>s made absolute, and normal computing to zero except on multi-column elements
Animation type	as each of the properties of the shorthand: • `row-gap`: a length, percentage or calc(); • `column-gap`: a length, percentage or calc();

Formal syntax

```
gap =
  <'row-gap'> <'column-gap'>?

<row-gap> =
  normal                      |
  <length-percentage [0,∞]>   |
  <line-width>

<column-gap> =
  normal                      |
```

```
  <length-percentage [0,∞]>  |
  <line-width>

<length-percentage> =
  <length>      |
  <percentage>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Flex layout

HTML

```
<div id="flexbox">
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
</div>
```

CSS

```
#flexbox {
  display: flex;
  flex-wrap: wrap;
  width: 300px;
  gap: 20px 5px;
}

#flexbox > div {
  border: 1px solid green;
  background-color: lime;
  flex: 1 1 auto;
  width: 100px;
  height: 50px;
}
```

Result

Grid layout

HTML

```
<div id="grid">
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
</div>
```

CSS

```
#grid {
  display: grid;
  height: 200px;
  grid-template: repeat(3, 1fr) / repeat(3, 1fr);
  gap: 20px 5px;
}

#grid > div {
  border: 1px solid green;
  background-color: lime;
}
```

Result

Multi-column layout

HTML

```
<p class="content-box">
  This is some multi-column text with a 40px column gap created with the CSS
  <code>gap</code> property. Don't you think that's fun and exciting? I sure do!
</p>
```

CSS

```
.content-box {
  column-count: 3;
  gap: 40px;
}
```

Result

Percentage gap value and explicit container size

If the container has a fixed size set, then gap percentage value calculations are based on the size of the container. Thus, gap behavior is consistent across all layouts. In the following example, there are two containers, one with a grid layout and the other with a flex layout. The containers have five red 20x20px children. Both containers are explicitly set to 200px high using `height: 200px` and the gap is set with `gap: 12.5% 0`. See Specifying gap values as percentages for more information.

```
<span>Grid</span>
<div id="grid">
  <div>1</div>
  <div>2</div>
  <div>3</div>
  <div>4</div>
  <div>5</div>
</div>
<span>Flex</span>
<div id="flex">
  <div>1</div>
  <div>2</div>
  <div>3</div>
  <div>4</div>
  <div>5</div>
</div>
```

```
body > div {
  background-color: #cccccc;
  width: 200px;
  flex-flow: column;
}
```

```
#grid {
  display: inline-grid;
  height: 200px;
  gap: 12.5% 0;
}

#flex {
  display: inline-flex;
  height: 200px;
  gap: 12.5% 0;
}

#grid > div,
#flex > div {
  background-color: coral;
  width: 20px;
  height: 20px;
}
```

Now inspect the grid and flex elements using Inspector tab in Web Developer Tools. In order to see the actual gaps hover mouse over `<div id="grid">` and `<div id="flex">` tags in the inspector. You will notice that the gap is the same in both cases which is 25px.

Percentage gap value and implicit container size

If size is not explicitly set on the container, then the percentage gap behaves differently in case of grid and flex layouts. In the following example the containers don't have height explicitly set.

```
<span>Grid</span>
<div id="grid">
  <div>1</div>
  <div>2</div>
  <div>3</div>
  <div>4</div>
  <div>5</div>
</div>
<span>Flex</span>
<div id="flex">
  <div>1</div>
  <div>2</div>
  <div>3</div>
  <div>4</div>
  <div>5</div>
</div>
```

```
body > div {
  background-color: #cccccc;
  width: 200px;
}

#grid {
  display: inline-grid;
  gap: 12.5% 0;
}

#flex {
  display: inline-flex;
  gap: 12.5% 0;
  flex-flow: column;
}

#grid > div,
#flex > div {
  background-color: coral;
  width: 20px;
  height: 20px;
}
```

In case of the grid layout, percentage gap doesn't contribute to the actual height of the grid. The container's height is calculated using `0px` gap, so the actual height turns out to be 100px (20px x 5). Then the actual percentage gap is calculated using the content box's height, the gap turns out to be `12.5px` (100px x 12.5%). The gap is applied just before rendering. Thus the grid remains 100px high but it overflows due to the percentage gap added later just before rendering.

In case of the flex layout, the percentage gap always results in zero value.

grid CSS property

The **`grid`** CSS shorthand property sets all of the explicit and implicit grid properties in a single declaration.

Using `grid` you specify one axis using `grid-template-rows` or `grid-template-columns`, you then specify how content should auto-repeat in the other axis using the implicit grid properties: `grid-auto-rows`, `grid-auto-columns`, and `grid-auto-flow`.

Try it

```
grid: auto-flow / 1fr 1fr 1fr;
```

```
grid: auto-flow dense / 40px 40px 1fr;
```

```
grid: repeat(3, 80px) / auto-flow;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">
      <div>One</div>
      <div>Two</div>
      <div>Three</div>
    </div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-gap: 10px;
  width: 200px;
}

#example-element :nth-child(1) {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}

#example-element :nth-child(2) {
  background-color: rgb(255 0 200 / 0.2);
  border: 3px solid rebeccapurple;
  grid-column: auto / span 3;
  grid-row: auto / span 2;
}

#example-element :nth-child(3) {
  background-color: rgb(94 255 0 / 0.2);
  border: 3px solid green;
  grid-column: auto / span 2;
}
```

> **Note:** The sub-properties you don't specify are set to their initial value, as normal for shorthands. Also, the gutter properties are NOT reset by this shorthand.

Constituent properties

This property is a shorthand for the following CSS properties:

- `grid-auto-columns`
- `grid-auto-flow`
- `grid-auto-rows`
- `grid-template-areas`
- `grid-template-columns`
- `grid-template-rows`

Syntax

```
/* <'grid-template'> values */
grid: none;
grid: "a" 100px "b" 1fr;
grid: [line-name1] "a" 100px [line-name2];
grid: "a" 200px "b" min-content;
grid: "a" minmax(100px, max-content) "b" 20%;
grid: 100px / 200px;
grid: minmax(400px, min-content) / repeat(auto-fill, 50px);

/* <'grid-template-rows'> /
   [ auto-flow && dense? ] <'grid-auto-columns'>? values */
grid: 200px / auto-flow;
grid: 30% / auto-flow dense;
grid: repeat(3, 200px) / auto-flow 300px;
grid: [line1] minmax(20em, max-content) / auto-flow dense 40%;
```

```
/* [ auto-flow && dense? ] <'grid-auto-rows'>? /
   <'grid-template-columns'> values */
grid: auto-flow / 200px;
grid: auto-flow dense / 30%;
grid: auto-flow 300px / repeat(3, 200px);
grid: auto-flow dense 40% / [line1] minmax(20em, max-content);

/* Global values */
grid: inherit;
grid: initial;
grid: revert;
grid: revert-layer;
grid: unset;
```

Values

`<'grid-template'>`

Defines the `grid-template` including `grid-template-columns`, `grid-template-rows` and `grid-template-areas`.

`<'grid-template-rows'> / [ auto-flow && dense? ] <'grid-auto-columns'>?`

Sets up an auto-flow by setting the row tracks explicitly via the `grid-template-rows` property (and the `grid-template-columns` property to `none`) and specifying how to auto-repeat the column tracks via `grid-auto-columns` (and setting `grid-auto-rows` to `auto`). `grid-auto-flow` is also set to `column` accordingly, with `dense` if it's specified.

All other `grid` sub-properties are reset to their initial values.

`[ auto-flow && dense? ] <'grid-auto-rows'>? / <'grid-template-columns'>`

Sets up an auto-flow by setting the column tracks explicitly via the `grid-template-columns` property (and the `grid-template-rows` property to `none`) and specifying how to auto-repeat the row tracks via `grid-auto-rows` (and setting `grid-auto-columns` to `auto`). `grid-auto-flow` is also set to `row` accordingly, with `dense` if it's specified.

All other `grid` sub-properties are reset to their initial values.

Formal definition

Initial value	as each of the properties of the shorthand: • `grid-template-rows`: `none` • `grid-template-columns`: `none` • `grid-template-areas`: `none` • `grid-auto-rows`: `auto` • `grid-auto-columns`: `auto` • `grid-auto-flow`: `row` • `grid-column-gap`: `0` • `grid-row-gap`: `0` • `column-gap`: `normal` • `row-gap`: `normal`
Applies to	grid containers
Inherited	no
Percentages	as each of the properties of the shorthand: • `grid-template-rows`: refer to corresponding dimension of the content area • `grid-template-columns`: refer to corresponding dimension of the content area • `grid-auto-rows`: refer to corresponding dimension of the content area • `grid-auto-columns`: refer to corresponding dimension of the content area
Computed value	as each of the properties of the shorthand: • `grid-template-rows`: as specified, but with relative lengths converted into absolute lengths • `grid-template-columns`: as specified, but with relative lengths converted into absolute lengths • `grid-template-areas`: as specified • `grid-auto-rows`: the percentage as specified or the absolute length • `grid-auto-columns`: the percentage as specified or the absolute length • `grid-auto-flow`: as specified • `grid-column-gap`: the percentage as specified or the absolute length • `grid-row-gap`: the percentage as specified or the absolute length • `column-gap`: as specified, with <length>s made absolute, and normal computing to zero except on multi-column elements • `row-gap`: as specified, with <length>s made absolute, and normal computing to zero except on multi-column elements
Animation type	as each of the properties of the shorthand: • `grid-template-rows`: simple list of length, percentage, or calc, provided the only differences are in the values of the length, percentage, or calc components in the list • `grid-template-columns`: simple list of length, percentage, or calc, provided the only differences are in the values of the length, percentage, or calc components in the list • `grid-template-areas`: discrete • `grid-auto-rows`: by computed value type • `grid-auto-columns`: by computed value type • `grid-auto-flow`: discrete • `grid-column-gap`: a length • `grid-row-gap`: a length • `column-gap`: a length, percentage or calc(); • `row-gap`: a length, percentage or calc();

Formal syntax

```
grid =
  <'grid-template'>                                |
  <'grid-template-rows'> / [ auto-flow && dense? ] <'grid-auto-columns'>?  |
  [ auto-flow && dense? ] <'grid-auto-rows'>? / <'grid-template-columns'>
```

```
<grid-template> =
  none                                          |
  [ <'grid-template-rows'> / <'grid-template-columns'> ]  |
  [ <line-names>? <string> <track-size>? <line-names>? ]+ [ / <explicit-track-list> ]?

<grid-template-rows> =
  none                      |
  <track-list>              |

  '[' <custom-ident>* ']'

<track-size> =
  <track-breadth>                               |
  minmax( <inflexible-breadth> , <track-breadth> )  |
  fit-content( <length-percentage [0,∞]> )

<explicit-track-list> =
  [ <line-names>? <track-size> ]+ <line-names>?

<track-list> =
  [ <line-names>? [ <track-size> | <track-repeat> ] ]+ <line-names>?

<auto-track-list> =
  [ <line-names>? [ <fixed-size> | <fixed-repeat> ] ]* <line-names>? <auto-repeat> [ <line-names>? [ <fixed-size> | <fixed-repeat> ] ]* <line-names>?

<line-name-list> =
  [ <line-names> | <name-repeat> ]+

<track-breadth> =
  <length-percentage [0,∞]>  |
  <flex [0,∞]>               |
  min-content                |
  max-content                |
  auto

<inflexible-breadth> =
  <length-percentage [0,∞]>  |
  min-content                |
  max-content                |
  auto

<length-percentage> =
  <length>      |
  <percentage>

<track-repeat> =
  repeat( [ <integer [1,∞]> ] , [ <line-names>? <track-size> ]+ <line-names>? )

<fixed-size> =
  <fixed-breadth>                               |
  minmax( <fixed-breadth> , <track-breadth> )       |
  minmax( <inflexible-breadth> , <fixed-breadth> )

<fixed-repeat> =
  repeat( [ <integer [1,∞]> ] , [ <line-names>? <fixed-size> ]+ <line-names>? )

<auto-repeat> =
  repeat( [ auto-fill | auto-fit ] , [ <line-names>? <track-size> ]+ <line-names>? )

<name-repeat> =
  repeat( [ <integer [1,∞]> | auto-fill ] , <line-names>+ )

<integer> =
  <number-token>

<fixed-breadth> =
  <length-percentage [0,∞]>
```

This syntax reflects the latest standard as per CSS Grid Layout Module Level 2, CSS Grid Layout Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Creating a grid layout

HTML

```
<div id="container">
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
</div>
```

CSS

```
#container {
  display: grid;
  grid: repeat(2, 60px) / auto-flow 80px;
}

#container > div {
  background-color: #8ca0ff;
  width: 50px;
  height: 50px;
}
```

Result

- `grid-auto-flow`
- Line-based placement with CSS grid
- Grid template areas: grid definition shorthands

grid-area CSS property

The **`grid-area`** CSS shorthand property specifies a grid item's size and location within a grid by contributing a line, a span, or nothing (automatic) to its grid placement, thereby specifying the edges of its grid area.

Try it

```
grid-area: a;
```

```
grid-area: b;
```

```
grid-area: c;
```

```
grid-area: 2 / 1 / 2 / 4;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">Example</div>
  </div>
</section>
```

```
.example-container {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-template-columns: 1fr 1fr 1fr;
  grid-template-rows: repeat(3, minmax(40px, auto));
  grid-template-areas:
    "a a a"
    "b c c"
    "b c c";
  grid-gap: 10px;
  width: 200px;
}

.example-container > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}

#example-element {
  background-color: rgb(255 0 200 / 0.2);
  border: 3px solid rebeccapurple;
}
```

If four `<grid-line>` values are specified, `grid-row-start` is set to the first value, `grid-column-start` is set to the second value, `grid-row-end` is set to the third value, and `grid-column-end` is set to the fourth value.

When `grid-column-end` is omitted, if `grid-column-start` is a `<custom-ident>`, `grid-column-end` is set to that `<custom-ident>`; otherwise, it is set to `auto`.

When `grid-row-end` is omitted, if `grid-row-start` is a `<custom-ident>`, `grid-row-end` is set to that `<custom-ident>`; otherwise, it is set to `auto`.

When `grid-column-start` is omitted, if `grid-row-start` is a `<custom-ident>`, all four longhands are set to that value. Otherwise, it is set to `auto`.

The `grid-area` property can also be set to a `<custom-ident>` which acts as a name for the area, which can then be placed using `grid-template-areas`.

Constituent properties

This property is a shorthand for the following CSS properties:

- `grid-row-start`
- `grid-column-start`
- `grid-row-end`
- `grid-column-end`

Syntax

```
/* Keyword values */
grid-area: auto;
grid-area: auto / auto;
grid-area: auto / auto / auto;
grid-area: auto / auto / auto / auto;
```

```
/* <custom-ident> values */
grid-area: some-grid-area;
grid-area: some-grid-area / another-grid-area;

/* <integer> && <custom-ident>? values */
grid-area: 4 some-grid-area;
grid-area: 4 some-grid-area / 2 another-grid-area;

/* span && [ <integer> || <custom-ident> ] values */
grid-area: span 3;
grid-area: span 3 / span some-grid-area;
grid-area: 2 span / another-grid-area span;

/* Global values */
grid-area: inherit;
grid-area: initial;
grid-area: revert;
grid-area: revert-layer;
grid-area: unset;
```

Values

`auto`

Is a keyword indicating that the property contributes nothing to the grid item's placement, indicating auto-placement or a default span of `1`.

`<custom-ident>`

If there is a named line with the name `<custom-ident>-start` or `<custom-ident>-end`, it contributes the first such line to the grid item's placement.

> **Note:** Named grid areas automatically generate implicit named lines of this form, so specifying `grid-area: foo;` will choose the start/end edge of that named grid area (unless another line named `foo-start`/`foo-end` was explicitly specified before it).

Otherwise, this is treated as if the integer `1` had been specified along with the `<custom-ident>`.

`<integer> && <custom-ident>?`

Contributes the n-th grid line to the grid item's placement. If a negative integer is given, it instead counts in reverse, starting from the end edge of the explicit grid.

If a name is given as a `<custom-ident>`, only lines with that name are counted. If not enough lines with that name exist, all implicit grid lines are assumed to have that name for the purpose of finding this position.

An `<integer>` value of `0` is invalid.

`span && [ <integer> || <custom-ident> ]`

Contributes a grid span to the grid item's placement such that the corresponding edge of the grid item's grid area is *n* lines from the opposite edge.

If a name is given as a `<custom-ident>`, only lines with that name are counted. If not enough lines with that name exist, all implicit grid lines on the side of the explicit grid corresponding to the search direction are assumed to have that name for the purpose of counting this span.

If the `<integer>` is omitted, it defaults to `1`. Negative integers or 0 are invalid.

Formal definition

Initial value	as each of the properties of the shorthand: • `grid-row-start`: `auto` • `grid-column-start`: `auto` • `grid-row-end`: `auto` • `grid-column-end`: `auto`
Applies to	grid items and absolutely-positioned boxes whose containing block is a grid container
Inherited	no
Computed value	as each of the properties of the shorthand: • `grid-row-start`: as specified • `grid-column-start`: as specified • `grid-row-end`: as specified • `grid-column-end`: as specified
Animation type	discrete

Formal syntax

```
grid-area =
  <grid-line> [ / <grid-line> ]{0,3}

<grid-line> =
  auto                                          |
  <custom-ident>                                |
  [ [ <integer [-∞,-1]> | <integer [1,∞]> ] && <custom-ident>? ]  |
  [ span && [ <integer [1,∞]> || <custom-ident> ] ]

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Grid Layout Module Level 2, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting grid areas

HTML

```
<div id="grid">
  <div id="item1"></div>
  <div id="item2"></div>
  <div id="item3"></div>
</div>
```

CSS

```
#grid {
  display: grid;
  height: 100px;
  grid-template: repeat(4, 1fr) / 50px 100px;
}

#item1 {
  background-color: lime;
  grid-area: 2 / 2 / auto / span 3;
}

#item2 {
  background-color: yellow;
}

#item3 {
  background-color: blue;
}
```

grid-auto-columns CSS property

The **`grid-auto-columns`** CSS property specifies the size of an implicitly-created grid column track or pattern of tracks.

If a grid item is positioned into a column that is not explicitly sized by `grid-template-columns`, implicit grid tracks are created to hold it. This can happen either by explicitly positioning into a column that is out of range, or by the auto-placement algorithm creating additional columns.

Try it

```
grid-auto-columns: auto;
```

```
grid-auto-columns: 1fr;
```

```
grid-auto-columns: min-content;
```

```
grid-auto-columns: minmax(10px, auto);
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">
      <div>One</div>
      <div>Two</div>
      <div>Three</div>
      <div>Four</div>
      <div></div>
    </div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-auto-rows: 40px;
  grid-gap: 10px;
  width: 220px;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}

#example-element > div:nth-child(1) {
  grid-column: 1 / 3;
}

#example-element > div:nth-child(2) {
  grid-column: 2;
}
```

Syntax

```
/* Keyword values */
grid-auto-columns: min-content;
grid-auto-columns: max-content;
grid-auto-columns: auto;

/* <length> values */
grid-auto-columns: 100px;
grid-auto-columns: 20cm;
grid-auto-columns: 50vmax;

/* <percentage> values */
grid-auto-columns: 10%;
grid-auto-columns: 33.3%;

/* <flex> values */
grid-auto-columns: 0.5fr;
grid-auto-columns: 3fr;

/* minmax() values */
grid-auto-columns: minmax(100px, auto);
grid-auto-columns: minmax(max-content, 2fr);
grid-auto-columns: minmax(20%, 80vmax);

/* fit-content() values */
grid-auto-columns: fit-content(400px);
grid-auto-columns: fit-content(5cm);
grid-auto-columns: fit-content(20%);

/* multiple track-size values */
grid-auto-columns: min-content max-content auto;
grid-auto-columns: 100px 150px 390px;
grid-auto-columns: 10% 33.3%;
grid-auto-columns: 0.5fr 3fr 1fr;
grid-auto-columns: minmax(100px, auto) minmax(max-content, 2fr)
  minmax(20%, 80vmax);
grid-auto-columns: 100px minmax(100px, auto) 10% 0.5fr fit-content(400px);

/* Global values */
grid-auto-columns: inherit;
grid-auto-columns: initial;
grid-auto-columns: revert;
grid-auto-columns: revert-layer;
grid-auto-columns: unset;
```

Values

`<length>`

Is a non-negative length.

`<percentage>`

Is a non-negative `<percentage>` value relative to the block size of the grid container. If the block size of the grid container is indefinite, the percentage value is treated like `auto`.

`<flex>`

Is a non-negative dimension with the unit `fr` specifying the track's flex factor. Each `<flex>`-sized track takes a share of the remaining space in proportion to its flex factor.

When appearing outside a `minmax()` notation, it implies an automatic minimum (i.e., `minmax(auto, <flex>)`).

`max-content`

Is a keyword representing the largest maximal content contribution of the grid items occupying the grid track.

`min-content`

Is a keyword representing the largest minimal content contribution of the grid items occupying the grid track.

`minmax(min, max)`

Is a functional notation that defines a size range greater than or equal to *min* and less than or equal to *max*. If *max* is smaller than *min*, then *max* is ignored and the function is treated as *min*. As a maximum, a `<flex>` value sets the track's flex factor. As a minimum, it is treated as zero (or minimal content, if the grid container is sized under a minimal content constraint).

`fit-content( [ <length> | <percentage> ] )`

Represents the formula `min(max-content, max(auto, argument))`, which is calculated similar to `auto` (i.e., `minmax(auto, max-content)`), except that the track size is clamped at *argument* if it is greater than the `auto` minimum.

`auto`

As a maximum represents the largest `max-content` size of the items in that track.

As a minimum represents the largest minimum size of items in that track (specified by the `min-width`/`min-height` of the items). This is often, though not always, the `min-content` size.

If used outside of `minmax()` notation, `auto` represents the range between the minimum and maximum described above. This behaves similarly to `minmax(min-content,max-content)` in most cases.

> **Note:** `auto` track sizes (and only `auto` track sizes) can be stretched by the `align-content` and `justify-content` properties. Therefore by default, an `auto` sized track will take up any remaining space in the grid container.

Formal definition

Initial value	`auto`
Applies to	grid containers
Inherited	no
Percentages	refer to corresponding dimension of the content area

Computed value	the percentage as specified or the absolute length
Animation type	by computed value type

Formal syntax

```
grid-auto-columns =
  <track-size>+

<track-size> =
  <track-breadth>                                  |
  minmax( <inflexible-breadth> , <track-breadth> )  |
  fit-content( <length-percentage [0,∞]> )

<track-breadth> =
  <length-percentage [0,∞]>  |
  <flex [0,∞]>               |
  min-content                |
  max-content                |
  auto

<inflexible-breadth> =
  <length-percentage [0,∞]>  |
  min-content                |
  max-content                |
  auto

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Grid Layout Module Level 2, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting grid column size

HTML

```
<div id="grid">
  <div id="item1"></div>
  <div id="item2"></div>
  <div id="item3"></div>
</div>
```

CSS

```
#grid {
  height: 100px;
  display: grid;
  grid-template-areas: "a a";
  gap: 10px;
  grid-auto-columns: 200px;
}

#grid > div {
  background-color: lime;
}
```

grid-auto-flow CSS property

The **`grid-auto-flow`** CSS property controls how the auto-placement algorithm works, specifying exactly how auto-placed items get flowed into the grid.

Try it

```
grid-auto-flow: row;
```

```
grid-auto-flow: column;
```

```
grid-auto-flow: row dense;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">
      <div>One</div>
      <div>Two</div>
      <div>Three</div>
      <div>Four</div>
      <div>Five</div>
    </div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-template-columns: 1fr 1fr 1fr;
  grid-template-rows: repeat(3, minmax(40px, auto));
  grid-gap: 10px;
```

```
  width: 220px;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}

#example-element > div:nth-child(1) {
  grid-column: auto / span 2;
}

#example-element > div:nth-child(2) {
  grid-column: auto / span 2;
}
```

Syntax

```
/* Keyword values */
grid-auto-flow: row;
grid-auto-flow: column;
grid-auto-flow: dense;
grid-auto-flow: row dense;
grid-auto-flow: column dense;

/* Global values */
grid-auto-flow: inherit;
grid-auto-flow: initial;
grid-auto-flow: revert;
grid-auto-flow: revert-layer;
grid-auto-flow: unset;
```

This property may take one of two forms:

- a single keyword: one of `row`, `column`, or `dense`.
- two keywords: `row dense` or `column dense`.

Values

`row`

Items are placed by filling each row in turn, adding new rows as necessary. If neither `row` nor `column` is provided, `row` is assumed.

`column`

Items are placed by filling each column in turn, adding new columns as necessary.

`dense`

"dense" packing algorithm attempts to fill in holes earlier in the grid, if smaller items come up later. This may cause items to appear out-of-order, when doing so would fill in holes left by larger items.

If it is omitted, a "sparse" algorithm is used, where the placement algorithm only ever moves "forward" in the grid when placing items, never backtracking to fill holes. This ensures that all of the auto-placed items appear "in order", even if this leaves holes that could have been filled by later items.

Formal definition

Initial value	`row`
Applies to	grid containers
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
grid-auto-flow =
  [ row | column ]  ||
  dense
```

This syntax reflects the latest standard as per CSS Grid Layout Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting grid auto-placement

HTML

```
<div id="grid">
  <div id="item1"></div>
  <div id="item2"></div>
  <div id="item3"></div>
  <div id="item4"></div>
  <div id="item5"></div>
</div>
<select id="direction">
  <option value="column">column</option>
  <option value="row">row</option>
</select>
<input id="dense" type="checkbox" />
<label for="dense">dense</label>
```

CSS

```
#grid {
  height: 200px;
  width: 200px;
  display: grid;
  gap: 10px;
  grid-template: repeat(4, 1fr) / repeat(2, 1fr);
  grid-auto-flow: column; /* or 'row', 'row dense', 'column dense' */
```

```
}

#item1 {
  background-color: lime;
  grid-row-start: 3;
}

#item2 {
  background-color: yellow;
}

#item3 {
  background-color: blue;
}

#item4 {
  grid-column-start: 2;
  background-color: red;
}

#item5 {
  background-color: aqua;
}
```

```
function changeGridAutoFlow() {
  const grid = document.getElementById("grid");
  const direction = document.getElementById("direction");
  const dense = document.getElementById("dense");
  let gridAutoFlow = direction.value === "row" ? "row" : "column";

  if (dense.checked) {
    gridAutoFlow += " dense";
  }

  grid.style.gridAutoFlow = gridAutoFlow;
}

const selectElem = document.querySelector("select");
const inputElem = document.querySelector("input");
selectElem.addEventListener("change", changeGridAutoFlow);
inputElem.addEventListener("change", changeGridAutoFlow);
```

grid-auto-rows CSS property

The **`grid-auto-rows`** CSS property specifies the size of an implicitly-created grid row track or pattern of tracks.

If a grid item is positioned into a row that is not explicitly sized by `grid-template-rows`, implicit grid tracks are created to hold it. This can happen either by explicitly positioning into a row that is out of range, or by the auto-placement algorithm creating additional rows.

Try it

```
grid-auto-rows: auto;
```

```
grid-auto-rows: 50px;
```

```
grid-auto-rows: min-content;
```

```
grid-auto-rows: minmax(30px, auto);
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">
      <div>One</div>
      <div>Two</div>
      <div>Three</div>
      <div>Four</div>
      <div>Five</div>
    </div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-template-columns: 1fr 1fr;
  grid-auto-rows: 40px;
  grid-gap: 10px;
  width: 220px;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
  font-size: 22px;
}

#example-element div:last-child {
```

```
  font-size: 13px;
}
```

Syntax

```
/* Keyword values */
grid-auto-rows: min-content;
grid-auto-rows: max-content;
grid-auto-rows: auto;

/* <length> values */
grid-auto-rows: 100px;
grid-auto-rows: 20cm;
grid-auto-rows: 50vmax;

/* <percentage> values */
grid-auto-rows: 10%;
grid-auto-rows: 33.3%;

/* <flex> values */
grid-auto-rows: 0.5fr;
grid-auto-rows: 3fr;

/* minmax() values */
grid-auto-rows: minmax(100px, auto);
grid-auto-rows: minmax(max-content, 2fr);
grid-auto-rows: minmax(20%, 80vmax);

/* fit-content() values */
grid-auto-rows: fit-content(400px);
grid-auto-rows: fit-content(5cm);
grid-auto-rows: fit-content(20%);

/* multiple track-size values */
grid-auto-rows: min-content max-content auto;
grid-auto-rows: 100px 150px 390px;
grid-auto-rows: 10% 33.3%;
grid-auto-rows: 0.5fr 3fr 1fr;

grid-auto-rows: 100px minmax(100px, auto) 10% 0.5fr fit-content(400px);

/* Global values */
grid-auto-rows: inherit;
grid-auto-rows: initial;
grid-auto-rows: revert;
grid-auto-rows: revert-layer;
grid-auto-rows: unset;
```

Values

`<length>`

Is a non-negative length.

`<percentage>`

Is a non-negative `<percentage>` value relative to the block size of the grid container. If the block size of the grid container is indefinite, the percentage value is treated like `auto`.

`<flex>`

Is a non-negative dimension with the unit `fr` specifying the track's flex factor. Each `<flex>`-sized track takes a share of the remaining space in proportion to its flex factor.

When appearing outside a `minmax()` notation, it implies an automatic minimum (i.e., `minmax(auto, <flex>)`).

`max-content`

Is a keyword representing the largest maximal content contribution of the grid items occupying the grid track.

`min-content`

Is a keyword representing the largest minimal content contribution of the grid items occupying the grid track.

`minmax(min, max)`

Is a functional notation that defines a size range greater than or equal to *min* and less than or equal to *max*. If *max* is smaller than *min*, then *max* is ignored and the function is treated as *min*. As a maximum, a `<flex>` value sets the track's flex factor. As a minimum, it is treated as zero (or minimal content, if the grid container is sized under a minimal content constraint).

`fit-content( [ <length> | <percentage> ] )`

Represents the formula `min(max-content, max(auto, argument))`, which is calculated similar to `auto` (i.e., `minmax(auto, max-content)`), except that the track size is clamped at *argument* if it is greater than the `auto` minimum.

`auto`

As a maximum represents the largest `max-content` size of the items in that track.

As a minimum represents the largest minimum size of items in that track (specified by the `min-width`/`min-height` of the items). This is often, though not always, the `min-content` size.

If used outside of `minmax()` notation, `auto` represents the range between the minimum and maximum described above. This behaves similarly to `minmax(min-content,max-content)` in most cases.

> **Note:** `auto` track sizes (and only `auto` track sizes) can be stretched by the `align-content` and `justify-content` properties. Therefore by default, an `auto` sized track will take up any remaining space in the grid container.

Formal definition

Initial value	`auto`
Applies to	grid containers
Inherited	no

Percentages	refer to corresponding dimension of the content area
Computed value	the percentage as specified or the absolute length
Animation type	by computed value type

Formal syntax

```
grid-auto-rows =
  <track-size>+

<track-size> =
  <track-breadth>                                  |
  minmax( <inflexible-breadth> , <track-breadth> )  |
  fit-content( <length-percentage [0,∞]> )

<track-breadth> =
  <length-percentage [0,∞]>  |
  <flex [0,∞]>               |
  min-content                |
  max-content                |
  auto

<inflexible-breadth> =
  <length-percentage [0,∞]>  |
  min-content                |
  max-content                |
  auto

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Grid Layout Module Level 2, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting grid row size

HTML

```
<div id="grid">
  <div id="item1"></div>
  <div id="item2"></div>
  <div id="item3"></div>
</div>
```

CSS

```
#grid {
  width: 200px;
  display: grid;
  grid-template-areas: "a a";
  gap: 10px;
  grid-auto-rows: 100px;
}

#grid > div {
  background-color: lime;
}
```

- Video: Introducing grid auto-placement and order

grid-column CSS property

The **`grid-column`** CSS shorthand property specifies a grid item's size and location within a grid column by contributing a line, a span, or nothing (automatic) to its grid placement, thereby specifying the inline-start and inline-end edge of its grid area.

Try it

```
grid-column: 1;
```

```
grid-column: 1 / 3;
```

```
grid-column: 2 / -1;
```

```
grid-column: 1 / span 2;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">One</div>
    <div>Two</div>
    <div>Three</div>
  </div>
</section>
```

```
.example-container {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-template-columns: 1fr 1.5fr 1fr;
  grid-template-rows: repeat(3, minmax(40px, auto));
```

```
  grid-gap: 10px;
  width: 200px;
}

.example-container > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}

#example-element {
  background-color: rgb(255 0 200 / 0.2);
  border: 3px solid rebeccapurple;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `grid-column-end`
- `grid-column-start`

Syntax

```
/* Keyword values */
grid-column: auto;
grid-column: auto / auto;

/* <custom-ident> values */
grid-column: some-grid-area;
grid-column: some-grid-area / some-other-grid-area;

/* <integer> + <custom-ident> values */
grid-column: some-grid-area 4;
grid-column: 4 some-grid-area / 6;

/* span + <integer> + <custom-ident> values */
grid-column: span 3;
grid-column: span some-grid-area;
grid-column: 5 some-grid-area span;
grid-column: span 3 / 6;
grid-column: span some-grid-area / span some-other-grid-area;
grid-column: 5 some-grid-area span / 2 span;

/* Global values */
grid-column: inherit;
grid-column: initial;
grid-column: revert;
grid-column: revert-layer;
grid-column: unset;
```

This property is specified as one or two `<grid-line>` values.

If two `<grid-line>` values are given, they are separated by `/`. The `grid-column-start` longhand is set to the value before the slash, and the `grid-column-end` longhand is set to the value after the slash.

Each `<grid-line>` value can be specified as:

- either the `auto` keyword
- or a `<custom-ident>` value
- or an `<integer>` value
- or both `<custom-ident>` and `<integer>`, separated by a space
- or the keyword `span` together with either a `<custom-ident>` or an `<integer>` or both.

Values

`auto`

Is a keyword indicating that the property contributes nothing to the grid item's placement, indicating auto-placement, an automatic span, or a default span of `1`.

`<custom-ident>`

If there is a named line with the name `<custom-ident>-start`/`<custom-ident>-end`, it contributes the first such line to the grid item's placement.

> **Note:** Named grid areas automatically generate implicit named lines of this form, so specifying `grid-column: foo;` will choose the start/end edge of that named grid area (unless another line named `foo-start`/`foo-end` was explicitly specified before it).

Otherwise, this is treated as if the integer `1` had been specified along with the `<custom-ident>`.

`<integer> && <custom-ident>?`

Contributes the nth grid line to the grid item's placement. If a negative integer is given, it instead counts in reverse, starting from the end edge of the explicit grid.

If a name is given as a `<custom-ident>`, only lines with that name are counted. If not enough lines with that name exist, all implicit grid lines are assumed to have that name for the purpose of finding this position.

An `<integer>` value of `0` is invalid.

`span && [ <integer> || <custom-ident> ]`

Contributes a grid span to the grid item's placement such that the corresponding edge of the grid item's grid area is n lines from the opposite edge.

If a name is given as a `<custom-ident>`, only lines with that name are counted. If not enough lines with that name exist, all implicit grid lines on the side of the explicit grid corresponding to the search direction are assumed to have that name for the purpose of counting this span.

If the `<integer>` is omitted, it defaults to `1`. Negative integers or 0 are invalid.

Formal definition

Initial value	as each of the properties of the shorthand:

	• grid-column-start: auto • grid-column-end: auto
Applies to	grid items and absolutely-positioned boxes whose containing block is a grid container
Inherited	no
Computed value	as each of the properties of the shorthand: • grid-column-start: as specified • grid-column-end: as specified
Animation type	discrete

Formal syntax

```
grid-column =
  <grid-line> [ / <grid-line> ]?

<grid-line> =
  auto                                          |
  <custom-ident>                                |
  [ [ <integer [-∞,-1]> | <integer [1,∞]> ] && <custom-ident>? ]  |
  [ span && [ <integer [1,∞]> || <custom-ident> ] ]

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Grid Layout Module Level 2, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting grid column size and location

HTML

```
<div id="grid">
  <div id="item1"></div>
  <div id="item2"></div>
  <div id="item3"></div>
</div>
```

CSS

```
#grid {
  display: grid;
  height: 100px;
  grid-template-columns: repeat(6, 1fr);
  grid-template-rows: 100px;
}

#item1 {
  background-color: lime;
}

#item2 {
  background-color: yellow;
  grid-column: 2 / 4;
}

#item3 {
  background-color: blue;
  grid-column: span 2 / 7;
}
```

grid-column-end CSS property

The **grid-column-end** CSS property specifies a grid item's end position within the grid column by contributing a line, a span, or nothing (automatic) to its grid placement, thereby specifying the block-end edge of its grid area.

Try it

```
grid-column-end: auto;
```

```
grid-column-end: 3;
```

```
grid-column-end: -1;
```

```
grid-column-end: span 3;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">One</div>
    <div>Two</div>
```

```
    <div>Three</div>
  </div>
</section>
```

```
.example-container {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-template-columns: 1fr 1.5fr 1fr;
  grid-template-rows: repeat(3, minmax(40px, auto));
  grid-gap: 10px;
  width: 200px;
}

.example-container > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}

#example-element {
  background-color: rgb(255 0 200 / 0.2);
  border: 3px solid rebeccapurple;
}
```

Syntax

```
/* Keyword value */
grid-column-end: auto;

/* <custom-ident> values */
grid-column-end: some-grid-area;

/* <integer> + <custom-ident> values */
grid-column-end: 2;
grid-column-end: some-grid-area 4;

/* span + <integer> + <custom-ident> values */
grid-column-end: span 3;
grid-column-end: span some-grid-area;
grid-column-end: 5 some-grid-area span;

/* Global values */
grid-column-end: inherit;
grid-column-end: initial;
grid-column-end: revert;
grid-column-end: revert-layer;
grid-column-end: unset;
```

Values

`auto`

Contributes nothing to the grid item's placement, indicating auto-placement, an automatic span, or a default span of `1`. This is the default value.

`<custom-ident>`

Contributes the first line to the grid item's placement if there is a named line with the name `<custom-ident>-end`.

> **Note:** Named grid areas automatically generate implicit named lines of this form, so specifying `grid-column-end: foo;` will choose the end edge of that named grid area (unless another line named `foo-end` was explicitly specified before it).

Otherwise, this is treated as if the integer `1` had been specified along with the `<custom-ident>`.

`<integer> && <custom-ident>?`

Contributes the nth grid line to the grid item's placement. If a negative integer is given, it instead counts in reverse, starting from the end edge of the explicit grid.

If a name is given as a <custom-ident>, only lines with that name are counted. If not enough lines with that name exist, all implicit grid lines are assumed to have that name for the purpose of finding this position.

An `<integer>` value of `0` is invalid.

`span && [ <integer> || <custom-ident> ]`

Contributes a grid span to the grid item's placement such that the column end edge of the grid item's grid area is n lines from the start edge.

If a name is given as a <custom-ident>, only lines with that name are counted. If not enough lines with that name exist, all implicit grid lines on the side of the explicit grid corresponding to the search direction are assumed to have that name for the purpose of counting this span.

If the <integer> is omitted, it defaults to `1`. Negative integers or 0 are invalid.

The `<custom-ident>` cannot take the `span` and `auto` values.

Formal definition

Initial value	`auto`
Applies to	grid items and absolutely-positioned boxes whose containing block is a grid container
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
grid-column-end =
  <grid-line>

<grid-line> =
  auto                                    |
```

```
  <custom-ident>                                  |
  [ [ <integer [-∞,-1]> | <integer [1,∞]> ] && <custom-ident>? ]  |
  [ span && [ <integer [1,∞]> || <custom-ident> ] ]

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Grid Layout Module Level 2, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting column end for a grid item

HTML

```
<div class="wrapper">
  <div class="box1">One</div>
  <div class="box2">Two</div>
  <div class="box3">Three</div>
  <div class="box4">Four</div>
  <div class="box5">Five</div>
</div>
```

CSS

```
.wrapper {
  display: grid;
  grid-template-columns: repeat(3, 1fr);
  grid-auto-rows: 100px;
}

.box1 {
  grid-column-start: 1;
  grid-column-end: 4;
  grid-row-start: 1;
  grid-row-end: 3;
}

.box2 {
  grid-column-start: 1;
  grid-row-start: 3;
  grid-row-end: 5;
}
```

```
* {
  box-sizing: border-box;
}

.wrapper {
  border: 2px solid #f76707;
  border-radius: 5px;
  background-color: #fff4e6;
}

.wrapper > div {
  border: 2px solid #ffa94d;
  border-radius: 5px;
  background-color: #ffd8a8;
  padding: 1em;
  color: #d9480f;
}

.nested {
  border: 2px solid #ffec99;
  border-radius: 5px;
  background-color: #fff9db;
  padding: 1em;
}
```

grid-column-start CSS property

The **grid-column-start** CSS property specifies a grid item's start position within the grid column by contributing a line, a span, or nothing (automatic) to its grid placement. This start position defines the block-start edge of the grid area.

Try it

```
grid-column-start: auto;
```

```
grid-column-start: 2;
```

```
grid-column-start: -1;
```

```
grid-column-start: span 2;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">One</div>
    <div>Two</div>
    <div>Three</div>
  </div>
</section>
```

```
.example-container {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-template-columns: 1fr 1.5fr 1fr;
  grid-template-rows: repeat(3, minmax(40px, auto));
  grid-gap: 10px;
  width: 200px;
}

.example-container > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}

#example-element {
  background-color: rgb(255 0 200 / 0.2);
  border: 3px solid rebeccapurple;
}
```

Syntax

```
/* Keyword value */
grid-column-start: auto;

/* <custom-ident> value */
grid-column-start: some-grid-area;

/* <integer> + <custom-ident> values */
grid-column-start: 2;
grid-column-start: some-grid-area 4;

/* span + <integer> + <custom-ident> values */
grid-column-start: span 3;
grid-column-start: span some-grid-area;
grid-column-start: span some-grid-area 5;

/* Global values */
grid-column-start: inherit;
grid-column-start: initial;
grid-column-start: revert;
grid-column-start: revert-layer;
grid-column-start: unset;
```

This property is specified as a single `<grid-line>` value. A `<grid-line>` value can be specified as:

- either the `auto` keyword
- or a `<custom-ident>` value
- or an `<integer>` value
- or both `<custom-ident>` and `<integer>`, separated by a space
- or the keyword `span` together with either a `<custom-ident>` or an `<integer>` or both.

Values

`auto`

A keyword indicating that the property contributes nothing to the grid item's placement, indicating auto-placement, an automatic span, or a default span of `1`.

`<custom-ident>`

If there is a named line with the name `<custom-ident>-start`, it contributes the first such line to the grid item's placement.

> **Note:** Named grid areas automatically generate implicit named lines of this form, so specifying `grid-column-start: foo;` will choose the start edge of that named grid area (unless another line named `foo-start` was explicitly specified before it).

Otherwise, this is treated as if the integer `1` had been specified along with the `<custom-ident>`.

`<integer> && <custom-ident>?`

Contributes the nth grid line to the grid item's placement. If a negative integer is given, it counts in reverse, starting from the end edge of the explicit grid.

If a name is given as a `<custom-ident>`, only lines with that name are counted. If not enough lines with that name exist, all implicit grid lines are assumed to have that name for the purpose of finding this position.

An `<integer>` value of `0` is invalid.

`span && [ <integer> || <custom-ident> ]`

Contributes a grid span to the grid item's placement, such that the column start edge of the grid item's grid area is n lines from the end edge.

If a name is given as a `<custom-ident>`, only lines with that name are counted. If not enough lines with that name exist, all implicit grid lines on the side of the explicit grid corresponding to the search direction are assumed to have that name for the purpose of counting this span.

If the <integer> is omitted, it defaults to `1`. Negative integers and `0` are invalid.

The `<custom-ident>` cannot take the `span` and `auto` values.

Formal definition

Initial value	`auto`

Applies to	grid items and absolutely-positioned boxes whose containing block is a grid container
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
grid-column-start =
  <grid-line>

<grid-line> =
  auto                                          |
  <custom-ident>                                |
  [ [ <integer [-∞,-1]> | <integer [1,∞]> ] && <custom-ident>? ]  |
  [ span && [ <integer [1,∞]> || <custom-ident> ] ]

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Grid Layout Module Level 2, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting column start for a grid item

HTML

```
<div class="wrapper">
  <div class="box1">One</div>
  <div class="box2">Two</div>
  <div class="box3">Three</div>
  <div class="box4">Four</div>
  <div class="box5">Five</div>
</div>
```

CSS

```
.wrapper {
  display: grid;
  grid-template-columns: repeat(3, 1fr);
  grid-auto-rows: 100px;
}

.box1 {
  grid-column-start: 1;
  grid-column-end: 4;
  grid-row-start: 1;
  grid-row-end: 3;
}

.box2 {
  grid-column-start: 1;
  grid-row-start: 3;
  grid-row-end: 5;
}
```

```
* {
  box-sizing: border-box;
}

.wrapper {
  border: 2px solid #f76707;
  border-radius: 5px;
  background-color: #fff4e6;
}

.wrapper > div {
  border: 2px solid #ffa94d;
  border-radius: 5px;
  background-color: #ffd8a8;
  padding: 1em;
  color: #d9480f;
}

.nested {
  border: 2px solid #ffec99;
  border-radius: 5px;
  background-color: #fff9db;
  padding: 1em;
}
```

grid-row CSS property

The **`grid-row`** CSS shorthand property specifies a grid item's size and location within a grid row by contributing a line, a span, or nothing (automatic) to its grid placement, thereby specifying the inline-start and inline-end edge of its grid area.

Try it

```
grid-row: 1;
```

```
grid-row: 1 / 3;
```

```
grid-row: 2 / -1;
```

```
grid-row: 1 / span 2;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">One</div>
    <div>Two</div>
    <div>Three</div>
  </div>
</section>
```

```
.example-container {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-template-columns: 1fr 1.5fr 1fr;
  grid-template-rows: repeat(3, minmax(40px, auto));
  grid-gap: 10px;
  width: 200px;
}

.example-container > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}

#example-element {
  background-color: rgb(255 0 200 / 0.2);
  border: 3px solid rebeccapurple;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `grid-row-end`
- `grid-row-start`

Syntax

```
/* Keyword values */
grid-row: auto;
grid-row: auto / auto;

/* <custom-ident> values */
grid-row: some-grid-area;
grid-row: some-grid-area / some-other-grid-area;

/* <integer> + <custom-ident> values */
grid-row: some-grid-area 4;
grid-row: 4 some-grid-area / 6;

/* span + <integer> + <custom-ident> values */
grid-row: span 3;
grid-row: span some-grid-area;
grid-row: 5 some-grid-area span;
grid-row: span 3 / 6;
grid-row: span some-grid-area / span some-other-grid-area;
grid-row: 5 some-grid-area span / 2 span;

/* Global values */
grid-row: inherit;
grid-row: initial;
grid-row: revert;
grid-row: revert-layer;
grid-row: unset;
```

This property is specified as one or two `<grid-line>` values.

If two `<grid-line>` values are given, they are separated by `/`. The `grid-row-start` longhand is set to the value before the slash, and the `grid-row-end` longhand is set to the value after the slash.

Each `<grid-line>` value can be specified as:

- either the `auto` keyword
- or a `<custom-ident>` value
- or an `<integer>` value
- or both `<custom-ident>` and `<integer>`, separated by a space
- or the keyword `span` together with either a `<custom-ident>` or an `<integer>` or both.

Values

`auto`

Is a keyword indicating that the property contributes nothing to the grid item's placement, indicating auto-placement, an automatic span, or a default span of `1`.

`<custom-ident>`

If there is a named line with the name `<custom-ident>-start/<custom-ident>-end`, it contributes the first such line to the grid item's placement.

> **Note:** Named grid areas automatically generate implicit named lines of this form, so specifying `grid-row: foo;` will choose the start/end edge of that named grid area (unless another line named `foo-start`/`foo-end` was explicitly specified before it).

Otherwise, this is treated as if the integer `1` had been specified along with the `<custom-ident>`.

`<integer> && <custom-ident>?`

Contributes the nth grid line to the grid item's placement. If a negative integer is given, it instead counts in reverse, starting from the end edge of the explicit grid.

If a name is given as a `<custom-ident>`, only lines with that name are counted. If not enough lines with that name exist, all implicit grid lines are assumed to have that name for the purpose of finding this position.

An `<integer>` value of `0` is invalid.

`span && [ <integer> || <custom-ident> ]`

Contributes a grid span to the grid item's placement such that the corresponding edge of the grid item's grid area is n lines from the opposite edge.

If a name is given as a `<custom-ident>`, only lines with that name are counted. If not enough lines with that name exist, all implicit grid lines on the side of the explicit grid corresponding to the search direction are assumed to have that name for the purpose of counting this span.

If the `<integer>` is omitted, it defaults to `1`. Negative integers or 0 are invalid.

Formal definition

Initial value	as each of the properties of the shorthand: • `grid-row-start`: `auto` • `grid-row-end`: `auto`
Applies to	grid items and absolutely-positioned boxes whose containing block is a grid container
Inherited	no
Computed value	as each of the properties of the shorthand: • `grid-row-start`: as specified • `grid-row-end`: as specified
Animation type	discrete

Formal syntax

```
grid-row =
  <grid-line> [ / <grid-line> ]?

<grid-line> =
  auto                                          |
  <custom-ident>                                |
  [ [ <integer [-∞,-1]> | <integer [1,∞]> ] && <custom-ident>? ]  |
  [ span && [ <integer [1,∞]> || <custom-ident> ] ]

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Grid Layout Module Level 2, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting grid row size and location

HTML

```
<div id="grid">
  <div id="item1"></div>
  <div id="item2"></div>
  <div id="item3"></div>
</div>
```

CSS

```
#grid {
  display: grid;
  height: 200px;
  grid-template-columns: 200px;
  grid-template-rows: repeat(6, 1fr);
}

#item1 {
  background-color: lime;
}

#item2 {
  background-color: yellow;
  grid-row: 2 / 4;
}

#item3 {
  background-color: blue;
  grid-row: span 2 / 7;
}
```

grid-row-end CSS property

The **`grid-row-end`** CSS property specifies a grid item's end position within the grid row by contributing a line, a span, or nothing (automatic) to its grid placement, thereby specifying the inline-end edge of its grid area.

Try it

```
grid-row-end: auto;
```

```
grid-row-end: 3;
```

```
grid-row-end: -1;
```

```
grid-row-end: span 3;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">One</div>
    <div>Two</div>
    <div>Three</div>
  </div>
</section>
```

```
.example-container {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-template-columns: 1fr 1.5fr 1fr;
  grid-template-rows: repeat(3, minmax(40px, auto));
  grid-gap: 10px;
  width: 200px;
}

.example-container > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}

#example-element {
  background-color: rgb(255 0 200 / 0.2);
  border: 3px solid rebeccapurple;
}
```

Syntax

```
/* Keyword value */
grid-row-end: auto;

/* <custom-ident> values */
grid-row-end: some-grid-area;

/* <integer> + <custom-ident> values */
grid-row-end: 2;
grid-row-end: some-grid-area 4;

/* span + <integer> + <custom-ident> values */
grid-row-end: span 3;
grid-row-end: span some-grid-area;
grid-row-end: 5 some-grid-area span;

/* Global values */
grid-row-end: inherit;
grid-row-end: initial;
grid-row-end: revert;
grid-row-end: revert-layer;
grid-row-end: unset;
```

Values

`auto`

Is a keyword indicating that the property contributes nothing to the grid item's placement, indicating auto-placement, an automatic span, or a default span of `1`.

`<custom-ident>`

If there is a named line with the name '<custom-ident>-end', it contributes the first such line to the grid item's placement.

> **Note:** Named grid areas automatically generate implicit named lines of this form, so specifying `grid-row-end: foo;` will choose the end edge of that named grid area (unless another line named `foo-end` was explicitly specified before it).

Otherwise, this is treated as if the integer `1` had been specified along with the `<custom-ident>`.

The `<custom-ident>` cannot take the `span` and `auto` values.

`<integer> && <custom-ident>?`

Contributes the nth grid line to the grid item's placement. If a negative integer is given, it instead counts in reverse, starting from the end edge of the explicit grid.

If a name is given as a <custom-ident>, only lines with that name are counted. If not enough lines with that name exist, all implicit grid lines are assumed to have that name for the purpose of finding this position.

An `<integer>` value of `0` is invalid.

`span && [ <integer> || <custom-ident> ]`

Contributes a grid span to the grid item's placement such that the row end edge of the grid item's grid area is n lines from the start edge.

If a name is given as a <custom-ident>, only lines with that name are counted. If not enough lines with that name exist, all implicit grid lines on the side of the explicit grid corresponding to the search direction are assumed to have that name for the purpose of counting this span.

If the <integer> is omitted, it defaults to 1. Negative integers or 0 are invalid.

Formal definition

Initial value	auto
Applies to	grid items and absolutely-positioned boxes whose containing block is a grid container
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
grid-row-end =
  <grid-line>

<grid-line> =
  auto                                          |
  <custom-ident>                                |
  [ [ <integer [-∞,-1]> | <integer [1,∞]> ] && <custom-ident>? ]  |
  [ span && [ <integer [1,∞]> || <custom-ident> ] ]

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Grid Layout Module Level 2, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting row end for a grid item

HTML

```
<div class="wrapper">
  <div class="box1">One</div>
  <div class="box2">Two</div>
  <div class="box3">Three</div>
  <div class="box4">Four</div>
  <div class="box5">Five</div>
</div>
```

CSS

```
.wrapper {
  display: grid;
  grid-template-columns: repeat(3, 1fr);
  grid-auto-rows: 100px;
}

.box1 {
  grid-column-start: 1;
  grid-column-end: 4;
  grid-row-start: 1;
  grid-row-end: 3;
}

.box2 {
  grid-column-start: 1;
  grid-row-start: 3;
  grid-row-end: 5;
}
```

```
* {
  box-sizing: border-box;
}

grid-row-start CSS property

The **`grid-row-start`** CSS property specifies a grid item's start position within the grid row by contributing a line, a span, or nothing (automatic) to its grid placement, thereby specifying the inline-start edge of its grid area.

Try it

```
grid-row-start: auto;
```

```
grid-row-start: 3;
```

```
grid-row-start: -1;
```

```
grid-row-start: span 2;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">One</div>
    <div>Two</div>
    <div>Three</div>
  </div>
</section>
```

```
.example-container {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-template-columns: 1fr 1.5fr 1fr;
  grid-template-rows: repeat(3, minmax(40px, auto));
  grid-gap: 10px;
  width: 200px;
}

.example-container > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}

#example-element {
  background-color: rgb(255 0 200 / 0.2);
  border: 3px solid rebeccapurple;
}
```

Syntax

```
/* Keyword value */
grid-row-start: auto;

/* <custom-ident> values */
grid-row-start: some-grid-area;

/* <integer> + <custom-ident> values */
grid-row-start: 2;
grid-row-start: some-grid-area 4;

/* span + <integer> + <custom-ident> values */
grid-row-start: span 3;
grid-row-start: span some-grid-area;
grid-row-start: 5 some-grid-area span;

/* Global values */
grid-row-start: inherit;
grid-row-start: initial;
grid-row-start: revert;
grid-row-start: revert-layer;
grid-row-start: unset;
```

This property is specified as a single `<grid-line>` value. A `<grid-line>` value can be specified as:

- either the `auto` keyword
- or a `<custom-ident>` value
- or an `<integer>` value
- or both `<custom-ident>` and `<integer>`, separated by a space
- or the keyword `span` together with either a `<custom-ident>` or an `<integer>` or both.

Values

`auto`

Is a keyword indicating that the property contributes nothing to the grid item's placement, indicating auto-placement, an automatic span, or a default span of `1`.

`<custom-ident>`

If there is a named line with the name '<custom-ident>-start', it contributes the first such line to the grid item's placement.

> **Note:** Named grid areas automatically generate implicit named lines of this form, so specifying `grid-row-start: foo;` will choose the start edge of that named grid area (unless another line named `foo-start` was explicitly specified before it).

Otherwise, this is treated as if the integer `1` had been specified along with the `<custom-ident>`.

`<integer> && <custom-ident>?`

Contributes the nth grid line to the grid item's placement. If a negative integer is given, it instead counts in reverse, starting from the end edge of the explicit grid.

If a name is given as a <custom-ident>, only lines with that name are counted. If not enough lines with that name exist, all implicit grid lines are assumed to have that name for the purpose of finding this position.

An `<integer>` value of `0` is invalid.

`span && [ <integer> || <custom-ident> ]`

Contributes a grid span to the grid item's placement; such that the row start edge of the grid item's grid area is n lines from the end edge.

If a name is given as a <custom-ident>, only lines with that name are counted. If not enough lines with that name exist, all implicit grid lines on the side of the explicit grid, corresponding to the search direction, are assumed to have that name for the purpose of counting this span.

If the <integer> is omitted, it defaults to `1`. Negative integers or 0 are invalid.

The `<custom-ident>` cannot take the `span` and `auto` values.

Formal definition

Initial value	`auto`
Applies to	grid items and absolutely-positioned boxes whose containing block is a grid container
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
grid-row-start =
  <grid-line>

<grid-line> =
  auto                                          |
  <custom-ident>                                |
  [ [ <integer [-∞,-1]> | <integer [1,∞]> ] && <custom-ident>? ]  |
  [ span && [ <integer [1,∞]> || <custom-ident> ] ]

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Grid Layout Module Level 2, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting row start for a grid item

HTML

```
<div class="wrapper">
  <div class="box1">One</div>
  <div class="box2">Two</div>
  <div class="box3">Three</div>
  <div class="box4">Four</div>
  <div class="box5">Five</div>
</div>
```

CSS

```
.wrapper {
  display: grid;
  grid-template-columns: repeat(3, 1fr);
  grid-auto-rows: 100px;
}

.box1 {
  grid-column-start: 1;
  grid-column-end: 4;
  grid-row-start: 1;
  grid-row-end: 3;
}

.box2 {
  grid-column-start: 1;
  grid-row-start: 3;
  grid-row-end: 5;
}
```

```
* {
  box-sizing: border-box;
}

.wrapper {
  border: 2px solid #f76707;
  border-radius: 5px;
  background-color: #fff4e6;
}

.wrapper > div {
  border: 2px solid #ffa94d;
  border-radius: 5px;
  background-color: #ffd8a8;
  padding: 1em;
  color: #d9480f;
}

.nested {
  border: 2px solid #ffec99;
  border-radius: 5px;
  background-color: #fff9db;
```

```
  padding: 1em;
}
```

grid-template CSS property

The **grid-template** CSS shorthand property specifies the grid columns, grid rows, and grid areas.

Try it

```
grid-template:
  "a a a" 40px
  "b c c" 40px
  "b c c" 40px / 1fr 1fr 1fr;
```

```
grid-template:
  "b b a" auto
  "b b c" 2ch
  "b b c" 1em / 20% 20px 1fr;
```

```
grid-template:
  "a a ." minmax(50px, auto)
  "a a ." 80px
  "b b c" auto / 2em 3em auto;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">
      <div>One</div>
      <div>Two</div>
      <div>Three</div>
    </div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-gap: 10px;
  width: 200px;
}

#example-element :nth-child(1) {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
  grid-area: a;
}

#example-element :nth-child(2) {
  background-color: rgb(255 0 200 / 0.2);
  border: 3px solid rebeccapurple;
  grid-area: b;
}

#example-element :nth-child(3) {
  background-color: rgb(94 255 0 / 0.2);
  border: 3px solid green;
  grid-area: c;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- grid-template-areas
- grid-template-columns
- grid-template-rows

Syntax

```
/* Keyword value */
grid-template: none;

/* grid-template-rows / grid-template-columns values */
grid-template: 100px 1fr / 50px 1fr;
grid-template: auto 1fr / auto 1fr auto;
grid-template: [line-name] 100px / [column-name1] 30% [column-name2] 70%;
grid-template: fit-content(100px) / fit-content(40%);

/* grid-template-areas grid-template-rows / grid-template-column values */
grid-template:
  "a a a"
  "b b b";
grid-template:
  "a a a" 20%
  "b b b" auto;
grid-template:
```

```
  [header-top] "a a a" [header-bottom]
  [main-top] "b b b" 1fr [main-bottom]
  / auto 1fr auto;

/* Global values */
grid-template: inherit;
grid-template: initial;
grid-template: revert;
grid-template: revert-layer;
grid-template: unset;
```

Values

`none`

Sets all three longhand properties to `none`, meaning there is no explicit grid. There are no named grid areas. Rows and columns will be implicitly generated; their size will be determined by the `grid-auto-rows` and `grid-auto-columns` properties. This is the default value.

`<'grid-template-rows'> / <'grid-template-columns'>`

Sets `grid-template-rows` and `grid-template-columns` to the specified values, and sets `grid-template-areas` to `none`.

`[ <line-names>? <string> <track-size>? <line-names>? ]+ [ / <explicit-track-list> ]?`

Sets `grid-template-areas` to the strings listed, `grid-template-rows` to the track sizes following each string (filling in `auto` for any missing sizes), and splicing in the named lines defined before/after each size, and `grid-template-columns` to the track listing specified after the slash (or `none`, if not specified).

> **Note:** The `repeat()` function isn't allowed in these track listings, as the tracks are intended to visually line up one-to-one with the rows/columns in the "ASCII art".

> **Note:** The `grid` shorthand accepts the same syntax, but also resets the implicit grid properties to their initial values. Use `grid` (as opposed to `grid-template`) to prevent these values from cascading in separately.

Formal definition

Initial value	as each of the properties of the shorthand: • `grid-template-columns`: none • `grid-template-rows`: none • `grid-template-areas`: none
Applies to	grid containers
Inherited	no
Percentages	as each of the properties of the shorthand: • `grid-template-columns`: refer to corresponding dimension of the content area • `grid-template-rows`: refer to corresponding dimension of the content area
Computed value	as each of the properties of the shorthand: • `grid-template-columns`: as specified, but with relative lengths converted into absolute lengths • `grid-template-rows`: as specified, but with relative lengths converted into absolute lengths • `grid-template-areas`: as specified
Animation type	as each of the properties of the shorthand: • `grid-template-columns`: simple list of length, percentage, or calc, provided the only differences are in the values of the length, percentage, or calc components in the list • `grid-template-rows`: simple list of length, percentage, or calc, provided the only differences are in the values of the length, percentage, or calc components in the list • `grid-template-areas`: discrete

Formal syntax

```
grid-template =
  none                                          |
  [ <'grid-template-rows'> / <'grid-template-columns'> ]  |
  [ <line-names>? <string> <track-size>? <line-names>? ]+ [ / <explicit-track-list> ]?

<grid-template-rows> =
  none                        |
  <track-list>                |
  <auto-track-list>           |
  subgrid <line-name-list>?

<grid-template-columns> =
  none                        |
  <track-list>                |
  <auto-track-list>           |
  subgrid <line-name-list>?

<line-names> =
  '[' <custom-ident>* ']'

<track-size> =
  <track-breadth>                               |
  minmax( <inflexible-breadth> , <track-breadth> )  |
  fit-content( <length-percentage [0,∞]> )

<explicit-track-list> =
  [ <line-names>? <track-size> ]+ <line-names>?

<track-list> =
  [ <line-names>? [ <track-size> | <track-repeat> ] ]+ <line-names>?
```

```
<auto-track-list> =
  [ <line-names>? [ <fixed-size> | <fixed-repeat> ] ]* <line-names>? <auto-repeat> [ <line-names>? [ <fixed-size> | <fixed-repeat> ] ]* <line-names>?

<line-name-list> =
  [ <line-names> | <name-repeat> ]+

<track-breadth> =
  <length-percentage [0,∞]>  |
  <flex [0,∞]>               |
  min-content                |
  max-content                |
  auto

<inflexible-breadth> =
  <length-percentage [0,∞]>  |
  min-content                |
  max-content                |
  auto

<length-percentage> =
  <length>      |
  <percentage>

<track-repeat> =
  repeat( [ <integer [1,∞]> ] , [ <line-names>? <track-size> ]+ <line-names>? )

<fixed-size> =
  <fixed-breadth>                              |
  minmax( <fixed-breadth> , <track-breadth> )  |
  minmax( <inflexible-breadth> , <fixed-breadth> )

<fixed-repeat> =
  repeat( [ <integer [1,∞]> ] , [ <line-names>? <fixed-size> ]+ <line-names>? )

<auto-repeat> =
  repeat( [ auto-fill | auto-fit ] , [ <line-names>? <track-size> ]+ <line-names>? )

<name-repeat> =
  repeat( [ <integer [1,∞]> | auto-fill ] , <line-names>+ )

<integer> =
  <number-token>

<fixed-breadth> =
  <length-percentage [0,∞]>
```

This syntax reflects the latest standard as per CSS Grid Layout Module Level 2, CSS Grid Layout Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Defining a grid template

CSS

```
#page {
  display: grid;
  width: 100%;
  height: 200px;
  grid-template:
    [header-left] "head head" 30px [header-right]
    [main-left] "nav  main" 1fr [main-right]
    [footer-left] "nav  foot" 30px [footer-right]
    / 120px 1fr;
}

header {
  background-color: lime;
  grid-area: head;
}

nav {
  background-color: lightblue;
  grid-area: nav;
}

main {
  background-color: yellow;
  grid-area: main;
}

footer {
  background-color: red;
  grid-area: foot;
}
```

HTML

```
<div id="page">
  <header>Header</header>
  <nav>Navigation</nav>
  <main>Main area</main>
  <footer>Footer</footer>
</div>
```

grid-template-areas CSS property

The **`grid-template-areas`** CSS property specifies named grid areas, establishing the cells in the grid and assigning them names.

Those areas are not associated with any particular grid item, but can be referenced from the grid-placement properties `grid-row-start`, `grid-row-end`, `grid-column-start`, `grid-column-end`, and their shorthands `grid-row`, `grid-column`, and `grid-area`.

Try it

```
grid-template-areas:
  "a a a"
  "b c c"
  "b c c";
```

```
grid-template-areas:
  "b b a"
  "b b c"
  "b b c";
```

```
grid-template-areas:
  "a a ."
  "a a ."
  ". b c";
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">
      <div>One (a)</div>
      <div>Two (b)</div>
      <div>Three (c)</div>
    </div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-template-columns: 1fr 1fr 1fr;
  grid-template-rows: repeat(3, minmax(40px, auto));
  grid-gap: 10px;
  width: 200px;
}

#example-element :nth-child(1) {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
  grid-area: a;
}

#example-element :nth-child(2) {
  background-color: rgb(255 0 200 / 0.2);
  border: 3px solid rebeccapurple;
  grid-area: b;
}

#example-element :nth-child(3) {
  background-color: rgb(94 255 0 / 0.2);
  border: 3px solid green;
  grid-area: c;
}
```

Syntax

```
/* Keyword value */
grid-template-areas: none;

/* <string> values */
grid-template-areas: "a b";
grid-template-areas:
  "a b ."
  "a c d";

/* Global values */
grid-template-areas: inherit;
grid-template-areas: initial;
grid-template-areas: revert;
grid-template-areas: revert-layer;
grid-template-areas: unset;
```

Values

`none`

The grid container doesn't define any named grid areas.

`<string>`

A row is created for every separate string listed, and a column is created for each cell in the string. Multiple cell tokens with the same name within and between rows create a single named grid area that spans the corresponding grid cells. Unless those cells form a rectangle, the declaration is invalid.

All the remaining unnamed areas in a grid can be referred using *null cell tokens*. A null cell token is a sequence of one or more `.` (U+002E FULL STOP) characters, e.g., `.`, `...`, or `.....` etc. A null cell token can be used to create empty spaces in the grid.

Formal definition

Initial value	none

Applies to	grid containers
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
grid-template-areas =
  none       |
  <string>+
```

This syntax reflects the latest standard as per CSS Grid Layout Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Specifying named grid areas

HTML

```
<div id="page">
  <header>Header</header>
  <nav>Navigation</nav>
  <main>Main area</main>
  <footer>Footer</footer>
</div>
```

CSS

```
#page {
  display: grid;
  width: 100%;
  height: 250px;
  grid-template-areas:
    "head head"
    "nav  main"
    ".  foot";
  grid-template-rows: 50px 1fr 30px;
  grid-template-columns: 150px 1fr;
}

#page > header {
  grid-area: head;
  background-color: #8ca0ff;
}

#page > nav {
  grid-area: nav;
  background-color: #ffa08c;
}

#page > main {
  grid-area: main;
  background-color: #ffff64;
}

#page > footer {
  grid-area: foot;
  background-color: #8cffa0;
}
```

In the above code, a null token (`.`) was used to create an unnamed area in the grid container, which we used to create an empty space at the bottom left corner of the grid.

grid-template-columns CSS property

The **`grid-template-columns`** CSS property defines the line names and track sizing functions of the grid columns.

Try it

```
grid-template-columns: 60px 60px;
```

```
grid-template-columns: 1fr 60px;
```

```
grid-template-columns: 1fr 2fr;
```

```
grid-template-columns: 8ch auto;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">
      <div>One</div>
      <div>Two</div>
      <div>Three</div>
      <div>Four</div>
      <div>Five</div>
    </div>
```

```
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-auto-rows: 40px;
  grid-gap: 10px;
  width: 200px;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}
```

Syntax

```
/* Keyword value */
grid-template-columns: none;

/* <track-list> values */
grid-template-columns: 100px 1fr;
grid-template-columns: [line-name] 100px;
grid-template-columns: [line-name1] 100px [line-name2 line-name3];
grid-template-columns: minmax(100px, 1fr);
grid-template-columns: fit-content(40%);
grid-template-columns: repeat(3, 200px);
grid-template-columns: subgrid;

/* <auto-track-list> values */
grid-template-columns: 200px repeat(auto-fill, 100px) 300px;
grid-template-columns:
  minmax(100px, max-content)
  repeat(auto-fill, 200px) 20%;
grid-template-columns:
  [line-name1] 100px [line-name2]
  repeat(auto-fit, [line-name3 line-name4] 300px)
  100px;
grid-template-columns:
  [line-name1 line-name2] 100px
  repeat(auto-fit, [line-name1] 300px) [line-name3];

/* Global values */
grid-template-columns: inherit;
grid-template-columns: initial;
grid-template-columns: revert;
grid-template-columns: revert-layer;
grid-template-columns: unset;
```

Values

`none`

Indicates that there is no explicit grid. Any columns will be implicitly generated and their size will be determined by the `grid-auto-columns` property.

`[line-name]`

A `<custom-ident>` specifying a name for the line in that location. The ident may be any valid string other than the reserved words `span` and `auto`. Lines may have multiple names separated by a space inside the square brackets, for example `[line-name-a line-name-b]`.

`<length>`

A non-negative length, giving the width of the column.

`<percentage>`

A non-negative `<percentage>` value relative to the inline size of the grid container. If the size of the grid container depends on the size of its tracks, the browser treats the percentage as `auto`. The browser may adjust the intrinsic size contributions of the track to the size of the grid container and may increase the final size of the track by the minimum amount that would result in honoring the percentage.

`<flex>`

Is a non-negative dimension with the unit `fr` specifying the track's flex factor. Each `<flex>`-sized track takes a share of the remaining space in proportion to its flex factor.

When appearing outside a `minmax()` notation, it implies an automatic minimum (i.e., `minmax(auto, <flex>)`).

`max-content`

Is a keyword representing the largest maximal content contribution of the grid items occupying the grid track. For example, if the first element of the grid track contains the sentence "*Repetitio est mater studiorum*" and the second element contains the sentence "*Dum spiro, spero*", maximal content contribution will be defined by the size of the largest sentence among all of the grid elements - "*Repetitio est mater studiorum*".

`min-content`

Is a keyword representing the largest minimal content contribution of the grid items occupying the grid track. For example, if the first element of the grid track contains the sentence "*Repetitio est mater studiorum*" and the second element contains the sentence "*Dum spiro, spero*", minimal content contribution will be defined by the size of the largest word among all of the sentences in the grid elements - "*studiorum*".

`minmax(min, max)`

Is a functional notation that defines a size range greater than or equal to *min* and less than or equal to *max*. If *max* is smaller than *min*, then *max* is ignored and the function is treated as *min*. As a maximum, a `<flex>` value sets the track's flex factor. It is invalid as a minimum.

`auto`

As a maximum value, it represents the largest `max-content` size of the items in that track.

As a minimum value, it represents the largest minimum size of items in that track (specified by the `min-width`/`min-height` properties of the items). This often corresponds to the `min-content` size, but not always.

If used outside of `minmax()` notation, `auto` represents the range between the minimum and maximum values described above. In most cases, this behaves similarly to `minmax(min-content,max-content)`.

> **Note:** `auto` track sizes (and only `auto` track sizes) can be stretched by the `align-content` and `justify-content` properties. Therefore, by default, an `auto`-sized track will take up any remaining space in the grid container.

`fit-content( [ <length> | <percentage> ] )`

Represents the formula `max(minimum, min(limit, max-content))`, where *minimum* represents an `auto` minimum (which is often, but not always, equal to a `min-content` minimum), and *limit* is the track sizing function passed as an argument to fit-content(). This is essentially calculated as the smaller of `minmax(auto, max-content)` and `minmax(auto, limit)`.

`repeat( [ <positive-integer> | auto-fill | auto-fit ] , <track-list> )`

Represents a repeated fragment of the track list, allowing a large number of columns that exhibit a recurring pattern to be written in a more compact form.

`subgrid`

The `subgrid` value indicates that the grid will adopt the spanned portion of its parent grid in that axis. Rather than being specified explicitly, the sizes of the grid rows/columns will be taken from the parent grid's definition.

Formal definition

Initial value	none
Applies to	grid containers
Inherited	no
Percentages	refer to corresponding dimension of the content area
Computed value	as specified, but with relative lengths converted into absolute lengths
Animation type	simple list of length, percentage, or calc, provided the only differences are in the values of the length, percentage, or calc components in the list

Formal syntax

```
grid-template-columns =
  none                        |
  <track-list>                |
  <auto-track-list>           |
  subgrid <line-name-list>?

<track-list> =
  [ <line-names>? [ <track-size> | <track-repeat> ] ]+ <line-names>?

<auto-track-list> =
  [ <line-names>? [ <fixed-size> | <fixed-repeat> ] ]* <line-names>? <auto-repeat> [ <line-names>? [ <fixed-size> | <fixed-repeat> ] ]* <line-names>?

<line-name-list> =
  [ <line-names> | <name-repeat> ]+

<line-names> =
  '[' <custom-ident>* ']'

<track-size> =
  <track-breadth>                             |
  minmax( <inflexible-breadth> , <track-breadth> )  |
  fit-content( <length-percentage [0,∞]> )

<track-repeat> =
  repeat( [ <integer [1,∞]> ] , [ <line-names>? <track-size> ]+ <line-names>? )

<fixed-size> =
  <fixed-breadth>                             |
  minmax( <fixed-breadth> , <track-breadth> )       |
  minmax( <inflexible-breadth> , <fixed-breadth> )

<fixed-repeat> =
  repeat( [ <integer [1,∞]> ] , [ <line-names>? <fixed-size> ]+ <line-names>? )

<auto-repeat> =
  repeat( [ auto-fill | auto-fit ] , [ <line-names>? <track-size> ]+ <line-names>? )

<name-repeat> =
  repeat( [ <integer [1,∞]> | auto-fill ] , <line-names>+ )

<track-breadth> =
  <length-percentage [0,∞]>  |
  <flex [0,∞]>               |
  min-content                |
  max-content                |
  auto

<inflexible-breadth> =
  <length-percentage [0,∞]>  |
  min-content                |
  max-content                |
  auto

<length-percentage> =
  <length>      |
  <percentage>

<integer> =
  <number-token>

<fixed-breadth> =
  <length-percentage [0,∞]>
```

This syntax reflects the latest standard as per CSS Grid Layout Module Level 2, CSS Grid Layout Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Specifying grid column sizes

HTML

```
<div id="grid">
  <div id="areaA">A</div>
  <div id="areaB">B</div>
</div>
```

CSS

```
#grid {
  display: grid;
  width: 100%;
  grid-template-columns: 50px 1fr;
}

#areaA {
  background-color: lime;
}

#areaB {
  background-color: yellow;
}
```

grid-template-rows CSS property

The **grid-template-rows** CSS property defines the line names and track sizing functions of the grid rows.

Try it

```
grid-template-rows: auto;
```

```
grid-template-rows: 40px 4em 40px;
```

```
grid-template-rows: 1fr 2fr 1fr;
```

```
grid-template-rows: 3ch auto minmax(10px, 60px);
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">
      <div>One</div>
      <div>Two</div>
      <div>Three</div>
      <div>Four</div>
      <div>Five</div>
    </div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-template-columns: 1fr 1fr;
  grid-gap: 10px;
  width: 200px;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}
```

Syntax

```
/* Keyword value */
grid-template-rows: none;

/* <track-list> values */
grid-template-rows: 100px 1fr;
grid-template-rows: [line-name] 100px;
grid-template-rows: [line-name1] 100px [line-name2 line-name3];
grid-template-rows: minmax(100px, 1fr);
grid-template-rows: fit-content(40%);
grid-template-rows: repeat(3, 200px);
grid-template-rows: subgrid;

/* <auto-track-list> values */
grid-template-rows: 200px repeat(auto-fill, 100px) 300px;
grid-template-rows:
  minmax(100px, max-content)
  repeat(auto-fill, 200px) 20%;
grid-template-rows:
  [line-name1] 100px [line-name2]
```

```
  repeat(auto-fit, [line-name3 line-name4] 300px)
  100px;
grid-template-rows:
  [line-name1 line-name2] 100px
  repeat(auto-fit, [line-name1] 300px) [line-name3];

/* Global values */
grid-template-rows: inherit;
grid-template-rows: initial;
grid-template-rows: revert;
grid-template-rows: revert-layer;
grid-template-rows: unset;
```

This property may be specified as:

- either the keyword value `none`
- or a `<track-list>` value
- or an `<auto-track-list>` value.

Values

`none`

A keyword meaning that there is no explicit grid. Any rows will be implicitly generated and their size will be determined by the `grid-auto-rows` property.

`[line-name]`

A `<custom-ident>` specifying a name for the line in that location. The ident may be any valid string other than the reserved words `span` and `auto`. Lines may have multiple names separated by a space inside the square brackets, for example `[line-name-a line-name-b]`.

`<length>`

A non-negative length.

`<percentage>`

A non-negative `<percentage>` value, relative to the block size of the grid container. If the size of the grid container depends on the size of its tracks, the browser treats the percentage as `auto` for the purpose of calculating the intrinsic size of the grid container. The percentage is then resolved against the resulting grid container size for laying out the grid and its items. The browser may adjust the intrinsic size contributions of the track to the size of the grid container and may increase the final size of the track by the minimum amount that would result in honoring the percentage.

`<flex>`

A non-negative dimension with the unit `fr` specifying the track's flex factor. Each `<flex>`-sized track takes a share of the remaining space in proportion to its flex factor. When appearing outside a `minmax()` notation, it implies an automatic minimum (i.e., `minmax(auto, <flex>)`).

`max-content`

A keyword representing the largest maximal content contribution of the grid items occupying the grid track.

`min-content`

A keyword representing the largest minimal content contribution of the grid items occupying the grid track.

`minmax(min, max)`

A functional notation that defines a size range, greater than or equal to *min*, and less than or equal to *max*. If *max* is smaller than *min*, then *max* is ignored and the function is treated as *min*. As a maximum, a `<flex>` value sets the track's flex factor. It is invalid as a minimum.

`auto`

As a maximum value, it represents the largest `max-content` size of the items in that track.

As a minimum value, it represents the largest minimum size of items in that track (specified by the `min-width`/`min-height` properties of the items). This often corresponds to the `min-content` size, but not always.

If used outside of `minmax()` notation, `auto` represents the range between the minimum and maximum values described above. In most cases, this behaves similarly to `minmax(min-content,max-content)`.

> **Note:** `auto` track sizes (and only `auto` track sizes) can be stretched by the `align-content` and `justify-content` properties. Therefore, by default, an `auto`-sized track will take up any remaining space in the grid container.

`fit-content( [ <length> | <percentage> ] )`

Represents the formula `min(max-content, max(auto, argument))`, which is calculated similar to `auto` (i.e., `minmax(auto, max-content)`), except that the track size is clamped at *argument* if it is greater than the `auto` minimum.

`repeat( [ <positive-integer> | auto-fill | auto-fit ] , <track-list> )`

Represents a repeated fragment of the track list, allowing a large number of rows that exhibit a recurring pattern to be written in a more compact form.

`subgrid`

Indicates that the grid will adopt the spanned portion of its parent grid in that axis. Rather than being specified explicitly, the sizes of the grid rows/columns will be taken from the parent grid's definition.

Formal definition

Initial value	none
Applies to	grid containers
Inherited	no
Percentages	refer to corresponding dimension of the content area
Computed value	as specified, but with relative lengths converted into absolute lengths
Animation type	simple list of length, percentage, or calc, provided the only differences are in the values of the length, percentage, or calc components in the list

Formal syntax

```
grid-template-rows =
  none                    |
```

```
  <track-list>              |
  <auto-track-list>         |
  subgrid <line-name-list>?

<track-list> =
  [ <line-names>? [ <track-size> | <track-repeat> ] ]+ <line-names>?

<auto-track-list> =
  [ <line-names>? [ <fixed-size> | <fixed-repeat> ] ]* <line-names>? <auto-repeat> [ <line-names>? [ <fixed-size> | <fixed-repeat> ] ]* <line-names>?

<line-name-list> =
  [ <line-names> | <name-repeat> ]+

<line-names> =
  '[' <custom-ident>* ']'

<track-size> =
  <track-breadth>                           |
  minmax( <inflexible-breadth> , <track-breadth> )  |
  fit-content( <length-percentage [0,∞]> )

<track-repeat> =
  repeat( [ <integer [1,∞]> ] , [ <line-names>? <track-size> ]+ <line-names>? )

<fixed-size> =
  <fixed-breadth>                           |
  minmax( <fixed-breadth> , <track-breadth> )       |
  minmax( <inflexible-breadth> , <fixed-breadth> )

<fixed-repeat> =
  repeat( [ <integer [1,∞]> ] , [ <line-names>? <fixed-size> ]+ <line-names>? )

<auto-repeat> =
  repeat( [ auto-fill | auto-fit ] , [ <line-names>? <track-size> ]+ <line-names>? )

<name-repeat> =
  repeat( [ <integer [1,∞]> | auto-fill ] , <line-names>+ )

<track-breadth> =
  <length-percentage [0,∞]>  |
  <flex [0,∞]>              |
  min-content               |
  max-content               |
  auto

<inflexible-breadth> =
  <length-percentage [0,∞]>  |
  min-content               |
  max-content               |
  auto

<length-percentage> =
  <length>      |
  <percentage>

<integer> =
  <number-token>

<fixed-breadth> =
  <length-percentage [0,∞]>
```

This syntax reflects the latest standard as per CSS Grid Layout Module Level 2, CSS Grid Layout Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Specifying grid row sizes

HTML

```
<div id="grid">
  <div id="areaA">A</div>
  <div id="areaB">B</div>
</div>
```

CSS

```
#grid {
  display: grid;
  height: 100px;
  grid-template-rows: 30px 1fr;
}

#areaA {
  background-color: lime;
}

#areaB {
  background-color: yellow;
}
```

hanging-punctuation CSS property

The **`hanging-punctuation`** CSS property specifies whether a punctuation mark should hang at the start or end of a line of text. Hanging punctuation may be placed outside the line box.

Syntax

```
/* Keyword values */
hanging-punctuation: none;
hanging-punctuation: first;
hanging-punctuation: last;
hanging-punctuation: allow-end;

/* Two keywords */
hanging-punctuation: first allow-end;
hanging-punctuation: first last;
hanging-punctuation: last allow-end;

/* Three keywords */
hanging-punctuation: first allow-end last;

/* Global values */
hanging-punctuation: inherit;
hanging-punctuation: initial;
hanging-punctuation: revert;
hanging-punctuation: revert-layer;
hanging-punctuation: unset;
```

The `hanging-punctuation` property may be specified with one, two, or three space-separated values.

Values

`none`

No character hangs.

`first`

An opening bracket or quote at the start of the first formatted line of an element hangs. This applies to:

- all characters in the Unicode categories Ps, Pf, Pi
- the quote marks `U+0027` APOSTROPHE (') and `U+0022` QUOTATION MARK (").

`last`

A closing bracket or quote at the end of the last formatted line of an element hangs. This applies to:

- all characters in the Unicode categories Pe, Pf, Pi
- the quote marks `U+0027` APOSTROPHE (') and `U+0022` QUOTATION MARK (").

`allow-end`

A stop or comma at the end of a line hangs if it does not otherwise fit prior to justification.

Stops and commas that are allowed to hang include:

- `U+002C`, COMMA
- `U+002E`, FULL STOP
- `U+060C`, ARABIC COMMA
- `U+06D4`, ARABIC FULL STOP
- `U+3001`, IDEOGRAPHIC COMMA
- `U+3002`, IDEOGRAPHIC FULL STOP
- `U+FF0C`, FULLWIDTH COMMA
- `U+FF0E`, FULLWIDTH FULL STOP
- `U+FE50`, SMALL COMMA
- `U+FE51`, SMALL IDEOGRAPHIC COMMA
- `U+FE52`, SMALL FULL STOP
- `U+FF61`, HALFWIDTH IDEOGRAPHIC FULL STOP
- `U+FF64`, HALFWIDTH IDEOGRAPHIC COMMA

User agents may include additional characters.

Formal definition

Initial value	none
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
hanging-punctuation =
  none                                  |
  [ first || [ force-end | allow-end ] || last ]
```

This syntax reflects the latest standard as per CSS Text Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting opening and closing quotes to hang

HTML

```
<p>
  «For a moment, nothing happened. Then, after a second or so, nothing continued
  to happen.»
</p>
```

```
<p class="hanging">
  «For a moment, nothing happened. Then, after a second or so, nothing continued
  to happen.»
</p>

<p class="hanging right">
  «For a moment, nothing happened. Then, after a second or so, nothing continued
  to happen.»
</p>
```

CSS

```
p {
  width: 15em;
  border: 1px solid #cccccc;
  font-size: 2rem;
  font-style: italic;
  margin: 1em;
}

p.hanging {
  hanging-punctuation: first last;
}

p.right {
  text-align: right;
}
```

Result

height CSS property

The **`height`** CSS property specifies the height of an element. By default, the property defines the height of the content area. If `box-sizing` is set to `border-box`, however, it instead determines the height of the border area.

Try it

```
height: 150px;
```

```
height: 6em;
```

```
height: 75%;
```

```
height: auto;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box where you can change the height.
  </div>
</section>
```

```
#example-element {
  display: flex;
  flex-direction: column;
  background-color: #5b6dcd;
  justify-content: center;
  color: white;
}
```

The `min-height` and `max-height` properties override `height`.

> **Note:** As a geometric property, `height` also applies to the `<svg>`, `<rect>`, `<image>`, and `<foreignObject>` SVG elements, with `auto` resolving to `0` and percent values being relative to the SVG viewport height for `<rect>`. The CSS `height` property value overrides any SVG `height` attribute value set on the SVG element.

Syntax

```
/* <length> values */
height: 120px;
height: 10em;
height: 100vh;
height: anchor-size(height);
height: anchor-size(--my-anchor self-block, 250px);
height: clamp(200px, anchor-size(width));

/* <percentage> value */
height: 75%;

/* Keyword values */
height: max-content;
height: min-content;
height: fit-content;
height: fit-content(20em);
height: auto;
height: stretch;

/* Global values */
height: inherit;
height: initial;
height: revert;
height: revert-layer;
height: unset;
```

Values

`<length>`

Defines the height as a distance value.

`<percentage>`

Defines the height as a percentage of the containing block's height.

`auto`

The browser will calculate and select a height for the specified element.

`max-content`

The intrinsic preferred height.

`min-content`

The intrinsic minimum height.

`fit-content`

Use the available space, but not more than max-content, i.e., `min(max-content, max(min-content, stretch))`.

`fit-content(<length-percentage>)`

Uses the fit-content formula with the available space replaced by the specified argument, i.e., `min(max-content, max(min-content, <length-percentage>))`.

`stretch`

Sets the height of the element's margin box to the height of its containing block. It attempts to make the margin box fill the available space in the containing block, so in a way behaving similar to `100%` but applying the resulting size to the margin box rather than the box determined by box-sizing.

Accessibility

Ensure that elements set with a `height` aren't truncated and/or don't obscure other content when the page is zoomed to increase text size.

- MDN Understanding WCAG, Guideline 1.4 explanations
- Understanding Success Criterion 1.4.4 | W3C Understanding WCAG 2.0

Formal definition

Initial value	`auto`
Applies to	all elements but non-replaced inline elements, table columns, and column groups
Inherited	no
Percentages	The percentage is calculated with respect to the height of the generated box's containing block. If the height of the containing block is not specified explicitly (i.e., it depends on content height), and this element is not absolutely positioned, the value computes to `auto`. A percentage height on the root element is relative to the initial containing block.
Computed value	a percentage or `auto` or the absolute length
Animation type	a length, percentage or calc();

Formal syntax

```
height =
  auto             |
  <box-size>       |
  <anchor-size()>

<box-size> =
  <length-percentage [0,∞]>                |
  stretch                                  |
  contain                                  |
  min-content                              |
  max-content                              |
  fit-content                              |
  stretch( <length-percentage [0,∞]> )     |
  fit-content( <length-percentage [0,∞]> ) |
  <calc-size()>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<length-percentage> =
  <length>      |
  <percentage>

<calc-size()> =
  calc-size( <calc-size-basis> , <calc-sum> )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width        |
  height       |
  block        |
  inline       |
  self-block   |
  self-inline

<calc-size-basis> =
  <size-keyword>  |
  <calc-sum>      |
  <calc-size()>   |
  any

<calc-sum> =
```

```
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Sizing Module Level 3, CSS Box Sizing Module Level 4, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting height using pixels and percentages

HTML

```
<div id="taller">I'm 50 pixels tall.</div>
<div id="shorter">I'm 25 pixels tall.</div>
<div id="parent">
  <div id="child">I'm half the height of my parent.</div>
</div>
```

CSS

```
div {
  width: 250px;
  margin-bottom: 5px;
  border: 2px solid blue;
}

#taller {
  height: 50px;
}

#shorter {
  height: 25px;
}

#parent {
  height: 100px;
}

#child {
  height: 50%;
  width: 75%;
}
```

Result

Stretch height to fill the containing block

HTML

```
<div class="parent">
  <div class="child">text</div>
</div>

<div class="parent">
  <div class="child stretch">stretch</div>
</div>
```

CSS

```
@supports not (height: stretch) {
  body::before {
    content: "Your browser doesn't support the `stretch` value yet.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

```
.parent {
  height: 150px;
  margin: 1rem;
  border: solid;
}

.child {
  margin: 1rem;
  background: #00999999;
}

.stretch {
  height: stretch;
}
```

hyphenate-character CSS property

The **`hyphenate-character`** CSS property sets the character (or string) used at the end of a line before a hyphenation break.

Both automatic and soft hyphens are displayed according to the specified hyphenate-character value.

Try it

```
hyphenate-character: auto;
```

```
hyphenate-character: "=";
```

```
hyphenate-character: "—";
```

```
<section id="default-example">
  <p id="example-element">An extraordinarily long English word!</p>
</section>
```

```
#example-element {
  border: 2px dashed #999999;
  font-size: 1.5rem;
  text-align: left;
  width: 7rem;
  hyphens: auto;
}
```

Syntax

```
hyphenate-character: <string>;
hyphenate-character: auto;
```

The value either sets the string to use instead of a hyphen, or indicates that the user agent should select an appropriate string based on the current typographic conventions (default).

Values

`<string>`

> The `<string>` to use at the end of the line before a hyphenation break. The user agent may truncate this value if too many characters are used.

`auto`

> The user-agent selects an appropriate string based on the content language's typographic conventions. This is the default property value, and only needs to be explicitly set in order to override a different inherited value.

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
hyphenate-character =
  auto      |
  <string>
```

This syntax reflects the latest standard as per CSS Text Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

This example shows two identical blocks of text that have `hyphens` set to ensure that they break wherever needed, and on soft hyphen breaks (created using ``). The first block has the value of the hyphen changed to the equals symbol (=). The second block has no hyphenate-character set, which is equivalent to `hyphenate-character: auto` for user agents that support this property.

HTML

```
<dl>
  <dt><code>hyphenate-character: "="</code></dt>
  <dd id="string" lang="en">Superc&shy;alifragilisticexpialidocious</dd>
  <dt><code>hyphenate-character is not set</code></dt>
  <dd lang="en">Superc&shy;alifragilisticexpialidocious</dd>
</dl>
```

CSS

```
dd {
  width: 90px;
  border: 1px solid black;
  hyphens: auto;
}
```

```
dd#string {
  -webkit-hyphenate-character: "=";
  hyphenate-character: "=";
}
```

Result

hyphenate-limit-chars CSS property

The **`hyphenate-limit-chars`** CSS property specifies the minimum word length to allow hyphenation of words as well as the minimum number of characters before and after the hyphen.

Syntax

```
/* Numeric values */
hyphenate-limit-chars: 10 4 4;
hyphenate-limit-chars: 10 4;
hyphenate-limit-chars: 10;

/* Keyword values */
hyphenate-limit-chars: auto auto auto;
hyphenate-limit-chars: auto auto;
hyphenate-limit-chars: auto;

/* Mix of numeric and keyword values */
hyphenate-limit-chars: 10 auto 4;
hyphenate-limit-chars: 10 auto;
hyphenate-limit-chars: auto 3;

/* Global values */
hyphenate-limit-chars: inherit;
hyphenate-limit-chars: initial;
hyphenate-limit-chars: revert;
hyphenate-limit-chars: revert-layer;
hyphenate-limit-chars: unset;
```

Values

This property is specified as one to three values from the following list:

`<integer>`

Specifies either the number of characters for the minimum word length for hyphenation, the minimum number of characters before the hyphen, or the minimum number of characters after the hyphen.

`auto`

Specifies the user agent to choose appropriate values for the current layout. This is the default.

Description

The `hyphenate-limit-chars` property provides fine-grained control over hyphenation in text. This control enables you to avoid awkward hyphenations and set appropriate hyphenation for different languages, which, in turn, allows for better typography.

The property accepts one to three values, each an `<integer>` or the keyword `auto`, specifying the number of characters for the minimum word length for hyphenation, the minimum number of characters before the hyphen, and the minimum number of characters after the hyphen, in that order:

- If one `<integer>` is specified, it sets the word length for the minimum number of characters a word must have in order for it to be able to be hyphenated, while the minimum number of characters before and after the hyphen are set to `auto`.
- If two values are specified, the first value sets the minimum word length and the second sets the minimum number of characters both before and after the hyphen; the omitted third value defaults to the second value.
- If three values are specified, they set the minimum word length, the minimum number of characters before the hyphen, and the minimum number of characters after the hyphen, respectively.

For `auto`, the user agent will choose an appropriate value for the current layout. Unless the user agent can calculate a better value, the following default values will be used:

- Minimum word length to allow hyphenation: 5
- Minimum number of characters before the hyphen: 2
- Minimum number of characters after the hyphen: 2

Note that if a word is too short to meet the given constraints, it will not be hyphenated. For example, given a value like `hyphenate-limit-chars: auto 3 4`, words shorter than 7 characters will never be hyphenated, since it is impossible to have 3 characters before the hyphen and 4 characters after it.

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
hyphenate-limit-chars =
  [ auto | <integer [0,∞]> ]{1,3}

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Text Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting hyphenation limits

In this example, we have four boxes each containing the same text. For the purpose of comparison, the first box shows the default hyphenation applied by the browser. The next three boxes demonstrate the result of constraining the browser's default behavior using different `hyphenate-limit-chars` values.

HTML

```
<div class="container">
  <p id="ex1">juxtaposition and acknowledgement</p>
  <p id="ex2">juxtaposition and acknowledgement</p>
  <p id="ex3">juxtaposition and acknowledgement</p>
  <p id="ex4">juxtaposition and acknowledgement</p>
</div>
```

CSS

```
.container {
  display: grid;
  grid-template-columns: repeat(auto-fit, minmax(160px, 1fr));
}

p {
  margin: 1rem;
  width: 120px;
  border: 2px dashed #999999;
  font-size: 1.5rem;
  hyphens: auto;
}

#ex2 {
  hyphenate-limit-chars: 14;
}

#ex3 {
  hyphenate-limit-chars: 5 9 2;
}

#ex4 {
  hyphenate-limit-chars: 5 2 7;
}
```

Result

In the first box, we don't set `hyphenate-limit-chars`, allowing the browser to apply its default algorithm. By default, the browser uses the values `5 2 2` unless it can find better values.

In the second box, we prevent the browser from hyphenating words unless they are at least 14 characters long by setting `hyphenate-limit-chars: 14`. As a result, "juxtaposition" is not hyphenated in the second box because it is only 13 characters long.

In the third box, we constrain the browser to include at least 9 characters before the hyphen by setting `hyphenate-limit-chars: 5 9 2`. The effect is that "acknowledgement" is now hyphenated as "acknowledge-ment" rather than the default version "acknowl-edgement", as shown in the first box.

Note that the browser does not have to include exactly 9 characters before the hyphen: as long as the constraints given in `hyphenate-limit-chars` are satisfied, the browser can break the word in the place it considers best. So in this case, for example, it chooses "acknowledge-ment" rather than the less readable "acknowled-gement".

In the fourth box, we make the browser include at least 7 characters after the hyphen by setting `hyphenate-limit-chars: 5 2 7`. The effect is that "juxtaposition" is hyphenated as "juxta-position" rather than the default "juxtaposi-tion".

hyphens CSS property

The **`hyphens`** CSS property specifies how words should be hyphenated when text wraps across multiple lines.

Try it

```
hyphens: none;
```

```
hyphens: manual;
```

```
hyphens: auto;
```

```
<section id="default-example">
  <p id="example-element">An extraordinarily long English word!</p>
</section>
```

```
#example-element {
  border: 2px dashed #999999;
  font-size: 1.5rem;
  text-align: left;
  width: 7rem;
}
```

The example text "An extraordinarily long English word!" contains the hidden `` (soft hyphen) character: `An extraordinarily long English word!`. This character is used to indicate a potential place to insert a hyphen when `hyphens: manual;` is specified.

Syntax

```
/* Keyword values */
hyphens: none;
hyphens: manual;
hyphens: auto;

/* Global values */
```

```
hyphens: inherit;
hyphens: initial;
hyphens: revert;
hyphens: revert-layer;
hyphens: unset;
```

Values

This property is specified as one of the following keyword values:

`none`

Words are not broken at line breaks, even if characters inside the words suggest line break points. Lines will only wrap at whitespace.

`manual`

Default value. Words are broken for line-wrapping only where characters inside the word suggest line break opportunities. See Suggesting line break opportunities below for details.

`auto`

The browser is free to automatically break words at appropriate hyphenation points, following whatever rules it chooses. However, suggested line break opportunities (see Suggesting line break opportunities below) will override automatic break point selection when present.

Description

The `hyphens` property can be used to define how words should be hyphenated when text wraps across multiple lines. It can prevent hyphenation entirely, hyphenate at manually-specified points within the text, or let the browser automatically insert hyphens where appropriate.

Hyphenation rules are language-specific. In HTML, the language is determined by the `lang` attribute. Browsers will only hyphenate if this attribute is present and the appropriate hyphenation dictionary is available. The `auto` setting's behavior depends on the language being properly tagged to select the appropriate hyphenation rules.

In XML, the `xml:lang` attribute must be used. The specification does not define rules for hyphenation in XML content, so the exact hyphenation may vary from browser to browser.

The `hyphenate-character` property can be used to specify an alternative hyphenation character to use at the end of the line, instead of the default language-specific hyphenation character.

If you apply `word-break: break-all` then no hyphens are shown, even if the word breaks at a hyphenation point. If you apply `text-wrap-mode: nowrap`, no wrapping occurs, so no hyphens will appear.

Suggesting line break opportunities

There are two Unicode characters used to manually specify potential line break points within text:

U+2010 (HYPHEN)

The "hard" hyphen character indicates a visible line break opportunity. Even if the line is not actually broken at that point, the hyphen is still rendered.

U+00AD (SHY)

An invisible, "**s**oft" **hy**phen. This character is not rendered visibly; instead, it marks a place where the browser should break the word if hyphenation is necessary. In HTML, use `` to insert a soft hyphen.

> **Note:** When the HTML `<wbr>` element leads to a line break, no hyphen is added.

Formal definition

Initial value	`manual`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
hyphens =
  none    |
  manual  |
  auto
```

This syntax reflects the latest standard as per CSS Text Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

This example demonstrates the three values of the `hyphens` property.

HTML

We include three `<dd>` elements containing the same text but with three different classes.

```
<dl>
  <dt><code>none</code>: no hyphen; overflow if needed</dt>
  <dd lang="en" class="none">An extreme&shy;ly long English word</dd>
  <dt>
    <code>manual</code>: hyphen only at &amp;hyphen; or &amp;shy; (if needed)
  </dt>
  <dd lang="en" class="manual">An extreme&shy;ly long English word</dd>
  <dt><code>auto</code>: hyphens where the algorithm decides (if needed)</dt>
  <dd lang="en" class="auto">An extreme&shy;ly long English word</dd>
</dl>
```

CSS

Each of the three classes is set to a different `hyphens` value.

```
dd {
  width: 55px;
  border: 1px solid black;
}
```

```
dd.none {
  hyphens: none;
}
dd.manual {
  hyphens: manual;
}
dd.auto {
  hyphens: auto;
}
```

- CSS text module

image-orientation CSS property

The **`image-orientation`** CSS property specifies a layout-independent correction to the orientation of an image.

Try it

```
image-orientation: none;
```

```
image-orientation: from-image;
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/hummingbird.jpg" />
</section>
```

```
#example-element {
  height: inherit;
}
```

Syntax

```
/* keyword values */
image-orientation: none;
image-orientation: from-image; /* Use EXIF data from the image */

/* Global values */
image-orientation: inherit;
image-orientation: initial;
image-orientation: revert;
image-orientation: revert-layer;
image-orientation: unset;
```

Values

This property is specified as one of the following keyword values:

`none`

Does not apply any additional image rotation; the image is oriented as encoded or as other CSS property values dictate.

`from-image`

Default initial value. The EXIF information contained in the image is used to rotate the image appropriately.

> **Warning:** `image-orientation: none;` **does not** override the orientation of non-secure-origin images as encoded by their EXIF information, due to security concerns. Find out more from the CSS working group draft issue.

Description

This property is intended *only* to be used for the purpose of correcting the orientation of images which were shot with the camera rotated. It should *not* be used for arbitrary rotations. For any purpose other than correcting an image's orientation due to how it was shot or scanned, use a `transform` property with the `rotate` keyword to specify rotation. This includes any user-directed changes to the orientation of the image, or changes required for printing in portrait versus landscape orientation.

If used in conjunction with other CSS properties, such as a `<transform-function>`, any `image-orientation` rotation is applied before any other transformations.

Formal definition

Initial value	`from-image`
Applies to	all elements
Inherited	yes
Computed value	an `<angle>`, rounded to the next quarter turn from `0deg` and normalized, that is moduloing the value by `1turn`
Animation type	discrete

Formal syntax

```
image-orientation =
  from-image           |
  none                 |
  [ <angle> || flip ]
```

This syntax reflects the latest standard as per CSS Images Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Orienting image from image data

The following image has been rotated through 180 degrees, and the `image-orientation` property is used to correct its orientation based on the EXIF data in the image. By changing the `image-orientation` to `none` you can see the effect of the property.

CSS

```
#image {
  image-orientation: from-image; /* Can be changed in the live sample */
}
```

```
img {
  margin: 0.5rem 0;
}

label {
  font-family: monospace;
}
```

```
<img id="image" src="oriole.jpg" alt="Orientation taken from the image" />

<div>
  <input
    type="radio"
    id="from-image"
    name="orientation"
    value="from-image"
    checked />
  <label for="from-image">from-image</label>
</div>

<div>
  <input type="radio" id="none" name="orientation" value="none" />
  <label for="none">none</label>
</div>
```

```
document.addEventListener("change", (evt) => {
  document.getElementById("image").style.imageOrientation = evt.target.value;
});
```

Result

- `transform` and `rotate`

image-rendering CSS property

The **`image-rendering`** CSS property sets an image scaling algorithm. The property applies to an element itself, to any images set in its other properties, and to its descendants.

The user agent will scale an image when the page author specifies dimensions other than its natural size. Scaling may also occur due to user interaction (zooming). For example, if the natural size of an image is `100×100px`, but its actual dimensions are `200×200px` (or `50×50px`), then the image will be upscaled (or downscaled) using the algorithm specified by `image-rendering`. This property has no effect on non-scaled images.

Try it

```
image-rendering: auto;
```

```
image-rendering: smooth;
```

```
image-rendering: crisp-edges;
```

```
image-rendering: pixelated;
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/lizard.png" />
</section>
```

```
#example-element {
  height: 480px;
  object-fit: cover;
}
```

Syntax

```
/* Keyword values */
image-rendering: auto;
image-rendering: smooth;
image-rendering: crisp-edges;
image-rendering: pixelated;

/* Global values */
image-rendering: inherit;
image-rendering: initial;
image-rendering: revert;
image-rendering: revert-layer;
image-rendering: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

The scaling algorithm is UA dependent. Since version 1.9 (Firefox 3.0), Gecko uses *bilinear* resampling (high quality).

`smooth`

The image should be scaled with an algorithm that maximizes the appearance of the image. In particular, scaling algorithms that "smooth" colors are acceptable, such as bilinear interpolation. This is intended for images such as photos.

`crisp-edges`

The image is scaled with an algorithm such as "nearest neighbor" that preserves contrast and edges in the image. Generally intended for images such as pixel art or line drawings, no blurring or color smoothing occurs.

`pixelated`

The image is scaled with the "nearest neighbor" or similar algorithm to the nearest integer multiple of the original image size, then uses smooth interpolation to bring the image to the final desired size. This is intended to preserve a "pixelated" look without introducing scaling artifacts when the upscaled resolution isn't an integer multiple of the original.

> **Note:** The values `optimizeQuality` and `optimizeSpeed` present in an early draft (and coming from its SVG counterpart `image-rendering`) are defined as synonyms for the `smooth` and `pixelated` values respectively.

> **Note:** The CSS images module defines a `high-quality` value for the `image-rendering` property to provide a preference for higher-quality scaling, however, this is not supported in any browsers.

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
image-rendering =
  auto          |
  smooth        |
  high-quality  |
  pixelated     |
  crisp-edges
```

This syntax reflects the latest standard as per CSS Images Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting image scaling algorithms

In this example, an image is repeated four times, with each having a different `image-rendering` value applied.

```
<div>
  <img
    class="auto"
    alt="A small photo of some white and yellow flower against a leafy green background. The image is about 33% smaller than the size it is being displayed at. This upscaling causes the image to appear blurry, with notable soft edges between objects."
    src="blumen.jpg" />
  <img
    class="smooth"
    alt="The same photo as the previous image, which is also being upscaled the same amount. Browsers that support the smooth value for the image-rendering property display the image with the maximize appearance."
    src="blumen.jpg" />
  <img
    class="pixelated"
    alt="The same photo as the previous image, which is also being upscaled the same amount. Browsers that support the pixelated value for the image-rendering property display the image as very pixelated. Individual pixels are clearly visible and edges appear much sharper."
    src="blumen.jpg" />
  <img
    class="crisp-edges"
    alt="The same photo as the previous images, which is also being upscaled the same amount. Browsers that support the crisp-edges value for the image-rendering property display the image as very pixelated. In these examples, there is virtually no perceivable difference between the pixelated and crisp-edges versions."
    src="blumen.jpg" />
</div>
```

```
img {
  height: 200px;
}
```

CSS

```
.auto {
  image-rendering: auto;
}

.smooth {
  image-rendering: smooth;
}

.pixelated {
  image-rendering: pixelated;
}

.crisp-edges {
  image-rendering: crisp-edges;
}
```

Result

- SVG `image-rendering` attribute

image-resolution CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`image-resolution`** CSS property specifies the intrinsic resolution of all raster images used in or on the element. It affects content images such as replaced elements and generated content, and decorative images such as `background-image` images.

The image resolution is defined as the number of image pixels per unit length, e.g., pixels per inch. By default, CSS assumes a resolution of one image pixel per CSS px unit; however, the `image-resolution` property allows a different resolution to be specified.

Syntax

```
image-resolution: from-image;
image-resolution: 300dpi;
image-resolution: from-image 300dpi;
image-resolution: 300dpi snap;

/* Global values */
image-resolution: inherit;
image-resolution: initial;
image-resolution: revert;
image-resolution: revert-layer;
image-resolution: unset;
```

Values

This property is specified as one or more space-separated values from the following list:

`<resolution>`

Specifies the intrinsic resolution explicitly.

`from-image`

Uses the intrinsic resolution as specified by the image format. If the image does not specify its own resolution, the explicitly specified resolution is used (if given), else it defaults to `1dppx` (1 image pixel per CSS px unit).

`snap`

If the `snap` keyword is provided, the computed resolution is the specified resolution rounded to the nearest value that would map one image pixel to an integer number of device pixels. If the resolution is taken from the image, then the used intrinsic resolution is the image's native resolution similarly adjusted.

> **Note:** As vector formats such as SVG do not have an intrinsic resolution, this property has no effect on vector images.

Formal definition

Initial value	`1dppx`
Applies to	all elements
Inherited	yes
Computed value	as specified, except with <resolution> possibly altered by computed for 'snap' value
Animation type	discrete

Formal syntax

```
image-resolution =
  [ from-image || <resolution> ]  &&
  snap?
```

This syntax reflects the latest standard as per CSS Images Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting a high dpi for print

When printing the document, use a higher resolution.

```
@media print {
  .my-image {
    image-resolution: 300dpi;
  }
}
```

Use image resolution with fallback

Uses the resolution from the image. If the image does not have a resolution, use 300dpi rather than the default 1dppx.

```
.my-image {
  image-resolution: from-image 300dpi;
}
```

Browser compatibility

Currently, no browsers support this feature.

- Chromium bug: 1086473.

initial-letter CSS property

The **`initial-letter`** CSS property sets the size and sink for dropped, raised, and sunken initial letters. This property applies to `::first-letter` pseudo-elements and inline-level first children of block containers.

Syntax

```
/* Keyword value */
initial-letter: normal;

/* One value */
initial-letter: 3; /* 3 lines tall, baseline at line 3 */
initial-letter: 1.5; /* 1.5 lines tall, baseline at line 2 */

/* Two values */
initial-letter: 3 2; /* 3 lines tall, baseline at line 2 (raised 1 line) */
initial-letter: 3 1; /* 3 lines tall, baseline unchanged (raised 2 lines) */

/* Global values */
initial-letter: inherit;
initial-letter: initial;
initial-letter: revert;
initial-letter: revert-layer;
initial-letter: unset;
```

Values

This property is specified as `normal` or a `<number>` optionally followed by an `<integer>`:

`normal`

No special initial-letter effect. Text behaves as normal.

`<number>`

Defines the size of the initial letter, in terms of how many lines it occupies. Negative values are not allowed.

`<integer>`

Defines the number of lines the initial letter should sink when the size of it is given. Values must be greater than zero. If omitted, it duplicates the size value, floored to the nearest positive whole number.

Formal definition

Initial value	`normal`
Applies to	`::first-letter` pseudo-elements and inline-level first child of a block container
Inherited	no
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
initial-letter =
  normal                          |
  <number [1,∞]> <integer [1,∞]>  |
  <number [1,∞]> && [ drop | raise ]?

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Inline Layout Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting initial letter size

HTML

```
<p class="normal">Initial letter is normal</p>
<p class="onefive">Initial letter occupies 1.5 lines</p>
<p class="three">Initial letter occupies 3 lines</p>
```

CSS

```
.normal::first-letter {
  -webkit-initial-letter: normal;
  initial-letter: normal;
}

.onefive::first-letter {
  -webkit-initial-letter: 1.5;
  initial-letter: 1.5;
}

.three::first-letter {
  -webkit-initial-letter: 3;
  initial-letter: 3;
}

p {
```

```
  outline: 1px dashed red;
}
```

Result

Setting the sink value

In this example, all the initial letters are the same size, but with different sink values.

HTML

```
<p class="four">Initial letter: Sink value = 4</p>
<p class="same">Initial letter: Sink value not declared (same as size)</p>
<p class="two">Initial letter: Sink value = 2</p>
<p class="one">Initial letter: Sink value = 1</p>
```

CSS

```
.four::first-letter {
  -webkit-initial-letter: 3 4;
  initial-letter: 3 4;
}

.same::first-letter {
  -webkit-initial-letter: 3;
  initial-letter: 3;
}

.two::first-letter {
  -webkit-initial-letter: 3 2;
  initial-letter: 3 2;
}

.one::first-letter {
  -webkit-initial-letter: 3 1;
  initial-letter: 3 1;
}

p {
  outline: 1px dashed red;
}
```

Result

inline-size CSS property

The **`inline-size`** CSS property defines the size of an element's block along the inline axis. If the `writing-mode` is horizontal, it corresponds to the `width`; if the writing mode is vertical, it corresponds to the `height`. A related property is `block-size`, which defines the other dimension of the element.

Try it

```
inline-size: 150px;
writing-mode: horizontal-tb;
```

```
inline-size: 150px;
writing-mode: vertical-rl;
```

```
inline-size: auto;
writing-mode: horizontal-tb;
```

```
inline-size: auto;
writing-mode: vertical-lr;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box where you can change the inline-size.
  </div>
</section>
```

```
#example-element {
  display: flex;
  flex-direction: column;
  background-color: #5b6dcd;
  height: 80%;
  justify-content: center;
  color: white;
}
```

Syntax

```
/* <length> values */
inline-size: 300px;
inline-size: 25em;
inline-size: anchor-size(width);
inline-size: anchor-size(--my-anchor inline);

/* <percentage> values */
inline-size: 75%;

/* Keyword values */
inline-size: max-content;
inline-size: min-content;
```

```
inline-size: fit-content;
inline-size: fit-content(20em);
inline-size: auto;

/* Global values */
inline-size: inherit;
inline-size: initial;
inline-size: revert;
inline-size: revert-layer;
inline-size: unset;
```

Values

The `inline-size` property takes the same values as the `width` and `height` properties.

Formal definition

Initial value	`auto`
Applies to	same as `width` and `height`
Inherited	no
Percentages	inline-size of containing block
Computed value	same as `width` and `height`
Animation type	a length, percentage or calc();

Formal syntax

```
inline-size =
  auto             |
  <box-size>       |
  <anchor-size()>

<box-size> =
  <length-percentage [0,∞]>                |
  stretch                                  |
  contain                                  |
  min-content                              |
  max-content                              |
  fit-content                              |
  stretch( <length-percentage [0,∞]> )     |
  fit-content( <length-percentage [0,∞]> ) |
  <calc-size()>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<length-percentage> =
  <length>      |
  <percentage>

<calc-size()> =
  calc-size( <calc-size-basis> , <calc-sum> )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width       |
  height      |
  block       |
  inline      |
  self-block  |
  self-inline

<calc-size-basis> =
  <size-keyword>  |
  <calc-sum>      |
  <calc-size()>   |
  any

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Sizing Module Level 3, CSS Box Sizing Module Level 4, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting inline size in pixels

HTML

```
<p class="exampleText">Example text</p>
```

CSS

```
.exampleText {
  writing-mode: vertical-rl;
  background-color: yellow;
  inline-size: 110px;
}
```

- The mapped physical properties: `width` and `height`
- `writing-mode`

inset CSS property

The **`inset`** CSS shorthand property corresponds to the `top`, `right`, `bottom`, and/or `left` properties. It has the same multi-value syntax of the `margin` shorthand.

This inset properties, including `inset`, have no effect on non-positioned elements.

While part of the CSS logical properties and values module, it does not define *logical* offsets. It defines *physical* offsets, regardless of the element's writing mode, directionality, and text orientation.

Try it

```
inset: 1em;
```

```
inset: 5% 0;
```

```
inset: 2em 50px 20px;
```

```
inset: 10px 30% 20px 0;
```

```
inset: 0;
```

```
<section id="default-example">
  <div class="example-container">
    <div id="example-element">I am absolutely positioned.</div>
    <p>
      As much mud in the streets as if the waters had but newly retired from the
      face of the earth, and it would not be wonderful to meet a Megalosaurus,
      forty feet long or so, waddling like an elephantine lizard up Holborn
      Hill.
    </p>
  </div>
</section>
```

```
.example-container {
  border: 0.75em solid #ad1457;
  padding: 0.75em;
  text-align: left;
  position: relative;
  width: 100%;
  min-height: 200px;
}

#example-element {
  background-color: #07136c;
  border: 6px solid #ffa000;
  color: white;
  position: absolute;
  inset: 0;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `top`
- `right`
- `bottom`
- `left`

Syntax

```
/* <length> values */
inset: 10px; /* value applied to all edges */
inset: 4px 8px; /* top/bottom left/right */
inset: 5px 15px 10px; /* top left/right bottom */
inset: 2.4em 3em 3em 3em; /* top right bottom left */
inset: calc(anchor(50%) + 10px) anchor(self-start) auto auto;
inset: anchor-size(block) calc(anchor(50%) + 10px) auto
  calc(anchor-size(width) / 4);

/* <percentage>s of the width (left/right) or height (top/bottom) of the containing block */
inset: 10% 5% 5% 5%;

/* Keyword value */
inset: auto;

/* Global values */
inset: inherit;
inset: initial;
inset: revert;
inset: revert-layer;
inset: unset;
```

Values

The `inset` property takes the same values as the `top` property.

Formal definition

Initial value	as each of the properties of the shorthand: • `top`: `auto` • `bottom`: `auto` • `left`: `auto` • `right`: `auto`
Applies to	positioned elements
Inherited	no
Percentages	relative to the containing block's size in the corresponding axis (e.g. width for left or right, height for top or bottom)
Computed value	as each of the properties of the shorthand: • `top`: if specified as a length, the corresponding absolute length; if specified as a percentage, the specified value; otherwise, `auto` • `bottom`: if specified as a length, the corresponding absolute length; if specified as a percentage, the specified value; otherwise, `auto` • `left`: if specified as a length, the corresponding absolute length; if specified as a percentage, the specified value; otherwise, `auto` • `right`: if specified as a length, the corresponding absolute length; if specified as a percentage, the specified value; otherwise, `auto`
Animation type	a length, percentage or calc();

Formal syntax

```
inset =
  <'top'>{1,4}

<top> =
  auto                  |
  <length-percentage>   |
  <anchor()>            |
  <anchor-size()>

<length-percentage> =
  <length>      |
  <percentage>

<anchor()> =
  anchor( <anchor-name>?                  &&
  <anchor-side> , <length-percentage>? )

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<anchor-name> =
  <dashed-ident>

<anchor-side> =
  inside        |
  outside       |
  top           |
  left          |
  right         |
  bottom        |
  start         |
  end           |
  self-start    |
  self-end      |
  <percentage>  |
  center

<anchor-size> =
  width         |
  height        |
  block         |
  inline        |
  self-block    |
  self-inline
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Positioned Layout Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting offsets for an element

HTML

```
<div>
  <span class="exampleText">Example text</span>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 150px;
  height: 120px;
  position: relative;
}

.exampleText {
  writing-mode: sideways-rl;
  position: absolute;
  inset: 20px 40px 30px 10px;
  background-color: #c8c800;
}
```

inset-block CSS property

The **`inset-block`** CSS shorthand property defines the logical block start and end offsets of an element, which maps to physical offsets depending on the element's writing mode, directionality, and text orientation. It corresponds to the `top` and `bottom`, or `right` and `left` properties depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

This inset property has no effect on non-positioned elements.

Try it

```
inset-block: 10px 20px;
writing-mode: horizontal-tb;
```

```
inset-block: 20px 40px;
writing-mode: vertical-rl;
```

```
inset-block: 5% 20%;
writing-mode: horizontal-tb;
```

```
inset-block: 1rem auto;
writing-mode: vertical-lr;
```

```
<section id="default-example">
  <div class="example-container">
    <div id="example-element">I am absolutely positioned.</div>
    <p>
      As much mud in the streets as if the waters had but newly retired from the
      face of the earth, and it would not be wonderful to meet a Megalosaurus,
      forty feet long or so, waddling like an elephantine lizard up Holborn
      Hill.
    </p>
  </div>
</section>
```

```
.example-container {
  border: 0.75em solid #ad1457;
  padding: 0.75em;
  text-align: left;
  position: relative;
  width: 100%;
  min-height: 200px;
}

#example-element {
  background-color: #07136c;
  border: 6px solid #ffa000;
  color: white;
  position: absolute;
  inset: 0;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `inset-block-end`
- `inset-block-start`

Syntax

```
/* <length> values */
inset-block: 3px 10px;
inset-block: 2.4em 3em;
inset-block: 10px; /* value applied to start and end */
inset-block: auto anchor(start);
inset-block: 10em anchor-size(--my-anchor height, 10%);

/* <percentage>s of the width or height of the containing block */
inset-block: 10% 5%;

/* Keyword value */
inset-block: auto;

/* Global values */
inset-block: inherit;
inset-block: initial;
inset-block: revert;
inset-block: revert-layer;
inset-block: unset;
```

Values

The `inset-block` property takes the same values as the `top` property.

Formal definition

Initial value	as each of the properties of the shorthand: • `inset-block-start`: `auto`

	• `inset-block-end`: `auto`
Applies to	positioned elements
Inherited	no
Percentages	logical-height of containing block
Computed value	as each of the properties of the shorthand: • `inset-block-start`: same as box offsets: `top`, `right`, `bottom`, `left` properties except that directions are logical • `inset-block-end`: same as box offsets: `top`, `right`, `bottom`, `left` properties except that directions are logical
Animation type	a length, percentage or calc();

Formal syntax

```
inset-block =
  <'top'>{1,2}

<top> =
  auto                  |
  <length-percentage>   |
  <anchor()>            |
  <anchor-size()>

<length-percentage> =
  <length>      |
  <percentage>

<anchor()> =
  anchor( <anchor-name>?                  &&
  <anchor-side> , <length-percentage>? )

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<anchor-name> =
  <dashed-ident>

<anchor-side> =
  inside        |
  outside       |
  top           |
  left          |
  right         |
  bottom        |
  start         |
  end           |
  self-start    |
  self-end      |
  <percentage>  |
  center

<anchor-size> =
  width         |
  height        |
  block         |
  inline        |
  self-block    |
  self-inline
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Positioned Layout Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting block start and end offsets

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  position: relative;
  inset-block: 20px 50px;
  background-color: #c8c800;
}
```

  inline-size: 140px;
  min-block-size: 200px;
}
```

Syntax

```
/* <length> values */
inset-block-end: 3px;
inset-block-end: 2.4em;
inset-block-end: calc(anchor(start) + 20px);
inset-block-end: anchor-size(--my-anchor width, 10%);

/* <percentage>s of the width or height of the containing block */
inset-block-end: 10%;

/* Keyword value */
inset-block-end: auto;

/* Global values */
inset-block-end: inherit;
inset-block-end: initial;
inset-block-end: revert;
inset-block-end: revert-layer;
inset-block-end: unset;
```

Values

The `inset-block-end` property takes the same values as the `top` property.

Formal definition

Initial value	`auto`
Applies to	positioned elements
Inherited	no
Percentages	logical-height of containing block
Computed value	same as box offsets: `top`, `right`, `bottom`, `left` properties except that directions are logical
Animation type	a length, percentage or calc();

Formal syntax

```
inset-block-end =
  auto                |
  <length-percentage>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Positioned Layout Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting block end offset

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-rl;
  position: relative;
  inset-block-end: 20px;
  background-color: #c8c800;
}

      forty feet long or so, waddling like an elephantine lizard up Holborn
      Hill.
    </p>
  </div>
</section>
```

```
.example-container {
  border: 0.75em solid #ad1457;
  padding: 0.75em;
  text-align: left;
  position: relative;
  width: 100%;
  min-height: 200px;
}

#example-element {
  background-color: #07136c;
  border: 6px solid #ffa000;
  color: white;
  position: absolute;
  inset: 0;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `inset-inline-end`
- `inset-inline-start`

Syntax

```
/* <length> values */
inset-inline: 3px 10px;
inset-inline: 2.4em 3em;
inset-inline: 10px; /* value applied to start and end */
inset-inline: auto calc(anchor(self-start) + 20px);
inset-inline: 400px anchor-size(--my-anchor height, 100px);

/* <percentage>s of the width or height of the containing block */
inset-inline: 10% 5%;

/* Keyword value */
inset-inline: auto;

/* Global values */
inset-inline: inherit;
inset-inline: initial;
inset-inline: revert;
inset-inline: revert-layer;
inset-inline: unset;
```

Values

The `inset-inline` property takes the same values as the `top` property.

Formal definition

Initial value	as each of the properties of the shorthand: • `inset-inline-start`: `auto` • `inset-inline-end`: `auto`
Applies to	positioned elements
Inherited	no
Percentages	logical-width of containing block
Computed value	as each of the properties of the shorthand: • `inset-inline-start`: same as box offsets: `top`, `right`, `bottom`, `left` properties except that directions are logical • `inset-inline-end`: same as box offsets: `top`, `right`, `bottom`, `left` properties except that directions are logical
Animation type	a length, percentage or calc();

Formal syntax

```
inset-inline =
  <'top'>{1,2}

<top> =
  auto                |
  <length-percentage> |
  <anchor()>          |
  <anchor-size()>

<length-percentage> =
  <length>     |
  <percentage>

<anchor()> =
  anchor( <anchor-name>?                &&
  <anchor-side> , <length-percentage>? )

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<anchor-name> =
  <dashed-ident>

<anchor-side> =
  inside       |
  outside      |
  top          |
  left         |
  right        |
  bottom       |
  start        |
```

```
  end           |
  self-start    |
  self-end      |
  <percentage>  |
  center

<anchor-size> =
  width         |
  height        |
  block         |
  inline        |
  self-block    |
  self-inline
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Positioned Layout Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting inline start and end offsets

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  position: relative;
  inset-inline: 20px 50px;
  background-color: #c8c800;
}
```

Result

- The mapped physical shortcut: `inset`
- The mapped block shortcut: `inset-block`
- `writing-mode`, `direction`, `text-orientation`

inset-inline-end CSS property

The **`inset-inline-end`** CSS property defines the logical inline end inset of an element, which maps to a physical offset depending on the element's writing mode, directionality, and text orientation. It corresponds to the `top`, `right`, `bottom`, or `left` property depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

This inset property has no effect on non-positioned elements.

Try it

```
writing-mode: horizontal-tb;
```

```
writing-mode: vertical-rl;
```

```
writing-mode: horizontal-tb;
direction: rtl;
```

```
writing-mode: vertical-lr;
```

```
<section id="default-example">
  <div class="example-container" id="example-element">
    <div id="abspos">
      I am absolutely positioned with inset-inline-end: 50px
    </div>
    <p>
      As much mud in the streets as if the waters had but newly retired from the
      face of the earth, and it would not be wonderful to meet a Megalosaurus,
      forty feet long or so, waddling like an elephantine lizard up Holborn
      Hill.
    </p>
  </div>
</section>
```

```
#example-element {
  border: 0.75em solid;
  padding: 0.75em;
  position: relative;
  width: 100%;
  min-height: 200px;
  unicode-bidi: bidi-override;
}

#abspos {
  background-color: yellow;
  color: black;
  border: 3px solid red;
  position: absolute;
  inset-inline-end: 50px;
  inline-size: 140px;
```

```
  min-block-size: 80px;
}
```

Syntax

```
/* <length> values */
inset-inline-end: 3px;
inset-inline-end: 2.4em;
inset-inline-end: calc(anchor(self-start) + 5px);
inset-inline-end: anchor-size(height);

/* <percentage>s of the width or height of the containing block */
inset-inline-end: 10%;

/* Keyword value */
inset-inline-end: auto;

/* Global values */
inset-inline-end: inherit;
inset-inline-end: initial;
inset-inline-end: revert;
inset-inline-end: revert-layer;
inset-inline-end: unset;
```

The shorthand for `inset-inline-start` and `inset-inline-end` is `inset-inline`.

Values

The `inset-inline-end` property takes the same values as the `top` property.

Formal definition

Initial value	`auto`
Applies to	positioned elements
Inherited	no
Percentages	logical-width of containing block
Computed value	same as box offsets: `top`, `right`, `bottom`, `left` properties except that directions are logical
Animation type	a length, percentage or calc();

Formal syntax

```
inset-inline-end =
  auto                |
  <length-percentage>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Positioned Layout Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting inline end offset

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-rl;
  position: relative;
  inset-inline-end: 20px;
  background-color: #c8c800;
}
```

interactivity CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`interactivity`** CSS property specifies whether an element and its descendant nodes are set to be inert.

Syntax

```
/* Keyword values */
interactivity: auto;
interactivity: inert;

/* Global values */
interactivity: inherit;
interactivity: initial;
interactivity: revert;
interactivity: revert-layer;
interactivity: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

Selected elements are in their default state in terms of inertness. This usually means that they are interactive, but this is not always the case. This is the default value.

`inert`

Selected elements and their descendants are inert.

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
interactivity =
  auto   |
  inert
```

This syntax reflects the latest standard as per CSS Basic User Interface Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Description

The `interactivity` property can be used to set whether an element and its descendants are inert. See the HTML `inert` attribute reference page for a detailed description of the inert state.

A typical use case for `interactivity: inert` is in paginated content, like carousels, when you only want the currently-visible page's content and controls to be interacted with. In such cases, unexpectedly focusing on an off-screen link or button could spoil the experience.

If an element's inert state is specified both by HTML (the `inert` attribute, or an automatic browser setting) and CSS (the `interactive` property) at the same time, the CSS will have no effect — it cannot override the HTML's inertness.

For example, the following HTML element will be inert:

```
<button inert>You can't press me</button>
```

Setting `interactive: auto` on it will have no effect.

Default inertness

Most elements are interactive by default, but this is not always the case:

- An element's ancestor may be set to an inert state, via the `interactive` property or the `inert` attribute.
- While a modal `<dialog>` is displayed, the rest of the page is set to an inert state automatically.

Examples

Basic <code>interactivity</code> usage

In this example we have two `<input>` elements. The second one has `interactivity: inert` set on it via a class, and therefore is not focusable or editable in supporting browsers.

```
<p>
  <label>
    This input is interactive:
    <input type="text" name="one" value="editable" />
  </label>
</p>
<p>
  <label>
    This input is not interactive:
    <input type="text" name="two" value="Not editable" class="inert" />
  </label>
</p>
```

```
.inert {
  interactivity: inert;
  background-color: lightpink;
}
```

Result

The output looks like this:

Exploring the effects of inertness

In this example we explore the effects of the `interactivity` property.

HTML

The markup features two `<p>` elements, each of which contain a link. The second paragraph also has a class of `inert` set on it, and a child `<span>` element with `contenteditable` set on it to make it editable.

```
<p>
  This paragraph is not
  <a
    href="https://developer.mozilla.org/en-US/docs/Web/HTML/Reference/Global_attributes/inert"
    >inert</a
  >. You should be able to select the text content, search for it using
  in-browser search features, and focus and click the link. There is a
  <code>click</code> event handler set on the paragraph that changes the border
  color for a second when it is clicked anywhere.
  <span contenteditable>This sentence has <code>contenteditable</code> set on
  it, so it is editable</span>.
</p>

<p class="inert">
  This paragraph is
  <a
    href="https://developer.mozilla.org/en-US/docs/Web/HTML/Reference/Global_attributes/inert"
    >inert</a
  >. You won't be able to select the text content, search for it using
  in-browser search features, focus and click the link, or issue
  <code>click</code> events on it (the border color won't change when it is
  clicked).
  <span contenteditable
    >This sentence has <code>contenteditable</code> set on it, but it is not
    editable because it is inert</span
  >.
</p>
```

CSS

We set the `interactivity` property on the second paragraph to a value of `inert`, making it inert. This means that you should be able to edit the `contenteditable` text in the first paragraph, but not in the second, and you shouldn't be able to search for text, select text, or interact with the link within the second paragraph.

```
.inert {
  interactivity: inert;
}

[contenteditable] {
  outline: 1px dashed lightblue;
}

.borderChanged {
  border-color: orange;
}
```

```
body {
  font: 1.2em / 1.5 system-ui;
}

p {
  border: 5px solid black;
  padding: 10px;
  width: 90%;
  margin: 20px auto;
}
```

JavaScript

We set an event handler on each paragraph that toggles a class name when clicked, adding the classname then removing the class after two seconds.

```
const paras = document.querySelectorAll("p");

function tempBorderChange(e) {
  const targetPara = e.currentTarget;
  targetPara.classList.add("borderChanged");
  setTimeout(() => {
    targetPara.classList.remove("borderChanged");
  }, 2000);
}

for (para of paras) {
  para.addEventListener("click", tempBorderChange);
}
```

Result

Note how the second paragraph is inert; it therefore does not behave like the first paragraph. For example, the link cannot be clicked or focused, the text cannot be selected or searched, the `contenteditable` `<span>` is not editable, and `click` events do not register on it.

Setting off-screen elements to inert using a view timeline

This example shows horizontally-scrolling paginated content, with each page snapped to using CSS Scroll Snap, and the inertness controlled via a scroll-driven animation that uses a view progress timeline. Content displayed in the scroll container is interactive; it becomes inert when it moves out into the overflowing content.

HTML

The HTML consists of a top-level heading and an unordered list with four list items, each containing the content for a separate page.

```
<h1>Pagination interactivity demo</h1>
<ul>
  <li>
    <h2>Page 1</h2>
    <p>This is the first page of content.</p>
    <p><a href="#">A demo link</a>.</p>
    <p><button>Press me</button></p>
  </li>
  <li>
    <h2>Page 2</h2>
    <p>This is the second page of content.</p>
    <p><a href="#">A demo link</a>.</p>
    <p><button>Press me</button></p>
  </li>
  <li>
    <h2>Page 3</h2>
    <p>This is the third page of content.</p>
    <p><a href="#">A demo link</a>.</p>
    <p><button>Press me</button></p>
  </li>
  <li>
    <h2>Page 4</h2>
    <p>This is the fourth page of content.</p>
    <p><a href="#">A demo link</a>.</p>
    <p><button>Press me</button></p>
  </li>
</ul>
```

CSS

A `width` of `100vw` is set on the unordered list to make it as wide as the viewport. We add a fixed `height`, some `padding`, and an `overflow-x` value of `scroll` so overflowing content will scroll. Its child list items are laid out horizontally with `display: flex`. This flex container is given a `scroll-snap-type` value of `x mandatory` to make it into a scroll snap container. The `x` keyword causes the container's snap targets to be snapped horizontally. The `mandatory` keyword means that the container will always snap to a snap target at the end of a scrolling action.

```
* {
  box-sizing: border-box;
}

body {
  margin: 0;
  font-family: "Helvetica", "Arial", sans-serif;
}

h1 {
  text-align: center;
  margin: 0;
}

button {
  background-color: white;
}
```

```
ul {
  width: 100vw;
  height: 250px;
  padding: 1vw;
  overflow-x: scroll;
  display: flex;
  gap: 1vw;
  scroll-snap-type: x mandatory;
}
```

Each list item has the following styles applied:

- A `flex` value of `0 0 98vw`, forcing each item to be as big as the scroll container minus the `gap` set on the list (see the `gap` declaration in the `ul` rule shown earlier). This also has the effect of centering each page inside the scroll container.
- A `scroll-snap-align` value of `center`, to cause the scroll container to snap to the center of each snap target.

- A `view-timeline` value of `--inner-change inline`, to declare the element as the subject of the `--inner-change` view progress timeline, and set that timeline to progress in the inline direction as it moves through its ancestor scroll container.
- An `animation-timeline` value with the same name as the `view-timeline-name`, as defined in the `view-timeline` shorthand, which means that the named view progress timeline will be used to control the progress of animations applied to the element.
- An `animation-name` and `animation-fill-mode` defining the animation applied to this element and its fill mode. The `both` value is required because you want the starting animation state to apply to the element before the animation starts, and the end animation state to apply to the element after the animation finishes. If the animation isn't persisted, the `interactivity: inert` declaration applied via the animation won't apply to list items when they are outside the scroll container.

```
li {
  list-style-type: none;
  background-color: #eeeeee;
  border: 1px solid #dddddd;
  padding: 20px;

  flex: 0 0 98vw;

  scroll-snap-align: center;

  view-timeline: --inner-change inline;
  animation-timeline: --inner-change;
  animation-name: inert-change;
  animation-fill-mode: both;
}
```

Finally, the animation `@keyframes` are defined. `interactivity: inert` is set at positions `entry 0%` and `exit 100%` of the view timeline. Combined with the `animation-fill-mode: both` value, this means that the list items will be inert before the start and after the end of the view timeline, that is, when they are outside the scroll container. Between positions `entry 1%` and `exit 99%`, `interactivity: auto` is set on the list items, meaning they can be interacted with normally when they are inside the scroll container.

```
@keyframes inert-change {
  entry 0%,
  exit 100% {
    interactivity: inert;
  }

  entry 1%,
  exit 99% {
    interactivity: auto;
  }
}
```

See the `animation-range` reference page for an explanation of the position values.

Result

Scroll the unordered list horizontally to see the pagination effect — each page snaps into view. Try tabbing between the links and the buttons; you'll find that only the ones on-screen are interactive and can be tabbed to.

Accessibility concerns

Consider accessibility carefully when making elements inert. By default, there is no visual way to tell whether or not an element or its subtree is inert. As a web developer, it is your responsibility to clearly indicate the content parts that are active and those that are inert.

While providing visual and non-visual cues about content inertness, also remember that the visual viewport may contain only sections of content. Users may be zoomed in to a small section of content, or users may not be able to view the content at all. Inert sections not being obviously inert can lead to frustration and bad user experience.

interest-delay CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`interest-delay`** CSS property specifies the delay between the user showing interest in an interest invoker element and the `interest` event firing, and the delay between the user losing interest and the `loseinterest` event firing.

Constituent properties

This property is a shorthand for the following properties:

- `interest-delay-start`
- `interest-delay-end`

Syntax

```
/* Single value */
interest-delay: normal;
interest-delay: 2s;
interest-delay: 250ms;

/* Two values */
interest-delay: 1s normal;
interest-delay: 0s 500ms;

/* Global values */
interest-delay: inherit;
interest-delay: initial;
interest-delay: revert;
interest-delay: revert-layer;
interest-delay: unset;
```

Values

The `interest-delay` property accepts one or two values. The first value sets the delay before interest is shown (`interest-delay-start`); the second value, if provided, sets the delay before interest is lost (`interest-delay-end`). Each value can be either the keyword `normal` or a `<time>` value:

`normal`

Sets the delay to the browser's default delay. This is the initial value.

`<time>`

Sets the delay to a specific duration. The value must be positive, otherwise the property becomes invalid.

Description

A control element such as an `<a>` or `<button>` can be set as an interest invoker by giving it the `interestfor` attribute. Its value should be the `id` of a target element. When this relationship is established, the target element is affected when the user "shows interest" in the invoker (for example, by hovering or focusing it). A common use case is to display a popover on hover or focus. When the user "loses interest", the effect stops.

When the user shows or loses interest, the associated effect doesn't start or stop immediately — the browser adds a short delay (which may vary by browser). This prevents preview popovers, for example, from appearing immediately when the user hovers a link, which could be annoying and distracting on a link-heavy page.

The `interest-delay` property allows you to customize these delays. You can use `interest-delay` to specify the delay before the interest effect starts (specified by the `interest-delay-start` property) and the delay before the interest effect ends (specified by the `interest-delay-end` property) in a single declaration.

The `interest-delay` property can take one or two values. These values can be the keyword `normal`, which sets the default browser delay, or a `<time>` value, which sets a custom delay. If a single value is specified, it applies to both `interest-delay-start` and `interest-delay-end`. If two values are specified, the first value sets `interest-delay-start`, and the second value sets `interest-delay-end`.

Formal definition

Initial value	as each of the properties of the shorthand: • `interest-delay-start`: `normal` • `interest-delay-end`: `normal`
Applies to	all elements
Inherited	yes
Computed value	as each of the properties of the shorthand: • `interest-delay-start`: `normal` or a computed time • `interest-delay-end`: `normal` or a computed time
Animation type	as each of the properties of the shorthand: • `interest-delay-start`: by computed value type • `interest-delay-end`: by computed value type

Formal syntax

```
interest-delay =
  <'interest-delay-start'>{1,2}

<interest-delay-start> =
  normal  |
  <time>
```

This syntax reflects the latest standard as per CSS Basic User Interface Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Creating a basic <code>interest-delay</code> effect

In this example, we demonstrate how `interest-delay` affects interest invoker behavior.

HTML

The markup includes a `<button>`, a `<p>`, and an `<input>` of type `checkbox`. We specify the `<button>` as an interest invoker by giving it the `interestfor` attribute whose value matches the `id` of the `<p>` element. This makes the paragraph the target element. The paragraph is turned into a popover by giving it the `popover` attribute, which hides it initially.

```
<button interestfor="mypopover">Button</button>
<p id="mypopover" popover>Hover tooltip</p>
<form>
  <input type="checkbox" id="apply-delay" />
  <label for="apply-delay">
    Apply an <code>interest-delay</code> of <code>1s 2s</code>
  </label>
</form>
```

CSS

In the CSS, we define a `.delay` rule that applies an `interest-delay` value of `1s 2s` to any interest invoker the `delay` class is set on. We will set this class on the `<button>` when the checkbox is checked using JavaScript.

```
.delay {
  interest-delay: 1s 2s;
}
```

JavaScript

In our script, we get references to the `<button>` and the checkbox, then create an event listener that toggles the `delay` class on the `<button>` whenever the checkbox value changes (when it is checked or unchecked).

```
const btn = document.querySelector("button");
const checkbox = document.querySelector("input");
checkbox.addEventListener("change", () => {
```

```
  btn.classList.toggle("delay");
});
```

Result

This renders as follows:

Try showing interest in the button (for example, by hovering or focusing it) and then losing interest to observe the popover showing and hiding. By default, the popover shows and hides after a very short delay.

Now check the checkbox and try the same actions again. This time, the popover should appear after a delay of `1s` when interest is shown, and hide after a delay of `2s` when interest is lost.

interest-delay-end CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`interest-delay-end`** CSS property specifies the delay between the user losing interest in an interest invoker element and the `loseinterest` event firing.

The `interest-delay-end` and `interest-delay-start` properties can both be set using the `interest-delay` shorthand.

Syntax

```
/* Keyword or custom delay */
interest-delay-end: normal;
interest-delay-end: 2s;
interest-delay-end: 250ms;

/* Global values */
interest-delay-end: inherit;
interest-delay-end: initial;
interest-delay-end: revert;
interest-delay-end: revert-layer;
interest-delay-end: unset;
```

Values

This property is specified as one `<time>` value or the keyword `normal`:

`normal`

Sets the delay to the browser's default delay. This is the initial value.

`<time>`

Sets the delay to a specific duration. The value must be positive, otherwise the property becomes invalid.

Formal definition

Initial value	`normal`
Applies to	all elements
Inherited	yes
Computed value	`normal` or a computed time
Animation type	by computed value type

Formal syntax

```
interest-delay-end =
  normal  |
  <time>
```

This syntax reflects the latest standard as per CSS Basic User Interface Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Creating a basic <code>interest-delay-end</code> effect

In this example, we demonstrate how `interest-delay-end` affects interest invoker behavior.

HTML

The markup includes a `<button>`, a `<p>`, and an `<input>` of type `checkbox`. We specify the `<button>` as an interest invoker by giving it the `interestfor` attribute, whose value matches the `id` of the `<p>` element. This makes the paragraph the target element. The paragraph is turned into a popover by giving it the `popover` attribute, which hides it initially.

```
<button interestfor="mypopover">Button</button>
<p id="mypopover" popover>Hover tooltip</p>
<form>
  <input type="checkbox" id="apply-delay" />
  <label for="apply-delay">
    Apply an <code>interest-delay-end</code> of <code>2s</code>
  </label>
</form>
```

CSS

In the CSS, we specify a rule with a `.delay` selector that applies an `interest-delay-end` value of `2s` to any interest invoker the `delay` class is set on. We will set this on the `<button>` when the checkbox is checked using JavaScript.

```
.delay {
  interest-delay-end: 2s;
}
```

JavaScript

In our script, we get references to the `<button>` and the checkbox, then create an event listener that toggles the `delay` class on the `<button>` whenever the checkbox value changes (when it is checked or unchecked).

```
const btn = document.querySelector("button");
const checkbox = document.querySelector("input");
checkbox.addEventListener("change", () => {
  btn.classList.toggle("delay");
});
```

Result

This renders as follows:

Try showing interest in the button (for example, by hovering or focusing it) and then losing interest to observe the popover showing and hiding. By default, the popover shows and hides after a very short delay.

Now check the checkbox and try the same actions again. This time, the delay between showing interest and the popover appearing is unaffected, but the delay between losing interest and the popover disappearing should be increased to `2s`.

interest-delay-start CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`interest-delay-start`** CSS property specifies the delay between the user showing interest in an interest invoker element and the `interest` event firing.

The `interest-delay-start` and `interest-delay-end` properties can both be set using the `interest-delay` shorthand.

Syntax

```
/* Keyword or custom delay */
interest-delay-start: normal;
interest-delay-start: 2s;
interest-delay-start: 250ms;

/* Global values */
interest-delay-start: inherit;
interest-delay-start: initial;
interest-delay-start: revert;
interest-delay-start: revert-layer;
interest-delay-start: unset;
```

Values

This property is specified as one `<time>` value or the keyword `normal`:

`normal`

Sets the delay to the browser's default delay. This is the initial value.

`<time>`

Sets the delay to a specific duration. The value must be positive, otherwise the property becomes invalid.

Formal definition

Initial value	`normal`
Applies to	all elements
Inherited	yes
Computed value	`normal` or a computed time
Animation type	by computed value type

Formal syntax

```
interest-delay-start =
  normal  |
  <time>
```

This syntax reflects the latest standard as per CSS Basic User Interface Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Creating a basic <code>interest-delay-start</code> effect

In this example, we demonstrate how `interest-delay-start` affects interest invoker behavior.

HTML

The markup includes a `<button>`, a `<p>`, and an `<input>` of type `checkbox`. We specify the `<button>` as an interest invoker by giving it the `interestfor` attribute, whose value matches the `id` of the `<p>` element. This makes the paragraph the target element. The paragraph is turned into a popover by giving it the `popover` attribute, which hides it initially.

```
<button interestfor="mypopover">Button</button>
<p id="mypopover" popover>Hover tooltip</p>
```

```
<form>
  <input type="checkbox" id="apply-delay" />
  <label for="apply-delay">
    Apply an <code>interest-delay-start</code> of <code>2s</code>
  </label>
</form>
```

CSS

In the CSS, we specify a rule with a `.delay` selector that applies an `interest-delay-start` value of `2s` to any interest invoker the `delay` class is set on. We will set this on the `<button>` when the checkbox is checked using JavaScript.

```
.delay {
  interest-delay-start: 2s;
}
```

JavaScript

In our script, we get references to the `<button>` and the checkbox, then create an event listener that toggles the `delay` class on the `<button>` whenever the checkbox value changes (when it is checked or unchecked).

```
const btn = document.querySelector("button");
const checkbox = document.querySelector("input");
checkbox.addEventListener("change", () => {
  btn.classList.toggle("delay");
});
```

Result

This renders as follows:

Try showing interest in the button (for example, by hovering or focusing it) and then losing interest to observe the popover showing and hiding. By default, the popover shows and hides after a very short delay.

Now check the checkbox and try the same actions again. This time, the popover should appear after a delay of `2s` when interest is shown. The delay after interest is lost should be unaffected.

Removing <code>interest-delay-start</code> after interest has been shown

In this example, we show how to remove the `interest-delay-start` from multiple interest invoker elements after interest has been shown on one of them.

This is a useful technique. Having a popover appear as soon as interest is shown on any invoker would create a distracting and annoying user experience, which is why browsers add a small delay by default (see the `interest-delay` description for more details). However, once users have shown interest in an invoker, it is convenient to allow them to move between other invokers quickly without delay.

HTML

The markup includes three `<button>` elements wrapped in a paragraph with a `container` class, and another paragraph that has been turned into a popover using the `popover` attribute. All three buttons are set up as interest invokers and reference the popover as their target using the `interestfor` attribute.

```
<p class="container">
  <button interestfor="mypopover">Button 1</button>
  <button interestfor="mypopover">Button 2</button>
  <button interestfor="mypopover">Button 3</button>
</p>
<p id="mypopover" popover>Hover tooltip</p>
```

CSS

In the CSS, we apply an `interest-delay-start` value of `1s` to the buttons, then position the popover below whatever button is having interest shown on it by giving it a `position-area` value of `bottom` (see Popover anchoring positioning for more information).

```
button {
  interest-delay-start: 1s;
}

#mypopover {
  position-area: bottom;
}
```

Finally, we combine the `:interest-source` pseudo-class with the `:has()` pseudo-class to apply `interest-delay-start: 0s` to all buttons inside the paragraph, but only when the paragraph contains a button on which interest has been shown (that is, matched by `button:interest-source`).

```
.container:has(button:interest-source) button {
  interest-delay-start: 0s;
}
```

Result

This renders as follows:

Try showing interest in any button and notice how, when you then immediately show interest in another button, the popover appears without delay. If you stop showing interest in the buttons and then start again, the initial delay will return.

interpolate-size CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`interpolate-size`** CSS property allows you to enable animations and transitions between a `<length-percentage>` value and an intrinsic size, `fit-content`, or `max-content`.

This property is typically used to animate the `width` and/or `height` of a container between a `<length-percentage>` and the full size of its content (i.e., between "closed" and "open" or "hide" and "reveal" states) when animating a non-box-model CSS property, such as `transform`, is not a viable solution.

> **Note:** The behavior opted-into by `interpolate-size` cannot be enabled by default across the web because many sites in the wild use stylesheets that assume intrinsic size values cannot be animated. Enabling it by default would cause several backwards-compatibility issues (see relevant CSS WG discussion).

Syntax

```
/* Keyword values */
interpolate-size: allow-keywords;
interpolate-size: numeric-only;

/* Global values */
interpolate-size: inherit;
interpolate-size: initial;
interpolate-size: revert;
interpolate-size: revert-layer;
interpolate-size: unset;
```

Values

This property is specified as one of the following keyword values:

`allow-keywords`

Enables interpolation between a `<length-percentage>` value and an intrinsic size value, to allow animation between the two.

`numeric-only`

The default behavior — intrinsic size values cannot be interpolated.

Description

Setting `interpolate-size: allow-keywords` enables interpolation between a `<length-percentage>` value and an intrinsic size value. Note that it does not enable animating between two intrinsic size values. One end of the animation must be a `<length-percentage>`.

The `interpolate-size` value is inherited, so animating to (or from) an intrinsic size value can be enabled for an entire document by setting it on the document root:

```
:root {
  interpolate-size: allow-keywords;
}
```

If you want to limit the scope, you can set it on the relevant container element. The following enables interpolating intrinsic sizes only for `<main>` and its descendants:

```
main {
  interpolate-size: allow-keywords;
}
```

> **Note:** The `calc-size()` function's return values can also be interpolated. In effect, including `calc-size()` in a property value automatically applies `interpolate-size: allow-keywords` to the selection. However, because `interpolate-size` is inherited as explained above, it is the preferred solution for enabling intrinsic size animations in most cases. You should only use `calc-size()` to enable intrinsic size animations if they also require calculations.

Values that can be interpolated

The following intrinsic values can currently be opted-in to animations:

- `auto`
- `min-content`
- `max-content`
- `fit-content`
- `content` (for containers sized using `flex-basis`).

Formal definition

Initial value	`numeric-only`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
interpolate-size =
  numeric-only    |
  allow-keywords
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic <code>interpolate-size</code> usage

This example demonstrates how to set `interpolate-size: allow-keywords` on a document to enable animations involving an intrinsic size. The demo features a character badge/"name tag", which can be hovered or focused to reveal information about the character. The reveal is handled by a `height` transition between a set length and `max-content`.

HTML

The HTML contains a single `<section>` element with `tabindex="0"` set on it so it can receive keyboard focus. The `<section>` contains `<header>` and `<main>` elements, each with their own child content.

```
<section tabindex="0">
  <header>
    <h2>Tanuki</h2>
```

```
  </header>
  <main>
    <p>Tanuki is the silent phantom of MDN.</p>
    <ul>
      <li><strong>Height</strong>: 3.03m</li>
      <li><strong>Weight</strong>: 160kg</li>
      <li><strong>Tech Fu</strong>: 7</li>
      <li><strong>Bad Jokes</strong>: 9</li>
    </ul>
  </main>
</section>
```

CSS

```
* {
  box-sizing: border-box;
}

section {
  font-family: "Helvetica", "Arial", sans-serif;
  width: 175px;
  border-radius: 5px;
  background: #eeeeee;
  box-shadow:
    inset 1px 1px 4px rgb(255 255 255 / 0.5),
    inset -1px -1px 4px rgb(0 0 0 / 0.5);
}

header {
  padding: 0.7rem;
  border-bottom: 2px solid #cccccc;
}

main {
  padding: 10px;
}

h2 {
  margin: 0;
  font-weight: normal;
  font-size: 1.1rem;
  text-align: center;
  letter-spacing: 1px;
}

p,
li {
  font-size: 0.8rem;
  line-height: 1.5;
}

p {
  margin-top: 0;
}
```

In the CSS, we first set `interpolate-size: allow-keywords` on the `:root`, to enable it for the whole document.

```
:root {
  interpolate-size: allow-keywords;
}
```

We then set the `<section>`'s `height` to `2.5rem` and `overflow` to `hidden` so only the `<header>` is shown by default, then specify a `transition` that animates the `<section>` `height` over 1 second during state change. Finally, we set the `<section>` `height` on `:hover` and `:focus` to `max-content`.

```
section {
  height: 2.5rem;
  overflow: hidden;
  transition: height ease 1s;
}

section:hover,
section:focus {
  height: max-content;
}
```

The rest of the CSS has been hidden for brevity.

Result

Try hovering over the `<section>` or focusing it via the keyboard — it will animate to its full height, revealing all the content.

isolation CSS property

The **`isolation`** CSS property determines whether an element must create a new stacking context.

This property is especially helpful when used in conjunction with `mix-blend-mode` and `z-index`.

Try it

```
isolation: auto;
```

```
isolation: isolate;
```

```
<section class="default-example" id="default-example">
  <div class="background-container">
    <div id="example-element">
      <img src="/shared-assets/images/examples/firefox-logo.svg" />
      <p><code>mix-blend-mode: multiply;</code></p>
    </div>
  </div>
</section>
```

```
.background-container {
  background-color: #f4f460;
  width: 250px;
}

#example-element {
  border: 1px solid black;
  margin: 2em;
}

#example-element * {
  mix-blend-mode: multiply;
  color: #8245a3;
}
```

Syntax

```
/* Keyword values */
isolation: auto;
isolation: isolate;

/* Global values */
isolation: inherit;
isolation: initial;
isolation: revert;
isolation: revert-layer;
isolation: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

A new stacking context is created only if one of the properties applied to the element requires it.

`isolate`

A new stacking context must be created.

Formal definition

Initial value	auto
Applies to	All elements. In SVG, it applies to container elements, graphics elements, and graphics referencing elements.
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
isolation =
  <isolation-mode>

<isolation-mode> =
  auto     |
  isolate
```

This syntax reflects the latest standard as per Compositing and Blending Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Forcing a new stacking context for an element

HTML

```
<div class="big-square">
  <div class="isolation-auto">
    <div class="small-square">auto</div>
  </div>
  <div class="isolation-isolate">
    <div class="small-square">isolate</div>
  </div>
</div>
```

CSS

```
.isolation-auto {
  isolation: auto;
}

.isolation-isolate {
  isolation: isolate;
}

.big-square {
  background-color: lime;
  width: 200px;
  height: 210px;
}
```

```
.small-square {
  background-color: lime;
  width: 100px;
  height: 100px;
  border: 1px solid black;
  padding: 2px;
  mix-blend-mode: difference;
}
```

Result

- `<blend-mode>`
- `mix-blend-mode`, `background-blend-mode`

justify-content CSS property

The CSS **`justify-content`** property defines how the browser distributes space between and around content items along the main axis of a flex container and the inline axis of grid and multicol containers.

The interactive example below demonstrates some `justify-content` values using grid layout.

Try it

```
justify-content: start;
```

```
justify-content: center;
```

```
justify-content: space-between;
```

```
justify-content: space-around;
```

```
justify-content: space-evenly;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">
      <div>One</div>
      <div>Two</div>
      <div>Three</div>
    </div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  width: 220px;
  display: grid;
  grid-template-columns: 60px 60px;
  grid-auto-rows: 40px;
  row-gap: 10px;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}
```

Syntax

```
/* Positional alignment */
justify-content: center;
justify-content: start;
justify-content: end;
justify-content: flex-start;
justify-content: flex-end;
justify-content: left;
justify-content: right;

/* Normal alignment */
justify-content: normal;

/* Distributed alignment */
justify-content: space-between;
justify-content: space-around;
justify-content: space-evenly;
justify-content: stretch;

/* Overflow alignment (for positional alignment only)*/
justify-content: safe center;
justify-content: unsafe center;

/* Global values */
justify-content: inherit;
justify-content: initial;
justify-content: revert;
justify-content: revert-layer;
justify-content: unset;
```

Values

This property is specified as one of the following keyword values:

`start`

> The items are packed flush to each other toward the start edge of the alignment container in the main axis.

`end`

The items are packed flush to each other toward the end edge of the alignment container in the main axis.

`flex-start`

The items are packed flush to each other toward the start edge of the alignment container on the flex container's main-start side. This only applies to flex layout items. For items that are not children of a flex container, this value is treated like `start`.

`flex-end`

The items are packed flush to each other at the end edge of the alignment container on the flex container's main-end side. This only applies to flex layout items. For items that are not children of a flex container, this value is treated like `end`.

`center`

The items are packed flush to each other toward the center of the alignment container along the main axis.

`left`

The items are packed flush to each other toward the left edge of the alignment container. When the property's horizontal axis is not parallel with the inline axis, such as when `flex-direction: column;` is set, this value behaves like `start`.

`right`

The items are packed flush to each other toward the right edge of the alignment container in the appropriate axis. If the property's axis is not parallel with the inline axis (in a grid container) or the main-axis (in a flexbox container), this value behaves like `start`.

`normal`

Behaves as `stretch`, except in the case of multi-column containers with a non-`auto` `column-width`, in which case the columns take their specified `column-width` rather than stretching to fill the container. As `stretch` behaves as `start` in flex containers, `normal` also behaves as `start`.

`space-between`

The items are evenly distributed within the alignment container along the main axis. The spacing between each pair of adjacent items is the same. The first item is flush with the main-start edge, and the last item is flush with the main-end edge.

`space-around`

The items are evenly distributed within the alignment container along the main axis. The spacing between each pair of adjacent items is the same. The empty space before the first and after the last item equals half of the space between each pair of adjacent items. If there is only one item, it will be centered.

`space-evenly`

The items are evenly distributed within the alignment container along the main axis. The spacing between each pair of adjacent items, the main-start edge and the first item, and the main-end edge and the last item, are all exactly the same.

`stretch`

If the combined size of the items along the main axis is less than the size of the alignment container, any `auto`-sized items have their size increased equally (not proportionally), while still respecting the constraints imposed by `max-height`/`max-width` (or equivalent functionality), so that the combined size exactly fills the alignment container along the main axis.

> **Note:** For flexboxes, the `stretch` value behaves as `flex-start` or `start`. This is because, in flexboxes, stretching is controlled using the `flex-grow` property.

`safe`

If the item overflows the alignment container, then the item is aligned as if the alignment mode is `start`. The desired alignment will not be implemented.

`unsafe`

Even if the item overflows the alignment container, the desired alignment will be implemented. Unlike `safe`, which will ignore the desired alignment in favor of preventing overflow.

Description

Defined in the CSS box alignment module, `justify-content` applies to multicol containers, flex containers, and grid containers. The property does not apply to and has no effect on block containers.

This property shares many keyword values with the `align-content` property, but not all! `justify-content` isn't involved in baseline alignment, and therefore does not take baseline values.

In flex layouts, the property defines how positive free space is distributed between or around flex items along the main axis. This property impacts the space between elements in a line, not the space between lines. The alignment is done after the lengths and auto margins are applied, which means that when one or more flex items in a line have a `flex-grow` factor greater than `0`, the property has no effect as there is no space to distribute along that line. Also, as stretching along the main axis is controlled by `flex`, the `stretch` value behaves as `flex-start`.

With grid layout, this property distributes available space between or around grid columns, not grid items. If the grid container is larger than the grid itself, the `justify-content` property can be used to justify the grid along the inline axis, aligning the grid columns.

Grid `auto` track sizes (and only `auto` track sizes) can be stretched by the `align-content` and `justify-content` properties. Therefore by default, an `auto` sized track will take up any remaining space in the grid container. As the grid's inline size has to be less than the grid container's inline size for there to be space to distribute, the property has no effect in this case.

Formal definition

Initial value	`normal`
Applies to	flex containers
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
justify-content =
  normal                                    |
  <content-distribution>                    |
  <overflow-position>? [ <content-position> | left | right ]

<content-distribution> =
  space-between  |
  space-around   |
  space-evenly   |
  stretch
```

```
<overflow-position> =
  unsafe  |
  safe

<content-position> =
  center      |
  start       |
  end         |
  flex-start  |
  flex-end
```

This syntax reflects the latest standard as per CSS Box Alignment Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic grid example

In this example, we have a grid that is narrower than its grid container, and we use `justify-content` to distribute the available space evenly around and between the grid columns.

HTML

The `<section>` container, our grid container to-be, has 16 nested `<div>`s that will become grid items.

```
<section class="container">
  <div>A</div>
  <div>B</div>
  <div>C</div>
  <div>D</div>
  <div>E</div>
  <div>F</div>
  <div>G</div>
  <div>H</div>
  <div>I</div>
  <div>J</div>
  <div>K</div>
  <div>L</div>
  <div>M</div>
  <div>N</div>
  <div>O</div>
  <div>P</div>
</section>
```

CSS

```
.container {
  margin: 5px;
  border: 1px solid;
  box-sizing: border-box;
}

div {
  line-height: 2em;
  border: 1px solid;
  box-sizing: border-box;
  text-align: center;
}
```

We set the container width to `500px` and specify three columns, each `80px` wide, meaning there is `260px` of available space to distribute between or around them. We then set `justify-content: space-evenly`, which means there will be `65px` of space before, between, and after each column.

We set different widths (and background colors) to demonstrate how the justification is applied to the columns.

```
.container {
  display: grid;
  grid: auto-flow / repeat(3, 80px);
  width: 500px;
  justify-content: space-evenly;
}

div {
  background-color: pink;
  width: 80px;
}

div:nth-of-type(n + 9) {
  width: 35px;
  background-color: lightgreen;
}

div:nth-last-of-type(3) {
  width: 250px;
  background-color: lightblue;
}
```

Result

Note that `justify-contents` aligns the columns and has no effect on the items or alignment in grid areas. Grid items, even those that overflow their grid cell, do not impact column justification.

The safe keyterm

This example demonstrates the `safe` keyterm. We specify four centered flex items that are not allowed to wrap, and as a result, overflow their single flex-line container. By adding `safe` to `center` in the `justify-content` property, overflowing content behaves as if the alignment mode is `start`

```
<p><code>justify-content: center;</code></p>
<section class="container safe">
  <div>A</div>
  <div>B</div>
  <div>C</div>
  <div>D</div>
</section>
```

```
<p><code>justify-content: safe center;</code></p>
<section class="container safe-center">
  <div>A</div>
  <div>B</div>
  <div>C</div>
  <div>D</div>
</section>
<p><code>justify-content: safe center;</code> with 3 items</p>
<section class="container safe-center">
  <div>A</div>
  <div>B</div>
  <div>C</div>
</section>
```

```
.container {
  margin: 5px auto;
  border: 1px dashed;
  box-sizing: border-box;
  background-color: lightblue;
}

div {
  line-height: 1em;
  border: 1px solid;
  box-sizing: border-box;
  text-align: center;
  background-color: pink;
}
```

The container is set to `center`, with every container other than the first having the `safe` keyword added:

```
.container {
  align-items: baseline;
  display: flex;
  width: 350px;
  height: 2em;
}

.safe {
  justify-content: center;
}

.safe-center {
  justify-content: safe center;
}

div {
  flex: 0 0 100px;
}
```

Result

As an item overflows the alignment container, with `safe` included the alignment mode behaves as `start` and the `center` alignment is not implemented. The `safe` keyterm has no effect if the items do not overflow the container.

Visualizing flex item distribution

This example includes a multi-line wrapping flex layout. The second flex item has a positive flex growth factor, consuming all the available free space in the first flex line.

CSS

```
#container {
  margin: 5px auto;
  border: 1px dashed black;
  box-sizing: border-box;
}

div {
  line-height: 2em;
  border: 1px solid;
  box-sizing: border-box;
  text-align: center;
}
```

```
#container {
  display: flex;
  flex-flow: row wrap;
  justify-content: space-between; /* Can be changed in the live sample */
  width: 510px;
}

div {
  line-height: 2em;
  flex: 0 0 120px;
  background-color: pink;
}

div:nth-of-type(2) {
  flex-grow: 1;
  background-color: yellow;
}

div:nth-of-type(n + 9) {
  flex: 0 0 35px;
  background-color: lightgreen;
}
div:last-of-type {
  flex: 0 0 300px;
  background-color: lightblue;
}
```

```
<section id="container">
  <div>A</div>
  <div>GROW</div>
  <div>C</div>
  <div>D</div>
  <div>E</div>
  <div>F</div>
  <div>G</div>
  <div>H</div>
  <div>I</div>
  <div>J</div>
  <div>K</div>
  <div>L</div>
  <div>M</div>
  <div>N</div>
  <div>O</div>
  <div>P</div>
</section>
<select id="justifyContent">
  <option value="start">start</option>
  <option value="end">end</option>
  <option value="flex-start">flex-start</option>
  <option value="flex-end">flex-end</option>
  <option value="center">center</option>
  <option value="left">left</option>
  <option value="right">right</option>
  <option value="space-between" selected>space-between</option>
  <option value="space-around">space-around</option>
  <option value="space-evenly">space-evenly</option>
  <option value="stretch">stretch</option>
</select>
```

```
const justifyContent = document.getElementById("justifyContent");
justifyContent.addEventListener("change", (evt) => {
  document.getElementById("container").style.justifyContent = evt.target.value;
});
```

Result

Select different keywords from the drop-down menu to visualize the different `justify-content` keyword values. Because an item on the first line can grow, there is no available space on that line for the `justify-content` property to distribute. With the `space-between` value, the first item on each line is flush with the main-start edge, and the last item is flush with the main-end edge. As a result, if a line has only one item, it will be aligned with the main-start edge (as seen in the last line). This is not the case for other `space-*` values, such as `space-evenly` and `space-around`, which center one-item flex-lines.

justify-items CSS property

The CSS **`justify-items`** property defines the default `justify-self` for all items of the box, giving them all a default way of justifying each box along the appropriate axis.

Try it

```
justify-items: stretch;
```

```
justify-items: center;
```

```
justify-items: start;
```

```
justify-items: end;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">
      <div>One</div>
      <div>Two</div>
      <div>Three</div>
    </div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-template-columns: 1fr 1fr;
  grid-auto-rows: 40px;
  grid-gap: 10px;
  width: 220px;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}
```

The effect of this property is dependent of the layout mode we are in:

- In block-level layouts, it aligns the items inside their containing block on the inline axis.
- For absolutely-positioned elements, it aligns the items inside their containing block on the inline axis, accounting for the offset values of top, left, bottom, and right.
- In table cell layouts, this property is *ignored* (see Box alignment for block, absolutely positioned, and table layouts)
- In flexbox layouts, this property is *ignored* (see Box alignment in flexbox)
- In grid layouts, it aligns the items inside their grid areas on the inline axis (see Box alignment in grid layout)

Syntax

```
/* Basic keywords */
justify-items: normal;
justify-items: stretch;

/* Positional alignment */
justify-items: center; /* Pack items around the center */
justify-items: start; /* Pack items from the start */
justify-items: end; /* Pack items from the end */
justify-items: flex-start; /* Equivalent to 'start'. Note that justify-items is ignored in flexbox layouts. */
justify-items: flex-end; /* Equivalent to 'end'. Note that justify-items is ignored in flexbox layouts. */
justify-items: self-start;
justify-items: self-end;
justify-items: left; /* Pack items from the left */
justify-items: right; /* Pack items from the right */
justify-items: anchor-center;

/* Baseline alignment */
justify-items: baseline;
justify-items: first baseline;
justify-items: last baseline;

/* Overflow alignment (for positional alignment only) */
justify-items: safe center;
justify-items: unsafe center;

/* Legacy alignment */
justify-items: legacy left;
justify-items: legacy right;
justify-items: legacy center;

/* Global values */
justify-items: inherit;
justify-items: initial;
justify-items: revert;
justify-items: revert-layer;
justify-items: unset;
```

This property can take one of four different forms:

- Basic keywords: one of the keyword values `normal` or `stretch`.
- Baseline alignment: the `baseline` keyword, plus optionally one of `first` or `last`.
- Positional alignment: one of: `center`, `start`, `end`, `flex-start`, `flex-end`, `self-start`, `self-end`, `left`, or `right`. Plus optionally `safe` or `unsafe`.
- Legacy alignment: the `legacy` keyword, followed by one of `left`, `right`, or `center`.

Values

`normal`

The effect of this keyword is dependent of the layout mode we are in:

- In block-level layouts, the keyword is a synonym of `start`.
- In absolutely-positioned layouts, the keyword behaves like `start` on *replaced* absolutely-positioned boxes, and as `stretch` on *all other* absolutely-positioned boxes.
- In table cell layouts, this keyword has no meaning as this property is *ignored*.
- In flexbox layouts, this keyword has no meaning as this property is *ignored*.
- In grid layouts, this keyword leads to a behavior similar to the one of `stretch`, except for boxes with an aspect ratio or an intrinsic size where it behaves like `start`.

`start`

The item is packed flush to each other toward the start edge of the alignment container in the appropriate axis.

`end`

The item is packed flush to each other toward the end edge of the alignment container in the appropriate axis.

`flex-start`

For items that are not children of a flex container, this value is treated like `start`.

`flex-end`

For items that are not children of a flex container, this value is treated like `end`.

`self-start`

The item is packed flush to the edge of the alignment container of the start side of the item, in the appropriate axis.

`self-end`

The item is packed flush to the edge of the alignment container of the end side of the item, in the appropriate axis.

`center`

The items are packed flush to each other toward the center of the alignment container.

`left`

The items are packed flush to each other toward the left edge of the alignment container. If the property's axis is not parallel with the inline axis, this value behaves like `start`.

`right`

The items are packed flush to each other toward the right edge of the alignment container in the appropriate axis. If the property's axis is not parallel with the inline axis, this value behaves like `start`.

`baseline`, `first baseline`, `last baseline`

Specifies participation in first- or last-baseline alignment: aligns the alignment baseline of the box's first or last baseline set with the corresponding baseline in the shared first or last baseline set of all the boxes in its baseline-sharing group. The fallback alignment for `first baseline` is `start`, the one for `last baseline` is `end`.

`stretch`

If the combined size of the items is less than the size of the alignment container, any `auto`-sized items have their size increased equally (not proportionally), while still respecting the constraints imposed by `max-height`/`max-width` (or equivalent functionality), so that the combined size exactly fills the alignment container.

`anchor-center`

In the case of anchor-positioned elements, aligns the items to the center of the associated anchor element in the inline direction. See Centering on the anchor using `anchor-center`.

`safe`

If the size of the item overflows the alignment container, the item is instead aligned as if the alignment mode were `start`.

`unsafe`

Regardless of the relative sizes of the item and alignment container, the given alignment value is honored.

`legacy`

Makes the value inherited by the box descendants. Note that if a descendant has a `justify-self: auto` value, the `legacy` keyword is not considered by the descend, only the `left`, `right`, or `center` value associated to it.

Formal definition

Initial value	`legacy`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
justify-items =
  normal                                          |
  stretch                                         |
  <baseline-position>                             |
  <overflow-position>? [ <self-position> | left | right ]  |
  legacy                                          |
  legacy && [ left | right | center ]

<baseline-position> =
  [ first | last ]?  &&
  baseline

<overflow-position> =
  unsafe  |
  safe

<self-position> =
  center      |
  start       |
  end         |
  self-start  |
  self-end    |
  flex-start  |
  flex-end
```

This syntax reflects the latest standard as per CSS Box Alignment Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic demonstration

In this example, we have a 2 x 2 grid layout. Initially the grid container is given a `justify-items` value of `stretch` (the default), which causes the grid items to stretch across the entire width of their cells.

If you hover or tab onto the grid container however, it is given a `justify-items` value of `center`, which causes the grid items to span only as wide as their content width, and align in the center of their cells.

HTML

```
<article class="container" tabindex="0">
  <span>First child</span>
  <span>Second child</span>
  <span>Third child</span>
  <span>Fourth child</span>
</article>
```

CSS

```
html {
  font-family: "Helvetica", "Arial", sans-serif;
  letter-spacing: 1px;
}

article {
  background-color: red;
  display: grid;
  grid-template-columns: 1fr 1fr;
  grid-auto-rows: 40px;
  grid-gap: 10px;
  margin: 20px;
  width: 300px;
  justify-items: stretch;
}

article:hover,
article:focus {
  justify-items: center;
}

article span {
  background-color: black;
  color: white;
  margin: 1px;
```

```
  text-align: center;
}

article,
span {
  padding: 10px;
  border-radius: 7px;
}
```

Result

justify-self CSS property

The CSS **`justify-self`** property sets the way a box is justified inside its alignment container along the appropriate axis.

Try it

```
justify-self: stretch;
```

```
justify-self: center;
```

```
justify-self: start;
```

```
justify-self: end;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">One</div>
    <div>Two</div>
    <div>Three</div>
  </div>
</section>
```

```
.example-container {
  border: 1px solid #c5c5c5;
  display: grid;
  width: 220px;
  grid-template-columns: 1fr 1fr;
  grid-auto-rows: 40px;
  grid-gap: 10px;
}

.example-container > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}
```

The effect of this property is dependent of the layout mode we are in:

- In block-level layouts, it aligns an item inside its containing block on the inline axis.
- For absolutely-positioned elements, it aligns an item inside its containing block on the inline axis, accounting for the offset values of top, left, bottom, and right.
- In table cell layouts, this property is *ignored*. Read more about alignment in block, absolute positioned and table layout.
- In flexbox layouts, this property is *ignored*. Read more about alignment in flexbox.
- In grid layouts, it aligns an item inside its grid area on the inline axis. Read more about alignment in grid layouts.

Syntax

```
/* Basic keywords */
justify-self: auto;
justify-self: normal;
justify-self: stretch;

/* Positional alignment */
justify-self: center; /* Pack item around the center */
justify-self: start; /* Pack item from the start */
justify-self: end; /* Pack item from the end */
justify-self: flex-start; /* Equivalent to 'start'. Note that justify-self is ignored in flexbox layouts. */
justify-self: flex-end; /* Equivalent to 'end'. Note that justify-self is ignored in flexbox layouts. */
justify-self: self-start;
justify-self: self-end;
justify-self: left; /* Pack item from the left */
justify-self: right; /* Pack item from the right */
justify-self: anchor-center;

/* Baseline alignment */
justify-self: baseline;
justify-self: first baseline;
justify-self: last baseline;

/* Overflow alignment (for positional alignment only) */
justify-self: safe center;
justify-self: unsafe center;

/* Global values */
justify-self: inherit;
justify-self: initial;
justify-self: revert;
justify-self: revert-layer;
justify-self: unset;
```

This property can take one of three different forms:

- Basic keywords: one of the keyword values `normal`, `auto`, or `stretch`.
- Baseline alignment: the `baseline` keyword, plus optionally one of `first` or `last`.
- Positional alignment:
  - one of: `center`, `start`, `end`, `flex-start`, `flex-end`, `self-start`, `self-end`, `left`, or `right`.
  - Plus optionally `safe` or `unsafe`.

Values

`auto`

The value used is the value of the `justify-items` property of the parents box, unless the box has no parent, or is absolutely positioned, in these cases, `auto` represents `normal`.

`normal`

The effect of this keyword is dependent of the layout mode we are in:

- In block-level layouts, the keyword is a synonym of `start`.
- In absolutely-positioned layouts, the keyword behaves like `start` on *replaced* absolutely-positioned boxes, and as `stretch` on *all other* absolutely-positioned boxes.
- In table cell layouts, this keyword has no meaning as this property is *ignored*.
- In flexbox layouts, this keyword has no meaning as this property is *ignored*.
- In grid layouts, this keyword leads to a behavior similar to the one of `stretch`, except for boxes with an aspect ratio or an intrinsic size where it behaves like `start`.

`start`

The item is packed flush to each other toward the start edge of the alignment container in the appropriate axis.

`end`

The item is packed flush to each other toward the end edge of the alignment container in the appropriate axis.

`flex-start`

For items that are not children of a flex container, this value is treated like `start`.

`flex-end`

For items that are not children of a flex container, this value is treated like `end`.

`self-start`

The item is packed flush to the edge of the alignment container of the start side of the item, in the appropriate axis.

`self-end`

The item is packed flush to the edge of the alignment container of the end side of the item, in the appropriate axis.

`center`

The items are packed flush to each other toward the center of the alignment container.

`left`

The items are packed flush to each other toward the left edge of the alignment container. If the property's axis is not parallel with the inline axis, this value behaves like `start`.

`right`

The items are packed flush to each other toward the right edge of the alignment container in the appropriate axis. If the property's axis is not parallel with the inline axis, this value behaves like `start`.

`baseline`, `first baseline`, `last baseline`

Specifies participation in first- or last-baseline alignment: aligns the alignment baseline of the box's first or last baseline set with the corresponding baseline in the shared first or last baseline set of all the boxes in its baseline-sharing group. The fallback alignment for `first baseline` is `start`, the one for `last baseline` is `end`.

`stretch`

If the combined size of the items is less than the size of the alignment container, any `auto`-sized items have their size increased equally (not proportionally), while still respecting the constraints imposed by `max-height`/`max-width` (or equivalent functionality), so that the combined size exactly fills the alignment container.

`anchor-center`

In the case of anchor-positioned elements, aligns the item to the center of the associated anchor element in the inline direction. See Centering on the anchor using `anchor-center`.

`safe`

If the size of the item overflows the alignment container, the item is instead aligned as if the alignment mode were `start`.

`unsafe`

Regardless of the relative sizes of the item and alignment container, the given alignment value is honored.

Formal definition

Initial value	`auto`
Applies to	block-level boxes, absolutely-positioned boxes, and grid items
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
justify-self =
  auto                                          |
  <overflow-position>? [ normal | <self-position> | left | right ]  |
  stretch                                       |
  <baseline-position>                           |
  anchor-center

<overflow-position> =
```

```
  unsafe  |
  safe

<self-position> =
  center      |
  start       |
  end         |
  self-start  |
  self-end    |
  flex-start  |
  flex-end

<baseline-position> =
  [ first | last ]?  &&
  baseline
```

This syntax reflects the latest standard as per CSS Box Alignment Module Level 3, CSS Specification. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic demonstration

In the following example we have a 2 x 2 grid layout. Initially the grid container is given a `justify-items` value of `stretch` — the default — which causes the grid items to stretch across the entire width of their cells.

The second, third, and fourth grid items are then given different values of `justify-self`, to show how these override the `justify-items` value. These values cause the grid items to span only as wide as their content width, and align in different positions across their cells.

HTML

```
<article class="container">
  <span>First child</span>
  <span>Second child</span>
  <span>Third child</span>
  <span>Fourth child</span>
</article>
```

CSS

```
html {
  font-family: "Helvetica", "Arial", sans-serif;
  letter-spacing: 1px;
}

article {
  background-color: red;
  display: grid;
  grid-template-columns: 1fr 1fr;
  grid-auto-rows: 40px;
  grid-gap: 10px;
  margin: 20px;
  width: 300px;
  justify-items: stretch;
}

span:nth-child(2) {
  justify-self: start;
}

span:nth-child(3) {
  justify-self: center;
}

span:nth-child(4) {
  justify-self: end;
}

article span {
  background-color: black;
  color: white;
  margin: 1px;
  text-align: center;
}

article,
span {
  padding: 10px;
  border-radius: 7px;
}
```

Result

- `justify-items`
- `align-self`
- `place-self`

left CSS property

The **`left`** CSS property participates in specifying the horizontal position of a positioned element. This inset property has no effect on non-positioned elements.

Try it

```
left: 0;
```

```
left: 4em;
```

```
left: 10%;
```

```
left: 20px;
```

```
<section id="default-example">
  <div class="example-container">
    <div id="example-element">I am absolutely positioned.</div>
    <p>
      As much mud in the streets as if the waters had but newly retired from the
      face of the earth, and it would not be wonderful to meet a Megalosaurus,
      forty feet long or so, waddling like an elephantine lizard up Holborn
      Hill.
    </p>
  </div>
</section>
```

```
.example-container {
  border: 0.75em solid;
  padding: 0.75em;
  text-align: left;
  position: relative;
  width: 100%;
  min-height: 200px;
}

#example-element {
  background-color: #264653;
  border: 4px solid #ffb500;
  color: white;
  position: absolute;
  width: 140px;
  height: 60px;
}
```

Syntax

```
/* <length> values */
left: 3px;
left: 2.4em;
left: anchor(--my-anchor 50%);
left: calc(anchor-size(--my-anchor inline, 100px) * 2);

/* <percentage>s of the width of the containing block */
left: 10%;

/* Keyword value */
left: auto;

/* Global values */
left: inherit;
left: initial;
left: revert;
left: revert-layer;
left: unset;
```

Values

`<length>`

A negative, null, or positive `<length>`:

- for *absolutely positioned elements*, it represents the distance to the left edge of the containing block.
- for *anchor-positioned elements*, the `anchor()` function resolves to a `<length>` value relative to the position of the associated *anchor element*'s left or right edge (see Using inset properties with `anchor()` function values), and the `anchor-size()` function resolves to a `<length>` value relative to the associated anchor element's width or height (see Setting element position based on anchor size).
- for *relatively positioned elements*, it represents the distance that the element is moved to the right of its normal position.

`<percentage>`

A `<percentage>` of the containing block's width.

`auto`

Specifies that:

- for *absolutely positioned elements*, the position of the element is based on the `right` property, while `width: auto` is treated as a width based on the content; or if `right` is also `auto`, the element is positioned where it should horizontally be positioned if it were a static element.
- for *relatively positioned elements*, the distance of the element from its normal position is based on the `right` property; or if `right` is also `auto`, the element is not moved horizontally at all.

Description

The effect of `left` depends on how the element is positioned (i.e., the value of the `position` property):

- When `position` is set to `absolute` or `fixed`, the `left` property specifies the distance between the element's outer margin of left edge and the inner border of left edge of its containing block. (The containing block is the ancestor to which the element is relatively positioned.) If the positioned element has an associated *anchor element*, and the property value includes an `anchor()` function, `left` positions the left edge of the positioned element relative to the position of the specified `<anchor-side>` edge. The `left` property is compatible with the `left`, `right`, `start`, `end`, `self-start`, `self-end`, `center`, and `<percentage>` values.
- When `position` is set to `relative`, the `left` property specifies the distance the element's left edge is moved to the right from its normal position.
- When `position` is set to `sticky`, the `left` property is used to compute the sticky-constraint rectangle.
- When `position` is set to `static`, the `left` property has *no effect*.

When both `left` and `right` are defined, and width constraints don't prevent it, the element will stretch to satisfy both. If the element cannot stretch to satisfy both, the position of the element is *overspecified*. When this is the case, the `left` value has precedence when the container is left-to-right; the `right` value has precedence when the container is right-to-left.

Formal definition

Initial value	`auto`

Applies to	positioned elements
Inherited	no
Percentages	refer to the width of the containing block
Computed value	if specified as a length, the corresponding absolute length; if specified as a percentage, the specified value; otherwise, `auto`
Animation type	a length, percentage or calc();

Formal syntax

```
left =
  auto                |
  <length-percentage>  |
  <anchor()>           |
  <anchor-size()>

<length-percentage> =
  <length>      |
  <percentage>

<anchor()> =
  anchor( <anchor-name>?                &&
  <anchor-side> , <length-percentage>? )

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<anchor-name> =
  <dashed-ident>

<anchor-side> =
  inside        |
  outside       |
  top           |
  left          |
  right         |
  bottom        |
  start         |
  end           |
  self-start    |
  self-end      |
  <percentage>  |
  center

<anchor-size> =
  width        |
  height       |
  block        |
  inline       |
  self-block   |
  self-inline
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Positioned Layout Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Positioning elements

HTML

```
<div id="wrap">
  <div id="example_1">
    <pre>
      position: absolute;
      left: 20px;
      top: 20px;
    </pre>
    <p>
      The only containing element for this div is the main window, so it
      positions itself in relation to it.
    </p>
  </div>

  <div id="example_2">
    <pre>
      position: relative;
      top: 0;
      right: 0;
    </pre>
    <p>Relative position in relation to its siblings.</p>
  </div>

  <div id="example_3">
    <pre>
      float: right;
      position: relative;
      top: 20px;
      left: 20px;
    </pre>
    <p>Relative to its sibling div above, but removed from flow of content.</p>

    <div id="example_4">
      <pre>
        position: absolute;
        bottom: 10px;
        right: 20px;
      </pre>
      <p>Absolute position inside of a parent with relative position</p>
    </div>

    <div id="example_5">
      <pre>
        position: absolute;
```

```
        right: 0;
        left: 0;
        top: 200px;
      </pre>
      <p>Absolute position with both left and right declared</p>
    </div>
  </div>
</div>
```

CSS

```
#wrap {
  width: 700px;
  margin: 0 auto;
  background: #5c5c5c;
}

pre {
  white-space: pre-line;
  word-wrap: break-word;
}

#example_1 {
  width: 200px;
  height: 200px;
  position: absolute;
  left: 20px;
  top: 20px;
  background-color: #d8f5ff;
}

#example_2 {
  width: 200px;
  height: 200px;
  position: relative;
  top: 0;
  right: 0;
  background-color: #c1ffdb;
}
#example_3 {
  width: 600px;
  height: 400px;
  position: relative;
  top: 20px;

letter-spacing CSS property

The **`letter-spacing`** CSS property sets the spacing between text characters. This value is added to the natural spacing between characters while rendering the text. Positive values of `letter-spacing` spread characters further apart, while negative values of `letter-spacing` bring characters closer together.

Try it

```
letter-spacing: normal;
```

```
letter-spacing: 0.2rem;
```

```
letter-spacing: 1px;
```

```
letter-spacing: 30%;
```

```
letter-spacing: -1px;
```

```
<section id="default-example">
  <p id="example-element">
    As much mud in the streets as if the waters had but newly retired from the
    face of the earth, and it would not be wonderful to meet a Megalosaurus,
    forty feet long or so, waddling like an elephantine lizard up Holborn Hill.
```

```
  </p>
</section>
```

```
@font-face {
  src: url("/shared-assets/fonts/variable-fonts/AmstelvarAlpha-VF.woff2");
  font-family: "Amstelvar";
  font-style: normal;
}

section {
  font-size: 1.2em;
  font-family: "Amstelvar", serif;
}
```

Syntax

```
/* Keyword value */
letter-spacing: normal;

/* <length-percentage> values */
letter-spacing: 0.3em;
letter-spacing: 3px;
letter-spacing: -0.5px;
letter-spacing: 50%;

/* Global values */
letter-spacing: inherit;
letter-spacing: initial;
letter-spacing: revert;
letter-spacing: revert-layer;
letter-spacing: unset;
```

Values

This property is specified as a single value from the following list:

`normal`

The normal letter spacing for the current font. Unlike a value of `0`, this keyword allows the user agent to alter the space between characters in order to justify text.

`<length-percentage>`

Specifies extra inter-character space *in addition to* the default space between characters. While values can be negative, these may be constrained to implementation-specific limits. User agents may not further increase or decrease the inter-character space in order to justify text.

Percentage values are calculated relative to the width of the space character of the font applied to the text.

> **Note:** When `letter-spacing` is non-zero, user agents do not apply optional ligatures, such as the `liga` (standard ligatures) and `clig` (contextual ligatures) OpenType features normally controlled by `font-variant-ligatures`. These features can be explicitly re-enabled with `font-feature-settings`.

Accessibility

A large positive or negative `letter-spacing` value will make the word(s) the styling is applied to unreadable. For text styled with a very large positive value, the letters will be so far apart that the word(s) will appear like a series of individual, unconnected letters. For text styled with a very large negative value, the letters can overlap each other to the point where the word(s) may be unrecognizable.

Legible letter-spacing must be determined on a case-by-case basis, as different font families have different character widths. There is no one value that can ensure all font families automatically maintain their legibility.

- MDN Understanding WCAG, Guideline 1.4 explanations
- Understanding Success Criterion 1.4.8 | W3C Understanding WCAG 2.0

Internationalization concerns

Some written languages should not have any letter spacing applied. For instance, languages that use the Arabic script expect connected letters to remain visually connected, as in the following example. Applying letter spacing may lead to the text looking broken.

```
<p lang="ar" dir="rtl">شسيبتنمك</p>
```

```
p {
  font-size: 3em;
  margin-inline-start: 5px;
}
```

Formal definition

Initial value	`normal`
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	an optimum value consisting of either an absolute length or the keyword `normal`
Animation type	a length

Formal syntax

```
letter-spacing =
  normal               |
  <length-percentage>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Text Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting letter-spacing with length values

This example shows several paragraphs with different length `letter-spacing` values set, allowing you to compare them.

HTML

The HTML contains several `<p>` elements containing text content.

```
<p class="normal">letter spacing</p>
<p class="em-wide">letter spacing</p>
<p class="em-wider">letter spacing</p>
<p class="em-tight">letter spacing</p>
<p class="px-wide">letter spacing</p>
```

CSS

Our CSS applies a different `letting-spacing` value to each paragraph.

```
.normal {
  letter-spacing: normal;
}
.em-wide {
  letter-spacing: 0.4em;
}
.em-wider {
  letter-spacing: 1em;
}
.em-tight {
  letter-spacing: -0.05em;
}
.px-wide {
  letter-spacing: 6px;
}
```

Result

The rendered result looks like this:

Comparing letter-spacing set with length and percentage

This example demonstrates that percentage `letter-spacing` values are useful for responsive text sizing.

The code displays several paragraphs that have the same `letter-spacing` set on text with increasing font size. We provide functionality to switch between a length and a percentage `letter-spacing` value, so that you can observe the responsive qualities of using a percentage value.

HTML

The HTML contains several `<p>` elements containing text content, and an `<input type="checkbox">` that we'll use to toggle between a length `letter-spacing` and a percentage `letter-spacing` value.

```
<p class="x-small">X-small font-size (0.8em)</p>
<p class="small">Small font-size (1.3em)</p>
<p class="medium">Medium font-size (2em)</p>
<p class="large">Large font-size (3em)</p>
<p class="x-large">X-Large (3.5em)</p>

<form>
  <label for="ls-toggle">
    Toggle <code>letter-spacing</code> (off: <code>8px</code>, on:
    <code>12%</code>)
  </label>
  <input type="checkbox" id="ls-toggle" />
</form>
```

CSS

Our CSS starts by applying increasing `font-size` values to each successive paragraph:

```
html {
  font-family: "Arial", sans-serif;
}
```

```
.x-small {
  font-size: 0.8em;
}

.small {
  font-size: 1.3em;
}

.medium {
  font-size: 2em;
}

.large {
  font-size: 3em;
}

.x-large {
  font-size: 3.5em;
}
```

We apply a `letter-spacing` value of `8px` to all paragraphs by default. When the checkbox is checked, however, we change the `letter-spacing` value to `12%`:

```
p {
  letter-spacing: 8px;
}

p:has(~ form > input:checked) {
```

```
  letter-spacing: 12%;
}
```

Result

The rendered result looks like this:

First, note how the initial length letter spacing value looks OK when applied to the larger font sizes, but it doesn't look good on the smaller font sizes. Now toggle the checkbox, and note how the percentage letter spacing looks appropriate on all lines, as it scales with the font size.

lighting-color CSS property

The **`lighting-color`** CSS property defines the color of the light source for the `<feDiffuseLighting>` and `<feSpecularLighting>` SVG lighting filter primitives within an SVG `<filter>`. If present, it overrides the element's `lighting-color` attribute.

> **Note:** The `lighting-color` property only applies to `<feDiffuseLighting>` and `<feSpecularLighting>` elements nested in an `<svg>`. It doesn't apply to other SVG, HTML, or pseudo-elements.

Syntax

```
/* <color> values */
lighting-color: red;
lighting-color: hsl(120deg 75% 25% / 60%);
lighting-color: currentColor;

/* Global values */
lighting-color: inherit;
lighting-color: initial;
lighting-color: revert;
lighting-color: revert-layer;
lighting-color: unset;
```

Values

This property is specified as one `<color>` value:

`<color>`

The lighting's color. This can be any valid CSS `<color>` value.

Formal definition

Initial value	`white`
Applies to	`<feDiffuseLighting>` and `<feSpecularLighting>` elements in `<svg>`
Inherited	no
Computed value	as specified
Animation type	by computed value

Formal syntax

```
lighting-color =
  <color>
```

This syntax reflects the latest standard as per Filter Effects Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Defining the color of filter lighting

This example demonstrates the basic use case of `lighting-color`, and how the CSS `lighting-color` property takes precedence over the `lighting-color` attribute.

HTML

We have an SVG with two `<filter>` elements, one with a `<feDiffuseLighting>` and one with a `<feSpecularLighting>` child. Each includes the SVG `lighting-color` attribute defining the lighting color as `red`. Both of these children have a `<fePointLight>`, the required child that sets the light source. We included two `<rect>` elements with a filter attribute; this is where the filters will be displayed.

```
<svg viewBox="0 0 420 120" xmlns="http://www.w3.org/2000/svg">
  <filter id="flood1">
    <feDiffuseLighting lighting-color="red">
      <fePointLight x="75" y="30" z="10" />
    </feDiffuseLighting>
  </filter>
  <filter id="flood2">
    <feSpecularLighting specularExponent="5" lighting-color="red">
      <fePointLight x="225" y="75" z="5" />
    </feSpecularLighting>
  </filter>

  <rect id="r1" filter="url(#flood1)" />
  <rect id="r2" filter="url(#flood2)" />
</svg>
```

CSS

We define the size and position of our `<rect>` using the CSS `height`, `width`, `x`, and `y` properties. We also add a background image to the SVG to make any color alpha transparency more apparent:

```
svg {
  background-image: repeating-linear-gradient(
    45deg,
    transparent 0 9px,
```

```
    #cccccc 0px 10px
  );
}

rect {
  width: 100px;
  height: 100px;
  x: 10px;
  y: 10px;
}

#r2 {
  x: 150px;
}
```

We then apply different lighting color values to the filter's child elements using the CSS `lighting-color` property. We use a named color and a 3-digit hexadecimal color, but we can use any valid CSS color syntax:

```
feDiffuseLighting {
  lighting-color: blue;
}

feSpecularLighting {
  lighting-color: #ff0099;
}
```

Results

The attributes defined the color of both light filters as `red`, but these values were overridden by the CSS `lighting-color` values.

line-break CSS property

The **`line-break`** CSS property sets how to break lines of Chinese, Japanese, or Korean (CJK) text when working with punctuation and symbols.

Try it

```
line-break: auto;
```

```
line-break: anywhere;
```

```
line-break: normal;
```

```
line-break: loose;
```

```
<section id="default-example">
  <p id="example-element">
    この喫茶店は、いつでもコーヒーの香りを漂わせています。<br />彼女はこの喫茶店で働いて、着々と実力をつけていきました。<br />今では知る人ぞ知る、名人です。
  </p>
</section>
```

```
#example-element {
  font-family: "Yu Gothic", "YuGothic", "Meiryo", "ＭＳ ゴシック", sans-serif;
  border: 2px dashed #999999;
  text-align: left;
  width: 240px;
  font-size: 16px;
}
```

Syntax

```
/* Keyword values */
line-break: auto;
line-break: loose;
line-break: normal;
line-break: strict;
line-break: anywhere;

/* Global values */
line-break: inherit;
line-break: initial;
line-break: revert;
line-break: revert-layer;
line-break: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

Break text using the default line break rule.

`loose`

Break text using the least restrictive line break rule. Typically used for short lines, such as in newspapers.

`normal`

Break text using the most common line break rule.

`strict`

Break text using the most stringent line break rule.

`anywhere`

There is a soft wrap opportunity around every typographic character unit, including around any punctuation character or preserved white spaces, or in the middle of words, disregarding any prohibition against line breaks, even those introduced by characters with the GL, WJ, or ZWJ character class or mandated by the `word-break` property. The different wrapping opportunities must not be prioritized. Hyphenation is not applied.

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
line-break =
  auto      |
  loose     |
  normal    |
  strict    |
  anywhere
```

This syntax reflects the latest standard as per CSS Text Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting text wrapping

See whether the text is wrapped before "々", "ぁ" and "。".

HTML

```
<div lang="ja">
  <p class="wrap-box auto">
    auto:<br />そこは湖のほとりで木々が輝いていた。<br />その景色に、美しいなぁと思わずつぶやいた。
  </p>
  <p class="wrap-box loose">
    loose:<br />そこは湖のほとりで木々が輝いていた。<br />その景色に、美しいなぁと思わずつぶやいた。
  </p>
  <p class="wrap-box normal">
    normal:<br />そこは湖のほとりで木々が輝いていた。<br />その景色に、美しいなぁと思わずつぶやいた。
  </p>
  <p class="wrap-box strict">
    strict:<br />そこは湖のほとりで木々が輝いていた。<br />その景色に、美しいなぁと思わずつぶやいた。
  </p>
  <p class="wrap-box anywhere">
    anywhere:<br />そこは湖のほとりで木々が輝いていた。<br />その景色に、美しいなぁと思わずつぶやいた。
  </p>
</div>
```

CSS

```
.wrap-box {
  width: 10em;
  margin: 0.5em;
  white-space: normal;
  vertical-align: top;
  display: inline-block;
}
.auto {
  line-break: auto;
}
.loose {
  line-break: loose;
}
.normal {
  line-break: normal;
}
.strict {
  line-break: strict;
}
.anywhere {
  line-break: anywhere;
}
```

Result

- CSS and international text on W3C

line-clamp CSS property

The **`line-clamp`** CSS property allows limiting of the contents of a block to the specified number of lines. Optionally, it also allows inserting content into the last line to indicate that content was truncated.

Syntax

```
/* Keyword value */
line-clamp: none;

/* <integer> value only */
line-clamp: 3;
line-clamp: 10;

/* <integer> and <'block-ellipsis'> values */
line-clamp: 3 no-ellipsis;
line-clamp: 10 "… (there is extra content)";

/* <'block-ellipsis'> value only */
line-clamp: no-ellipsis;
line-clamp: "… (there is extra content)";

/* Global values */
line-clamp: inherit;
line-clamp: initial;
line-clamp: revert;
line-clamp: revert-layer;
line-clamp: unset;
```

Values

This property is specified as one or two space-separated values from the following list:

`none`

Specifies that content is not clamped. This keyword cannot be combined with the other values. This is the default.

`<integer>` Optional

Specifies the number of lines after which content is clamped. It must be greater than 0.

`<'block-ellipsis'>` Optional

Specifies the content inserted into the last line. It can take one of the following values:

- `no-ellipsis`: No ellipsis (character U+2026) is added if the text is truncated due to the number of line specified.
- `auto`: Renders an ellipsis character (U+2026) if the text is truncated.
- `<string>`: Renders the specified string at the end of the affected line. Browsers may truncate this string if it is very long. An empty string behaves like the `no-ellipsis` value.

> **Note:** If `<'block-ellipsis'>` is specified without an `<integer>`, it applies only when content is clamped by the height of the container.

Description

In most cases you will also want to set `overflow` to `hidden`, otherwise the contents won't be clipped but an ellipsis will still be shown after the specified number of lines.

When applied to anchor elements, the truncating can happen in the middle of the text, not necessarily at the end.

> **Note:** For legacy support, the vendor-prefixed `-webkit-line-clamp` property only works in combination with the `display` property set to `-webkit-box` or `-webkit-inline-box` and the `-webkit-box-orient` property set to `vertical`. Despite these prefixed properties being deprecated, the co-dependency of these three properties is a fully specified behavior and will continue to be supported.

Formal definition

Initial value	none
Applies to	Block containers except multi-column containers
Inherited	no
Computed value	as specified
Animation type	an integer

Formal syntax

```
line-clamp =
  none                                          |
  [ <'max-lines'> || <'block-ellipsis'> ] -webkit-legacy?

<max-lines> =
  auto            ||
  <integer [1,∞]>

<block-ellipsis> =
  no-ellipsis  |
  ellipsis     |
  <string>

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Overflow Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Truncating content with an ellipsis or a custom string

In this example, there are three cards, each with a different `line-clamp` value:

- The first has only an `<integer>` to restrict the number of lines.
- The second has an `<integer>` and the `no-ellipsis` value.
- The third has an `<integer>` and a custom `<string>`.

HTML

```
<section>
  <div class="card">
    <h2>number of lines</h2>
    <p class="integer">
      In this card, the <em>number of lines</em> is specified by an
      <code>&lt;integer&gt;</code>. Any content that does not fit is truncated
      and an ellipsis is shown.
    </p>
  </div>
  <div class="card">
    <h2>no ellipsis</h2>
    <p class="no-ellipsis">
      In this card, an <code>&lt;integer&gt;</code> and a
      <em>no-ellipsis</em> value are specified. Any content that does not fit is
      truncated and no ellipsis is shown.
    </p>
  </div>
  <div class="card">
    <h2>custom string</h2>
    <p class="string">
      In this card, an <code>&lt;integer&gt;</code> and a <em>string</em> value
      are specified. Any content that does not fit is truncated and the custom
      string is shown instead of an ellipsis.
    </p>
  </div>
</section>
```

CSS

```
/* layout for the cards */
section {
  display: grid;
  grid-template-columns: 1fr 1fr 1fr;
  gap: 0.5rem;
  justify-content: space-between;
}
em {
  color: tomato;
}
.card {
  padding: 0.2rem;
  border: 1px solid tomato;
  border-radius: 0.2rem;
  max-width: 250px;
}
```

```
.integer {
  line-clamp: 2;
  overflow: hidden;
}
.no-ellipsis {
  line-clamp: 2 no-ellipsis;
  overflow: hidden;
}
.string {
  line-clamp: 2 "… (my custom text)";
  overflow: hidden;
}
```

Result

Truncating a paragraph with the legacy property

This example uses the legacy `-webkit-line-clamp` property with `display` set to `-webkit-box`.

> **Note:** When using the legacy `-webkit-line-clamp` property, you will also want to set `overflow` to `hidden`, otherwise the content is not clipped, although an ellipsis is still shown after the specified number of lines.

HTML

```
<p>
  In this example the <code>-webkit-line-clamp</code> property is set to
  <code>3</code>, which means the text is clamped after three lines. An ellipsis
  will be shown at the point where the text is clamped.
</p>
```

CSS

```
p {
  width: 300px;
  display: -webkit-box;
  -webkit-box-orient: vertical;
  -webkit-line-clamp: 3;
  overflow: hidden;
}
```

Result

See also

- Line Clampin' (Truncating Multiple Line Text)

line-height CSS property

The **`line-height`** CSS property sets the height of a line box in horizontal writing modes. In vertical writing modes, it sets the width of a line box. It's commonly used to set the distance between lines of text. On block-level elements in horizontal writing modes, it specifies the preferred height of line boxes within the element, and on non-replaced inline elements, it specifies the height that is used to calculate line box

height.

Try it

```
line-height: normal;
```

```
line-height: 2.5;
```

```
line-height: 3em;
```

```
line-height: 150%;
```

```
line-height: 32px;
```

```
<section id="default-example">
  <div class="transition-all" id="example-element">
    Far out in the uncharted backwaters of the unfashionable end of the western
    spiral arm of the Galaxy lies a small unregarded yellow sun.
  </div>
</section>
```

```
#example-element {
  font-family: "Georgia", serif;
  max-width: 200px;
}
```

Syntax

```
/* Keyword value */
line-height: normal;

/* Unitless values: use this number multiplied
by the element's font size */
line-height: 3.5;

/* <length> values */
line-height: 3em;

/* <percentage> values */
line-height: 34%;

/* Global values */
line-height: inherit;
line-height: initial;
line-height: revert;
line-height: revert-layer;
line-height: unset;
```

Values

This property is specified as a single value from the following list:

`normal`

Depends on the user agent. Desktop browsers (including Firefox) use a default value of roughly **`1.2`**, depending on the element's `font-family`.

`<number>` (unitless)

The used value is this unitless `<number>` multiplied by the element's own font size. The computed value is the same as the specified `<number>`. In most cases, **this is the preferred way** to set `line-height` and avoid unexpected results due to inheritance.

`<length>`

The specified `<length>` is used in the calculation of the line box height. Values given in **em** units may produce unexpected results (see example below).

`<percentage>`

Relative to the font size of the element itself. The computed value is this `<percentage>` multiplied by the element's computed font size. **Percentage** values may produce unexpected results (see the second example below).

Accessibility

Use a minimum value of `1.5` for `line-height` for main paragraph content. This will help people experiencing low vision conditions, as well as people with cognitive concerns such as Dyslexia. If the page is zoomed to increase the text size, using a unitless value ensures that the line height will scale proportionately.

W3C Understanding WCAG 2.2

Formal definition

Initial value	`normal`
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Percentages	refer to the font size of the element itself
Computed value	for percentage and length values, the absolute length, otherwise as specified
Animation type	either number or length

Formal syntax

```
line-height =
  normal                  |
  <number [0,∞]>          |
  <length-percentage [0,∞]>

<length-percentage> =
```

```
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Inline Layout Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

```
/* All rules below have the same resultant line height */

/* number/unitless */
div {
  line-height: 1.2;
  font-size: 10pt;
}

/* length */
div {
  line-height: 1.2em;
  font-size: 10pt;
}

/* percentage */
div {
  line-height: 120%;
  font-size: 10pt;
}

/* font shorthand */
div {
  font:
    10pt/1.2 "Bitstream Charter",
    "Georgia",
    serif;
}
```

It is often more convenient to set `line-height` by using the `font` shorthand as shown above, but this requires the `font-family` property to be specified as well.

Prefer unitless numbers for line-height values

This example shows why it is better to use `<number>` values instead of `<length>` values. We will use two `<div>` elements. The first div, with the green border, uses a unitless `line-height` value. The second div, with the red border, uses a `line-height` value defined in `em`s.

HTML

```
<div class="box green">
  <h1>Avoid unexpected results by using unitless line-height.</h1>
  Length and percentage line-heights have poor inheritance behavior.
</div>

<div class="box red">
  <h1>Avoid unexpected results by using unitless line-height.</h1>
  Length and percentage line-heights have poor inheritance behavior
</div>

<!-- The first <h1> line-height is calculated from its own font-size   (30px × 1.1) = 33px -->
<!-- The second <h1> line-height results from the red div's font-size  (15px × 1.1) = 16.5px, probably not what you want -->
```

CSS

```
.green {
  line-height: 1.1;
  border: solid limegreen;
}

.red {
  line-height: 1.1em;
  border: solid red;
}

h1 {
  font-size: 30px;
}

.box {
  width: 18em;
  display: inline-block;
  vertical-align: top;
  font-size: 15px;
}
```

Result

Space between lines in vertical writing modes

The `line-height` property can be used to adjust space between vertical lines in vertical writing modes.

```
<div class="haiku">
  古池や蛙飛び込む水の音<br />
  ふるいけやかわずとびこむみずのおと<br />
  富士の風や扇にのせて江戸土産<br />
  ふじのかぜやおうぎにのせてえどみやげ<br />
</div>

<div class="haiku wide">
  古池や蛙飛び込む水の音<br />
  ふるいけやかわずとびこむみずのおと<br />
  富士の風や扇にのせて江戸土産<br />
```

```
  ふじのかぜやおうぎにのせてえどみやげ<br />
</div>
```

```
.haiku {
  border: 1px solid;
  margin-bottom: 1rem;
  padding: 0.5rem;
  background-color: wheat;

  writing-mode: vertical-rl;
}

.wide {
  line-height: 2;
}
```

Result

line-height-step CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`line-height-step`** CSS property sets the step unit for line box heights. When the property is set, line box heights are rounded up to the closest multiple of the unit.

Syntax

```
/* Point values */
line-height-step: 18pt;

/* Global values */
line-height-step: inherit;
line-height-step: initial;
line-height-step: revert;
line-height-step: revert-layer;
line-height-step: unset;
```

Values

This property is specified as the following value:

`<length>`

The specified `<length>` is used in the calculation of the line box height step.

Formal definition

Initial value	`0`
Applies to	block containers
Inherited	yes
Computed value	absolute `<length>`
Animation type	by computed value type

Formal syntax

```
line-height-step =
  <length [0,∞]>
```

This syntax reflects the latest standard as per CSS Rhythmic Sizing Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting step unit for line box height

In the following example, the height of line box in each paragraph is rounded up to the step unit. The line box in `<h1>` does not fit into one step unit and thus occupies two, but it is still centered within the two step unit.

```
:root {
  font-size: 12pt;
  --my-grid: 18pt;
  line-height-step: var(--my-grid);
}
h1 {
  font-size: 20pt;
  margin-top: calc(2 * var(--my-grid));
}
```

The result of these rules is shown below in the following screenshot:

Specifications

Currently, no browsers support this feature.

link-parameters CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`link-parameters`** CSS property sets values of external resources, such as SVGs, whose attributes have been set with the `env()` CSS function

Syntax

```
/* single value */
link-parameters: param(--color, red);

/* multiple values */
link-parameters:
  param(--color1, red),
  param(--color2, blue),
  param(--color3, green);
```

Values

`none`

No link parameters are specified.

`param()`

A list of one or more link parameters.

Formal definition

Initial value	none
Applies to	all elements, `::before` and `::after` pseudo-elements
Inherited	no
Computed value	as specified
Animation type	discrete

Example

Updating the colors of an external SVG file

In this example the original SVG, on the left, is a square with `stroke` attribute set with `env(--color1, chartreuse)` and `fill` attribute set with `env(--color2, darkgreen)`. The `link-parameters` property is used to update both of these attributes on the updated square, on the right, with multiple `param()` CSS functions.

```
<div class="squares">
  <img
    class="original"
    src="square.svg"
    alt="A square with a chartreuse border and a dark green fill." />
  <img
    class="updated"
    src="square.svg"
    alt="A square with a red border and a tomato fill." />
</div>
```

```
.squares {
  height: 200px;
  display: flex;
  flex-direction: row;
  justify-content: space-between;
```

```
}
img {
  height: 100%;
}
```

```
.updated {
  link-parameters:
    param(--color1, red),
    param(--color2, tomato);
}
```

- `env()`

list-style CSS property

The **`list-style`** CSS shorthand property allows you to set all the list style properties at once.

Try it

```
list-style: square;
```

```
list-style: inside;
```

```
list-style: url("/shared-assets/images/examples/rocket.svg");
```

```
list-style: none;
```

```
list-style: georgian inside url("/shared-assets/images/examples/rocket.svg");
```

```
list-style: georgian outside url("/non-existent.svg");
```

```
<section class="default-example" id="default-example">
  <div>
    <p>NASA Notable Missions</p>
    <ul class="transition-all" id="example-element">
      <li>Apollo</li>
      <li>Hubble</li>
      <li>Chandra</li>
      <li>Cassini-Huygens</li>
      <li>Spitzer</li>
    </ul>
  </div>
</section>
```

```
.default-example {
  font-size: 1.2rem;
}

#example-element {
  width: 100%;
  background: #be094b;
  color: white;
}

section {
  text-align: left;
  flex-direction: column;
}

hr {
  width: 50%;
  color: lightgray;
  margin: 0.5em;
}

.note {
  font-size: 0.8rem;
}

.note a {
  color: #009e5f;
}

@counter-style space-counter {
  symbols: "\1F680" "\1F6F8" "\1F6F0" "\1F52D";
  suffix: " ";
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `list-style-image`
- `list-style-position`
- `list-style-type`

Syntax

```
/* type */
list-style: square;

/* image */
list-style: url("../img/shape.png");
```

```
/* position */
list-style: inside;

/* two values */
list-style: georgian outside;
list-style: url("img/pip.svg") inside;

/* three values */
list-style: lower-roman url("img/shape.png") outside;

/* Keyword value */
list-style: none;

/* Global values */
list-style: inherit;
list-style: initial;
list-style: revert;
list-style: revert-layer;
list-style: unset;
```

The `list-style` property is specified as one, two, or three values in any order. If `list-style-type` and `list-style-image` are both set, the `list-style-type` is used as a fallback if the image is unavailable.

Values

`list-style-type`

A `<counter-style>`, `<string>`, or `none`. If omitted in the shorthand, it defaults to `disc`. See `list-style-type`.

`list-style-image`

An `<image>` or `none`. If omitted, it defaults to `none`. See `list-style-image`.

`list-style-position`

Either `inside` or `outside`. If omitted, it defaults to `outside`. See `list-style-position`.

`none`

No list style is used.

Description

The `list-style` property lets you customize the appearance of list items. The values of this property are applied to list items, including `<li>` elements and elements with `display: list-item;`.

List style inheritance

Because the `list-style-type` longhand property is inherited, `list-style` can be set on a parent element (normally `<ol>` or `<ul>`) to make the same list styling apply to its list items. However, user-agent stylesheets set `list-style-type` on `<ul>`, `<ol>`, and `<menu>` elements, so nested lists use these default values instead of inheriting the ancestor list's `list-style`. The `list-style-position` and `list-style-image` values normally inherit into nested lists. To make nested lists inherit the marker type as well, set `list-style` or `list-style-type` to `inherit` on the nested list elements.

For example, in cases like this:

```
<ul>
  <li>One</li>
  <li>Two</li>
  <li>
    Three
    <ul>
      <li>Four</li>
      <li>Five</li>
      <li>Six</li>
    </ul>
  </li>
</ul>
```

Where a custom style is set on the outer list:

```
body > ul {
  list-style: square;
}
```

The inner list won't inherit the custom style unless you set it to inherit:

```
ul ul {
  list-style: inherit;
}
```

Accessibility

Safari does not recognize ordered or unordered lists as lists in the accessibility tree if they have a `list-style` value of `none`, unless the list is nested within the `<nav>` navigation element. This behavior is intentional and is not considered a bug.

To ensure lists are announced as lists, include `role="list"` to `<ol>` and `<ul>` elements, especially if the list is not nested in a `<nav>`. This restores list semantics without affecting the design:

```
<ul role="list">
  <li>An item</li>
  <li>Another item</li>
</ul>
```

If an ARIA `role` is not an option for your code, CSS can be used instead. Adding non-empty pseudo-content such as text or images before each list item can restore list semantics, but impacts the visual appearance. Safari determines if the added pseudo-content suffices as accessible content, restoring list semantics if so. Generally, Safari considers text and images as sufficient, which is why the `content: "+ ";` shown below works (but requires additional styling to not affect the design).

```
ul {
  list-style: none;
}

ul li::before {
```

```
  content: "+ ";
}
```

A declaration of `content: "";` (an empty string) is ignored, as are `content` values that contain only spaces, such as `content: " ";`.

These CSS workarounds should only be used when an HTML solution is unavailable, and only after testing to ensure that they don't result in unexpected behaviors that may negatively impact user experience.

- VoiceOver and list-style-type: none (2017)
- Understanding WCAG: Create content that can be presented in different ways
- Understanding success criterion 1.3.1: Info and relationships | WCAG 2.1

Formal definition

Initial value	as each of the properties of the shorthand: • `list-style-type`: `disc` • `list-style-position`: `outside` • `list-style-image`: `none`
Applies to	list items
Inherited	yes
Computed value	as each of the properties of the shorthand: • `list-style-image`: The keyword `none` or the computed <image> • `list-style-position`: as specified • `list-style-type`: as specified
Animation type	as each of the properties of the shorthand: • `list-style-image`: discrete • `list-style-position`: discrete • `list-style-type`: discrete

Formal syntax

```
list-style =
  <'list-style-position'>  ||
  <'list-style-image'>     ||
  <'list-style-type'>

<list-style-position> =
  inside   |
  outside

<list-style-image> =
  <image>  |
  none

<list-style-type> =
  <counter-style>  |
  <string>         |
  none

<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
  <gradient>

<counter-style> =
  <counter-style-name>  |
  <symbols()>

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-set()> =
  image-set( <image-set-option># )

<cross-fade()> =
  cross-fade( <cf-image># )

<element()> =
  element( <id-selector> )

<counter-style-name> =
  <custom-ident>

<symbols()> =
  symbols( <symbols-type>? [ <string> | <image> ]+ )

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

```
<symbols-type> =
  cyclic      |
  numeric     |
  alphabetic  |
  symbolic    |
  fixed
```

This syntax reflects the latest standard as per CSS Counter Styles Level 3, CSS Images Module Level 4, CSS Images Module Level 5, CSS Lists and Counters Module Level 3, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting list style type and position

HTML

```
List 1
<ul class="one">
  <li>List Item1</li>
  <li>List Item2</li>
  <li>List Item3</li>
</ul>
List 2
<ul class="two">
  <li>List Item A</li>
  <li>List Item B</li>
  <li>List Item C</li>
</ul>
```

CSS

```
.one {
  list-style: circle;
}

.two {
  list-style: square inside;
}
```

Result

- CSS counter styles module

list-style-image CSS property

The **`list-style-image`** CSS property sets an image to be used as the list item marker.

It is often more convenient to use the shorthand `list-style`.

Try it

```
list-style-image: url("/shared-assets/images/examples/rocket.svg");
```

```
list-style-image: none;
```

```
<section class="default-example" id="default-example">
  <div>
    <p>NASA Notable Missions</p>
    <ul class="transition-all unhighlighted" id="example-element">
      <li>Apollo</li>
      <li>Hubble</li>
      <li>Chandra</li>
      <li>Cassini-Huygens</li>
      <li>Spitzer</li>
    </ul>
  </div>
</section>
```

```
.default-example {
  font-size: 1.2rem;
}

#example-element {
  width: 100%;
  background: #be094b;
  color: white;
}

section {
  text-align: left;
  flex-direction: column;
}

hr {
  width: 50%;
  color: lightgray;
  margin: 0.5em;
}

.note {
  font-size: 0.8rem;
}

.note a {
```

```
  color: #009e5f;
}

@counter-style space-counter {
  symbols: "\1F680" "\1F6F8" "\1F6F0" "\1F52D";
  suffix: " ";
}
```

> **Note:** This property is applied to list items, i.e., elements with `display: list-item;` by default this includes `<li>` elements. Because this property is inherited, it can be set on the parent element (normally `<ol>` or `<ul>`) to let it apply to all list items.

Syntax

```
/* Keyword value */
list-style-image: none;

/* <url> values */
list-style-image: url("star-solid.gif");

/* valid image values */
list-style-image: linear-gradient(to left bottom, red, blue);

/* Global values */
list-style-image: inherit;
list-style-image: initial;
list-style-image: revert;
list-style-image: revert-layer;
list-style-image: unset;
```

Values

This property is specified as a single value from the following list:

`<image>`

A valid image to use as the marker.

`none`

Specifies that no image is used as the marker. If this value is set, the marker defined in `list-style-type` will be used instead. This is the default value for `list-style`.

Formal definition

Initial value	none
Applies to	list items
Inherited	yes
Computed value	The keyword none or the computed <image>
Animation type	discrete

Formal syntax

```
list-style-image =
  <image>  |
  none

<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
  <gradient>

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-set()> =
  image-set( <image-set-option># )

<cross-fade()> =
  cross-fade( <cf-image># )

<element()> =
  element( <id-selector> )

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Images Module Level 4, CSS Images Module Level 5, CSS Lists and Counters Module Level 3, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using a url value

This example has a star as a marker, which we include using the `<url>` image function.

HTML

```
<ul>
  <li>Item 1</li>
  <li>Item 2</li>
</ul>
```

CSS

```
ul {
  list-style-image: url("star-solid.gif");
}
```

Result

Using a gradient

This example has a CSS gradient as a marker, which we create uses the `linear-gradient()` image function.

HTML

```
<ul>
  <li>Item 1</li>
  <li>Item 2</li>
</ul>
```

CSS

```
ul {
  font-size: 200%;
  list-style-image: linear-gradient(to left bottom, red, blue);
}
```

Result

- CSS counter styles module

list-style-position CSS property

The **`list-style-position`** CSS property sets the position of the `::marker` relative to a list item.

Try it

```
list-style-position: inside;
```

```
list-style-position: outside;
```

```
<section class="default-example" id="default-example">
  <div>
    <p>NASA Notable Missions</p>
    <ul class="transition-all" id="example-element">
      <li>Apollo 11: First Human Landing</li>
      <li>City in Space: The International Space Station</li>
      <li>Great Observatory: The Hubble Space Telescope</li>
      <li>Everlasting Mars Rovers</li>
    </ul>
  </div>
</section>
```

```
.default-example {
  font-size: 1.2rem;
}

#example-element {
  width: 100%;
  background: #be094b;
  color: white;
}

section {
  text-align: left;
  flex-direction: column;
}

hr {
  width: 50%;
  color: lightgray;
  margin: 0.5em;
}

.note {
  font-size: 0.8rem;
}

.note a {
  color: #009e5f;
```

```
}

@counter-style space-counter {
  symbols: "\1F680" "\1F6F8" "\1F6F0" "\1F52D";
  suffix: " ";
}
```

Syntax

```
/* Keyword values */
list-style-position: inside;
list-style-position: outside;

/* Global values */
list-style-position: inherit;
list-style-position: initial;
list-style-position: revert;
list-style-position: revert-layer;
list-style-position: unset;
```

Values

This property is specified as one of the following keyword values:

`inside`

> The `::marker` is the first element among the list item's contents.

`outside`

> The `::marker` is outside the principal block box. This is the default value for `list-style`.

Description

This property is applied to list items, i.e., elements with `display: list-item;`. By default this includes `<li>` elements. Because this property is inherited, it can be set on the parent element (normally `<ol>` or `<ul>`) to let it apply to all list items.

If a block element is the first child of a list element declared as `list-style-position: inside`, then the block element is placed on the line after the marker-box.

It is often more convenient to use the shorthand `list-style`.

Formal definition

Initial value	`outside`
Applies to	list items
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
list-style-position =
  inside   |
  outside
```

This syntax reflects the latest standard as per CSS Lists and Counters Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting list item position

HTML

```
<p>List 1</p>
<ul class="inside">
  <li>List Item 1-1</li>
  <li>List Item 1-2</li>
  <li>List Item 1-3</li>
  <li>List Item 1-4</li>
</ul>
<p>List 2</p>
<ul class="outside">
  <li>List Item 2-1</li>
  <li>List Item 2-2</li>
  <li>List Item 2-3</li>
  <li>List Item 2-4</li>
</ul>
<p>List 3</p>
<ul class="inside-img">
  <li>List Item 3-1</li>
  <li>List Item 3-2</li>
  <li>List Item 3-3</li>
  <li>List Item 3-4</li>
</ul>
```

CSS

```
.inside {
  list-style-position: inside;
  list-style-type: square;
}

.outside {
  list-style-position: outside;
  list-style-type: circle;
}

.inside-img {
  list-style-position: inside;
```

```
  list-style-image: url("star-solid.gif");
}
```

Result

list-style-type CSS property

The **`list-style-type`** CSS property sets the marker (such as a disc, character, or custom counter style) of a list item element.

Try it

```
list-style-type: space-counter;
```

```
list-style-type: disc;
```

```
list-style-type: circle;
```

```
list-style-type: "\1F44D";
```

```
<section class="default-example" id="default-example">
  <div>
    <p>NASA Notable Missions</p>
    <ul class="transition-all unhighlighted" id="example-element">
      <li>Apollo</li>
      <li>Hubble</li>
      <li>Chandra</li>
      <li>Cassini-Huygens</li>
    </ul>
  </div>
  <hr />
  <div class="note">
    <p>

        target="_parent"
        ><code>@counter-style</code></a
      >
    </p>
  </div>
</section>
```

```
.default-example {
  font-size: 1.2rem;
}

#example-element {
  width: 100%;
  background: #be094b;
  color: white;
}

section {
  text-align: left;
  flex-direction: column;
}

hr {
  width: 50%;
  color: lightgray;
  margin: 0.5em;
}

.note {
  font-size: 0.8rem;
}

.note a {
  color: #009e5f;
}

@counter-style space-counter {
  symbols: "\1F680" "\1F6F8" "\1F6F0" "\1F52D";
  suffix: " ";
}
```

Syntax

```
/* Partial list of types */
list-style-type: disc;
list-style-type: circle;
list-style-type: square;
list-style-type: decimal;
list-style-type: georgian;
list-style-type: trad-chinese-informal;
list-style-type: kannada;

/* <string> value */
list-style-type: "-";
```

```
/* Identifier matching an @counter-style rule */
list-style-type: custom-counter-style;

/* Keyword value */
list-style-type: none;

/* Global values */
list-style-type: inherit;
list-style-type: initial;
list-style-type: revert;
list-style-type: revert-layer;
list-style-type: unset;
```

The `list-style-type` property may be defined as any one of:

- a `<custom-ident>` value,
- a `symbols()` value,
- a `<string>` value, or
- the keyword `none`.

Note that:

- Some types require a suitable font installed to display as expected.
- The `cjk-ideographic` is identical to `trad-chinese-informal`; it exists for legacy reasons.

Values

`<custom-ident>`

An identifier matching the value of a `@counter-style` or one of the predefined styles:

`symbols()`

Defines an anonymous style of the list.

`<string>`

The specified string will be used as the item's marker.

`none`

No item marker is shown.

`disc`

A filled circle (default value).

`circle`

A hollow circle.

`square`

A filled square.

`decimal`

Decimal numbers, beginning with 1.

`cjk-decimal`

Han decimal numbers.

`decimal-leading-zero`

Decimal numbers, padded by initial zeros.

`lower-roman`

Lowercase roman numerals.

`upper-roman`

Uppercase roman numerals.

`lower-greek`

Lowercase classical Greek.

`lower-alpha`, `lower-latin`

Lowercase ASCII letters.

`upper-alpha`, `upper-latin`

Uppercase ASCII letters.

`arabic-indic`, `-moz-arabic-indic`

Arabic-Indic numbers.

`armenian`

Traditional Armenian numbering.

`bengali`, `-moz-bengali`

Bengali numbering.

`cambodian/khmer`

Cambodian/Khmer numbering.

`cjk-earthly-branch`, `-moz-cjk-earthly-branch`

Han "Earthly Branch" ordinals.

`cjk-heavenly-stem`, `-moz-cjk-heavenly-stem`

Han "Heavenly Stem" ordinals.

`cjk-ideographic`

Identical to `trad-chinese-informal`.

`devanagari`, `-moz-devanagari`

Devanagari numbering.

`ethiopic-numeric`

Ethiopic numbering.

`georgian`

Traditional Georgian numbering.

`gujarati`, `-moz-gujarati`

Gujarati numbering.

`gurmukhi`, `-moz-gurmukhi`

Gurmukhi numbering.

`hebrew`

Traditional Hebrew numbering.

`hiragana`

Dictionary-order hiragana lettering.

`hiragana-iroha`

Iroha-order hiragana lettering.

`japanese-formal`

Japanese formal numbering to be used in legal or financial documents. The kanjis are designed so that they can't be modified to look like another correct one.

`japanese-informal`

Japanese informal numbering.

`kannada`, `-moz-kannada`

Kannada numbering.

`katakana`

Dictionary-order katakana lettering.

`katakana-iroha`

Iroha-order katakana lettering.

`korean-hangul-formal`

Korean hangul numbering.

`korean-hanja-formal`

Formal Korean Han numbering.

`korean-hanja-informal`

Korean hanja numbering.

`lao`, `-moz-lao`

Laotian numbering.

`lower-armenian`

Lowercase Armenian numbering.

`malayalam`, `-moz-malayalam`

Malayalam numbering.

`mongolian`

Mongolian numbering.

`myanmar`, `-moz-myanmar`

Myanmar (Burmese) numbering.

`oriya`, `-moz-oriya`

Oriya numbering.

`persian`, `-moz-persian`

Persian numbering.

`simp-chinese-formal`

Simplified Chinese formal numbering.

`simp-chinese-informal`

Simplified Chinese informal numbering.

`tamil`, `-moz-tamil`

Tamil numbering.

`telugu`, `-moz-telugu`

Telugu numbering.

`thai`, `-moz-thai`

Thai numbering.

`tibetan`

Tibetan numbering.

`trad-chinese-formal`

Traditional Chinese formal numbering.

`trad-chinese-informal`

Traditional Chinese informal numbering.

`upper-armenian`

Traditional uppercase Armenian numbering.

`disclosure-open`

Symbol indicating that a disclosure widget such as `<details>` is opened.

`disclosure-closed`

Symbol indicating that a disclosure widget, like `<details>` is closed.

Refer to the All list style types example to see the above values in action. Details of all the available counter styles used by various cultures around the world can be found in Ready-made Counter Styles.

Non-standard extensions

Mozilla (Firefox) supports a few predefined types with a `-moz-` prefix.

- `ethiopic-halehame`: `-moz-ethiopic-halehame`
- `ethiopic-halehame-am`: `-moz-ethiopic-halehame-am`
- `ethiopic-halehame-ti-er`: `-moz-ethiopic-halehame-ti-er`
- `ethiopic-halehame-ti-et`: `-moz-ethiopic-halehame-ti-et`
- `ethiopic-numeric`: `-moz-ethiopic-numeric`
- `hangul`: `-moz-hangul`
- `hangul-consonant`: `-moz-hangul-consonant`
- `urdu`: `-moz-urdu`

See the compatibility table to check which browsers support which extension.

Description

The `list-style-type` property sets the marker (such as a disc, character, or custom counter style) of a list item element. The marker will be `currentColor`, the same as the computed color of the element it applies to.

Only a few elements (`<li>` and `<summary>`) have a default value of `display: list-item`. However, the `list-style-type` property may be applied to any element whose `display` value is set to `list-item`.

List style inheritance

Because `list-style-type` is inherited, it can be set on a parent element (commonly `<ol>` or `<ul>`) to make it apply to its list items. However, user-agent stylesheets set `list-style-type` on `<ul>`, `<ol>`, and `<menu>` elements, so nested lists use these default values instead of inheriting the ancestor list's value. To make nested lists inherit this value, set `list-style-type: inherit` on the nested list elements.

For example, in cases like this:

```
<ul>
  <li>One</li>
  <li>Two</li>
  <li>
    Three
    <ul>
      <li>Four</li>
      <li>Five</li>
      <li>Six</li>
    </ul>
  </li>
</ul>
```

Where a custom style is set on the outer list:

```
body > ul {
  list-style-type: square;
}
```

The inner list won't inherit the custom style unless you set it to inherit:

```
ul ul {
  list-style-type: inherit;
}
```

Accessibility

Safari will not recognize an ordered or unordered list as a list in the accessibility tree if it has a `list-style-type` value of `none`. This can be resolved by adding `role="list"` to the list's opening tag. To learn more about this and potential workarounds, see `list-style`.

Formal definition

Initial value	`disc`
Applies to	list items
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
list-style-type =
  <counter-style>  |
  <string>         |
  none

<counter-style> =
  <counter-style-name>  |
  <symbols()>

<counter-style-name> =
  <custom-ident>

<symbols()> =
  symbols( <symbols-type>? [ <string> | <image> ]+ )

<symbols-type> =
  cyclic      |
  numeric     |
  alphabetic  |
  symbolic    |
  fixed

<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
  <gradient>

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-set()> =
  image-set( <image-set-option># )

<cross-fade()> =
  cross-fade( <cf-image># )

<element()> =
  element( <id-selector> )

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Counter Styles Level 3, CSS Images Module Level 4, CSS Images Module Level 5, CSS Lists and Counters Module Level 3, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting list item markers

HTML

```
List 1
<ol class="normal">
  <li>Hello</li>
  <li>World</li>
  <li>What's up?</li>
</ol>

List 2
<ol class="shortcut">
  <li>Looks</li>
  <li>Like</li>
  <li>The</li>
  <li>Same</li>
</ol>
```

CSS

```
ol.normal {
  list-style-type: upper-alpha;
}

/* or use the shortcut "list-style": */
ol.shortcut {
```

```
  list-style: upper-alpha;
}
```

Result

All list style types

HTML

```
<ol>
  <li>Apollo</li>
  <li>Hubble</li>
  <li>Chandra</li>
  <li>Cassini-Huygens</li>
  <li>Spitzer</li>
</ol>

<h2>Choose a list style type:</h2>

<div class="container">
  <label for="disc">
    <input type="radio" id="disc" name="type" value="disc" />disc
  </label>

  <label for="circle">
    <input type="radio" id="circle" name="type" value="circle" />circle
  </label>

      name="type"
      value="-moz-hangul-consonant" />-moz-hangul-consonant
  </label>

  <label for="moz-urdu">
    <input type="radio" id="moz-urdu" name="type" value="-moz-urdu" />-moz-urdu
  </label>
</div>
```

CSS

```
ol {
  font-size: 1.2rem;
}

.container {
  column-count: 3;
}

label {
  display: block;
}

input {
  margin: 0.4rem;
}
```

JavaScript

```
const container = document.querySelector(".container");
const list = document.querySelector("ol");

container.addEventListener("change", (event) => {
  list.setAttribute("style", `list-style-type: ${event.target.value}`);
});
```

Result

We're not limited to the list style types defined on this page or the specification. The `@counter-style` at-rule enables creating counters using any alphabet.

margin CSS property

The **`margin`** CSS shorthand property sets the margin area on all four sides of an element.

Try it

```
margin: 1em;
```

```
margin: 5% 0;
```

```
margin: 10px 50px 20px;
```

```
margin: 10px 50px 20px 0;
```

```
margin: 0;
```

```
<section id="default-example">
  <div id="container">
    <div class="row"></div>
    <div class="row transition-all" id="example-element"></div>
    <div class="row"></div>
  </div>
</section>
```

```
#container {
  width: 300px;
  height: 200px;
  display: flex;
  align-content: flex-start;
  flex-direction: column;
  justify-content: flex-start;
}

.row {
  height: 33.33%;
  display: inline-block;
  border: solid #ce7777 10px;
  background-color: #2b3a55;
  flex-shrink: 0;
}
```

```
#example-element {
  border: solid 10px #ffbf00;
  background-color: #2b3a55;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `margin-top`
- `margin-right`
- `margin-bottom`
- `margin-left`

Syntax

```
/* apply to all four sides */
margin: 1em;
margin: -3px;

/* top and bottom | left and right */
margin: 5% auto;

/* top | left and right | bottom */
margin: 1em auto 2em;

/* top | right | bottom | left */
margin: 2px 1em 0 auto;

/* anchor-size() values */
margin: 5% anchor-size(width);
margin: calc(anchor-size(width) / 4) 1em 0
  anchor-size(--my-anchor self-inline, 50px);

/* Keyword value */
margin: auto;

/* Global values */
margin: inherit;
margin: initial;
margin: revert;
margin: revert-layer;
margin: unset;
```

The `margin` property may be specified using one, two, three, or four values. Each value is a `<length>`, a `<percentage>`, or the keyword `auto`. Negative values draw the element closer to its neighbors than it would be by default.

- When **one** value is specified, it applies the same margin to **all four sides**.
- When **two** values are specified, the first margin applies to the **top and bottom**, the second to the **left and right**.
- When **three** values are specified, the first margin applies to the **top**, the second to the **right and left**, the third to the **bottom**.
- When **four** values are specified, the margins apply to the **top**, **right**, **bottom**, and **left** in that order (clockwise).

Values

`<length>`

The size of the margin as a fixed value.

- For *anchor-positioned elements*, the `anchor-size()` function resolves to a `<length>` value relative to the associated *anchor element*'s width or height (see Setting element margin based on anchor size).

`<percentage>`

The size of the margin as a percentage, relative to the inline size (*width* in a horizontal language, defined by `writing-mode`) of the containing block.

`auto`

The browser selects a suitable margin to use. For example, in certain cases this value can be used to center an element.

Description

This property can be used to set a margin on all four sides of an element. Margins create extra space *around* an element, unlike `padding`, which creates extra space *within* an element.

The top and bottom margins have no effect on *non-replaced* inline elements, such as `<span>` or `<code>`.

Horizontal centering

You can horizontally center an element within its parent by setting `margin: 0 auto;`.

A more common method to center an element horizontally is by setting `display: flex;` and `justify-content: center;` on a container, which centers its flex item children.

Margin collapsing

Elements' top and bottom margins are sometimes collapsed into a single margin that is equal to the larger of the two margins. See Mastering margin collapsing for more information.

Formal definition

Initial value	as each of the properties of the shorthand: • `margin-bottom`: `0` • `margin-left`: `0` • `margin-right`: `0` • `margin-top`: `0`
Applies to	all elements, except elements with table `display` types other than `table-caption`, `table` and `inline-table`. It also applies to `::first-letter`.
Inherited	no
Percentages	refer to the width of the containing block
Computed value	as each of the properties of the shorthand:

	• `margin-bottom`: the percentage as specified or the absolute length • `margin-left`: the percentage as specified or the absolute length • `margin-right`: the percentage as specified or the absolute length • `margin-top`: the percentage as specified or the absolute length
Animation type	a length

Formal syntax

```
margin =
  <'margin-top'>{1,4}

<margin-top> =
  <length-percentage>  |
  auto                 |
  <anchor-size()>

<length-percentage> =
  <length>      |
  <percentage>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width       |
  height      |
  block       |
  inline      |
  self-block  |
  self-inline
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Model Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

HTML

```
<div class="center">This element is centered.</div>

<div class="outside">This element is positioned outside of its container.</div>
```

CSS

```
.center {
  margin: auto;
  background: lime;
  width: 66%;
}

.outside {
  margin: 3rem 0 0 -3rem;
  background: cyan;
  width: 66%;
}
```

More examples

```
margin: 5%; /* All sides: 5% margin */

margin: 10px; /* All sides: 10px margin */

margin: 1.6em 20px; /* top and bottom: 1.6em margin */
/* left and right: 20px margin */

margin: 10px 3% -1em; /* top:           10px margin */
/* left and right: 3% margin   */
/* bottom:         -1em margin */

margin: 10px 3px 30px 5px; /* top:    10px margin */
/* right:  3px margin  */
/* bottom: 30px margin */
/* left:   5px margin  */

margin: 2em auto; /* top and bottom: 2em margin   */
/* Box is horizontally centered */

margin: auto; /* top and bottom: 0 margin     */
/* Box is horizontally centered */
```

margin-block CSS property

The **`margin-block`** CSS shorthand property defines the logical block start and end margins of an element, which maps to physical margins depending on the element's writing mode, directionality, and text orientation.

Try it

```
margin-block: 10px 20px;
writing-mode: horizontal-tb;
```

```
margin-block: 20px 40px;
writing-mode: vertical-rl;
```

```
margin-block: 5% 20%;
writing-mode: horizontal-tb;
```

```
margin-block: 1rem auto;
writing-mode: vertical-lr;
```

```
<section id="default-example">
  <div id="container">
    <div class="row">One</div>
    <div class="row transition-all" id="example-element">Two</div>
    <div class="row">Three</div>
  </div>
</section>
```

```
#container {
  width: 300px;
  height: 200px;
  display: flex;
  align-content: flex-start;
  flex-direction: column;
  justify-content: flex-start;
}

.row {
  height: 33.33%;
  display: inline-block;
  border: solid #ce7777 10px;
  background-color: #2b3a55;
  color: white;
  flex-shrink: 0;
}

#example-element {
  border: solid 10px #ffbf00;
  background-color: #2b3a55;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `margin-block-start`
- `margin-block-end`

Syntax

```
/* <length> values */
margin-block: 10px 20px; /* An absolute length */
margin-block: 1em 2em; /* relative to the text size */
margin-block: 5% 2%; /* relative to the nearest block container's width */
margin-block: 10px; /* sets both start and end values */
margin-block: anchor-size(inline);
margin-block: calc(anchor-size(width) / 4) 1em;

/* Keyword value */
margin-block: auto;

/* Global values */
margin-block: inherit;
margin-block: initial;
margin-block: revert;
margin-block: revert-layer;
margin-block: unset;
```

This property corresponds to the `margin-top` and `margin-bottom`, or the `margin-right` and `margin-left` properties, depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

The `margin-block` property may be specified using one or two values.

- When **one** value is specified, it applies the same margin to **both start and end**.
- When **two** values are specified, the first margin applies to the **start**, the second to the **end**.

Values

The `margin-block` property takes the same values as the `margin-top` property.

Formal definition

Initial value	as each of the properties of the shorthand: • `margin-block-start`: `0` • `margin-block-end`: `0`
Applies to	same as `margin`
Inherited	no
Percentages	depends on layout model
Computed value	as each of the properties of the shorthand: • `margin-block-start`: if specified as a length, the corresponding absolute length; if specified as a percentage, the specified value; otherwise, `auto`

	• `margin-block-end`: if specified as a length, the corresponding absolute length; if specified as a percentage, the specified value; otherwise, `auto`
Animation type	a length

Formal syntax

```
margin-block =
  <'margin-top'>{1,2}

<margin-top> =
  <length-percentage>  |
  auto                 |
  <anchor-size()>

<length-percentage> =
  <length>      |
  <percentage>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width        |
  height       |
  block        |
  inline       |
  self-block   |
  self-inline
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Model Module Level 4, CSS Logical Properties and Values Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting block start and end margins

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: auto;
  border: 1px solid green;
}

p {
  margin: 0;
  margin-block: 20px 40px;
  background-color: tan;
}

.verticalExample {
  writing-mode: vertical-rl;
}
```

HTML

```
<div>
  <p>Example text</p>
</div>
<div class="verticalExample">
  <p>Example text</p>
</div>
```

Result

- `writing-mode`, `direction`, `text-orientation`

margin-block-end CSS property

The **`margin-block-end`** CSS property defines the logical block end margin of an element, which maps to a physical margin depending on the element's writing mode, directionality, and text orientation.

Try it

```
margin-block-end: 20px;
writing-mode: horizontal-tb;
```

```
margin-block-end: 20px;
writing-mode: vertical-rl;
```

```
margin-block-end: 20%;
writing-mode: horizontal-tb;
```

```
margin-block-end: auto;
writing-mode: vertical-lr;
```

```
<section id="default-example">
  <div id="container">
    <div class="row">One</div>
    <div class="row transition-all" id="example-element">Two</div>
    <div class="row">Three</div>
  </div>
</section>
```

```
#container {
  width: 300px;
  height: 200px;
  display: flex;
  align-content: flex-start;
  flex-direction: column;
  justify-content: flex-start;
}

.row {
  height: 33.33%;
  display: inline-block;
  border: solid #ce7777 10px;
  background-color: #2b3a55;
  color: white;
  flex-shrink: 0;
}

#example-element {
  border: solid 10px #ffbf00;
  background-color: #2b3a55;
}
```

Syntax

```
/* <length> values */
margin-block-end: 10px; /* An absolute length */
margin-block-end: 1em; /* relative to the text size */
margin-block-end: 5%; /* relative to the nearest block container's width */
margin-block-end: anchor-size(inline);
margin-block-end: calc(anchor-size(--my-anchor block, 20px) / 4);

/* Keyword value */
margin-block-end: auto;

/* Global values */
margin-block-end: inherit;
margin-block-end: initial;
margin-block-end: revert;
margin-block-end: revert-layer;
margin-block-end: unset;
```

It corresponds to the `margin-top`, `margin-right`, `margin-bottom`, or `margin-left` property depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

It relates to `margin-block-start`, `margin-inline-start`, and `margin-inline-end`, which define the other margins of the element.

Values

The `margin-block-end` property takes the same values as the `margin-top` property.

Formal definition

Initial value	`0`
Applies to	same as `margin`
Inherited	no
Percentages	depends on layout model
Computed value	if specified as a length, the corresponding absolute length; if specified as a percentage, the specified value; otherwise, `auto`
Animation type	a length

Formal syntax

```
margin-block-end =
  <'margin-top'>

<margin-top> =
  <length-percentage>  |
  auto                 |
  <anchor-size()>

<length-percentage> =
  <length>      |
  <percentage>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width       |
  height      |
  block       |
  inline      |
  self-block  |
  self-inline
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Model Module Level 4, CSS Logical Properties and Values Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting block end margin

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-rl;
  margin-block-end: 20px;
  background-color: #c8c800;
}
```

Result

See also

- CSS Logical Properties and Values
- The mapped physical properties: `margin-top`, `margin-right`, `margin-bottom`, and `margin-left`
- `writing-mode`, `direction`, `text-orientation`

margin-block-start CSS property

The **`margin-block-start`** CSS property defines the logical block start margin of an element, which maps to a physical margin depending on the element's writing mode, directionality, and text orientation.

Try it

```
margin-block-start: 20px;
writing-mode: horizontal-tb;
```

```
margin-block-start: 20px;
writing-mode: vertical-rl;
```

```
margin-block-start: 20%;
writing-mode: horizontal-tb;
```

```
margin-block-start: auto;
writing-mode: vertical-lr;
```

```
<section id="default-example">
  <div id="container">
    <div class="row">One</div>
    <div class="row transition-all" id="example-element">Two</div>
    <div class="row">Three</div>
  </div>
</section>
```

```
#container {
  width: 300px;
  height: 200px;
  display: flex;
  align-content: flex-start;
  flex-direction: column;
  justify-content: flex-start;
}

.row {
  height: 33.33%;
  display: inline-block;
  border: solid #ce7777 10px;
  background-color: #2b3a55;
  color: white;
  flex-shrink: 0;
}

#example-element {
  border: solid 10px #ffbf00;
  background-color: #2b3a55;
}
```

Syntax

```
/* <length> values */
margin-block-start: 10px; /* An absolute length */
margin-block-start: 1em; /* relative to the text size */
margin-block-start: 5%; /* relative to the nearest block container's width */
margin-block-start: anchor-size(width);
margin-block-start: calc(anchor-size(--my-anchor block, 20px) / 3);

/* Keyword value */
margin-block-start: auto;

/* Global values */
margin-block-start: inherit;
margin-block-start: initial;
margin-block-start: revert;
margin-block-start: revert-layer;
margin-block-start: unset;
```

It corresponds to the `margin-top`, `margin-right`, `margin-bottom`, or `margin-left` property depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

It relates to `margin-block-end`, `margin-inline-start`, and `margin-inline-end`, which define the other margins of the element.

Values

The `margin-block-start` property takes the same values as the `margin-top` property.

Formal definition

Initial value	`0`
Applies to	same as `margin`
Inherited	no
Percentages	depends on layout model
Computed value	if specified as a length, the corresponding absolute length; if specified as a percentage, the specified value; otherwise, `auto`
Animation type	a length

Formal syntax

```
margin-block-start =
  <'margin-top'>

<margin-top> =
  <length-percentage>  |
  auto                 |
  <anchor-size()>

<length-percentage> =
  <length>      |
  <percentage>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width       |
  height      |
  block       |
  inline      |
  self-block  |
  self-inline
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Model Module Level 4, CSS Logical Properties and Values Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting block start margin

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  margin-block-start: 20px;
  background-color: #c8c800;
}
```

Result

See also

- CSS Logical Properties and Values
- The mapped physical properties: `margin-top`, `margin-right`, `margin-bottom`, and `margin-left`
- `writing-mode`, `direction`, `text-orientation`

margin-bottom CSS property

The **`margin-bottom`** CSS property sets the margin area on the bottom of an element. A positive value places it farther from its neighbors, while a negative value places it closer.

Try it

```
margin-bottom: 1em;
```

```
margin-bottom: 10%;
```

```
margin-bottom: 10px;
```

```
margin-bottom: 0;
```

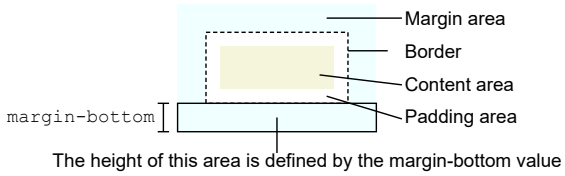
```
<section id="default-example">
  <div id="container">
    <div class="row"></div>
    <div class="row transition-all" id="example-element"></div>
    <div class="row"></div>
  </div>
</section>
```

```
#container {
  width: 300px;
```

```
  height: 200px;
  display: flex;
  align-content: flex-start;
  flex-direction: column;
  justify-content: flex-start;
}

.row {
  height: 33.33%;
  display: inline-block;
  border: solid #ce7777 10px;
  background-color: #2b3a55;
  flex-shrink: 0;
}

#example-element {
  border: solid 10px #ffbf00;
  background-color: #2b3a55;
}
```



This property has no effect on *non-replaced* inline elements, such as `<span>` or `<code>`.

Syntax

```
/* <length> values */
margin-bottom: 10px; /* An absolute length */
margin-bottom: 1em; /* relative to the text size */
margin-bottom: 5%; /* relative to the nearest block container's width */
margin-bottom: anchor-size(width);
margin-bottom: calc(anchor-size(--my-anchor self-block, 20px) / 3);

/* Keyword value */
margin-bottom: auto;

/* Global values */
margin-bottom: inherit;
margin-bottom: initial;
margin-bottom: revert;
margin-bottom: revert-layer;
margin-bottom: unset;
```

The `margin-bottom` property is specified as the keyword `auto`, or a `<length>`, or a `<percentage>`. Its value can be positive, zero, or negative.

Values

`<length>`

The size of the margin as a fixed value.

- For *anchor-positioned elements*, the `anchor-size()` function resolves to a `<length>` value relative to the associated *anchor element*'s width or height (see Setting element margin based on anchor size).

`<percentage>`

The size of the margin as a percentage, relative to the inline size (*width* in a horizontal language, defined by `writing-mode`) of the containing block.

`auto`

The browser selects a suitable value to use. See `margin`.

Formal definition

Initial value	`0`
Applies to	all elements, except elements with table `display` types other than `table-caption`, `table` and `inline-table`. It also applies to `::first-letter`.
Inherited	no
Percentages	refer to the width of the containing block
Computed value	the percentage as specified or the absolute length
Animation type	a length

Formal syntax

```
margin-bottom =
  <length-percentage>  |
  auto                 |
  <anchor-size()>

<length-percentage> =
  <length>      |
  <percentage>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width        |
  height       |
```

```
  block       |
  inline      |
  self-block  |
  self-inline
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Model Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting positive and negative bottom margins

HTML

```
<div class="container">
  <div class="box0">Box 0</div>
  <div class="box1">Box 1</div>
  <div class="box2">Box one's negative margin pulls me up</div>
</div>
```

CSS

CSS for divs to set margin-bottom and height

```
.box0 {
  margin-bottom: 1em;
  height: 3em;
}
.box1 {
  margin-bottom: -1.5em;
  height: 4em;
}
.box2 {
  border: 1px dashed black;
  border-width: 1px 0;
  margin-bottom: 2em;
}
```

Some definitions for container and divs so margins' effects can be seen more clearly

```
.container {
  background-color: orange;
  width: 320px;
  border: 1px solid black;
}
div {
  width: 320px;
  background-color: gold;
}
```

Result

See also

- `margin-top`, `margin-right`, and `margin-left`
- `margin` shorthand
- `margin-block-start`, `margin-block-end`, `margin-inline-start`, and `margin-inline-end`
- `margin-block` and `margin-inline` shorthands
- CSS box model module

margin-inline CSS property

The **`margin-inline`** CSS shorthand property defines both the logical inline start and end margins of an element, which maps to physical margins depending on the element's writing mode, directionality, and text orientation.

Try it

```
margin-inline: 5% 10%;
writing-mode: horizontal-tb;
```

```
margin-inline: 10px 40px;
writing-mode: vertical-rl;
```

```
margin-inline: 5% 10%;
writing-mode: horizontal-tb;
direction: rtl;
```

```
<section id="default-example">
  <div id="container">
    <div class="col">One</div>
    <div class="col transition-all" id="example-element">Two</div>
    <div class="col">Three</div>
  </div>
</section>
```

```
#container {
  width: 300px;
  height: 200px;
  display: flex;
  align-content: flex-start;
  justify-content: flex-start;
}

.col {
  width: 33.33%;
  border: solid #ce7777 10px;
  background-color: #2b3a55;
  color: white;
```

```
  flex-shrink: 0;
}

#example-element {
  border: solid 10px #ffbf00;
  background-color: #2b3a55;
  unicode-bidi: bidi-override;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `margin-inline-start`
- `margin-inline-end`

Syntax

```
/* <length> values */
margin-inline: 10px 20px; /* An absolute length */
margin-inline: 1em 2em; /* relative to the text size */
margin-inline: 5% 2%; /* relative to the nearest block container's width */
margin-inline: 10px; /* sets both start and end values */
margin-inline: anchor-size(width);
margin-inline: calc(anchor-size(self-block) / 5) auto;

/* Keyword value */
margin-inline: auto;

/* Global values */
margin-inline: inherit;
margin-inline: initial;
margin-inline: revert;
margin-inline: revert-layer;
margin-inline: unset;
```

This property corresponds to the `margin-top` and `margin-bottom`, or the `margin-right` and `margin-left` properties, depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

The `margin-inline` property may be specified using one or two values.

- When **one** value is specified, it applies the same margin to **both start and end**.
- When **two** values are specified, the first margin applies to the **start**, the second to the **end**.

Values

The `margin-inline` property takes the same values as the `margin-top` property.

Formal definition

Initial value	as each of the properties of the shorthand: • `margin-inline-start`: `0` • `margin-inline-end`: `0`
Applies to	same as `margin`
Inherited	no
Percentages	depends on layout model
Computed value	as each of the properties of the shorthand: • `margin-inline-start`: if specified as a length, the corresponding absolute length; if specified as a percentage, the specified value; otherwise, `auto` • `margin-inline-end`: if specified as a length, the corresponding absolute length; if specified as a percentage, the specified value; otherwise, `auto`
Animation type	a length

Formal syntax

```
margin-inline =
  <'margin-top'>{1,2}

<margin-top> =
  <length-percentage>  |
  auto                 |
  <anchor-size()>

<length-percentage> =
  <length>      |
  <percentage>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width       |
  height      |
  block       |
  inline      |
  self-block  |
  self-inline
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Model Module Level 4, CSS Logical Properties and Values Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting inline start and end margins

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: auto;
  border: 1px solid green;
}

p {
  margin: 0;
  margin-inline: 20px 40px;
  background-color: tan;
}

.verticalExample {
  writing-mode: vertical-rl;
}
```

HTML

```
<div>
  <p>Example text</p>
</div>
<div class="verticalExample">
  <p>Example text</p>
</div>
```

- The mapped physical properties: `margin-top`, `margin-right`, `margin-bottom`, and `margin-left`
- `writing-mode`, `direction`, `text-orientation`

margin-inline-end CSS property

The **`margin-inline-end`** CSS property defines the logical inline end margin of an element, which maps to a physical margin depending on the element's writing mode, directionality, and text orientation. In other words, it corresponds to the `margin-top`, `margin-right`, `margin-bottom` or `margin-left` property depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

Try it

```
margin-inline-end: 20px;
writing-mode: horizontal-tb;
```

```
margin-inline-end: 20px;
writing-mode: vertical-rl;
```

```
margin-inline-end: 20%;
writing-mode: horizontal-tb;
direction: rtl;
```

```
<section id="default-example">
  <div id="container">
    <div class="col">One</div>
    <div class="col transition-all" id="example-element">Two</div>
    <div class="col">Three</div>
  </div>
</section>
```

```
#container {
  width: 300px;
  height: 200px;
  display: flex;
  align-content: flex-start;
  justify-content: flex-start;
}

.col {
  width: 33.33%;
  border: solid #ce7777 10px;
  background-color: #2b3a55;
  color: white;
  flex-shrink: 0;
}

#example-element {
  border: solid 10px #ffbf00;
  background-color: #2b3a55;
  unicode-bidi: bidi-override;
}
```

Syntax

```
/* <length> values */
margin-inline-end: 10px; /* An absolute length */
margin-inline-end: 1em; /* relative to the text size */
margin-inline-end: 5%; /* relative to the nearest block container's width */
margin-inline-end: anchor-size(height);
margin-inline-end: calc(anchor-size(--my-anchor self-inline, 25px) / 5);

/* Keyword value */
margin-inline-end: auto;
```

```
/* Global values */
margin-inline-end: inherit;
margin-inline-end: initial;
margin-inline-end: revert;
margin-inline-end: revert-layer;
margin-inline-end: unset;
```

It relates to `margin-block-start`, `margin-block-end`, and `margin-inline-start`, which define the other margins of the element.

Values

The `margin-inline-end` property takes the same values as the `margin-top` property.

Formal definition

Initial value	`0`
Applies to	same as `margin`
Inherited	no
Percentages	depends on layout model
Computed value	if specified as a length, the corresponding absolute length; if specified as a percentage, the specified value; otherwise, `auto`
Animation type	a length

Formal syntax

```
margin-inline-end =
  <'margin-top'>

<margin-top> =
  <length-percentage>  |
  auto                 |
  <anchor-size()>

<length-percentage> =
  <length>     |
  <percentage>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width       |
  height      |
  block       |
  inline      |
  self-block  |
  self-inline
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Model Module Level 4, CSS Logical Properties and Values Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting inline end margin

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  margin-inline-end: 20px;
  background-color: #c8c800;
}
```

- `margin-inline-start`
- The mapped physical properties: `margin-top`, `margin-right`, `margin-bottom`, and `margin-left`
- `writing-mode`, `direction`, `text-orientation`

margin-inline-start CSS property

The **`margin-inline-start`** CSS property defines the logical inline start margin of an element, which maps to a physical margin depending on the element's writing mode, directionality, and text orientation. It corresponds to the `margin-top`, `margin-right`, `margin-bottom`, or `margin-left` property depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

Try it

```
margin-inline-start: 20px;
writing-mode: horizontal-tb;
```

```
margin-inline-start: 20px;
writing-mode: vertical-rl;
```

```
margin-inline-start: 20%;
writing-mode: horizontal-tb;
direction: rtl;
```

```
<section id="default-example">
  <div id="container">
    <div class="col">One</div>
    <div class="col transition-all" id="example-element">Two</div>
    <div class="col">Three</div>
  </div>
</section>
```

```
#container {
  width: 300px;
  height: 200px;
  display: flex;
  align-content: flex-start;
  justify-content: flex-start;
}

.col {
  width: 33.33%;
  border: solid #ce7777 10px;
  background-color: #2b3a55;
  color: white;
  flex-shrink: 0;
}

#example-element {
  border: solid 10px #ffbf00;
  background-color: #2b3a55;
  unicode-bidi: bidi-override;
}
```

Syntax

```
/* <length> values */
margin-inline-start: 10px; /* An absolute length */
margin-inline-start: 1em; /* relative to the text size */
margin-inline-start: 5%; /* relative to the nearest block container's width */
margin-inline-start: anchor-size(block);
margin-inline-start: calc(anchor-size(--my-anchor width, 30px) / 4);

/* Keyword value */
margin-inline-start: auto;

/* Global values */
margin-inline-start: inherit;
margin-inline-start: initial;
margin-inline-start: revert;
margin-inline-start: revert-layer;
margin-inline-start: unset;
```

It relates to `margin-block-start`, `margin-block-end`, and `margin-inline-end`, which define the other margins of the element.

Values

The `margin-inline-start` property takes the same values as the `margin-top` property.

Formal definition

Initial value	`0`
Applies to	same as `margin`
Inherited	no
Percentages	depends on layout model
Computed value	if specified as a length, the corresponding absolute length; if specified as a percentage, the specified value; otherwise, `auto`
Animation type	a length

Formal syntax

```
margin-inline-start =
  <'margin-top'>

<margin-top> =
  <length-percentage>  |
  auto                 |
  <anchor-size()>

<length-percentage> =
  <length>      |
  <percentage>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width        |
  height       |
  block        |
  inline       |
```

```
  self-block   |
  self-inline
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Model Module Level 4, CSS Logical Properties and Values Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting inline start margin

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  margin-inline-start: 20px;
  background-color: #c8c800;
}
```

Result

See also

- CSS Logical Properties and Values
- `margin-inline-end`
- The mapped physical properties: `margin-top`, `margin-right`, `margin-bottom`, and `margin-left`
- `writing-mode`, `direction`, `text-orientation`

margin-left CSS property

The **`margin-left`** CSS property sets the margin area on the left side of an element. A positive value places it farther from its neighbors, while a negative value places it closer.

Try it

```
margin-left: 1em;
```

```
margin-left: 10%;
```

```
margin-left: 10px;
```

```
margin-left: 0;
```

```
<section id="default-example">
  <div id="container">
    <div class="col"></div>
    <div class="col transition-all" id="example-element"></div>
    <div class="col"></div>
  </div>
</section>
```

```
#container {
  width: 300px;
  height: 200px;
  display: flex;
  align-content: flex-start;
  justify-content: flex-start;
}

.col {
  width: 33.33%;
  border: solid #5b6dcd 10px;
  background-color: rgb(229 232 252 / 0.6);
  flex-shrink: 0;
}

#example-element {
  border: solid 10px #ffc129;
  background-color: rgb(255 244 219 / 0.6);
}
```

The vertical margins of two adjacent boxes may fuse. This is called *margin collapsing*.

In the rare cases where width is overconstrained (i.e., when all of `width`, `margin-left`, `border`, `padding`, the content area, and `margin-right` are defined), `margin-left` is ignored, and will have the same calculated value as if the `auto` value was specified.

Syntax

```
/* <length> values */
margin-left: 10px; /* An absolute length */
margin-left: 1em; /* relative to the text size */
margin-left: 5%; /* relative to the nearest block container's width */
margin-left: anchor-size(self-inline);
margin-left: calc(anchor-size(--my-anchor width, 20px) / 4);

/* Keyword value */
margin-left: auto;
```

```
/* Global values */
margin-left: inherit;
margin-left: initial;
margin-left: revert;
margin-left: revert-layer;
margin-left: unset;
```

The `margin-left` property is specified as the keyword `auto`, or a `<length>`, or a `<percentage>`. Its value can be positive, zero, or negative.

Values

`<length>`

The size of the margin as a fixed value.

- For *anchor-positioned elements*, the `anchor-size()` function resolves to a `<length>` value relative to the associated *anchor element*'s width or height (see Setting element margin based on anchor size).

`<percentage>`

The size of the margin as a percentage, relative to the inline size (*width* in a horizontal language, defined by `writing-mode`) of the containing block.

`auto`

The left margin receives a share of the unused horizontal space, as determined mainly by the layout mode that is used. If the values of `margin-left` and `margin-right` are both `auto`, the calculated space is evenly distributed. This table summarizes the different cases:

Value of `display`	Value of `float`	Value of `position`	Computed value of `auto`	Comment
`inline`, `inline-block`, `inline-table`	***any***	`static` or `relative`	`0`	Inline layout mode
`block`, `inline`, `inline-block`, `block`, `table`, `inline-table`, `list-item`, `table-caption`	***any***	`static` or `relative`	`0`, except if both `margin-left` and `margin-right` are set to `auto`. In this case, it is set to the value centering the element inside its parent.	Block layout mode
`block`, `inline`, `inline-block`, `block`, `table`, `inline-table`, `list-item`, `table-caption`	`left` or `right`	`static` or `relative`	`0`	Block layout mode (floating element)
any `table-*`***, except*** `table-caption`	***any***	***any***	`0`	Internal `table-*` elements don't have margins, use `border-spacing` instead
any, except `flex`***,*** `inline-flex`***, or*** `table-*`	***any***	***fixed*** or `absolute`	`0`, except if both `margin-left` and `margin-right` are set to `auto`. In this case, it is set to the value centering the border area inside the available `width`, if fixed.	Absolutely positioned layout mode
`flex`, `inline-flex`	***any***	***any***	`0`, except if there is any positive horizontal free space. In this case, it is evenly distributed to all horizontal `auto` margins.	Flexbox layout mode

Formal definition

Initial value	`0`
Applies to	all elements, except elements with table `display` types other than `table-caption`, `table` and `inline-table`. It also applies to `::first-letter`.
Inherited	no
Percentages	refer to the width of the containing block
Computed value	the percentage as specified or the absolute length
Animation type	a length

Formal syntax

```
margin-left =
  <length-percentage>  |
  auto                 |
  <anchor-size()>

<length-percentage> =
  <length>     |
  <percentage>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width        |
  height       |
  block        |
  inline       |
  self-block   |
  self-inline
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Model Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting margin-left as a percentage

Percentage values for `margin-left` are relative to the container's inline size.

HTML

```
<p>
  A large rose-tree stood near the entrance of the garden: the roses growing on
  it were white, but there were three gardeners at it, busily painting them red.
```

```
</p>
<p class="example">
  Alice thought this a very curious thing, and she went nearer to watch them,
  and just as she came up to them she heard one of them say, "Look out now,
  Five! Don't go splashing paint over me like that!"
</p>
<p>
  "I couldn't help it," said Five, in a sulky tone; "Seven jogged my elbow."
</p>
```

CSS

```
.example {
  margin-left: 50%;
}
```

Result

See also

margin-right CSS property

The **`margin-right`** CSS property sets the margin area on the right side of an element. A positive value places it farther from its neighbors, while a negative value places it closer.

The vertical margins of two adjacent boxes may fuse. This is called *margin collapsing*.

Try it

```
margin-right: 1em;
```

```
margin-right: 10%;
```

```
margin-right: 10px;
```

```
margin-right: 0;
```

```
<section id="default-example">
  <div id="container">
    <div class="col"></div>
    <div class="col transition-all" id="example-element"></div>
    <div class="col"></div>
  </div>
</section>
```

```
#container {
  width: 300px;
  height: 200px;
  display: flex;
  align-content: flex-start;
  justify-content: flex-start;
}

.col {
  width: 33.33%;
  border: solid #5b6dcd 10px;
  background-color: rgb(229 232 252 / 0.6);
  flex-shrink: 0;
}

#example-element {
  border: solid 10px #ffc129;
  background-color: rgb(255 244 219 / 0.6);
}
```

Syntax

```
/* <length> values */
margin-right: 20px; /* An absolute length */
margin-right: 1em; /* relative to the text size */
margin-right: 5%; /* relative to the nearest block container's width */
margin-right: anchor-size(self-block);
margin-right: calc(anchor-size(--my-anchor height, 20px) / 4);

/* Keyword value */
margin-right: auto;

/* Global values */
margin-right: inherit;
margin-right: initial;
margin-right: revert;
margin-right: revert-layer;
margin-right: unset;
```

The `margin-right` property is specified as the keyword `auto`, or a `<length>`, or a `<percentage>`. Its value can be positive, zero, or negative.

Values

`<length>`

The size of the margin as a fixed value.

- For *anchor-positioned elements*, the `anchor-size()` function resolves to a `<length>` value relative to the associated *anchor element*'s width or height (see Setting element margin based on anchor size).

`<percentage>`

The size of the margin as a percentage, relative to the inline size (*width* in a horizontal language, defined by `writing-mode`) of the containing block.

`auto`

The right margin receives a share of the unused horizontal space, as determined mainly by the layout mode that is used. If the values of `margin-left` and `margin-right` are both `auto`, the calculated space is evenly distributed. This table summarizes the different cases:

Value of `display`	Value of `float`	Value of `position`	Computed value of `auto`	Comment
`inline`, `inline-block`, `inline-table`	***any***	`static` or `relative`	`0`	Inline layout mode
`block`, `inline`, `inline-block`, `block`, `table`, `inline-table`, `list-item`, `table-caption`	***any***	`static` or `relative`	`0`, except if both `margin-left` and `margin-right` are set to `auto`. In this case, it is set to the value centering the element inside its parent.	Block layout mode
`block`, `inline`, `inline-block`, `block`, `table`, `inline-table`, `list-item`, `table-caption`	`left` or `right`	`static` or `relative`	`0`	Block layout mode (floating element)
any `table-*`***, except*** `table-caption`	***any***	***any***	`0`	Internal `table-*` elements don't have margins, use `border-spacing` instead
any, except `flex`***,*** `inline-flex`***, or*** `table-*`	***any***	***fixed*** or `absolute`	`0`, except if both `margin-left` and `margin-right` are set to `auto`. In this case, it is set to the value centering the border area inside the available `width`, if fixed.	Absolutely positioned layout mode
`flex`, `inline-flex`	***any***	***any***	`0`, except if there is any positive horizontal free space. In this case, it is evenly distributed to all horizontal `auto` margins.	Flexbox layout mode

Formal definition

Initial value	`0`
Applies to	all elements, except elements with table `display` types other than `table-caption`, `table` and `inline-table`. It also applies to `::first-letter`.
Inherited	no
Percentages	refer to the width of the containing block
Computed value	the percentage as specified or the absolute length
Animation type	a length

Formal syntax

```
margin-right =
  <length-percentage>  |
  auto                 |
  <anchor-size()>

<length-percentage> =
  <length>      |
  <percentage>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width       |
  height      |
  block       |
  inline      |
  self-block  |
  self-inline
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Model Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting right margin using pixels and percentages

```
.content {
  margin-right: 5%;
}
.side-box {
  margin-right: 10px;
}
.logo {
  margin-right: -5px;
}
```

See also

- `margin-top`, `margin-bottom`, and `margin-left`
- `margin` shorthand
- `margin-block-start`, `margin-block-end`, `margin-inline-start`, and `margin-inline-end`
- `margin-block` and `margin-inline` shorthands
- CSS box model module

margin-top CSS property

The **`margin-top`** CSS property sets the margin area on the top of an element. A positive value places it farther from its neighbors, while a negative value places it closer.

This property has no effect on *non-replaced* inline elements, such as `<span>` or `<code>`.

Try it

```
margin-top: 1em;
```

```
margin-top: 10%;
```

```
margin-top: 10px;
```

```
margin-top: 0;
```

```
<section id="default-example">
  <div id="container">
    <div class="row"></div>
    <div class="row transition-all" id="example-element"></div>
    <div class="row"></div>
  </div>
</section>
```

```
#container {
  width: 300px;
  height: 200px;
  display: flex;
  align-content: flex-start;
  flex-direction: column;
  justify-content: flex-start;
}

.row {
  height: 33.33%;
  display: inline-block;
  border: solid #ce7777 10px;
  background-color: #2b3a55;
  flex-shrink: 0;
}

#example-element {
  border: solid 10px #ffbf00;
  background-color: #2b3a55;
}
```

Syntax

```
/* <length> values */
margin-top: 10px; /* An absolute length */
margin-top: 1em; /* relative to the text size */
margin-top: 5%; /* relative to the nearest block container's width */
margin-top: anchor-size(height);
margin-top: calc(anchor-size(--my-anchor self-inline, 25px) / 4);

/* Keyword value */
margin-top: auto;

/* Global values */
margin-top: inherit;
margin-top: initial;
margin-top: revert;
margin-top: revert-layer;
margin-top: unset;
```

The `margin-top` property is specified as the keyword `auto`, or a `<length>`, or a `<percentage>`. Its value can be positive, zero, or negative.

Values

`<length>`

The size of the margin as a fixed value.

- For *anchor-positioned elements*, the `anchor-size()` function resolves to a `<length>` value relative to the associated *anchor element*'s width or height (see Setting element margin based on anchor size).

`<percentage>`

The size of the margin as a percentage, relative to the inline size (*width* in a horizontal language, defined by `writing-mode`) of the containing block.

`auto`

The browser selects a suitable value to use. See `margin`.

Formal definition

Initial value	`0`
Applies to	all elements, except elements with table `display` types other than `table-caption`, `table` and `inline-table`. It also applies to `::first-letter`.
Inherited	no
Percentages	refer to the width of the containing block
Computed value	the percentage as specified or the absolute length
Animation type	a length

Formal syntax

```
margin-top =
  <length-percentage>  |
  auto                 |
  <anchor-size()>

<length-percentage> =
  <length>      |
  <percentage>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width        |
  height       |
  block        |
  inline       |
  self-block   |
  self-inline
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Model Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting positive and negative top margins

```
.content {
  margin-top: 5%;
}
.side-box {
  margin-top: 10px;
}
.logo {
  margin-top: -5px;
}
#footer {
  margin-top: 1em;
}
```

See also

- `margin-right`, `margin-bottom`, and `margin-left`
- `margin` shorthand
- `margin-block-start`, `margin-block-end`, `margin-inline-start`, and `margin-inline-end`
- `margin-block` and `margin-inline` shorthands
- CSS box model module

margin-trim CSS property

The `margin-trim` property allows the container to trim the margins of its children where they adjoin the container's edges.

Syntax

```
margin-trim: none;
margin-trim: block;
margin-trim: block-start;
margin-trim: block-end;
margin-trim: inline;
margin-trim: inline-start;
margin-trim: inline-end;

/* Global values */
margin-trim: inherit;
margin-trim: initial;
margin-trim: revert;
margin-trim: revert-layer;
margin-trim: unset;
```

Values

This property is specified as one of the following keyword values:

`none`

Margins are not trimmed by the container.

`block`

Margins provided to the block children where they adjoin the container's edges are trimmed to zero without affecting the margins provided to the container.

`block-start`

Margin of the first block child with the container's edge is trimmed to zero.

`block-end`

Margin of last block child with the container's edge is trimmed to zero.

`inline`

Margins provided to the inline children where they adjoin the container's edges are trimmed to zero, without affecting the spacing at the beginning and end of the row.

`inline-start`

Margin between the container's edge and the first inline child is trimmed to zero.

`inline-end`

Margin between the container's edge and the last inline child is trimmed to zero.

Formal definition

Initial value	none
Applies to	Block containers and multi-column containers. It also applies to `::first-letter`.
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
margin-trim =
  none                          |
  block                         |
  [ block-start || block-end ]
```

This syntax reflects the latest standard as per CSS Box Model Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

Once support is implemented for this property, it will probably work like so:

When you've got a container with some inline children and you want to put a margin between each child but not have it interfere with the spacing at the end of the row, you might do something like this:

```
article {
  background-color: red;
  margin: 20px;
  padding: 20px;
  display: inline-block;
}

article > span {
  background-color: black;
  color: white;
  text-align: center;
  padding: 10px;
  margin-right: 20px;
  margin-left: 30px;
}
```

The problem here is that you'd end up with 20px too much spacing at the right of the row, so you'd maybe do this to fix it:

```
span:last-child {
  margin-right: 0;
  margin-left: 0;
}
```

It is a pain having to write another rule to achieve this, and it is also not very flexible. Instead, `margin-trim` could fix it:

```
article {
  margin-trim: inline-end;
  /* … */
}
```

Similarly, to remove left margin with the container's edge:

```
article {
  margin-trim: inline-start;
  /* … */
}
```

- `margin`

marker CSS property

The **`marker`** CSS property points to a marker that will be drawn on the first, middle, and last vertices of the element's path; that is, at all of its vertices. The marker must have been defined using an SVG `<marker>` element, and can only be referenced with a `<url>` value. The value of the CSS property overrides any values of the `marker-start`, `marker`, and `marker-end` attributes in the SVG.

For many marker-supporting shapes, the first and last vertices are in the same place: for example, the top left corner of a `<rect>`. In such shapes, if both the first and last markers are defined, two markers will be drawn at that point, though they may not point in the same direction.

For the middle vertices, the direction each marker points is defined as the direction halfway between the direction at the end of the preceding path segment and the direction of the start of the following path segment. This can be thought of as the cross product of the vectors defined by the two path directions.

> **Note:** The `marker` property will only have an effect for elements that can use SVG markers. See `marker-start` for a list.

Syntax

```
marker: none;
marker: url("markers.svg#arrow");

/* Global values */
marker: inherit;
marker: initial;
marker: revert;
marker: revert-layer;
marker: unset;
```

Values

`none`

This means no marker will be drawn at each vertex of the element's path.

`<marker-ref>`

A `<url>` that refers to a marker defined by an SVG `<marker>` element, to be drawn at each vertex of the element's path. If the URL reference is invalid, no marker will be drawn at the path's vertices.

Formal definition

Initial value	as each of the properties of the shorthand: • `marker-start`: none • `marker-mid`: none • `marker-end`: none
Applies to	`<circle>`, `<ellipse>`, `<line>`, `<path>`, `<polygon>`, `<polyline>`, and `<rect>` elements in an `svg`
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
marker =
  none          |
  <marker-ref>

<marker-ref> =
  <url>
```

This syntax reflects the latest standard as per CSS Specification. Not all browsers may have implemented every part. See Browser compatibility for support information.

Example

```
html,
body,
svg {
  height: 100%;
}
```

```
<svg viewBox="0 0 240 120" xmlns="http://www.w3.org/2000/svg">
  <defs>
    <marker
      id="triangle"
      viewBox="0 0 10 10"
      markerWidth="10"
      markerHeight="10"
      refX="1"
      refY="5"
      markerUnits="strokeWidth"
      orient="auto">
      <path d="M 0 0 L 10 5 L 0 10 z" fill="red" />
    </marker>
  </defs>
  <polyline
    id="test"
    fill="none"
    stroke="black"
    points="20,100 40,60 70,80 100,20 130,10 150,10 170,20 170,100 120,100" />
</svg>
```

```
polyline#test {
  marker: url("#triangle");
}
```

- `marker-end`
- SVG `<marker>` element

marker-end CSS property

The **`marker-end`** CSS property points to a marker that will be drawn on the last vertex of the element's path; that is, at its ending vertex. The marker must have been defined using an SVG `<marker>` element, and can only be referenced with a `<url>` value. The value of the CSS property overrides any values of the `marker-end` attribute in the SVG.

For many marker-supporting shapes, the first and last vertices are the same point: for example, the top left corner of a `<rect>`. In such shapes, if both the first and last markers are defined, two markers will be drawn at that point, though they may not face the same direction.

> **Note:** The `marker-end` property will only have an effect for elements that can use SVG markers. See `marker-end` for a list.

Syntax

```
marker-end: none;
marker-end: url("markers.svg#arrow");

/* Global values */
marker-end: inherit;
marker-end: initial;
marker-end: revert;
marker-end: revert-layer;
marker-end: unset;
```

Values

`none`

This means no marker will be drawn at the last vertex of the element's path.

`<marker-ref>`

A `<url>` that refers to a marker defined by an SVG `<marker>` element, to be drawn at the last vertex of the element's path. If the URL reference is invalid, no marker will be drawn at the path's last vertex.

Formal definition

Initial value	none
Applies to	`<circle>`, `<ellipse>`, `<line>`, `<path>`, `<polygon>`, `<polyline>`, and `<rect>` elements in an `svg`
Inherited	yes
Computed value	as specified, but with `<url>` values made absolute
Animation type	discrete

Formal syntax

```
marker-end =
  none          |
  <marker-ref>

<marker-ref> =
  <url>
```

This syntax reflects the latest standard as per CSS Specification. Not all browsers may have implemented every part. See Browser compatibility for support information.

Example

```
html,
body,
svg {
  height: 100%;
}
```

```
<svg viewBox="0 0 120 120" xmlns="http://www.w3.org/2000/svg">
  <defs>
    <marker
      id="triangle"
      viewBox="0 0 10 10"
      markerWidth="10"
      markerHeight="10"
      refX="1"
      refY="5"
      markerUnits="strokeWidth"
      orient="auto">
      <path d="M 0 0 L 10 5 L 0 10 z" fill="red" />
    </marker>
  </defs>
  <polyline
    id="test"
    fill="none"
    stroke="black"
    points="20,100 40,60 70,80 100,20" />
</svg>
```

```
polyline#test {
  marker-end: url("#triangle");
}
```

See also

- `marker-start`
- `marker-mid`
- `marker`
- SVG `marker-end` attribute

marker-mid CSS property

The **`marker-mid`** CSS property points to a marker that will be drawn on the middle vertices of the element's path; that is, at each of its vertices between the start and end vertices. The marker must have been defined using an SVG `<marker>` element, and can only be referenced with a `<url>` value. The value of the CSS property overrides any values of the `marker-mid` attribute in the SVG.

The direction each marker points is defined as the direction halfway between the direction at the end of the preceding path segment and the direction of the start of the following path segment. This can be thought of as the cross product of the vectors defined by the two path directions.

> **Note:** The `marker-mid` property will only have an effect for elements that can use SVG markers. See `marker-mid` for a list.

Syntax

```
marker-mid: none;
marker-mid: url("markers.svg#arrow");

/* Global values */
marker-mid: inherit;
marker-mid: initial;
marker-mid: revert;
marker-mid: revert-layer;
marker-mid: unset;
```

Values

`none`

This means no marker will be drawn at each middle vertex of the element's path.

`<marker-ref>`

A `<url>` that refers to a marker defined by an SVG `<marker>` element, to be drawn at each middle vertex of the element's path. If the URL reference is invalid, no marker will be drawn at the path's middle vertices.

Formal definition

Initial value	none
Applies to	`<circle>`, `<ellipse>`, `<line>`, `<path>`, `<polygon>`, `<polyline>`, and `<rect>` elements in an `svg`
Inherited	yes
Computed value	as specified, but with `<url>` values made absolute
Animation type	discrete

Formal syntax

```
marker-mid =
  none          |
  <marker-ref>

<marker-ref> =
  <url>
```

This syntax reflects the latest standard as per CSS Specification. Not all browsers may have implemented every part. See Browser compatibility for support information.

Example

```
html,
body,
svg {
  height: 100%;
}
```

```
<svg viewBox="0 0 240 120" xmlns="http://www.w3.org/2000/svg">
  <defs>
    <marker
      id="triangle"
      viewBox="0 0 10 10"
      markerWidth="10"
      markerHeight="10"
      refX="1"
      refY="5"
      markerUnits="strokeWidth"
      orient="auto">
      <path d="M 0 0 L 10 5 L 0 10 z" fill="red" />
    </marker>
  </defs>
  <polyline
    id="test"
    fill="none"
    stroke="black"
    points="20,100 40,60 70,80 100,20 130,10 150,10 170,20 170,100 120,100" />
</svg>
```

```
polyline#test {
  marker-mid: url("#triangle");
}
```

marker-start CSS property

The **`marker-start`** CSS property points to a marker that will be drawn on the first vertex of the element's path; that is, at its starting vertex. The marker must have been defined using an SVG `<marker>` element, and can only be referenced with a `<url>` value. The value of the CSS property overrides any values of the `marker-start` attribute in the SVG.

For many marker-supporting shapes, the first and last vertices are in the same place: for example, the top left corner of a `<rect>`. In such shapes, if both the first and last markers are defined, two markers will be drawn at that point, though they may not point in the same direction.

> **Note:** The `marker-start` property will only have an effect for elements that can use SVG markers. See `marker-start` for a list.

Syntax

```
marker-start: none;
marker-start: url("markers.svg#arrow");

/* Global values */
marker-start: inherit;
marker-start: initial;
marker-start: revert;
marker-start: revert-layer;
marker-start: unset;
```

Values

`none`

This means no marker will be drawn at the first vertex of the element's path.

`<marker-ref>`

A `<url>` that refers to a marker defined by an SVG `<marker>` element, to be drawn at the first vertex of the element's path. If the URL reference is invalid, no marker will be drawn at the path's first vertex.

Formal definition

Initial value	none
Applies to	`<circle>`, `<ellipse>`, `<line>`, `<path>`, `<polygon>`, `<polyline>`, and `<rect>` elements in an `svg`
Inherited	yes
Computed value	as specified, but with `<url>` values made absolute
Animation type	discrete

Formal syntax

```
marker-start =
  none          |
  <marker-ref>

<marker-ref> =
  <url>
```

This syntax reflects the latest standard as per CSS Specification. Not all browsers may have implemented every part. See Browser compatibility for support information.

Example

```
html,
body,
svg {
  height: 100%;
}
```

```
<svg viewBox="0 0 120 120" xmlns="http://www.w3.org/2000/svg">
  <defs>
    <marker
      id="triangle"
      viewBox="0 0 10 10"
      markerWidth="10"
      markerHeight="10"
      refX="1"
      refY="5"
      markerUnits="strokeWidth"
      orient="auto">
      <path d="M 0 0 L 10 5 L 0 10 z" fill="red" />
    </marker>
  </defs>
  <polyline
    id="test"
    fill="none"
    stroke="black"
    points="20,100 40,60 70,80 100,20" />
</svg>
```

```
polyline#test {
  marker-start: url("#triangle");
}
```

mask CSS property

The **`mask`** CSS shorthand property hides an element (partially or fully) by masking or clipping a specified area of the image. It is a shorthand for all the `mask-*` properties. The property accepts one or more comma-separated values, where each value corresponds to a `<mask-layer>`.

Constituent properties

This property is a shorthand for the following CSS properties:

- `mask-clip`
- `mask-composite`
- `mask-image`
- `mask-mode`
- `mask-origin`
- `mask-position`
- `mask-repeat`
- `mask-size`

Reset-only sub-properties

This property resets the following CSS properties to their initial values:

- `mask-border-mode`
- `mask-border-outset`
- `mask-border-repeat`
- `mask-border-slice`
- `mask-border-source`
- `mask-border-width`

Syntax

```
/* Keyword value */
mask: none;

/* Image values */
mask: url("mask.png"); /* Raster image used as mask */
mask: url("masks.svg#star"); /* SVG used as mask */

/* Combined values */
mask: url("masks.svg#star") luminance; /* Luminance mask */
mask: url("masks.svg#star") 40px 20px; /* Mask positioned 40px from the top and 20px from the left */
mask: url("masks.svg#star") 0 0/50px 50px; /* Mask with a width and height of 50px */
mask: url("masks.svg#star") repeat-x; /* Horizontally-repeated mask */
mask: url("masks.svg#star") stroke-box; /* Mask extends to the inside edge of the stroke box */
mask: url("masks.svg#star") exclude; /* Mask combined with background using non-overlapping parts */

/* Multiple masks */
mask:
  url("masks.svg#star") left / 16px repeat-y,
  /* 16px-wide mask on the left side */ url("masks.svg#circle") right / 16px
    repeat-y; /* 16px-wide mask against right side */

/* Global values */
mask: inherit;
mask: initial;
mask: revert;
mask: revert-layer;
mask: unset;
```

Values

`<mask-layer>`

One or more comma-separated mask layers, consisting of the following components:

`<mask-reference>`

Sets the mask image source. See `mask-image`.

`<masking-mode>`

Sets the masking mode of the mask image. See `mask-mode`.

`<position>`

Sets the position of the mask image. See `mask-position`.

`<bg-size>`

Sets the size of the mask image. See `mask-size`.

`<repeat-style>`

Sets the repetition of the mask image. See `mask-repeat`.

`<geometry-box>`

If only one `<geometry-box>` value is given, it sets both the `mask-origin` and `mask-clip` property values. If two `<geometry-box>` values are present, the first defines the `mask-origin` and the second defines the `mask-clip`.

`<geometry-box> | no-clip`

Sets the area affected by the mask image. See `mask-clip`.

`<compositing-operator>`

Sets the compositing operation used on the current mask layer. See `mask-composite`.

Description

The `mask` shorthand property hides part or all of the element it is applied to. The parts of the element that are hidden, visible, or partially shown depend on either the opacity (alpha channel of the mask) or the brightness (luminance) of the mask. In alpha masking, opaque areas of the mask reveal the element, and transparent areas hide it. In luminance masking, light opaque areas of the mask reveal the element, and dark or transparent areas hide it.

While not all constituent mask properties need to be declared, any values that are omitted default to their initial values, which are:

```
mask-image: none;
mask-mode: match-source;
mask-position: 0% 0%;
mask-size: auto;
mask-repeat: repeat;
mask-origin: border-box;
mask-clip: border-box;
mask-composite: add;
```

Within each `<mask-layer>`, the `mask-size` component must go after the `mask-position` value, with a forward slash (`/`) separating the two.

If there are two `<geometry-box>` values present, the first is the `mask-origin` value, while the second is the `mask-clip` value. If one `<geometry-box>` value and the `no-clip` keyword are present, the `<geometry-box>` is the value of the `mask-origin` property, as the `no-clip` is only valid for the `mask-clip` property. In this case, the order of the two values doesn't matter. If only one `<geometry-box>` value is present (with no `no-clip` keyterm specified), this value is used for both the `mask-origin` and `mask-clip` properties.

As the `mask` shorthand resets all the `mask-border-*` properties to their `initial` value, you should declare these properties — or the `mask-border` shorthand — after any `mask` declarations. When setting `mask` in your declaration block, you also implicitly set the following:

```
mask-border-source: none;
mask-border-mode: alpha;
mask-border-outset: 0;
mask-border-repeat: stretch;
```

```
mask-border-slice: 0;
mask-border-width: auto;
```

For this reason, the specification recommends using the `mask` shorthand rather than the individual component properties to override any masks set earlier in the cascade. This ensures that `mask-border` has also been reset.

Formal definition

Initial value	as each of the properties of the shorthand: • `mask-image`: `none` • `mask-mode`: `match-source` • `mask-repeat`: `repeat` • `mask-position`: `0% 0%` • `mask-clip`: `border-box` • `mask-origin`: `border-box` • `mask-size`: `auto` • `mask-composite`: `add`
Applies to	all elements; In SVG, it applies to container elements excluding the `<defs>` element and all graphics elements
Inherited	no
Percentages	as each of the properties of the shorthand: • `mask-position`: refer to size of mask painting area minus size of mask layer image (see the text for `background-position`)
Computed value	as each of the properties of the shorthand: • `mask-image`: as specified, but with `<url>` values made absolute • `mask-mode`: as specified • `mask-repeat`: Consists of two keywords, one per dimension • `mask-position`: Consists of two keywords representing the origin and two offsets from that origin, each given as an absolute length (if given a <length>), otherwise as a percentage. • `mask-clip`: as specified • `mask-origin`: as specified • `mask-size`: as specified, but with relative lengths converted into absolute lengths • `mask-composite`: as specified
Animation type	as each of the properties of the shorthand: • `mask-image`: discrete • `mask-mode`: discrete • `mask-repeat`: discrete • `mask-position`: a repeatable list • `mask-clip`: discrete • `mask-origin`: discrete • `mask-size`: a repeatable list • `mask-composite`: discrete
Creates stacking context	yes

This syntax reflects the latest standard as per CSS Backgrounds Module Level 4, CSS Box Model Module Level 4, CSS Images Module Level 4, CSS Images Module Level 5, CSS Masking Module Level 1, CSS Shapes Module Level 1, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Masking an image

In this example, an image is masked using a CSS-generated repeating conic gradient as a mask source. We'll also show the gradient as a background image for comparison.

HTML

We include an `<img>` and an empty `<div>` element.

```
<img
  src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
  alt="Pride flag" />
<div></div>
```

CSS

We set the same `border`, `padding`, and sizing on both the `<img>` and `<div>`.

```
img,
div {
  border: 20px dashed rebeccapurple;
  box-sizing: content-box;
  padding: 20px;
  height: 220px;
  width: 220px;
}
```

We then apply a mask to the `<img>`. The `mask-image` is generated using a `repeating-conic-gradient()` function. We define it to be a `100px` by `100px` gradient, which repeats starting at the top and left corner of the image's `content-box`. We include two `<geometry-box>` values; the first sets the `mask-origin` and the second defines the `mask-clip` property value. The gradient goes from transparent to solid `lightgreen`. We used `lightgreen` to demonstrate that it isn't the color of the mask that is important, but rather its transparency.

```
img {
  mask: repeating-radial-gradient(
      circle,
      transparent 0 5px,
      lightgreen 15px 20px
    )
    content-box border-box 0% 0% / 100px 100px repeat;
}
```

Finally, we use the same value for the `<div>`'s `background` shorthand property as we used for the `mask`.

```
div {
  background: repeating-radial-gradient(
      circle,
      transparent 0 5px,
      lightgreen 15px 20px
    )
    content-box border-box 0% 0% / 100px 100px repeat;
}
```

mask-border CSS property

The **`mask-border`** CSS shorthand property lets you create a mask along the edge of an element's border.

Constituent properties

This property is a shorthand for the following CSS properties:

- `mask-border-mode`
- `mask-border-outset`
- `mask-border-repeat`
- `mask-border-slice`
- `mask-border-source`
- `mask-border-width`

Syntax

```
/* source | slice */
mask-border: url("border-mask.png") 25;

/* source | slice | repeat */
mask-border: url("border-mask.png") 25 space;

/* source | slice | width */
mask-border: url("border-mask.png") 25 / 35px;

/* source | slice | width | outset | repeat | mode */
mask-border: url("border-mask.png") 25 / 35px / 12px space alpha;

/* Global values */
mask-border: inherit;
mask-border: initial;
mask-border: revert;
mask-border: revert-layer;
mask-border: unset;
```

Values

`<'mask-border-source'>`

The source image. See `mask-border-source`.

`<'mask-border-slice'>`

The dimensions for slicing the source image into regions. Up to four values may be specified. See `mask-border-slice`.

`<'mask-border-width'>`

The width of the border mask. Up to four values may be specified. See `mask-border-width`.

`<'mask-border-outset'>`

The distance of the border mask from the element's outside edge. Up to four values may be specified. See `mask-border-outset`.

`<'mask-border-repeat'>`

Defines how the edge regions of the source image are adjusted to fit the dimensions of the border mask. Up to two values may be specified. See `mask-border-repeat`.

`<'mask-border-mode'>`

Defines whether the source image is treated as a luminance mask or alpha mask. See `mask-border-mode`.

Formal definition

Initial value	as each of the properties of the shorthand: • `mask-border-mode`: `alpha` • `mask-border-outset`: `0` • `mask-border-repeat`: `stretch` • `mask-border-slice`: `0` • `mask-border-source`: `none` • `mask-border-width`: `auto`
Applies to	all elements; In SVG, it applies to container elements excluding the `<defs>` element and all graphics elements
Inherited	no
Percentages	as each of the properties of the shorthand: • `mask-border-slice`: refer to size of the mask border image • `mask-border-width`: relative to width/height of the mask border image area
Computed value	as each of the properties of the shorthand: • `mask-border-mode`: as specified • `mask-border-outset`: as specified, but with relative lengths converted into absolute lengths • `mask-border-repeat`: as specified • `mask-border-slice`: as specified • `mask-border-source`: as specified, but with `<url>` values made absolute • `mask-border-width`: as specified, but with relative lengths converted into absolute lengths
Animation type	as each of the properties of the shorthand: • `mask-border-mode`: discrete • `mask-border-outset`: discrete • `mask-border-repeat`: discrete • `mask-border-slice`: discrete • `mask-border-source`: discrete • `mask-border-width`: discrete
Creates stacking context	yes

Formal syntax

```
mask-border =
  <'mask-border-source'>                            ||
  <'mask-border-slice'> [ / <'mask-border-width'>? [ / <'mask-border-outset'> ]? ]?  ||
  <'mask-border-repeat'>                            ||
  <'mask-border-mode'>

<mask-border-source> =
  <'border-image-source'>

<mask-border-slice> =
  <'border-image-slice'>

<mask-border-width> =
  <'border-image-width'>

<mask-border-outset> =
  <'border-image-outset'>

<mask-border-repeat> =
  <'border-image-repeat'>

<mask-border-mode> =
  luminance  |
  alpha

<border-image-source> =
  none     |
  <image>

<border-image-slice> =
  [ <number [0,∞]> | <percentage [0,∞]> ]{1,4}  &&
  fill?

<border-image-width> =
  [ <length-percentage [0,∞]> | <number [0,∞]> | auto ]{1,4}

<border-image-outset> =
  [ <length [0,∞]> | <number [0,∞]> ]{1,4}
```

```
<border-image-repeat> =
  [ stretch | repeat | round | space ]{1,2}

<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
  <gradient>

<length-percentage> =
  <length>      |
  <percentage>

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-set()> =
  image-set( <image-set-option># )

<cross-fade()> =
  cross-fade( <cf-image># )

<element()> =
  element( <id-selector> )

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Images Module Level 4, CSS Images Module Level 5, CSS Masking Module Level 1, CSS Values and Units Module Level 4, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting a bitmap-based mask border

In this example, we will mask an element's border with a diamond pattern. The source for the mask is a ".png" file of 90 by 90 pixels, with three diamonds going vertically and horizontally:

To match the size of a single diamond, we will use a value of 90 divided by 3, or `30`, for slicing the image into corner and edge regions. A repeat value of `round` will make the mask slices fit evenly, i.e., without clipping or gaps.

```
<div class="masked">
  This element is surrounded by a bitmap-based mask border! Pretty neat, isn't
  it?
</div>
```

```
.masked {
  width: 200px;
  background-color: lavender;
  border: 18px solid salmon;
  padding: 10px;

  -webkit-mask-box-image: url("https://mdn.github.io/shared-assets/images/examples/mask-border-diamonds.png")
    30 fill /          /* slice */
    20px /             /* width */
    1px                /* outset */
    round;             /* repeat */

  mask-border:
    url("https://mdn.github.io/shared-assets/images/examples/mask-border-diamonds.png")
    30 fill /        /* slice */
    20px /           /* width */
    1px              /* outset */
    round;           /* repeat */
}
```

mask-border-mode CSS property

The **`mask-border-mode`** CSS property specifies the blending mode used in a mask border.

Syntax

```
/* Keyword values */
mask-border-mode: luminance;
mask-border-mode: alpha;

/* Global values */
mask-border-mode: inherit;
mask-border-mode: initial;
mask-border-mode: revert;
mask-border-mode: revert-layer;
mask-border-mode: unset;
```

Values

This property is specified as one of the following keyword values:

`luminance`

The luminance values of the mask border image are used as the mask values.

`alpha`

The alpha values of the mask border image are used as the mask values.

Formal definition

Initial value	`alpha`
Applies to	all elements; In SVG, it applies to container elements excluding the `<defs>` element and all graphics elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
mask-border-mode =
  luminance  |
  alpha
```

This syntax reflects the latest standard as per CSS Masking Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Browser compatibility

Currently, no browsers support this feature.

- CSS masking module

mask-border-outset CSS property

The **`mask-border-outset`** CSS property specifies the distance by which an element's mask border is set out from its border box.

Syntax

```
/* <length> value */
mask-border-outset: 1rem;

/* <number> value */
mask-border-outset: 1.5;

/* top and bottom | left and right */
mask-border-outset: 1 1.2;

/* top | left and right | bottom */
mask-border-outset: 30px 2 45px;

/* top | right | bottom | left */
mask-border-outset: 7px 12px 14px 5px;

/* Global values */
mask-border-outset: inherit;
mask-border-outset: initial;
mask-border-outset: revert;
mask-border-outset: revert-layer;
mask-border-outset: unset;
```

The `mask-border-outset` property may be specified as one, two, three, or four values. Each value is a `<length>` or `<number>`. Negative values are invalid.

- When **one** value is specified, it applies the same outset to **all four sides**.
- When **two** values are specified, the first outset applies to the **top and bottom**, the second to the **left and right**.
- When **three** values are specified, the first outset applies to the **top**, the second to the **left and right**, the third to the **bottom**.
- When **four** values are specified, the outsets apply to the **top**, **right**, **bottom**, and **left** in that order (clockwise).

Values

`<length>`

The size of the mask border outset as a dimension.

`<number>`

The size of the mask border outset as a multiple of the corresponding `border-width`.

Formal definition

Initial value	`0`
Applies to	all elements; In SVG, it applies to container elements excluding the `<defs>` element and all graphics elements
Inherited	no
Computed value	as specified, but with relative lengths converted into absolute lengths
Animation type	discrete

Formal syntax

```
mask-border-outset =
  <'border-image-outset'>

<border-image-outset> =
  [ <length [0,∞]> | <number [0,∞]> ]{1,4}
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Masking Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This property doesn't appear to be supported anywhere yet. When it eventually starts to be supported, it will serve to move the mask away from the inner edge of the element's border box — you can use it to make the mask start from part way across the border, rather than the inside of it.

```
mask-border-outset: 1rem;
```

Chromium-based browsers support an outdated version of this property — `mask-box-image-outset` — with a prefix:

```
-webkit-mask-box-image-outset: 1rem;
```

> **Note:** The `mask-border` page features a working example (using the out-of-date prefixed border mask properties supported in Chromium), so you can get an idea of the effect.

- `mask-border-source`
- `mask-border-width`

mask-border-repeat CSS property

The **`mask-border-repeat`** CSS property specifies how the images for the sides and the middle part of the mask border image are scaled and tiled.

Syntax

```
/* Keyword values */
mask-border-repeat: stretch;
mask-border-repeat: repeat;
mask-border-repeat: round;
mask-border-repeat: space;

/* top and bottom | left and right */
mask-border-repeat: round stretch;

/* Global values */
mask-border-repeat: inherit;
mask-border-repeat: initial;
mask-border-repeat: revert;
mask-border-repeat: revert-layer;
mask-border-repeat: unset;
```

The `mask-border-repeat` property may be specified using one or two values chosen from the list of values below.

- When **one** value is specified, it applies the same behavior on **all four sides**.
- When **two** values are specified, the first applies to the **top and bottom**, the second to the **left and right**.

Values

`stretch`

The source image's edge regions are stretched to fill the gap between each border.

`repeat`

The source image's edge regions are tiled (repeated) to fill the gap between each border. Tiles may be clipped to achieve the proper fit.

`round`

The source image's edge regions are tiled (repeated) to fill the gap between each border. Tiles may be stretched to achieve the proper fit.

`space`

The source image's edge regions are tiled (repeated) to fill the gap between each border. Extra space will be distributed in between tiles to achieve the proper fit.

Formal definition

Initial value	`stretch`
Applies to	all elements; In SVG, it applies to container elements excluding the `<defs>` element and all graphics elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
mask-border-repeat =
  <'border-image-repeat'>

<border-image-repeat> =
  [ stretch | repeat | round | space ]{1,2}
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Masking Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This property doesn't appear to be supported anywhere yet. When it eventually starts to be supported, it will serve to define how the border mask slice will repeat around the border — i.e., will it just repeat, or be scaled slightly so a whole number of slices fits, or be stretched so one slice fits?

```
mask-border-repeat: round;
```

Chromium-based browsers support an outdated version of this property — `mask-box-image-repeat` — with a prefix:

```
-webkit-mask-box-image-repeat: round;
```

> **Note:** The `mask-border` page features a working example (using the out-of-date prefixed border mask properties supported in Chromium), so you can get an idea of the effect.

See also

- `mask-border`
- `mask-border-mode`
- `mask-border-outset`
- `mask-border-source`
- `mask-border-width`

mask-border-slice CSS property

The **`mask-border-slice`** CSS property divides the image set by `mask-border-source` into regions. These regions are used to form the components of an element's mask border.

Syntax

```
/* All sides */
mask-border-slice: 30%;

/* top and bottom | left and right */
mask-border-slice: 10% 30%;

/* top | left and right | bottom */
mask-border-slice: 30 30% 45;

/* top | right | bottom | left */
mask-border-slice: 7 12 14 5;

/* Using the `fill` keyword */
mask-border-slice: 10% fill 7 12;

/* Global values */
mask-border-slice: inherit;
mask-border-slice: initial;
mask-border-slice: revert;
mask-border-slice: revert-layer;
mask-border-slice: unset;
```

The `mask-border-slice` property may be specified using one to four `<number-percentage>` values to represent the position of each image slice. Negative values are invalid; values greater than their corresponding dimension are clamped to `100%`.

- When **one** position is specified, it creates all four slices at the same distance from their respective sides.
- When **two** positions are specified, the first value creates slices measured from the **top and bottom**, the second creates slices measured from the **left and right**.
- When **three** positions are specified, the first value creates a slice measured from the **top**, the second creates slices measured from the **left and right**, the third creates a slice measured from the **bottom**.
- When **four** positions are specified, they create slices measured from the **top**, **right**, **bottom**, and **left** in that order (clockwise).

The optional `fill` value, if used, can be placed anywhere in the declaration.

Values

`<number>`

Represents an edge offset in *pixels* for raster images and *coordinates* for vector images. For vector images, the number is relative to the element's size, not the size of the source image, so percentages are generally preferable in these cases.

`<percentage>`

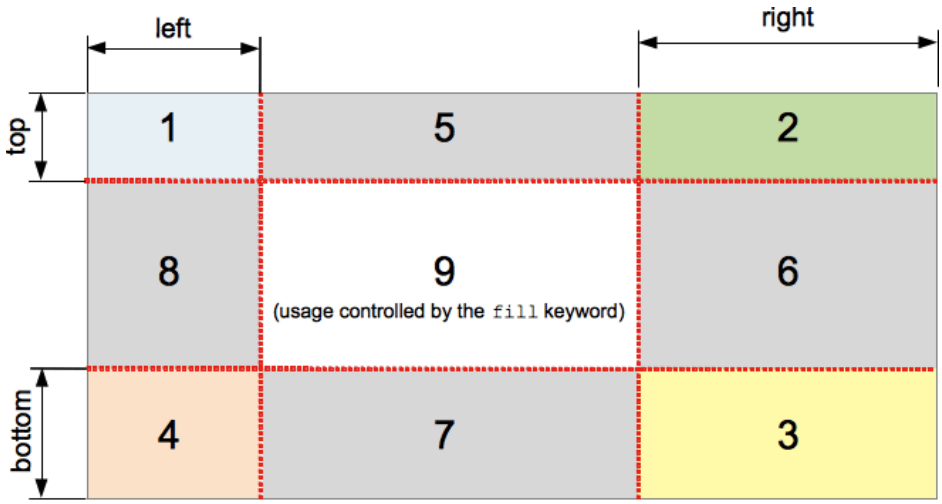
Represents an edge offset as a percentage of the source image's size: the width of the image for horizontal offsets, the height for vertical offsets.

`fill`

Preserves the middle image region. Its width and height are sized to match the top and left image regions, respectively.

Description

The slicing process creates nine regions in total: four corners, four edges, and a middle region. Four slice lines, set a given distance from their respective sides, control the size of the regions.



The above diagram illustrates the location of each region.

- Zones 1-4 are corner regions. Each one is used a single time to form the corners of the final border image.
- Zones 5-8 are edge regions. These are repeated, scaled, or otherwise modified in the final border image to match the dimensions of the element.
- Zone 9 is the middle region. It is discarded by default, but is used like a background image if the keyword `fill` is set.

The `mask-border-repeat`, `mask-border-width`, and `mask-border-outset` properties determine how these regions are used to form the final mask border.

Formal definition

Initial value	`0`
Applies to	all elements; In SVG, it applies to container elements excluding the `<defs>` element and all graphics elements
Inherited	no
Percentages	refer to size of the mask border image
Computed value	as specified
Animation type	discrete

Formal syntax

```
mask-border-slice =
  <'border-image-slice'>

<border-image-slice> =
  [ <number [0,∞]> | <percentage [0,∞]> ]{1,4}  &&
  fill?
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Masking Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

`mask-border-slice` serves to define the size of the slices taken from the source image, and is used to create the border mask.

```
mask-border-slice: 30 fill;
```

Chromium-based browsers support an outdated version of this property — `mask-box-image-slice` — with a prefix:

```
-webkit-mask-box-image-slice: 30 fill;
```

> **Note:** The `mask-border` page features a working example (using the out-of-date prefixed border mask properties supported in Chromium), so you can get an idea of the effect.

> **Note:** The fill keyword needs to be included if you want the element's content to be visible.

See also

- `mask-border`
- `mask-border-mode`
- `mask-border-outset`
- `mask-border-repeat`
- `mask-border-source`
- `mask-border-width`
- Illustrated description of the 1-to-4-value syntax

mask-border-source CSS property

The **`mask-border-source`** CSS property sets the source image used to create an element's mask border.

The `mask-border-slice` property is used to divide the source image into regions, which are then dynamically applied to the final mask border.

Syntax

```
/* Keyword value */
mask-border-source: none;

/* <image> values */
mask-border-source: url("image.jpg");
mask-border-source: linear-gradient(to top, red, yellow);

/* Global values */
mask-border-source: inherit;
mask-border-source: initial;
mask-border-source: revert;
mask-border-source: revert-layer;
mask-border-source: unset;
```

Values

`none`

No mask border is used.

`<image>`

Image reference to use for the mask border.

Formal definition

Initial value	none
Applies to	all elements; In SVG, it applies to container elements excluding the `<defs>` element and all graphics elements
Inherited	no
Computed value	as specified, but with `<url>` values made absolute
Animation type	discrete

Formal syntax

```
mask-border-source =
  <'border-image-source'>

<border-image-source> =
  none     |
  <image>

<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
  <gradient>

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-set()> =
  image-set( <image-set-option># )

<cross-fade()> =
  cross-fade( <cf-image># )

<element()> =
  element( <id-selector> )

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Images Module Level 4, CSS Images Module Level 5, CSS Masking Module Level 1, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This property doesn't appear to be supported anywhere yet. When it eventually starts to be supported, it will serve to define the source of the border mask.

```
mask-border-source: url("image.jpg");
```

Chromium-based browsers support an outdated version of this property — `mask-box-image-source` — with a prefix:

```
-webkit-mask-box-image-source: url("image.jpg");
```

> **Note:** The `mask-border` page features a working example (using the out-of-date prefixed border mask properties supported in Chromium), so you can get an idea of the effect.

See also

- `mask-border`
- `mask-border-mode`
- `mask-border-outset`
- `mask-border-repeat`
- `mask-border-width`

mask-border-width CSS property

The **`mask-border-width`** CSS property sets the width of an element's mask border.

Syntax

```
/* Keyword value */
mask-border-width: auto;

/* <length> value */
mask-border-width: 1rem;

/* <percentage> value */
mask-border-width: 25%;

/* <number> value */
mask-border-width: 3;

/* top and bottom | left and right */
mask-border-width: 2em 3em;

/* top | left and right | bottom */
mask-border-width: 5% 15% 10%;

/* top | right | bottom | left */
mask-border-width: 5% 2em 10% auto;

/* Global values */
mask-border-width: inherit;
mask-border-width: initial;
mask-border-width: revert;
mask-border-width: revert-layer;
mask-border-width: unset;
```

The `mask-border-width` property may be specified using one, two, three, or four values chosen from the list of values below.

- When **one** value is specified, it applies the same width to **all four sides**.
- When **two** values are specified, the first width applies to the **top and bottom**, the second to the **left and right**.
- When **three** values are specified, the first width applies to the **top**, the second to the **left and right**, the third to the **bottom**.
- When **four** values are specified, the widths apply to the **top**, **right**, **bottom**, and **left** in that order (clockwise).

Values

`<length-percentage>`

> The width of the mask border, specified as a `<length>` or a `<percentage>`. Percentages are relative to the *width* of the border area for horizontal offsets and the *height* of the border area for vertical offsets. Must not be negative.

`<number>`

> The width of the mask border, specified as a multiple of the corresponding `border-width`. Must not be negative.

`auto`

> The width of the mask border is made equal to the intrinsic width or height (whichever is applicable) of the corresponding `mask-border-slice`. If the image does not have the required intrinsic dimension, the corresponding `border-width` is used instead.

Formal definition

Initial value	`auto`
Applies to	all elements; In SVG, it applies to container elements excluding the `<defs>` element and all graphics elements
Inherited	no
Percentages	relative to width/height of the mask border image area
Computed value	as specified, but with relative lengths converted into absolute lengths
Animation type	discrete

Formal syntax

```
mask-border-width =
  <'border-image-width'>

<border-image-width> =
  [ <length-percentage [0,∞]> | <number [0,∞]> | auto ]{1,4}

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Masking Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

`mask-border-width` defines the width of the border mask — setting this to a different value to `mask-border-slice` will cause the slices to be scaled to fit the border mask.

```
/* Final mask scaled down to 20px wide */
mask-border-slice: 30 fill;
mask-border-width: 20px;
```

Chromium-based browsers support an outdated version of this property — `mask-box-image-width` — with a prefix:

```
-webkit-mask-box-image-width: 20px;
```

> **Note:** The `mask-border` page features a working example (using the out-of-date prefixed border mask properties supported in Chromium), so you can get an idea of the effect.

See also

- `mask-border-mode`
- `mask-border-outset`
- `mask-border-repeat`
- `mask-border-source`

mask-clip CSS property

The **`mask-clip`** CSS property determines the area which is affected by a mask. The painted content of an element must be restricted to this area.

Syntax

```
/* <coord-box> values */
mask-clip: content-box;
mask-clip: padding-box;
mask-clip: border-box;
mask-clip: fill-box;
mask-clip: stroke-box;
mask-clip: view-box;

/* Keyword value */
mask-clip: no-clip;

/* Multiple values */
mask-clip: padding-box, no-clip;
mask-clip: view-box, fill-box, border-box;

/* Global values */
mask-clip: inherit;
mask-clip: initial;
mask-clip: revert;
mask-clip: revert-layer;
mask-clip: unset;
```

Values

The property accepts a comma-separated list of keyword values. Each value is a `<coord-box>` or `no-clip`:

`content-box`

The painted content is clipped to the content box.

`padding-box`

The painted content is clipped to the padding box.

`border-box`

The painted content is clipped to the border box.

`fill-box`

The painted content is clipped to the object bounding box.

`stroke-box`

The painted content is clipped to the stroke bounding box.

`view-box`

Uses the nearest SVG viewport as reference box. If a `viewBox` attribute is specified for the element creating the SVG viewport, the reference box is positioned at the origin of the coordinate system established by the `viewBox` attribute and the dimension of the reference box is set to the width and height values of the `viewBox` attribute.

`no-clip`

The painted content is not clipped.

`border`

This keyword behaves the same as `border-box`.

`padding`

This keyword behaves the same as `padding-box`.

`content`

This keyword behaves the same as `content-box`.

`text`

This keyword clips the mask image to the text of the element.

Description

The `mask-clip` property defines the area of the element that is affected by the applied mask.

For mask layer images that do not reference an SVG `<mask>` element, the `mask-clip` property defines the mask painting area, or the area affected by the mask. The painted content of the element will be restricted to this area.

The `mask-clip` property has no effect on a mask layer image that references a `<mask>` element. The `<mask>` element's `x`, `y`, `width`, `height`, and `maskUnits` attributes determine the mask painting area when the source of the `mask-image` is a `<mask>`.

An element can have multiple mask layers applied. The number of layers is determined by the number of comma-separated values in the `mask-image` property value (even if a value is `none`). Each `mask-clip` value in the comma-separated list of values is matched up with the `mask-image` values, in order. If the number of values in the two properties differs, any excess values of `mask-clip` are not used, or, if `mask-clip` has fewer values than `mask-image`, the `mask-clip` values are repeated.

Formal definition

Initial value	`border-box`
Applies to	all elements; In SVG, it applies to container elements excluding the `<defs>` element and all graphics elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
mask-clip =
  [ <coord-box> | no-clip ]#

<coord-box> =
  <paint-box>  |
  view-box

<paint-box> =
  <visual-box>  |
  fill-box      |
  stroke-box

<visual-box> =
  content-box  |
  padding-box  |
  border-box
```

This syntax reflects the latest standard as per CSS Box Model Module Level 4, CSS Masking Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Clipping a mask to the border box

This examples demonstrates three `mask-clip` values.

HTML

We include three elements, each with a different `<coord-box>` value as a class name.

```
<div class="border-box"></div>
<div class="padding-box"></div>
<div class="content-box"></div>
```

CSS

The CSS defines the element to have a background, border, padding, and margin, along with a mask image, with each `<div>` having a different `<coord-box>`. We generated content with the name of the class, moving that text up 10px to prevent it from being masked out of view.

```
div {
  width: 100px;
  height: 100px;
  background-color: #8cffa0;
  margin: 10px;
  border: 20px solid #8ca0ff;
  padding: 20px;
  mask-image: url("https://mdn.github.io/shared-assets/images/examples/mdn.svg");
  mask-size: 100% 100%;
}
.content-box {
  mask-clip: content-box;
}
.border-box {
  mask-clip: border-box;
}
.padding-box {
  mask-clip: padding-box;
}
div::before {
  content: attr(class);
  position: relative;
  top: -10px;
}
```

```
body {
  display: flex;
  flex-flow: row wrap;
}
```

mask-composite CSS property

The **`mask-composite`** CSS property represents a compositing operation used on the current mask layer with the mask layers below it.

Syntax

```
/* Keyword values */
mask-composite: add;
mask-composite: subtract;
mask-composite: intersect;
mask-composite: exclude;

/* Global values */
mask-composite: inherit;
mask-composite: initial;
mask-composite: revert;
mask-composite: revert-layer;
mask-composite: unset;
```

Values

The property accepts a comma-separated list of `<compositing-operator>` keyword values, each representing a Porter-Duff compositing operator which defines the compositing operation used on the current mask layer with the mask layers below it, including:

`add`

The associated mask image is placed over all mask layers below it (with the corresponding compositing operators applied). This is the default value.

`subtract`

The associated mask image is placed, where it falls outside of all mask layers below it (with the corresponding compositing operators applied).

`intersect`

The parts of the associated mask image that overlap all composited mask layers below it replace those previously composited layers.

`exclude`

The non-overlapping regions of the associated mask image and the mask layers below it, with their corresponding compositing operators applied, are combined.

Description

When an element has multiple mask layers applied, the `mask-composite` property can be used to define how the multiple masks interact with each other, or are combined, in creating the final mask effect.

The number of layers is determined by the number of comma-separated values in the `mask-image` property value (even if a value is `none`). Each `mask-composite` value in the comma-separated list of values is matched up with a `mask-image` value, in order. If the number of values in `mask-composite` are equal to or greater than the number of `mask-image` values, the extra values are ignored. If the `mask-composite` property doesn't have enough comma-separated values to match the number of layers, the list of values are repeated until there are enough.

For processing, the *source layer*, which is current or associated mask layer image, is either added to (the default), subtracted from, intersected with, or is excluded from, the destination layers. The *destination layers* are the mask layers below the source with their corresponding compositing operators applied; this includes all the previous layers, composed in order of appearance within the comma-separated list of masks. All mask layers below the current mask layer must be composited before applying the compositing operation for the current mask layer. Mask layer images are transformed to alpha masks for processing before being combined by the defined compositing value.

The multiple mask layers applied to any element or pseudo-element act as if they are rendered into an isolated group. In other words, the mask layers are composited with other mask layers, not with the element's content or the content behind the element.

Formal definition

Initial value	`add`
Applies to	all elements; In SVG, it applies to container elements excluding the `<defs>` element and all graphics elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
mask-composite =
  <compositing-operator>#

<compositing-operator> =
  add       |
  subtract  |
  intersect |
  exclude
```

This syntax reflects the latest standard as per CSS Masking Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates the basic usage of the `mask-composite` property.

HTML

We include an HTML `<div>` element, that we will then style.

```
<div></div>
```

CSS

We provide size and color our `<div>`, then add two `mask-image`s, and make their size match that of the element they're masking with the `mask-size` property. Lastly, we subtract the second mask image from the first mask image with the `mask-composite` property set to `subtract`.

```
div {
  width: 100px;
  height: 100px;
  background-color: red;

  mask-image:
    url("https://mdn.github.io/shared-assets/images/examples/mdn.svg"),
    url("https://mdn.github.io/shared-assets/images/examples/mask-star.svg");
  mask-size: 100% 100%;

  mask-composite: subtract;
}
```

Results

Value comparison

This example demonstrates the `mask-composite` property's four `<compositing-operator>` keyword values, along with comparing the effects of `alpha` and `luminance` mask modes.

HTML

We have a `<table>` that contains eight images. The `<table>` has been hidden for brevity.

```
<table>
  <tbody>
    <tr>
      <th colspan="4">mask-type: alpha</th>
    </tr>
    <tr>
      <th>mask-composite: add</th>
      <th>mask-composite: subtract</th>
      <th>mask-composite: intersect</th>
      <th>mask-composite: exclude</th>
    </tr>
    <tr class="alphaMaskType">
      <td>
        <img
          src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
          alt="Pride flag" />
      </td>
      <td>
        <img
          src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
          alt="Pride flag" />
      </td>
      <td>
        <img
          src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
          alt="Pride flag" />
      </td>
      <td>
        <img
          src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
          alt="Pride flag" />
      </td>
    </tr>

    <tr>
      <th colspan="4">
        <code>mask-type: luminance</code>
      </th>
    </tr>
    <tr>
      <th>mask-composite: add</th>
      <th>mask-composite: subtract</th>
      <th>mask-composite: intersect</th>
      <th>mask-composite: exclude</th>
    </tr>
    <tr class="luminanceMaskType">
      <td>
        <img
          src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
          alt="Pride flag" />
      </td>
      <td>
        <img
          src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
          alt="Pride flag" />
      </td>
      <td>
        <img
          src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
          alt="Pride flag" />
      </td>
      <td>
        <img
          src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
          alt="Pride flag" />
      </td>
    </tr>
  </tbody>
</table>
```

```
<img
  src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
  alt="Pride flag" />
```

And an SVG with 4 masks; an alpha heart and circle and a luminance heart and circle. The heart masks are defined using solid colors. The circle masks are created using semi-transparent white and black `stroke` and `fill` colors.

```
<svg height="0" width="0">
  <mask id="heartAlpha" class="alpha">
    <path
      d="M20,70 A40,40,0,0,1,100,70 A40,40,0,0,1,180,70 Q180,130,100,190 Q20,130,20,70 Z"
      fill="green"
      stroke="white"
      stroke-width="20" />
  </mask>
  <mask id="circleAlpha" class="alpha">
    <circle
      cx="130"
      cy="130"
      r="50"
      fill="rgb(0 0 0 / 0.5)"
      stroke="rgb(255 255 255 / 0.5)"
      stroke-width="20" />
  </mask>
  <mask id="heartLuminance" class="luminance">
    <path
      d="M20,70 A40,40,0,0,1,100,70 A40,40,0,0,1,180,70 Q180,130,100,190 Q20,130,20,70 Z"
      fill="green"
      stroke="white"
      stroke-width="20" />
  </mask>
  <mask id="circleLuminance" class="luminance">
    <circle
      cx="130"
      cy="130"
      r="50"
      fill="rgb(0 0 0 / 0.5)"
      stroke="rgb(255 255 255 / 0.5)"
      stroke-width="20" />
  </mask>
</svg>
```

CSS

First we style the `<mask>` elements, providing each mask with a `mask-type` property value of either `alpha` or `luminance`.

```
mask.luminance {
  mask-type: luminance;
}

mask.alpha {
  mask-type: alpha;
}
```

We then apply the heart and circle masks as the comma-separated `mask-image` property values. These are applied to each `<img>` element, with all the images in a row getting the same masks.

```
/* apply the mask images */
tr.alphaMaskType img {
  mask-image: url("#heartAlpha"), url("#circleAlpha");
}

tr.luminanceMaskType img {
  mask-image: url("#heartLuminance"), url("#circleLuminance");
}
```

Finally, we compose the masks using the `mask-composite` property, applying the four different enumerated `mask-composite` values by table column.

```
/* property we're testing */
td:nth-of-type(1) img {
  mask-composite: add;
}
td:nth-of-type(2) img {
  mask-composite: subtract;
}
td:nth-of-type(3) img {
  mask-composite: intersect;
}
td:nth-of-type(4) img {
  mask-composite: exclude;
}
```

The table styles have been hidden for the sake of brevity.

```
mask {
  height: 50%;
}

table,
td,
th {
  border: 1px solid;
}
th {
  font-family: monospace;
}
th {
  color: green;
}
body > img {
```

```
  display: none;
}
```

mask-image CSS property

The **`mask-image`** CSS property sets the image that is used as the mask layer for an element, hiding sections of the element on which the masking image is set based on the alpha channel of the mask image and, depending on the `mask-mode` property value, the luminance of the mask image's colors.

Syntax

```
/* Keyword value */
mask-image: none;

/* <mask-source> value */
mask-image: url("masks.svg#mask1");

/* <image> values */
mask-image: linear-gradient(black, transparent);
mask-image: image(url("mask.png"), skyblue);

/* Multiple values */
mask-image: url("mask.png"), linear-gradient(black 25%, transparent 35%);

/* Global values */
mask-image: inherit;
mask-image: initial;
mask-image: revert;
mask-image: revert-layer;
mask-image: unset;
```

Values

`none`

This keyword is interpreted as a transparent black image layer.

`<mask-source>`

A `<url>` reference to a `<mask>` or to a CSS image.

`<image>`

An image value used as a mask image layer.

Description

The `mask-image` property provides a mask that hides part of the element to which it is applied. The value is a comma-separated list of mask references. Each mask reference is an `<image>`, a `<mask-source>`, or the keyword `none`.

An `<image>` can be any type of image, including generated images such as CSS gradients.

If only one value is specified in the `mask-image` property value, and that value is `none`, no masking effect will be apparent. If multiple values are specified, a `none` value included in the list may have no direct effect, however, other `mask-*` values in the same list position will apply to a transparent black mask layer and have no visual effect.

Only image sources served over HTTP and HTTPS protocols are accepted as `<image>` values due to the CORS policy. Images served locally, including relative or absolute `file://` protocols, are not accepted, and will render as transparent black. To test URL image sources locally, set up a local server.

A mask will be counted as a transparent black image layer, not revealing anything, in the following cases:

- The mask image is empty (zero width or zero height).
- The mask image fails to download.
- The browser does not support the mask image format.
- The mask image doesn't exist.
- The mask value doesn't point to a mask image.

The default value of the `mask-mode` property is `match-source`, which means the mode is defined by the mode of the mask image itself. The mask image's mode is generally `alpha` except when the mask source is an SVG `<mask>` element, in which case the mode is `luminance` unless the mode is changed to `alpha` via the CSS `mask-type` property or SVG `mask-type` attribute.

The `mask-mode` value is significant, because it determines whether the masking effect depends on the image source's alpha channel values alone or a combination of those and the mask's luminance (the lightness/darkness of the colors that make up the `mask-image`):

- In all cases, the alpha transparency of the mask matters; element areas masked by opaque sections of the `mask-image` will be rendered, while areas masked by transparent image sections are hidden.
- When the `mask-mode` value is set or resolves to `alpha`, only the alpha-channel of the colors matter; the hue, lightness, etc., don't matter.
- If the `mask-mode` property is set or defaults to `luminance`, the masking value is the luminance value of each color multiplied by its alpha value. The `mask-mode` will resolve to `luminance` if explicitly set to that value, or if the property is set to `match-source` and the `mask-image` source is an SVG `<mask>` that does not have its `mask-type` property or `mask-type` attribute explicitly set to `alpha`.

Formal definition

Initial value	none
Applies to	all elements; In SVG, it applies to container elements excluding the `<defs>` element and all graphics elements
Inherited	no
Computed value	as specified, but with `<url>` values made absolute
Animation type	discrete

Formal syntax

```
mask-image =
  <mask-reference>#

<mask-reference> =
  none          |
  <image>       |
  <mask-source>

<image> =
  <url>          |
  <image()>      |
  <image-set()>  |
  <cross-fade()> |
  <element()>    |
  <gradient>

<mask-source> =
  <url>

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-set()> =
  image-set( <image-set-option># )

<cross-fade()> =
  cross-fade( <cf-image># )

<element()> =
  element( <id-selector> )

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Images Module Level 4, CSS Images Module Level 5, CSS Masking Module Level 1, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Gradient as a mask image

In this example, we use an `<image>` value as a mask, defining a CSS radial gradient as our mask image to create a round image with a soft edge.

HTML

We include an HTML `<img>` element, which will also be used in all other examples.

```
<img
  src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
  alt="Pride flag" />
```

CSS

We use the CSS `radial-gradient()` function to create a mask that has a black circle with a radius that is half the width of the mask, before transitioning to being transparent over 10%.

```
img {
  mask-image: radial-gradient(black 50%, transparent 60%);
}
```

Results

The part of the original element that is masked by the black circle is fully opaque, fading to transparent as the mask fades to transparent.

Image resource as a mask image

In this example, the `<mask-source>` used as our mask image is an external SVG.

HTML

We include the same image as the previous example. We've also included the image we will be using as the mask; a star whose `fill-opacity` is `0.5`, or 50% opaque.

```
<img
  src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
  alt="Pride flag" />

<img
  src="https://mdn.github.io/shared-assets/images/examples/mask-star.svg"
  alt="A star" />
```

CSS

We use `mask-star.svg` as a mask image on our first image:

```
img:first-of-type {
  mask-image: url("https://mdn.github.io/shared-assets/images/examples/mask-star.svg");
}
```

Results

The mask is semi-opaque, which is why the colors are not as vibrant as the previous example. The part of the image that is visible is 50% opaque; the opacity of the mask applied. The mask is smaller than the image, so repeats by default. We could have used `mask-repeat` to control the repeating or `mask-size` to change the size of the mask, which we do in the next example.

Multiple masks

This example demonstrates applying multiple masks.

```
<img
  src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
  alt="Pride flag" />
```

CSS

We apply two masks — the same semi-transparent SVG as in the previous example, and a `repeating-radial-gradient()`. We control the size of the masks using the `mask-size` property. Because our first mask is not sized at 100%, we make sure our masks are centered and don't repeat with the `mask-position` and `mask-repeat` properties, respectively.

```
img {
  mask-size: 95%, 100%;
  mask-position: center;
  mask-repeat: no-repeat;
  mask-image:
    url("https://mdn.github.io/shared-assets/images/examples/mask-star.svg"),
    repeating-radial-gradient(transparent 0 5px, black 5px 10px);
}
```

Results

Masking with SVG <code><mask></code>

This example demonstrates using SVG `<mask>` elements as masks. In this case, the color of the mask matters as the `mask-type` value for SVG masks defaults to `luminance`, which means white opaque areas (100% luminance) will be masked and visible, transparent and black areas (0% luminance) will be clipped, and anything in between will be partially masked.

HTML

We've included an `id` for each of our four images, and an SVG that contains an equal number of `<mask>` elements.

```
<img
  id="green"
  src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
  alt="Pride flag" />
<img
  id="stroke"
  src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
  alt="Pride flag" />
<img
  id="both"
  src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
  alt="Pride flag" />
<img
  id="alphaMode"
  src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
  alt="Pride flag" />

<svg height="0" width="0">
  <mask id="greenMask">
    <path
      d="M20,70 A40,40,0,0,1,100,70 A40,40,0,0,1,180,70 Q180,130,100,190 Q20,130,20,70 Z"
      fill="green" />
  </mask>
  <mask id="strokeMask">
    <path
      d="M20,70 A40,40,0,0,1,100,70 A40,40,0,0,1,180,70 Q180,130,100,190 Q20,130,20,70 Z"
      fill="none"
      stroke="white"
      stroke-width="20" />
  </mask>
  <mask id="bothMask">
    <path
      d="M20,70 A40,40,0,0,1,100,70 A40,40,0,0,1,180,70 Q180,130,100,190 Q20,130,20,70 Z"
      fill="green"
      stroke="white"
      stroke-width="20" />
  </mask>
  <mask id="black">
    <path
      d="M20,70 A40,40,0,0,1,100,70 A40,40,0,0,1,180,70 Q180,130,100,190 Q20,130,20,70 Z"
      fill="black" />
  </mask>
</svg>
```

```
<p>
  <label>
    <input type="checkbox" />
    Set the <code>mask-mode</code> to <code>alpha</code>.
  </label>
</p>
```

CSS

We apply a different `<mask>` to each `<img>`. No part of the last image, with the `black` fill, will be visible by default. In this case, while all colors used in this example are fully opaque, the `mask-mode` defaults to `match-type`, which resolves to `luminance` in this case.

```
#green {
  mask-image: url("#greenMask");
}
#stroke {
  mask-image: url("#strokeMask");
}
```

```
#both {
  mask-image: url("#bothMask");
}
#alphaMode {
  mask-image: url("#black");
}

body:has(:checked) img {
  mask-mode: alpha;
}
```

The luminance values of `black`, `white`, and `green` are `0`, `100`, and `46.228`, respectively. This means the areas where the mask is white will be visible, whereas areas where the mask is black or fully transparent will be clipped (not visible). Areas where the mask is green will be visible but lighter, equivalent to having a white mask that is 46.228% opaque.

Results

Toggle the checkbox to toggle the value of the `mask-mode` between `alpha` (checked) and the initial value, which resolves to `luminance` (unchecked). When `alpha` is used, the color of the mask doesn't matter; all that matters is the alpha-transparency. When the value resolves to `luminance`, `white` areas are visible, `black` areas are not, and `green` areas are visible but at an opacity that matches the luminance of the color `green`. When `mask-mode` is set to `alpha`, the colors are equivalent as they are all fully opaque.

mask-mode CSS property

The **`mask-mode`** CSS property is set on the element being masked. It sets whether the mask reference defined by the `mask-image` is treated as a luminance or alpha mask.

Syntax

```
/* Keyword values */
mask-mode: alpha;
mask-mode: luminance;
mask-mode: match-source;

/* Multiple values */
mask-mode: alpha, match-source;

/* Global values */
mask-mode: inherit;
mask-mode: initial;
mask-mode: revert;
mask-mode: revert-layer;
mask-mode: unset;
```

Values

The `mask-mode` property can take multiple comma-separated `<masking-mode>` keyword values, including:

`alpha`

> Indicates that the alpha (transparency) values of the mask image should be used.

`luminance`

> Indicates that the luminance (brightness) values of the mask image should be used.

`match-source`

> Indicates that the type of mask is determined by the source. This is the default property value.
>
> - If the `mask-image` references an SVG `<mask>`, its `mask-type` property value is used, or its `mask-type` attribute, if present. If neither is explicitly set, this value defaults to `luminance`.
> - If the mask image source is an `<image>` or a `<gradient>`, the `alpha` values of the mask image are used.

Description

A mask transfers its transparency, and depending on the mask type, its luminance, to the element it is masking. If the mask is of type `<image>`, by default the alpha values of the mask image determine the visibility of each part of the masked element: where the mask is opaque, the corresponding part of the masked element is visible; where the mask is translucent, the element is as well, with those areas of the element being hidden. This is the default behavior for `<image>` masks when the `mask-mode` property is set to or defaults to `match-source`, and it is always the case when the `mask-mode` is explicitly set to `alpha`.

Understanding luminance

In the case of `luminance` masks, the visibility of the masked element depends on both the opacity of the mask and the lightness of the color of the opaque areas. White (100% luminance) opaque areas (alpha = 1) will be masked and visible, and black areas (0% luminance) transparent (alpha = 0) will be clipped. Areas with colors in between white and black and with partial opacity will be partially masked, reflecting the luminance and alpha transparency of each color making up the mask.

The opacity of a `luminance` mask is determined by the `R`, `G`, `B`, and `A` values of an `rgb()` color using the formula:

```
((0.2125 * R) + (0.7154 * G) + (0.0721 * B)) * A
```

For example, the color `green` is `#008000` or `rgb(0% 50% 0% / 1)`. In a `luminance` mask, any area masked by a solid `green` mask will be `35.77%` opaque. If the `mask-mode` for this mask is set to `alpha`, since `green` is a fully opaque color, the masked area will be `100%` opaque.

Multiple values

Each `mask-mode` value is a comma-separated list of values. When multiple values are present, each value corresponds to a mask layer in the same position in the `mask-image` property. The values define whether the associated mask images are treated as a `luminance` or an `alpha` mask.

Understanding <code>match-source</code>

In the case of `match-source`, whether `luminance` or `alpha` is used depends on the mask mode of the mask source. If the `mask-image` property values is a reference to an SVG `<mask>` element, the `<mask>` element's `mask-type` property value is used. If there is no CSS `mask-type` property set on the `<mask>` element, the value of the `<mask>` element's `mask-type` attribute is used, if present and supported. If neither is explicitly set, this value defaults to `luminance`; but only in the case of the `<mask>` element as the mask source. Otherwise, as noted before, if the mask image source is an `<image>`, rather than an SVG `<mask>`, the `alpha` values of the mask layer image is used.

Formal definition

Initial value	`match-source`
Applies to	all elements; In SVG, it applies to container elements excluding the `<defs>` element and all graphics elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
mask-mode =
  <masking-mode>#

<masking-mode> =
  alpha         |
  luminance     |
  match-source
```

This syntax reflects the latest standard as per CSS Masking Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Usage and values

This example demonstrates the basic usage and different values of the `mask-mode` property.

HTML

We include three `<div>` elements, so we can demonstrate the three enumerated `mask-mode` keyword values.

```
<div class="alpha">ALPHA</div>
<div class="luminance">LUMINANCE</div>
<div class="matchSource">MATCH-SOURCE</div>
```

CSS

Each `<div>` is provided with the same background and masking image. The only difference between each `<div>` is the value of the `mask-mode` property:

```
div {
  background: blue linear-gradient(red, blue);
  mask-image: url("https://mdn.github.io/shared-assets/images/examples/mdn.svg");
}

.alpha {
  mask-mode: alpha;
}

.luminance {
  mask-mode: luminance;
}

.matchSource {
  mask-mode: match-source;
}
```

```
div {
  width: 227px;
  height: 200px;
  float: left;
  text-align: center;
  line-height: 65px;
  color: white;
  text-shadow: 1px 1px 2px black;
  font-family: sans-serif;
}
```

Results

Because the mask source is an `<image>` and not an SVG `<mask>`, the `match-source` value resolves to `alpha`.

mask-origin CSS property

The **`mask-origin`** CSS property sets the origin of a mask. This property determines the mask positioning area: the area within which a mask image is positioned. HTML elements can have masks contained within their content border box, padding box, or content box, whereas SVG elements (which don't have the associated CSS layout boxes) can have masks contained inside their fill, stroke, or view box. For elements rendered as multiple boxes, such as a `<span>` of text that spans more than one line, the `mask-origin` property specifies which boxes the `box-decoration-break` property operates on to determine the mask positioning area.

Syntax

```
/* Keyword values */
mask-origin: content-box;
mask-origin: padding-box;
mask-origin: border-box;
mask-origin: fill-box;
mask-origin: stroke-box;
mask-origin: view-box;

/* Multiple values */
mask-origin: padding-box, content-box;
mask-origin: view-box, fill-box, border-box;

/* Global values */
mask-origin: inherit;
mask-origin: initial;
mask-origin: revert;
mask-origin: revert-layer;
mask-origin: unset;
```

Values

The `mask-origin` property is a comma-separated list of `<coord-box>` keyword values, including:

`content-box`

: The position is relative to the content box.

`padding-box`

: The position is relative to the padding box.

`border-box`

: The position is relative to the border box.

`fill-box`

: The position is relative to the object bounding box.

`stroke-box`

: The position is relative to the stroke bounding box.

`view-box`

: Uses the nearest SVG viewport as reference box. If a `viewBox` attribute is specified for the element creating the SVG viewport, the reference box is positioned at the origin of the coordinate system established by the `viewBox` attribute and the dimension of the reference box is set to the width and height values of the `viewBox` attribute.

There are three non-standard values that are shortcuts for standard `<coord-box>` values: `content` is an alias for `content-box`, `padding` is an alias for `padding-box`, and `border` is an alias for `border-box`.

Description

The `mask-origin` property is very similar to the `background-origin` property, but it has a different set of values and a different initial value. The initial value depends on if there is an associated CSS layout box; if yes, the default value is `border-box`. In comparison, the default for `background-origin` is `padding-box`.

For SVG elements without an associated CSS layout box, the values `content-box`, `padding-box`, and `border-box` (the default value) compute to `fill-box`, meaning the position is relative to the object bounding box. For HTML elements, if an SVG-related value of `fill-box`, `stroke-box`, or `view-box` is set, the value is computed to `border-box`.

An element can have multiple mask layers applied. The number of layers is determined by the number of comma-separated values in the `mask-image` property value (even if one or more of those values is `none`). Each `mask-origin` value in the comma-separated list of values is matched with a comma-separated `mask-image` value, in the same order.

If the number of values in the two properties differs, any excess values of `mask-origin` are not used in cases where `mask-origin` has more values than `mask-image`. If `mask-origin` has fewer values than `mask-image`, the `mask-origin` values are repeated.

For elements rendered as a single box, this property specifies the mask positioning area — or the origin position — of the image referenced by the `mask-image` property.

For elements rendered as multiple boxes, such as inline boxes that span more than one line, the `mask-origin` property specifies which boxes the `box-decoration-break` property operates upon to determine the mask positioning area.

The `mask-origin` can cause the mask layer image to be clipped. For example, if the `mask-clip` property is set to `padding-box`, the `mask-origin` is set to `border-box`, the `mask-position` is set to the `top left` edge, and the element has a border, then the mask layer image will be clipped at the top-left edge.

Formal definition

Initial value	`border-box`
Applies to	all elements; In SVG, it applies to container elements excluding the `<defs>` element and all graphics elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
mask-origin =
  <coord-box>#

<coord-box> =
  <paint-box>  |
  view-box

<paint-box> =
  <visual-box>  |
  fill-box      |
  stroke-box

<visual-box> =
  content-box  |
```

```
  padding-box  |
  border-box
```

This syntax reflects the latest standard as per CSS Box Model Module Level 4, CSS Masking Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Comparing content, padding, and border

This example demonstrates basic usage while comparing three values of the `mask-origin` property.

HTML

We include four `<section>` elements, each containing one `<div>` element.

```
<section class="content">
  <div></div>
</section>
<section class="padding">
  <div></div>
</section>
<section class="border">
  <div></div>
</section>
<section class="comparison">
  <div></div>
</section>
```

CSS

We apply `border`, `padding`, and `margin` to every `<div>`. These create the reference points for the mask image origin. The `border` shorthand includes a `border-color`. We also include a `background-color`. These provide a green background and a blue border to mask. Finally, all our `<div>` elements are provided with a `mask-image`.

```
div {
  width: 100px;
  height: 100px;
  margin: 10px;
  border: 10px solid blue;
  background-color: #8cffa0;
  padding: 10px;
  mask-image: url("https://mdn.github.io/shared-assets/images/examples/mask-star.svg");
}
section {
  border: 1px solid black;
}
```

We give each `<div>` a different `mask-origin` value.

```
.content div {
  mask-origin: content-box;
}

.padding div {
  mask-origin: padding-box;
}

.border div {
  mask-origin: border-box;
}

.comparison div {
  mask-image: none;
}
```

We also generate some text inside each `<section>` to indicate the mask origin for each `<div>` container.

```
section::before {
  content: attr(class);
  display: block;
  text-align: center;
}
```

```
body {
  display: flex;
  flex-flow: row wrap;
  gap: 10px;
}
```

Result

Notice the difference between the three values. In the first three boxes, respectively, the mask originates from:

- The outside edge of the border.
- The inside border edge, which is the outer edge of the padding box.
- The inside padding edge, which is the outer edge of the content box.

The fourth box has no `mask-image` specified: it is a reference image, included to allow you to easily visualize the extent of the content and padding areas.

Multiple values

This example demonstrates using different `mask-origin` values for different `mask-image`s applied to a single element.

HTML

We include a single `<div>`.

```
<div></div>
```

CSS

We apply three mask images instead of one, each with a different `mask-position`. We also set the mask images not to repeat.

```
div {
  width: 120px;
  height: 120px;
  margin: 10px;
  border: 10px solid blue;
  background-color: #8cffa0;
  padding: 10px;
  mask-image:
    url("https://mdn.github.io/shared-assets/images/examples/mask-star.svg"),
    url("https://mdn.github.io/shared-assets/images/examples/mask-star.svg"),
    url("https://mdn.github.io/shared-assets/images/examples/mask-star.svg");
  mask-position:
    top left,
    top right,
    bottom center;
  mask-repeat: no-repeat;
  mask-origin: content-box, border-box;
}
```

Results

We have three `mask-image` values, but only two `mask-origin` values. This means the `mask-origin` values are repeated, as if we had set `mask-origin: content-box, padding-box, content-box;`. The `border-box` star, the only mask overlapping the border, is the top-right star.

mask-position CSS property

The **`mask-position`** CSS property sets the initial position, relative to the mask position layer set by `mask-origin`, for each defined mask image.

Syntax

```
/* Single <position> keyword value */
/* Sets second value to 'center' */
mask-position: left;
mask-position: center;
mask-position: right;
mask-position: top;
mask-position: bottom;

/* Two <position> keyword values */
mask-position: left center;
mask-position: right top;

/* One length or percentage <position> value */
/* Horizontal position. Vertical position set to 'center' */
mask-position: 25%;
mask-position: 0px;
mask-position: 8em;

/* Two length or percentage <position> values */
/* First value: horizontal position. Second value: vertical position */
mask-position: 25% 75%;
mask-position: 0px 0px;
mask-position: 10% 8em;

/* Edge offsets: Four <position> values */
mask-position: bottom 10px right 20px;
mask-position: right 3em bottom 10px;
mask-position: bottom 10px right 0;

/* Multiple <position> values */
mask-position:
  top left,
  bottom 10px right 10px;
mask-position:
  1rem 1rem,
  center;

/* Global values */
mask-position: inherit;
mask-position: initial;
mask-position: revert;
mask-position: revert-layer;
mask-position: unset;
```

Values

This property is specified as a comma-separated list of values. Each value has the following type:

`<position>`

> One, two, or four values representing a 2D position specifying the edges of the element's box. Relative or absolute offsets can be given.

Description

The `mask-position` property defines the position of each mask layer. An element can have multiple mask layers applied. The number of layers is determined by the number of comma-separated values in the `mask-image` property value (even `none` values create a layer).

Each `mask-position` value in the comma-separated list of values is matched up with an associated mask layer as defined by the list of `mask-image` values, in order. If the number of values in the two properties differs:

- If `mask-position` has more values than mask-image, the excess values of `mask-position` are not used.
- If `mask-position` has fewer values than mask-image, the `mask-position` values are repeated.

Each `mask-position` defines the associated mask layer's position relative to the associated `mask-origin` value. The `mask-origin` property values are similarly matched up with the `mask-image` values, in order, with excess `mask-position` values being unused or `mask-position` values being repeated if they are fewer in number than the `mask-origin` values. Each mask layer, therefore, has an associated `mask-origin` and `mask-position` value.

If no `mask-origin` is set, the value defaults to `padding-box`, meaning the origin of each `mask-position` is the element's padding-box.

One-value syntax

If only one `mask-position` value is specified, the second value is assumed to be `center`. If the value is a `<length>` or `<percentage>`, it defines the position of the mask along the horizontal axis, with the mask being vertically centered within the origin box. For example, `mask-position: 0%;` is equal to `mask-position: 0% center`.

If you use a single keyword for positioning, the other value will resolve to `center`. The default of `mask-position` is `0% 0%`, which equates to `mask-position: top left`. However:

- `mask-position: top;` is equivalent to `mask-position: top center;`.
- `mask-position: left;` is equivalent to `mask-position: center left`.
- `mask-position: center;` is equal to `mask-position: center center`.

If the value is a `<length>` value, it represents the horizontal position as an offset from the left edge of the mask positioning. A positive value represents an offset inward from the left edge of the box container. The position can be set outside of the element's box using a negative value — this creates an outward offset that places the item outside the container's left edge.

Percentage values

A `<percentage>` value represents the mask's horizontal position value relative to the width of the container, positioned relative to the left edge. However, the offset is not from the mask edge to the box edge. Instead, the mask image dimension is subtracted from the container's dimension, and then a percentage of the resulting value is used as the direct offset from the box's left edge, which is the same as percentage values for `background-position`.

The equation is:

```
(container dimension - mask dimension) * position percentage = dimension offset value
```

Given a `100px`-wide mask and a `1000px`-wide origin box, setting `mask-position: 10%;` (the equivalent of `10% 50%`) results in the mask being vertically centered at `90px` from the left edge. The equation is `(1000 - 100) * 10% = 90`. If the left offset had been `0%`, the mask's left edge would be flush to the left of the container (`(1000 - 100) * 0% = 0`).

If the left offset had been `100%`, the mask's right edge would be flush to the right of the container as the left edge of the `100px` wide mask would be `900px` (`(1000 - 100) * 100% = 900`) from the left edge of the container (the `100px` mask width plus `900px` distance from the left edge means the right edge would be `1000px` from the left edge, which is the right edge of the container).

Two-value syntax

A two-value `<position>` specifies the position of the mask image inside its mask positioning area, with length and percentage values specifying offsets from the `left` and `top` of the area.

If the two values are `<length>` values, `<percentage>` values, or the keyword `center`, the first value represents the horizontal position as an offset from the left edge of the mask positioning area, and the second value represents the vertical position as an offset from it's top edge, with percentages being offset by the mask's size in that dimension.

In addition, if `<percentage>` values are specified, the first value is also the horizontal position value relative to the left edge, and the second value is also the vertical position value relative to the top edge.

A pair of axis-specific keywords can be reordered, as can an axis-specific keyword and a length or percentage, but two length or percentage values are not interchangeable. If one of the two values is `top`, `right`, `bottom`, or `left`, the order of the two values doesn't matter. Any `center` or `<length-percentage>` value in the pair of values will be applied to the other dimension.

Four-value syntax

The four-value syntax consists of two pairs of values, each pair containing a keyword specifying the edge to offset from, and a `<length>` and `<percentage>` value specifying the offset distance. For example, `mask-position: left 1em top 2em` specifies a `1em` horizontal offset from the left box edge and a `2em` vertical offset from the top edge. The two-value equivalent would be `mask-position: 1em 2em`.

Because we're defining the offset edges when using the four-value syntax, the order isn't important: `mask-position: top 2em left 1em` and `mask-position: left 1em top 2em` both produce the same result.

The real power of the four-value syntax is that it allows us to specify offset edges other than `left` and `top`. For example, `mask-position: bottom 10px right 20px` creates a `10px` vertical offset up from the bottom edge and a `20px` horizontal offset leftward from the right edge. Usually, the four-value syntax is used to offset from the bottom and/or right. But this syntax is also helpful if you can't remember the offset edge order for the two-value syntax.

One thing to note is that, unlike the `<bg-position>` data type values for `background-position`, the `<position>` values for `mask-position` do not allow for a 3-value syntax and do not allow offsetting from `center`. When offsetting the mask from the `bottom` or `right`, the `mask-position` requires all four values to be declared.

For the four-value syntax to be valid, it needs to specify either `top` or `bottom` as the vertical offset edge, along with the vertical length or percentage offset value, and either `left` or `right` as the horizontal offset edge, along with the horizontal length or percentage offset value.

Formal definition

Initial value	`0% 0%`
Applies to	all elements; In SVG, it applies to container elements excluding the `<defs>` element and all graphics elements
Inherited	no
Percentages	refer to size of mask painting area minus size of mask layer image (see the text for `background-position`)
Computed value	Consists of two keywords representing the origin and two offsets from that origin, each given as an absolute length (if given a <length>), otherwise as a percentage.
Animation type	a repeatable list

Formal syntax

```
mask-position =
  <position>#

<position> =
  <position-one>   |
  <position-two>   |
  <position-four>

<position-one> =
```

```
  left                |
  center              |
  right               |
  top                 |
  bottom              |
  x-start             |
  x-end               |
  y-start             |
  y-end               |
  block-start         |
  block-end           |
  inline-start        |
  inline-end          |
  <length-percentage>

<position-two> =
  [ left | center | right | x-start | x-end ] && [ top | center | bottom | y-start | y-end ]  |
  [ left | center | right | x-start | x-end | <length-percentage> ] [ top | center | bottom | y-start | y-end | <length-percentage> ]  |
  [ block-start | center | block-end ] && [ inline-start | center | inline-end ]  |
  [ start | center | end ]{2}

<position-four> =
  [ [ left | right | x-start | x-end ] <length-percentage> ] && [ [ top | bottom | y-start | y-end ] <length-percentage> ]  |
  [ [ block-start | block-end ] <length-percentage> ] && [ [ inline-start | inline-end ] <length-percentage> ]  |
  [ [ start | end ] <length-percentage> ]{2}

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Masking Module Level 1, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

```
<section>
  <div></div>
</section>
```

```
section {
  border: 1px solid black;
  width: 250px;
  height: 250px;
}

div {
  width: 250px;
  height: 250px;
  margin-bottom: 10px;
  background: blue linear-gradient(red, blue);

  mask-image: url("/shared-assets/images/examples/mask-star.svg");
  mask-repeat: no-repeat;
  mask-position: top right;
}
```

mask-repeat CSS property

The **`mask-repeat`** CSS property sets how mask images are repeated. A mask image can be repeated along the horizontal axis, the vertical axis, both axes, or not repeated at all.

Syntax

```
/* One-value syntax */
mask-repeat: repeat-x;
mask-repeat: repeat-y;
mask-repeat: repeat;
mask-repeat: space;
mask-repeat: round;
mask-repeat: no-repeat;

/* Two-value syntax: horizontal | vertical */
mask-repeat: repeat space;
mask-repeat: repeat repeat;
mask-repeat: round space;
mask-repeat: no-repeat round;

/* Multiple values */
mask-repeat:
  space round,
  no-repeat;
mask-repeat:
```

```
  round repeat,
  space,
  repeat-x;

/* Global values */
mask-repeat: inherit;
mask-repeat: initial;
mask-repeat: revert;
mask-repeat: revert-layer;
mask-repeat: unset;
```

Values

The `mask-repeat` property is a comma-separated list of two `<repeat-style>` values, with the first `<repeat-style>` value being the horizontal repetition value and the second value the vertical repetition value, or one keyword value that is a shorthand for two `<repeat-style>` values.

`<repeat-style>` values

The `<repeat-style>` values include:

`repeat`

> The image is repeated as much as needed to cover the whole mask painting area. Mask images along the edges are clipped when the size of the mask origin box is not an exact multiple of the mask image's size.

`space`

> The mask image is repeated as many times as possible without clipping. If the element's origin size is at least twice the size as the mask image's size in the associated dimension, the `mask-position` property is ignored and the first and last images are positioned at the edges of the mask origin container. If the mask origin box is not an exact multiple of the mask image's size, whitespace is distributed evenly between the repeated mask images.
>
> If the origin box size is less than twice the mask image's size in the given dimension, only one mask image can be displayed. In this case, the image is positioned as defined by the `mask-position` property, which defaults to `0% 0%`. The mask image will only be clipped if the mask image is larger than the mask origin box.

`round`

> The mask image is repeated as many times as possible in its original dimensions. If the size of the mask origin box is not an exact multiple of the mask image's size, all mask images will be rescaled, shrinking or stretching to ensure no repetitions are clipped.

`no-repeat`

> The mask image is not repeated (and hence the mask painting area will not necessarily be entirely covered). The position of the non-repeated mask image is defined by the `mask-position` CSS property.

Shorthand values

The one-value syntax is a shorthand for the full two-value syntax:

Single value	Two-value equivalent
`repeat-x`	`repeat no-repeat`
`repeat-y`	`no-repeat repeat`
`repeat`	`repeat repeat`
`space`	`space space`
`round`	`round round`
`no-repeat`	`no-repeat no-repeat`

`repeat-x`

> The equivalent of `repeat no-repeat`. The image is repeated in the horizontal direction as many times as needed to cover the width of the mask painting area. Mask images along the right or left edges, or both depending on the `mask-position` value, will be clipped if the width of the mask origin box is not an exact multiple of the mask image's width.

`repeat-y`

> The equivalent of `no-repeat repeat`. The image is repeated in the vertical direction as many times as needed to cover the height of the mask painting area. Mask images along the top or bottom edges, or both depending on the `mask-position` value, will be clipped if the height of the mask origin box is not an exact multiple of the mask image's height.

Description

The `mask-repeat` property accepts a comma-separated pair of values or one shorthand value. In the two-value syntax, the first value represents the horizontal repetition behavior and the second value represents the vertical behavior.

Multiple values

Each `mask-repeat` value in this comma-separated list applies to a separate mask layer. An element can have multiple mask layers applied. The number of layers is determined by the number of comma-separated values in the `mask-image` property value (even if a value is `none`). Each `mask-repeat` value is matched up with the `mask-image` values, in order. If the number of values in the two properties differs, any excess values of `mask-repeat` values are ignored, or, if `mask-repeat` has fewer values than `mask-image`, the `mask-repeat` values are repeated.

Sizing and positioning

The `mask-repeat` property value defines how mask images are tiled after they have been sized and positioned. The first (and possibly only) mask-image repetition is positioned by the `mask-position` property, which defaults to `0% 0%`, the top-left corner of the origin box. The size is defined by the `mask-size` property, which defaults to `auto`. The positions of the repeated masks are based on this initial mask instance.

Clipping

Mask images will not repeat but will be clipped if the mask image's size is larger than the origin box, except in the case of `round`, where a single mask will be scaled down to fit the origin box.

With `repeat` values, mask images may be clipped at the edge of the origin box if the dimension (width or height) of the box is not an exact multiple of the mask's.

Aspect ratio

By default, mask images maintain the aspect ratio set by the `mask-size` property or their default aspect ratio if the `mask-size` defaults to or is explicitly set to `auto`. Only in the case of `round` value in both directions might the mask aspect ratio be distorted.

If `round` is set in both directions, the resulting repeated mask images will match the aspect ratio of the origin box. As the mask images are scaled to fit, they may be distorted, ensuring the mask images are not clipped. If `round` is set in only one dimension, the aspect ratio of the mask size is respected.

Rounded repetitions

In the case of `round`, mask images are scaled up or down to fit the mask image in the positioning area a whole number of times. The mask size increases or decreases to fit the nearest natural number or masks, with a minimum of one mask.

The rendered dimensions of the mask is the size of the origin box divided by the number of iterations of masks in that dimension, where the iterations being an integer greater than zero. The number of iterations is: `X' = D / round(D / X)` where `D` is the width or height, and `round()` is a function that returns the nearest integer greater than zero.

For example, if `mask-repeat` is set to `round` and the `mask-size` sets the mask to be `40px` wide, when the origin box is present (greater than `0px` wide) but less than `60px` wide, there will be a single iteration that is 100% of the width of that box. If the box is at least `60px` wide but less than `100px` wide, there will be two iterations that are each `50%` of the box. From 100px to 140px, three masks will fit along the horizontal axis. These "`40px`-wide" masks will only be `40px` wide if the origin box is an exact multiple of `40px`.

Formal definition

Initial value	`repeat`
Applies to	all elements; In SVG, it applies to container elements excluding the `<defs>` element and all graphics elements
Inherited	no
Computed value	Consists of two keywords, one per dimension
Animation type	discrete

Formal syntax

```
mask-repeat =
  <repeat-style>#

<repeat-style> =
  repeat-x          |
  repeat-y          |
  repeat-block      |
  repeat-inline     |
  <repetition>{1,2}

<repetition> =
  repeat     |
  space      |
  round      |
  no-repeat
```

This syntax reflects the latest standard as per CSS Backgrounds Module Level 4, CSS Masking Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates setting the `mask-repeat` property for a single mask.

HTML

Our HTML includes a basic `<div>` element:

```
<div></div>
```

CSS

We define a `250px` square with a red to blue gradient with a `100px` by `100px` star as a mask image. We use the `mask-repeat` property, setting `round` for the horizontal direction and `space` for the vertical value.

```
div {
  width: 250px;
  height: 250px;
  background-image: linear-gradient(red, blue);

  mask-image: url("/shared-assets/images/examples/mask-star.svg");
  mask-size: 100px 100px;

  mask-repeat: round space;
}
```

Results

With `space` and `round` on a mask image that is smaller than the origin box, the mask is not clipped. Rather, the `round` value distorts the star to prevent clipping and preventing white space, while `space` maintains the star's aspect ratio, but adds space as needed between masks.

Round iterations

Using the same HTML and CSS, this demonstration includes a slider that changes the width of the container to show how, with `round`, masks will grow as space allows until another iteration of the mask fits, or shrink until the number of iterations no longer fits.

```
<div></div>
<label
  >width: <span></span><br />
  <input type="range" min="0" max="400" value="250" id="width" />
</label>
```

```
div {
  width: 250px;
  height: 250px;
  background-image: linear-gradient(red, blue);

  mask-image: url("/shared-assets/images/examples/mask-star.svg");
  mask-size: 100px 100px;

  mask-repeat: round space;
}
input {
  clear: both;
```

```
  width: 90%;
}
```

```
const div = document.querySelector("div");
const range = document.getElementById("width");
const output = document.querySelector("span");

range.addEventListener("change", () => {
  const value = `${range.value}px`;
  output.innerText = value;
  div.style.width = value;
});
```

The mask is defined as `100px` wide. There is a single star when the origin box is from `1px` to `149px` wide, two stars from `150px` to `249px`, three stars from `250px` to `349px`, and so on.

The shorthand values

This examples demonstrates all `mask-repeat` shorthand (single-keyword) values.

HTML

We include several `<section>` elements each containing a `<div>`, each with a different class name.

```
<section class="repeat">
  <div></div>
</section>
<section class="space">
  <div></div>
</section>
<section class="round">
  <div></div>
</section>
<section class="no-repeat">
  <div></div>
</section>
<section class="repeat-x">
  <div></div>
</section>
<section class="repeat-y">
  <div></div>
</section>
```

CSS

We give every `<div>` the same CSS, except for the `mask-repeat` value, which we match to their parent's class name. We define a mask size, setting the initial `mask-image` at the bottom right, meaning any clipping will occur on the top-most and left-most masks, on their top and left sides.

```
div {
  width: 180px;
  height: 180px;
  background-image: linear-gradient(red, blue);

  mask-image: url("/shared-assets/images/examples/mask-star.svg");

  mask-size: 50px 50px;
  mask-position: bottom right;
}

.repeat div {
  mask-repeat: repeat;
}
.space div {
  mask-repeat: space;
}
.round div {
  mask-repeat: round;
}
.no-repeat div {
  mask-repeat: no-repeat;
}
.repeat-x div {
  mask-repeat: repeat-x;
}
.repeat-y div {
  mask-repeat: repeat-y;
}
```

We display the class name using generated content.

```
section::before {
  content: attr(class);
  display: block;
  text-align: center;
  border-bottom: 1px solid;
}
```

```
body {
  display: flex;
  flex-flow: row wrap;
  gap: 10px;
}
section {
  border: 1px solid;
}
```

Results

The first (and, in the case of `no-repeat`, only) mask star is sized to be 50px by 50px, and positioned at the bottom-right of the painting area, with repeated stars placed above and/or to the left of it with any clipping occurring on the top and left of the top-most and left-most stars. Note that all the stars are the same size and shape, except for `round`, where all the masks shrank to 45px x 45px to fit four complete

masks in each direction. Had the container been 174px, there would have been three stars in each direction, instead of four, and each star would have been stretched.

Multiple mask images and repeats

You can specify a different `<repeat-style>` for each mask image, separated by commas:

```
.extra-repeats {
  mask-image: url("mask1.png"), url("mask2.png");
  mask-repeat: repeat-x, repeat-y, space;
}
```

Each image is matched with the corresponding repeat style. As there are more `mask-repeat` values than `mask-image` values, the excess `mask-repeat` values are ignored.

```
.missing-repeats {
  mask-image:
    url("mask1.png"), url("mask2.png"), url("mask3.png"), url("mask4.png");
  mask-repeat: repeat-x, repeat-y;
}
```

Each image is matched with a corresponding repeat style. As there are more `mask-image` values than `mask-repeat` values, the `mask-repeat` is repeated until every `mask-image` has an associated `mask-repeat` value. Here, odd numbered masks repeat along the x-axis, while the even numbered masks repeat along the y-axis.

mask-size CSS property

The **`mask-size`** CSS property specifies the sizes of specified mask images. Mask image sizes can be fully or partially constrained to preserve their intrinsic aspect ratios.

Syntax

```
/* Keyword syntax */
mask-size: cover;
mask-size: contain;
mask-size: auto;

/* One-value syntax */
/* Mask width. Sets height to 'auto'. */
mask-size: 50%;
mask-size: 3em;
mask-size: 12px;

/* Two-value syntax */
/* First value: mask width. Second value: mask height */
mask-size: 3em 25%;
mask-size: auto 6px;
mask-size: auto 50%;

/* Multiple values */
mask-size: auto, contain;
mask-size:
  50%,
  50% 25%,
  auto 25%;
mask-size: 6px, auto, contain;

/* Global values */
mask-size: inherit;
mask-size: initial;
mask-size: revert;
mask-size: revert-layer;
mask-size: unset;
```

Values

The `mask-size` property accepts a comma-separated list of `<bg-size>` values. A `<bg-size>` value is either `cover`, `contain`, a pair of values specifying the width and height (in that order), or a single value specifying the width (in which case, the height is set to `auto`). Values include:

`contain`

> Scales the mask image up or down, while preserving its aspect-ratio, making the mask as large as possible within its container without cropping or stretching it. If the mask image is smaller than the container, the mask will tile, or repeat, unless the `mask-repeat` property is set to `no-repeat`.

`cover`

> Scales the mask image to the smallest possible size to fill the container while preserving its aspect ratio. If the aspect ratio of the mask image differs from the element, it will be cropped vertically or horizontally.

`auto`

> Maintains the original aspect ratio of the mask source. When set for both the width and height, the origin size of the mask resource is used. Otherwise, `auto` scales the mask image in the corresponding direction such that its original aspect ratio is maintained.

`<length>`

> Renders the mask image at the specified length in the corresponding dimension (width if set as the first or only value, height if set as the second value). Negative values are not allowed.

`<percentage>`

> Renders the mask image in the corresponding dimension to the specified percentage of the box origin area as defined by the `mask-origin` property, which defaults to `padding-box`. Negative values are not allowed.

Description

The `mask-size` property is used to size mask layers.

An element can have multiple mask layers applied. The number of mask layers is determined by the number of comma-separated values in the `mask-image` property value (a value creates a mask layer, even if it is `none`).

Each `mask-size` value in the comma-separated list of values is matched up with an associated mask layer as defined by the list of `mask-image` values, in order. If the number of values in the two properties differs:

- If `mask-size` has more values than `mask-image`, the excess values of `mask-size` are not used.
- If `mask-size` has fewer values than `mask-image`, the `mask-size` values are repeated.

Each `mask-size` value is a `<bg-size>` value. There are three ways to declare each `<bg-size>`: one keyword, two lengths, percentages or the keyword `auto`, or one length, percentage, or `auto`:

- The available keywords are `cover` and `contain`.
- When two values are specified, the first defines the mask width and the second defines its height.
- When one value is specified, it defines only the mask width, with the height set to `auto`.

The width and height values are a `<length>`, a `<percentage>`, or the `auto` keyword, which is the default. Setting one or both values to `auto` maintains the mask image's original aspect ratio.

The rendered size of the mask image is computed as follows:

- If both components of `mask-size` are specified and are not `auto`, the mask image renders at the specified size.
- If the `mask-size` is `contain` or `cover`, the image is rendered by preserving its aspect ratio at the largest size contained within or covering the mask positioning area. If the image has no intrinsic proportion, such as with gradients, then it is rendered at the size of the mask positioning area.
- If the `mask-size` is `auto` (which resolves to `auto auto`), it is rendered at the size at which the mask would be displayed if no CSS were applied to change the rendering; this is its intrinsic size. If it has no intrinsic dimensions and no intrinsic proportion, as is the case with CSS gradients, it is rendered at the size of the mask positioning area, defined by the `mask-origin` (which defaults to `border-box`). If the mask source has no dimensions but has a proportion (aspect-ratio), a value of `auto` will render it as if `contain` had been specified instead. If the image has one intrinsic dimension and a proportion, it is rendered at the size determined by that one dimension and the proportion. If the image has one intrinsic dimension but no proportion, it's rendered using the intrinsic dimension and the corresponding dimension of the mask positioning area.
- If `mask-size` has one `auto` component and one non-`auto` component, which applies to all single-value values, the aspect ratio is maintained if the mask source has an intrinsic proportion. If there are no intrinsic proportions, the `auto` value is assumed to be the dimension of the mask positioning area.

Like with all longhand components of shorthand property, if the `mask` shorthand property is set and the value of the `mask-size` property is not defined within any mask layer, the `mask-size` value is reset to its initial value of `auto` for those mask layers.

Formal definition

Initial value	`auto`
Applies to	all elements; In SVG, it applies to container elements excluding the `<defs>` element and all graphics elements
Inherited	no
Computed value	as specified, but with relative lengths converted into absolute lengths
Animation type	a repeatable list

Formal syntax

```
mask-size =
  <bg-size>#

<bg-size> =
  [ <length-percentage [0,∞]> | auto ]{1,2}  |
  cover                                      |
  contain

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Backgrounds Module Level 4, CSS Masking Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting mask size as a percentage

This example demonstrates basic usage, while also demonstrating percentage values for `mask-size`.

HTML

We include two `<div>` elements:

```
<div class="width"></div>
<div class="height"></div>
```

CSS

The `<div>` elements are defined to be twice as tall as they are wide, with a gradient background and mask:

```
div {
  width: 200px;
  height: 400px;
  background: blue linear-gradient(red, blue);
  mask-image: url("/shared-assets/images/examples/mdn.svg");
}
```

The width of one `<div>` element's mask is set to `50%`, with the height defaulting to `auto`. The mask's height for the second `<div>` element is set to `50%` with the width set to `auto`:

```
.width {
  mask-size: 50%;
}

.height {
  mask-size: auto 50%;
}
```

In the `width` case, the mask is rendered `100px` wide (`50%` of the `200px`-wide element). The height defaults to `auto`, maintaining the mask's aspect ratio. In the `height` case, the mask is rendered `200px` tall (`50%` of the `400px`-high container). The width is explicitly set to `auto`, maintaining the mask's aspect ratio.

```
body {
  display: flex;
  gap: 20px;
}
```

Results

Cover and contain

This example demonstrates the keyword values for `mask-size`.

HTML

Three `<section>` elements are defined, each with a different class name, and each containing a `<div>`.

```
<section class="auto">
  <div></div>
</section>
<section class="cover">
  <div></div>
</section>
<section class="contain">
  <div></div>
</section>
```

CSS

The `<div>` elements are defined to be twice as tall as they are wide, with a gradient background and mask:

```
div {
  width: 200px;
  height: 400px;
  background: blue linear-gradient(red, blue);
  mask-image: url("/shared-assets/images/examples/mask-star.svg");
}
```

The `mask-size` of two of the `<div>` elements is set to one of the property's keyword values. The third `<div>` has a `mask-size` of `auto` set demonstrating the original intrinsic dimensions of the mask:

```
.auto div {
  mask-size: auto;
}

.cover div {
  mask-size: cover;
}

.contain div {
  mask-size: contain;
}
```

The property values is displayed using generated content.

```
section::before {
  content: "mask-size: " attr(class) ";";
  display: block;
  text-align: center;
  border-bottom: 1px solid;
}
```

```
body {
  display: flex;
  flex-flow: row wrap;
  gap: 10px;
}
section {
  border: 1px solid;
}
```

Results

With `auto`, the star is displayed at its intrinsic `100px` by `100px` size. With `cover`, the star grows to be `400px` tall, covering the entire origin box. With `contain`, the star grows until one dimension equals the same dimension of the origin box, meaning that the star is as large as it can be (`200px` wide) but still contained by it.

When the mask is larger than the container

Using the same HTML and CSS as above, with just a different origin box size, this example explores what happens when the origin box is smaller than the intrinsic dimensions of the mask.

```
<section class="auto">
  <div></div>
</section>
<section class="cover">
  <div></div>
</section>
<section class="contain">
  <div></div>
</section>
```

```
div {
  background: blue linear-gradient(red, blue);
  mask-image: url("/shared-assets/images/examples/mask-star.svg");
}

.auto div {
  mask-size: auto;
}
```

```
.cover div {
  mask-size: cover;
}

.contain div {
  mask-size: contain;
}

section::before {
  content: attr(class);
  display: block;
  text-align: center;
  border-bottom: 1px solid;
}

body {
  display: flex;
  flex-flow: row wrap;
  gap: 10px;
}
section {
  border: 1px solid;
}
```

The only difference is the size of the containing box (and the generated content):

```
div {
  width: 70px;
  height: 70px;
}
```

The `contain` value contains the mask within the origin box. The `cover` value covers it. In both cases, the mask shrinks while maintaining the original aspect ratio. With `auto`, the mask is clipped because the intrinsic dimensions are larger than the box dimensions.

mask-type CSS property

The **`mask-type`** CSS property applies to the SVG `<mask>` element. It defines whether to use the *luminance* (brightness) or *alpha* (transparency) content of the mask. This property may be overridden by the `mask-mode` property. The `mask-type` property has no effect on image or gradient masks.

Syntax

```
/* Keyword values */
mask-type: luminance;
mask-type: alpha;

/* Global values */
mask-type: inherit;
mask-type: initial;
mask-type: revert;
mask-type: revert-layer;
mask-type: unset;
```

Values

`alpha`

Indicates that the alpha (transparency) values of the `<mask>` should be used.

`luminance`

Indicates that the luminance (brightness) values of the `<mask>` should be used.

Description

The `mask-type` property is only relevant for the SVG `<mask>` element. If you set `mask-type: luminance`, the mask will use how bright each part of the mask is; if you set `mask-type: alpha`, it will use how transparent or opaque each part of the mask is.

Default behavior

By default, the SVG `<mask>` element uses `mask-type: luminance`. This means both the color and the transparency of the mask content affect masking. Whether the mask is opaque partially depends on the lightness of the color of the opaque areas:

- Fully opaque white areas (100% luminance) will be masked and visible.
- Black (0% luminance) or fully transparent areas will be clipped and invisible.
- Areas with intermediate luminance values will be partially masked, reflecting both the luminance, or lightness of the mask color, and the alpha transparency of each area of the mask.

Understanding luminance

The opacity of a `luminance` mask is determined by the `R`, `G`, `B`, and `A` values of an `rgb()` color using the following formula:

`((0.2125 * R) + (0.7154 * G) + (0.0721 * B)) * A`

For example, the color `green` (`#008000` or `rgb(0% 50% 0% / 1)`) has a luminance value of `35.77%`. Any area masked by a solid `green` luminance mask will be `35.77%` visible. If the `mask-type` is set to `alpha`, the same fully opaque `green` color will make the masked area `100%` visible.

If the SVG `<mask>` element has `fill="rgb(0 0 0 / 0.5)"`, which is a 50% transparent black, the corresponding shape on the masked element will display at 50% opacity when `mask-type` is set to `alpha` because the alpha values is `0.5` (50% opacity). But if the `mask-type` defaults to or is set as `luminance` the masked area will be fully clipped and invisible because its luminance is `0`.

Effect of <code>mask-mode</code> on <code>mask-type</code>

While the `mask-type` property is set on the SVG `<mask>` element, the `mask-mode` property is set on the element being masked (the element you're applying the mask to). If the mask image source is not an SVG `<mask>`, this property has no effect.

The default value of `mask-mode` is `match-source`, which means the browser uses the `mask-type` value from the `<mask>` element to determine how to interpret it. If `mask-mode` is set to a value other than `match-source`, that value takes precedence and overrides the `mask-type` value of the applied mask.

If the `<mask>` is defined as the mask image's source, and the `mask-mode` is set as or defaults to `match-source`, the `mask-mode` will resolve to the `<mask>` element's `mask-type` value: `luminance` or `alpha`. If not explicitly set, the value defaults to `luminance`.

Formal definition

Initial value	`luminance`
Applies to	`<mask>` elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
mask-type =
  luminance  |
  alpha
```

This syntax reflects the latest standard as per CSS Masking Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using the <code>mask-type</code> property

This example demonstrates how to use the `mask-type` property and the effect of its different values.

HTML

We've included two images that will be masked. Other than their class names, the two images are identical. We've also included an SVG with two `<mask>` elements. Other than their `id` values, the two masks are also identical: each has a green and white heart shape and a semi-transparent white-and-black-filled circle.

```
<img
  class="alphaMaskType"
  src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
  alt="Pride flag" />
<img
  class="luminanceMaskType"
  src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
  alt="Pride flag" />

<svg height="0" width="0">
  <mask id="alphaMask">
    <path
      d="M20,70 A40,40,0,0,1,100,70 A40,40,0,0,1,180,70 Q180,130,100,190 Q20,130,20,70 Z"
      fill="green"
      stroke="white"
      stroke-width="20" />
    <circle
      cx="170"
      cy="170"
      r="40"
      fill="rgb(0 0 0 / 0.5)"
      stroke="rgb(255 255 255 / 0.5)"
      stroke-width="20" />
  </mask>
  <mask id="luminanceMask">
    <path
      d="M20,70 A40,40,0,0,1,100,70 A40,40,0,0,1,180,70 Q180,130,100,190 Q20,130,20,70 Z"
      fill="green"
      stroke="white"
      stroke-width="20" />
    <circle
      cx="170"
      cy="170"
      r="40"
      fill="rgb(0 0 0 / 0.5)"
      stroke="rgb(255 255 255 / 0.5)"
      stroke-width="20" />
  </mask>
</svg>
```

CSS

We apply the `mask-type` property to the `<mask>` elements, and then apply the `<mask>` elements and the mask source to the images.

```
mask#alphaMask {
  mask-type: alpha;
}

mask#luminanceMask {
  mask-type: luminance;
}
```

```
img.alphaMaskType {
  mask-image: url("#alphaMask");
}

img.luminanceMaskType {
  mask-image: url("#luminanceMask");
}
```

Result

As the default value for the `mask-mode` property is `match-source`, the first mask uses the alpha channels only to define the mask: the white and green are fully opaque, and the 50% white and black colors are 50% opaque because only the alpha value of the colors matters. The second example uses the luminance of the colors to determine the opacity of the mask, with white being brighter than green, and semi-transparent white being brighter than semi-transparent black.

math-depth CSS property

The **`math-depth`** property describes a notion of *depth* for each element of a mathematical formula, with respect to the top-level container of that formula. This is used to scale the computed value of the font-size of elements when `font-size: math` is applied.

> **Note:** `font-size: math` is the default for `<math>` elements in the MathML Core User Agent stylesheet, so it's not necessary to specify it explicitly.

Syntax

```
/* Keyword value */
math-depth: auto-add;

/* Relative values */
math-depth: add(2);
math-depth: add(-2);

/* Absolute value */
math-depth: 4;

/* Global values */
math-depth: inherit;
math-depth: initial;
math-depth: revert;
math-depth: revert-layer;
math-depth: unset;
```

Values

`auto-add`

Set to the inherited `math-depth` plus 1 when inherited math-style is `compact`.

`add(<integer>)`

Set to the inherited `math-depth` plus the specified integer.

`<integer>`

Set to the specified integer.

Formal definition

Initial value	`0`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
math-depth =
  auto-add          |
  add( <integer> )  |
  <integer>

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4, MathML Core. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Specifying a math depth

The following example shows the effect of changing the `math-depth` property on the font size of subformulas. The numbers in each subformula indicate the `math-depth` and scale factor applied.

The first `<mtext>` element is used as a reference to other subformulas and has no specific styles applied. The second and third subformulas have `math-depth` set to `auto-add` and show the effect of scaling depending on the `math-style`.

The last two subformulas show the effect of setting `math-depth` to a specific value.

HTML

```
<p>
  <math>
    <mtext>0</mtext>

    <!-- auto-add value has no effect when math-style is normal -->
    <mrow style="math-style: normal">
      <mrow style="math-depth: auto-add">
        <mtext>0</mtext>
      </mrow>
    </mrow>

    <!-- the inherited math-style is compact, so math-depth is set to 1 -->
    <mrow style="math-depth: auto-add">
      <mtext>1</mtext>
    </mrow>

    <mrow style="math-depth: add(2)">
      <mtext>2</mtext>
      <mrow style="math-depth: add(-1)">
        <mtext>1</mtext>
      </mrow>
      <mrow style="math-depth: 0">
        <mtext>0</mtext>
      </mrow>
    </mrow>
  </math>
</p>
```

```
p {
  font-size: 3rem;
  margin: 1rem 0;
}
```

Result

See also

- font-size
- math-style

math-shift CSS property

The `math-shift` property indicates whether superscripts inside MathML formulas should be raised by a normal or compact shift.

Syntax

```
/* Keyword values */
math-shift: normal;
math-shift: compact;

/* Global values */
math-shift: inherit;
math-shift: initial;
math-shift: revert;
math-shift: revert-layer;
math-shift: unset;
```

Values

This property is specified as one of the following keyword values:

`normal`

The initial value, indicates normal rendering. Superscripts in MathML formulas use the superscriptShiftUp parameter from the OpenType MATH table.

`compact`

Indicates compact rendering. Superscripts in MathML formulas use the superscriptShiftUpCramped parameter from the OpenType MATH table, which is generally smaller.

Formal definition

Initial value	`normal`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
math-shift =
  normal   |
  compact
```

This syntax reflects the latest standard as per MathML Core. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Normal and compact shift

The following MathML displays two versions of "x squared" using a font with an OpenType MATH table. The `math-shift` property is used to raise the superscripts using the `normal` and `compact` shift.

CSS

```
math {
  font-size: 64pt;
  math-shift: normal;
```

```
}

.compact-shift {
  math-shift: compact;
}
```

MathML

```
<math>
  <msup>
    <mi>x</mi>
    <mn>2</mn>
  </msup>
  <msup class="compact-shift">
    <mi>x</mi>
    <mn>2</mn>
  </msup>
</math>
```

Results

Note that the second "2" has a more compact (lower) shift.

See also

- `math-depth`
- `font-size`

math-style CSS property

The `math-style` property indicates whether MathML equations should render with normal or compact height.

Syntax

```
/* Keyword values */
math-style: normal;
math-style: compact;

/* Global values */
math-style: inherit;
math-style: initial;
math-style: revert;
math-style: revert-layer;
math-style: unset;
```

Values

This property is specified as one of the following keyword values:

`normal`

The initial value, indicates normal rendering.

`compact`

The math layout on descendants tries to minimize the logical height.

Formal definition

Initial value	`normal`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
math-style =
  normal   |
  compact
```

This syntax reflects the latest standard as per MathML Core. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Changing the style of a formula to compact

CSS

```
math {
  math-style: normal;
}
.compact {
  math-style: compact;
}
```

HTML

```
<p>
  Normal height
  <math>
    <mrow>
      <munderover>
        <mo>∑</mo>
        <mrow>
          <mi>n</mi>
          <mo>=</mo>
          <mn>1</mn>
```

```
        </mrow>
        <mrow>
          <mo>+</mo>
          <mn>∞</mn>
        </mrow>
      </munderover>
    </mrow>
  </math>
  and compact height
  <math class="compact">
    <mrow>
      <munderover>
        <mo>∑</mo>
        <mrow>
          <mi>n</mi>
          <mo>=</mo>
          <mn>1</mn>
        </mrow>
        <mrow>
          <mo>+</mo>
          <mn>∞</mn>
        </mrow>
      </munderover>
    </mrow>
  </math>
  equations.
</p>
```

max-block-size CSS property

The **`max-block-size`** CSS property specifies the maximum size of an element in the direction opposite that of the writing direction as specified by `writing-mode`. That is, if the writing direction is horizontal, then `max-block-size` is equivalent to `max-height`; if the writing direction is vertical, `max-block-size` is the same as `max-width`.

The other dimension's maximum length is specified using the `max-inline-size` property.

This is useful because the `max-width` is always used for horizontal sizes and `max-height` is always used for vertical sizes, and if you need to set lengths based on the size of your text content, you need to be able to do so with the writing direction in mind.

Any time you would normally use `max-height` or `max-width`, you should instead use `max-block-size` to set the maximum "height" of the content (even though this may not be a vertical value) and `max-inline-size` to set the maximum "width" of the content (although this may instead be vertical rather than horizontal). See `writing-mode` examples, which show the different writing modes in action.

Try it

```
max-block-size: 150px;
writing-mode: horizontal-tb;
```

```
max-block-size: 150px;
writing-mode: vertical-rl;
```

```
max-block-size: 20px;
writing-mode: horizontal-tb;
```

```
max-block-size: 75%;
writing-mode: vertical-lr;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box where you can change the maximum block size. <br />This will
    limit the size in the block dimension, potentially causing an overflow.
  </div>
</section>
```

```
#example-element {
  display: flex;
  flex-direction: column;
  background-color: #5b6dcd;
  justify-content: center;
  color: white;
}
```

Syntax

```
/* <length> values */
max-block-size: 300px;
max-block-size: 25em;
max-block-size: anchor-size(--my-anchor self-inline, 250px);
max-block-size: calc(anchor-size(width) / 2);

/* <percentage> values */
max-block-size: 75%;

/* Keyword values */
max-block-size: none;
max-block-size: max-content;
max-block-size: min-content;
max-block-size: fit-content;
max-block-size: fit-content(20em);

/* Global values */
max-block-size: inherit;
max-block-size: initial;
max-block-size: revert;
```

```
max-block-size: revert-layer;
max-block-size: unset;
```

Values

The `max-block-size` property's value can be any value that's legal for the `max-width` and `max-height` properties:

`<length>`

Defines the `max-block-size` as an absolute value.

`<percentage>`

Defines the `max-block-size` as a percentage of the containing block's size in block axis.

`none`

No limit on the size of the box.

`max-content`

The intrinsic preferred `max-block-size`.

`min-content`

The intrinsic minimum `max-block-size`.

`fit-content`

Use the available space, but not more than max-content, i.e., `min(max-content, max(min-content, stretch))`.

`fit-content(<length-percentage>)`

Uses the `fit-content` formula with the available space replaced by the specified argument, i.e., `min(max-content, max(min-content, argument))`.

How writing-mode affects directionality

The values of `writing-mode` affect the mapping of `max-block-size` to `max-width` or `max-height` as follows:

Values of `writing-mode`	**`max-block-size` is equivalent to**
`horizontal-tb`, `lr`, `lr-tb`, `rl`, `rb`, `rb-rl`	`max-height`
`vertical-rl`, `vertical-lr`, `sideways-rl`, `sideways-lr`, `tb`, `tb-rl`	`max-width`

Note: The `writing-mode` values `sideways-lr` and `sideways-rl` were removed from the CSS Writing Modes Level 3 specification late in its design process. They may be restored in Level 4.

Note: The writing modes `lr`, `lr-tb`, `rl`, `rb`, and `rb-tl` are no longer allowed in HTML contexts; they may only be used in SVG 1.x contexts.

Formal definition

Initial value	none
Applies to	same as `width` and `height`
Inherited	no
Percentages	block-size of containing block
Computed value	same as `max-width` and `max-height`
Animation type	a length, percentage or calc();

Formal syntax

```
max-block-size =
  none             |
  <box-size>       |
  <anchor-size()>

<box-size> =
  <length-percentage [0,∞]>               |
  stretch                                 |
  contain                                 |
  min-content                             |
  max-content                             |
  fit-content                             |
  stretch( <length-percentage [0,∞]> )    |
  fit-content( <length-percentage [0,∞]> )  |
  <calc-size()>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<length-percentage> =
  <length>      |
  <percentage>

<calc-size()> =
  calc-size( <calc-size-basis> , <calc-sum> )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width        |
  height       |
  block        |
  inline       |
  self-block   |
  self-inline

<calc-size-basis> =
```

```
  <size-keyword>  |
  <calc-sum>      |
  <calc-size()>   |
  any

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Sizing Module Level 3, CSS Box Sizing Module Level 4, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting max-block-size with horizontal and vertical text

In this example, the same text (the opening sentences from Herman Melville's novel *Moby-Dick*) is presented in both the `horizontal-tb` and `vertical-rl` writing modes.

Everything else about the two boxes is identical, including the values used for `max-block-size`.

HTML

The HTML establishes the two `<div>` blocks that will be presented with their `writing-mode` set using the classes `horizontal` or `vertical`. Both boxes share the `standard-box` class, which establishes coloring, padding, and their respective values of `max-block-size`.

```
<p>Writing mode <code>horizontal-tb</code> (the default):</p>
<div class="standard-box horizontal">
  Call me Ishmael. Some years ago—never mind how long precisely—having little or
  no money in my purse, and nothing particular to interest me on shore, I
  thought I would sail about a little and see the watery part of the world. It
  is a way I have of driving off the spleen and regulating the circulation.
</div>

<p>Writing mode <code>vertical-rl</code>:</p>
<div class="standard-box vertical">
  Call me Ishmael. Some years ago—never mind how long precisely—having little or
  no money in my purse, and nothing particular to interest me on shore, I
  thought I would sail about a little and see the watery part of the world. It
  is a way I have of driving off the spleen and regulating the circulation.
</div>
```

CSS

The CSS defines three classes. The first, `standard-box`, is applied to both boxes, as seen above. It provides standard styling including the minimum and maximum block sizes, font size, and so forth.

After that come the classes `horizontal` and `vertical`, which add the `writing-mode` property to the box, with the value set to `horizontal-tb` or `vertical-rl` depending on which class is used.

```
.standard-box {
  padding: 4px;
  background-color: #abcdef;
  color: black;
  font:
    16px "Open Sans",
    "Helvetica",
    "Arial",
    sans-serif;
  max-block-size: 160px;
  min-block-size: 100px;
}

.horizontal {
  writing-mode: horizontal-tb;
}

.vertical {
  writing-mode: vertical-rl;
}
```

Result

- The mapped physical properties: `max-width` and `max-height`
- Setting the other direction's maximum size: `max-inline-size`
- `writing-mode`

max-height CSS property

The **`max-height`** CSS property sets the maximum height of an element. It prevents the used value of the `height` property from becoming larger than the value specified for `max-height`.

`max-height` overrides `height`, but `min-height` overrides `max-height`.

Try it

```
max-height: 150px;
```

```
max-height: 7em;
```

```
max-height: 75%;
```

```
max-height: 10px;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box where you can change the maximum height. <br />This will limit
    how tall the box can be, potentially causing an overflow.
  </div>
</section>
```

```
#example-element {
  display: flex;
  flex-direction: column;
  background-color: #5b6dcd;
  justify-content: center;
  color: white;
}
```

Syntax

```
/* <length> value */
max-height: 3.5em;
max-height: anchor-size(height);
max-height: calc(anchor-size(--my-anchor self-block, 250px) + 2em);

/* <percentage> value */
max-height: 75%;

/* Keyword values */
max-height: none;
max-height: max-content;
max-height: min-content;
max-height: fit-content;
max-height: fit-content(20em);
max-height: stretch;

/* Global values */
max-height: inherit;
max-height: initial;
max-height: revert;
max-height: revert-layer;
max-height: unset;
```

Values

`<length>`

Defines the `max-height` as an absolute value.

`<percentage>`

Defines the `max-height` as a percentage of the containing block's height.

`none`

No limit on the size of the box.

`max-content`

The intrinsic preferred `max-height`.

`min-content`

The intrinsic minimum `max-height`.

`fit-content`

Use the available space, but not more than max-content, i.e., `min(max-content, max(min-content, stretch))`.

`fit-content(<length-percentage>)`

Uses the `fit-content` formula with the available space replaced by the specified argument, i.e., `min(max-content, max(min-content, argument))`.

`stretch`

Limits the maximum height of the element's margin box to the height of its containing block. It attempts to make the margin box fill the available space in the containing block, so in a way behaving similar to `100%` but applying the resulting size to the margin box rather than the box determined by box-sizing.

> **Note:** To check aliases used by browsers for the `stretch` value and its implementation status, see the Browser compatibility section.

Accessibility

Ensure that elements set with a `max-height` are not truncated and/or do not obscure other content when the page is zoomed to increase text size.

- MDN Understanding WCAG, Guideline 1.4 explanations
- Understanding Success Criterion 1.4.4 | W3C Understanding WCAG 2.0

Formal definition

Initial value	none
Applies to	all elements but non-replaced inline elements, table columns, and column groups
Inherited	no

Percentages	The percentage is calculated with respect to the height of the generated box's containing block. If the height of the containing block is not specified explicitly (i.e., it depends on content height), and this element is not absolutely positioned, the percentage value is treated as none.
Computed value	the percentage as specified or the absolute length or none
Animation type	a length, percentage or calc();

Formal syntax

```
max-height =
  none              |
  <box-size>        |
  <anchor-size()>

<box-size> =
  <length-percentage [0,∞]>                 |
  stretch                                   |
  contain                                   |
  min-content                               |
  max-content                               |
  fit-content                               |
  stretch( <length-percentage [0,∞]> )      |
  fit-content( <length-percentage [0,∞]> )  |
  <calc-size()>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<length-percentage> =
  <length>      |
  <percentage>

<calc-size()> =
  calc-size( <calc-size-basis> , <calc-sum> )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width        |
  height       |
  block        |
  inline       |
  self-block   |
  self-inline

<calc-size-basis> =
  <size-keyword>  |
  <calc-sum>      |
  <calc-size()>   |
  any

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Sizing Module Level 3, CSS Box Sizing Module Level 4, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting max-height using percentage and keyword values

```
table {
  max-height: 75%;
}

form {
  max-height: none;
}
```

max-inline-size CSS property

The **max-inline-size** CSS property defines the horizontal or vertical maximum size of an element's block, depending on its writing mode. It corresponds to either the max-width or the max-height property, depending on the value of writing-mode.

If the writing mode is vertically oriented, the value of `max-inline-size` relates to the maximal height of the element; otherwise, it relates to the maximal width of the element. A related property is `max-block-size`, which defines the other dimension of the element.

Try it

```
max-inline-size: 150px;
writing-mode: horizontal-tb;
```

```
max-inline-size: 150px;
writing-mode: vertical-rl;
```

```
max-inline-size: 20px;
writing-mode: horizontal-tb;
```

```
max-inline-size: 75%;
writing-mode: vertical-lr;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box where you can change the max-inline-size.
  </div>
</section>
```

```
#example-element {
  display: flex;
  flex-direction: column;
  background-color: #5b6dcd;
  height: 80%;
  justify-content: center;
  color: white;
}
```

Syntax

```
/* <length> values */
max-inline-size: 300px;
max-inline-size: 25em;
max-inline-size: anchor-size(width);
max-inline-size: anchor-size(--my-anchor self-block, 200px);

/* <percentage> values */
max-inline-size: 75%;

/* Keyword values */
max-inline-size: none;
max-inline-size: max-content;
max-inline-size: min-content;
max-inline-size: fit-content;
max-inline-size: fit-content(20em);

/* Global values */
max-inline-size: inherit;
max-inline-size: initial;
max-inline-size: revert;
max-inline-size: revert-layer;
max-inline-size: unset;
```

Values

The `max-inline-size` property takes the same values as the `max-width` and `max-height` properties.

Formal definition

Initial value	none
Applies to	same as `width` and `height`
Inherited	no
Percentages	inline-size of containing block
Computed value	same as `max-width` and `max-height`
Animation type	a length, percentage or calc();

Formal syntax

```
max-inline-size =
  none             |
  <box-size>       |
  <anchor-size()>

<box-size> =
  <length-percentage [0,∞]>               |
  stretch                                 |
  contain                                 |
  min-content                             |
  max-content                             |
  fit-content                             |
  stretch( <length-percentage [0,∞]> )    |
  fit-content( <length-percentage [0,∞]> ) |
  <calc-size()>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<length-percentage> =
  <length>      |
  <percentage>

<calc-size()> =
  calc-size( <calc-size-basis> , <calc-sum> )
```

```
<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width        |
  height       |
  block        |
  inline       |
  self-block   |
  self-inline

<calc-size-basis> =
  <size-keyword>  |
  <calc-sum>      |
  <calc-size()>   |
  any

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Sizing Module Level 3, CSS Box Sizing Module Level 4, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting maximum inline size in pixels

HTML

```
<p class="exampleText">Example text</p>
```

CSS

```
.exampleText {
  writing-mode: vertical-rl;
  background-color: yellow;
  block-size: 100%;
  max-inline-size: 200px;
}
```

Result

- The mapped physical properties: `max-width` and `max-height`
- `writing-mode`

max-width CSS property

The **`max-width`** CSS property sets the maximum width of an element. It prevents the used value of the `width` property from becoming larger than the value specified by `max-width`.

`max-width` overrides `width`, but `min-width` overrides `max-width`.

Try it

```
max-width: 150px;
```

```
max-width: 20em;
```

```
max-width: 75%;
```

```
max-width: 20ch;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    Change the maximum width.
  </div>
</section>
```

```
#example-element {
  display: flex;
  flex-direction: column;
  background-color: #5b6dcd;
  height: 80%;
  justify-content: center;
  color: white;
}
```

Syntax

```
/* <length> value */
max-width: 3.5em;
max-width: anchor-size(--my-anchor inline, 245px);
```

```
max-width: calc(anchor-size(width) + 4em);

/* <percentage> value */
max-width: 75%;

/* Keyword values */
max-width: none;
max-width: max-content;
max-width: min-content;
max-width: fit-content;
max-width: fit-content(20em);
max-width: stretch;

/* Global values */
max-width: inherit;
max-width: initial;
max-width: revert;
max-width: revert-layer;
max-width: unset;
```

Values

`<length>`

Defines the `max-width` as an absolute value.

`<percentage>`

Defines the `max-width` as a percentage of the containing block's width.

`none`

No limit on the size of the box.

`max-content`

The intrinsic preferred `max-width`.

`min-content`

The intrinsic minimum `max-width`.

`fit-content`

Use the available space, but not more than max-content, i.e., `min(max-content, max(min-content, stretch))`.

`fit-content(<length-percentage>)`

Uses the `fit-content` formula with the available space replaced by the specified argument, i.e., `min(max-content, max(min-content, argument))`.

`stretch`

Limits the maximum width of the element's margin box to the width of its containing block. It attempts to make the margin box fill the available space in the containing block, so in a way behaving similar to `100%` but applying the resulting size to the margin box rather than the box determined by box-sizing.

> **Note:** To check aliases used by browsers for the `stretch` value and its implementation status, see the Browser compatibility section.

Accessibility

Ensure that elements set with a `max-width` are not truncated and/or do not obscure other content when the page is zoomed to increase text size.

- MDN Understanding WCAG, Guideline 1.4 explanations
- Understanding Success Criterion 1.4.4 | W3C Understanding WCAG 2.0

Formal definition

Initial value	none
Applies to	all elements but non-replaced inline elements, table rows, and row groups
Inherited	no
Percentages	refer to the width of the containing block
Computed value	the percentage as specified or the absolute length or `none`
Animation type	a length, percentage or calc();

Formal syntax

```
max-width =
  none             |
  <box-size>       |
  <anchor-size()>

<box-size> =
  <length-percentage [0,∞]>                |
  stretch                                  |
  contain                                  |
  min-content                              |
  max-content                              |
  fit-content                              |
  stretch( <length-percentage [0,∞]> )     |
  fit-content( <length-percentage [0,∞]> ) |
  <calc-size()>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<length-percentage> =
  <length>      |
  <percentage>
```

```
<calc-size()> =
  calc-size( <calc-size-basis> , <calc-sum> )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width        |
  height       |
  block        |
  inline       |
  self-block   |
  self-inline

<calc-size-basis> =
  <size-keyword>  |
  <calc-sum>      |
  <calc-size()>   |
  any

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Sizing Module Level 3, CSS Box Sizing Module Level 4, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting max width in pixels

In this example, the "child" will be either 150 pixels wide or the width of the "parent," whichever is smaller.

HTML

```
<div id="parent">
  <div id="child">
    Fusce pulvinar vestibulum eros, sed luctus ex lobortis quis.
  </div>
</div>
```

CSS

```
#parent {
  background: lightblue;
  width: 300px;
}

#child {
  background: gold;
  width: 100%;
  max-width: 150px;
}
```

min-block-size CSS property

The **`min-block-size`** CSS property defines the minimum horizontal or vertical size of an element's block, depending on its writing mode. It corresponds to either the `min-width` or the `min-height` property, depending on the value of `writing-mode`.

If the writing mode is vertically oriented, the value of `min-block-size` relates to the minimum width of the element; otherwise, it relates to the minimum height of the element. A related property is `min-inline-size`, which defines the other dimension of the element.

Try it

```
min-block-size: 150px;
writing-mode: horizontal-tb;
```

```
min-block-size: 150px;
writing-mode: vertical-rl;
```

```
min-block-size: 20px;
writing-mode: horizontal-tb;
```

```
min-block-size: 15em;
writing-mode: vertical-lr;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box where you can change the minimum block size. <br />If there is
    more content than the minimum the box will grow in the block dimension as
    needed by the content.
  </div>
</section>
```

```
#example-element {
  display: flex;
  flex-direction: column;
  background-color: #5b6dcd;
  justify-content: center;
  color: white;
}
```

Syntax

```
/* <length> values */
min-block-size: 100px;
min-block-size: 5em;
min-block-size: anchor-size(self-inline);

/* <percentage> values */
min-block-size: 10%;

/* Keyword values */
min-block-size: max-content;
min-block-size: min-content;
min-block-size: fit-content;
min-block-size: fit-content(20em);

/* Global values */
min-block-size: inherit;
min-block-size: initial;
min-block-size: revert;
min-block-size: revert-layer;
min-block-size: unset;
```

Values

The `min-block-size` property takes the same values as the `min-width` and `min-height` properties.

Formal definition

Initial value	`0`
Applies to	same as `width` and `height`
Inherited	no
Percentages	block-size of containing block
Computed value	same as `min-width` and `min-height`
Animation type	a length, percentage or calc();

Formal syntax

```
min-block-size =
  auto             |
  <box-size>       |
  <anchor-size()>

<box-size> =
  <length-percentage [0,∞]>                |
  stretch                                  |
  contain                                  |
  min-content                              |
  max-content                              |
  fit-content                              |
  stretch( <length-percentage [0,∞]> )     |
  fit-content( <length-percentage [0,∞]> ) |
  <calc-size()>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<length-percentage> =
  <length>      |
  <percentage>

<calc-size()> =
  calc-size( <calc-size-basis> , <calc-sum> )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width        |
  height       |
  block        |
  inline       |
  self-block   |
  self-inline

<calc-size-basis> =
  <size-keyword>  |
  <calc-sum>      |
  <calc-size()>   |
  any
```

```
<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Sizing Module Level 3, CSS Box Sizing Module Level 4, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting minimum block size for vertical text

HTML

```
<p class="exampleText">Example text</p>
```

CSS

```
.exampleText {
  writing-mode: vertical-rl;
  background-color: yellow;
  min-block-size: 200px;
}
```

Result

- The mapped physical properties: `min-width` and `min-height`
- `writing-mode`

min-height CSS property

The **`min-height`** CSS property sets the minimum height of an element. It prevents the used value of the `height` property from becoming smaller than the value specified for `min-height`.

The element's height is set to the value of `min-height` whenever `min-height` is larger than `max-height` or `height`.

Try it

```
min-height: 150px;
```

```
min-height: 7em;
```

```
min-height: 75%;
```

```
min-height: 10px;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box where you can change the minimum height. <br />If there is
    more content than the minimum the box will grow to the height needed by the
    content.
  </div>
</section>
```

```
#example-element {
  display: flex;
  flex-direction: column;
  background-color: #5b6dcd;
  justify-content: center;
  color: white;
}
```

Syntax

```
/* <length> value */
min-height: 3.5em;
min-height: anchor-size(height);
min-height: anchor-size(--my-anchor block, 200px);

/* <percentage> value */
min-height: 10%;

/* Keyword values */
min-height: max-content;
min-height: min-content;
min-height: fit-content;
min-height: fit-content(20em);
min-height: stretch;

/* Global values */
min-height: inherit;
min-height: initial;
min-height: revert;
```

```
min-height: revert-layer;
min-height: unset;
```

Values

`<length>`

Defines the `min-height` as an absolute value.

`<percentage>`

Defines the `min-height` as a percentage of the containing block's height.

`auto`

The browser will calculate and select a `min-height` for the specified element.

`max-content`

The intrinsic preferred `min-height`.

`min-content`

The intrinsic minimum `min-height`.

`fit-content`

Use the available space, but not more than max-content, i.e., `min(max-content, max(min-content, stretch))`.

`fit-content(<length-percentage>)`

Uses the `fit-content` formula with the available space replaced by the specified argument, i.e., `min(max-content, max(min-content, argument))`.

`stretch`

Limits the minimum height of the element's margin box to the height of its containing block. It attempts to make the margin box fill the available space in the containing block, so in a way behaving similar to `100%` but applying the resulting size to the margin box rather than the box determined by box-sizing.

> **Note:** To check aliases used by browsers for the `stretch` value and its implementation status, see the Browser compatibility section.

Formal definition

Initial value	`auto`
Applies to	all elements but non-replaced inline elements, table columns, and column groups
Inherited	no
Percentages	The percentage is calculated with respect to the height of the generated box's containing block. If the height of the containing block is not specified explicitly (i.e., it depends on content height), and this element is not absolutely positioned, the percentage value is treated as `0`.
Computed value	the percentage as specified or the absolute length
Animation type	a length, percentage or calc();

Formal syntax

```
min-height =
  auto             |
  <box-size>       |
  <anchor-size()>

<box-size> =
  <length-percentage [0,∞]>                |
  stretch                                  |
  contain                                  |
  min-content                              |
  max-content                              |
  fit-content                              |
  stretch( <length-percentage [0,∞]> )     |
  fit-content( <length-percentage [0,∞]> ) |
  <calc-size()>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<length-percentage> =
  <length>      |
  <percentage>

<calc-size()> =
  calc-size( <calc-size-basis> , <calc-sum> )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width        |
  height       |
  block        |
  inline       |
  self-block   |
  self-inline

<calc-size-basis> =
  <size-keyword>  |
  <calc-sum>      |
  <calc-size()>   |
  any

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*
```

```
<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>       |
  <dimension>    |
  <percentage>   |
  <calc-keyword> |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Sizing Module Level 3, CSS Box Sizing Module Level 4, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting min-height

```
table {
  min-height: 75%;
}

form {
  min-height: 0;
}
```

min-inline-size CSS property

The **`min-inline-size`** CSS property defines the horizontal or vertical minimal size of an element's block, depending on its writing mode. It corresponds to either the `min-width` or the `min-height` property, depending on the value of `writing-mode`.

Try it

```
min-inline-size: 200px;
writing-mode: horizontal-tb;
```

```
min-inline-size: 200px;
writing-mode: vertical-rl;
```

```
min-inline-size: 20px;
writing-mode: horizontal-tb;
```

```
min-inline-size: 75%;
writing-mode: vertical-lr;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">Change min-inline-size</div>
</section>
```

```
#example-element {
  display: flex;
  flex-direction: column;
  background-color: #5b6dcd;
  height: 80%;
  justify-content: center;
  color: white;
}
```

Syntax

```
/* <length> values */
min-inline-size: 100px;
min-inline-size: 5em;
min-inline-size: anchor-size(width);

/* <percentage> values */
min-inline-size: 10%;

/* Keyword values */
min-inline-size: max-content;
min-inline-size: min-content;
min-inline-size: fit-content;
min-inline-size: fit-content(20em);

/* Global values */
min-inline-size: inherit;
min-inline-size: initial;
min-inline-size: revert;
min-inline-size: revert-layer;
min-inline-size: unset;
```

If the writing mode is vertically oriented, the value of `min-inline-size` relates to the minimum height of the element; otherwise, it relates to the minimum width of the element. A related property is `min-block-size`, which defines the other dimension of the element.

Values

The `min-inline-size` property takes the same values as the `min-width` and `min-height` properties.

Formal definition

Initial value	`0`
Applies to	same as `width` and `height`
Inherited	no
Percentages	inline-size of containing block
Computed value	same as `min-width` and `min-height`
Animation type	a length, percentage or calc();

Formal syntax

```
min-inline-size =
  auto             |
  <box-size>       |
  <anchor-size()>

<box-size> =
  <length-percentage [0,∞]>                |
  stretch                                  |
  contain                                  |
  min-content                              |
  max-content                              |
  fit-content                              |
  stretch( <length-percentage [0,∞]> )     |
  fit-content( <length-percentage [0,∞]> ) |
  <calc-size()>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<length-percentage> =
  <length>     |
  <percentage>

<calc-size()> =
  calc-size( <calc-size-basis> , <calc-sum> )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width        |
  height       |
  block        |
  inline       |
  self-block   |
  self-inline

<calc-size-basis> =
  <size-keyword>  |
  <calc-sum>      |
  <calc-size()>   |
  any

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Sizing Module Level 3, CSS Box Sizing Module Level 4, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting minimum inline size for vertical text

HTML

```
<p class="exampleText">Example text</p>
```

CSS

```
.exampleText {
  writing-mode: vertical-rl;
  background-color: yellow;
  block-size: 5%;
  min-inline-size: 200px;
}
```

min-width CSS property

The **`min-width`** CSS property sets the minimum width of an element. It prevents the used value of the `width` property from becoming smaller than the value specified for `min-width`.

The element's width is set to the value of `min-width` whenever `min-width` is larger than `max-width` or `width`.

Try it

```
min-width: 150px;
```

```
min-width: 20em;
```

```
min-width: 75%;
```

```
min-width: 40ch;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    Change the minimum width.
  </div>
</section>
```

```
#example-element {
  display: flex;
  flex-direction: column;
  background-color: #5b6dcd;
  height: 80%;
  justify-content: center;
  color: white;
}
```

Syntax

```
/* <length> value */
min-width: 3.5em;
min-width: anchor-size(width);
min-width: anchor-size(--my-anchor self-inline, 200%);

/* <percentage> value */
min-width: 10%;

/* Keyword values */
min-width: max-content;
min-width: min-content;
min-width: fit-content;
min-width: fit-content(20em);
min-width: stretch;

/* Global values */
min-width: inherit;
min-width: initial;
min-width: revert;
min-width: revert-layer;
min-width: unset;
```

Values

`<length>`

Defines the `min-width` as an absolute value.

`<percentage>`

Defines the `min-width` as a percentage of the containing block's width.

`auto`

The default value. The source of the automatic value for the specified element depends on its display value. For block boxes, inline boxes, inline blocks, and all table layout boxes `auto` resolves to `0`.

For flex items and grid items, the minimum width value is either the specified suggested size, such as the value of the `width` property, the transferred size, calculated if the element has an `aspect-ratio` set and the height is a definite size, otherwise, the `min-content` size is used. If the flex or grid item is a scroll container, or if a grid item spans more than one flexible column track, the automatic minimum size is `0`.

`max-content`

The intrinsic preferred `min-width`.

`min-content`

The intrinsic minimum `min-width`.

`fit-content`

Use the available space, but not more than `max-content`, i.e., `min(max-content, max(min-content, stretch))`.

`fit-content(<length-percentage>)`

Uses the `fit-content` formula with the available space replaced by the specified argument, i.e., `min(max-content, max(min-content, argument))`.

`stretch`

Limits the minimum width of the element's margin box to the width of its containing block. It attempts to make the margin box fill the available space in the containing block, so in a way behaving similar to `100%` but applying the resulting size to the margin box rather than the box determined by box-sizing.

> **Note:** To check aliases used by browsers for the `stretch` value and its implementation status, see the Browser compatibility section.

Formal definition

Initial value	`auto`
Applies to	all elements but non-replaced inline elements, table rows, and row groups
Inherited	no
Percentages	refer to the width of the containing block
Computed value	the percentage as specified or the absolute length
Animation type	a length, percentage or calc();

Formal syntax

```
min-width =
  auto             |
  <box-size>       |
  <anchor-size()>

<box-size> =
  <length-percentage [0,∞]>                |
  stretch                                  |
  contain                                  |
  min-content                              |
  max-content                              |
  fit-content                              |
  stretch( <length-percentage [0,∞]> )     |
  fit-content( <length-percentage [0,∞]> ) |
  <calc-size()>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<length-percentage> =
  <length>     |
  <percentage>

<calc-size()> =
  calc-size( <calc-size-basis> , <calc-sum> )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width        |
  height       |
  block        |
  inline       |
  self-block   |
  self-inline

<calc-size-basis> =
  <size-keyword>  |
  <calc-sum>      |
  <calc-size()>   |
  any

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Sizing Module Level 3, CSS Box Sizing Module Level 4, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting minimum element width

```
table {
  min-width: 75%;
}

form {
  min-width: 0;
}
```

mix-blend-mode CSS property

The **`mix-blend-mode`** CSS property sets how an element's content should blend with its *backdrop* — the content rendered behind the element within the same stacking context.

> **Note:** This property blends the element with content *behind* it in the stacking context. To blend an element's own background layers with each other, use `background-blend-mode` instead.

Try it

```
mix-blend-mode: normal;
```

```
mix-blend-mode: multiply;
```

```
mix-blend-mode: hard-light;
```

```
mix-blend-mode: difference;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <img
      id="example-element"
      src="/shared-assets/images/examples/firefox-logo.svg"
      width="200" />
  </div>
</section>
```

```
.example-container {
  background-color: sandybrown;
}
```

Syntax

```
/* Keyword values */
mix-blend-mode: normal;
mix-blend-mode: multiply;
mix-blend-mode: screen;
mix-blend-mode: overlay;
mix-blend-mode: darken;
mix-blend-mode: lighten;
mix-blend-mode: color-dodge;
mix-blend-mode: color-burn;
mix-blend-mode: hard-light;
mix-blend-mode: soft-light;
mix-blend-mode: difference;
mix-blend-mode: exclusion;
mix-blend-mode: hue;
mix-blend-mode: saturation;
mix-blend-mode: color;
mix-blend-mode: luminosity;
mix-blend-mode: plus-darker;
mix-blend-mode: plus-lighter;

/* Global values */
mix-blend-mode: inherit;
mix-blend-mode: initial;
mix-blend-mode: revert;
mix-blend-mode: revert-layer;
mix-blend-mode: unset;
```

Values

`<blend-mode>`

: The blending mode that should be applied.

`plus-darker`

: Blending using the *plus-darker* compositing operator.

`plus-lighter`

: Blending using the *plus-lighter* compositing operator. Useful for cross-fade effects (prevents unwanted blinking when two overlaying elements animate their opacity in opposite directions).

Formal definition

Initial value	`normal`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	Not animatable
Creates stacking context	yes

Formal syntax

```
mix-blend-mode =
  <blend-mode>  |
  plus-lighter

<blend-mode> =
```

```
  normal      |
  darken      |
  multiply    |
  color-burn  |
  lighten     |
  screen      |
  color-dodge |
  overlay     |
  soft-light  |
  hard-light  |
  difference  |
  exclusion   |
  hue         |
  saturation  |
  color       |
  luminosity
```

This syntax reflects the latest standard as per Compositing and Blending Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Effect of different mix-blend-mode values

```
<div class="grid">
  <div class="col">
    <div class="note">
      Blending in isolation (no blending with the background)
    </div>
    <div class="row isolate">
      <div class="cell">
        normal
        <div class="container normal">
          <div class="group">
            <div class="item firefox"></div>
            <svg class="item" viewBox="0 0 150 150">
              <defs>
                <linearGradient id="red">
                  <stop offset="0" stop-color="hsl(0 100% 50%)" />
                  <stop offset="100%" stop-color="hsl(0 0% 100%)" />
                </linearGradient>
                <linearGradient id="green">
                  <stop offset="0" stop-color="hsl(120 100% 50%)" />
                  <stop offset="100%" stop-color="hsl(120 0% 100%)" />
                </linearGradient>
                <linearGradient id="blue">
                  <stop offset="0" stop-color="hsl(240 100% 50%)" />
                  <stop offset="100%" stop-color="hsl(240 0% 100%)" />
                </linearGradient>
              </defs>
              <ellipse class="item R" cx="75" cy="75" rx="25" ry="70"></ellipse>
              <ellipse class="item G" cx="75" cy="75" rx="25" ry="70"></ellipse>
              <ellipse class="item B" cx="75" cy="75" rx="25" ry="70"></ellipse>

Using mix-blend-mode with HTML

HTML

```
<div class="isolate">
  <div class="circle circle-1"></div>
  <div class="circle circle-2"></div>
  <div class="circle circle-3"></div>
</div>
```

CSS

```
.circle {
  width: 80px;
  height: 80px;
  border-radius: 50%;
  mix-blend-mode: screen;
  position: absolute;
}

.circle-1 {
  background: red;
}

.circle-2 {
  background: lightgreen;
  left: 40px;
}

.circle-3 {
  background: blue;
  left: 20px;
  top: 40px;
}

.isolate {
  isolation: isolate; /* Without isolation, the background color will be taken into account */
  position: relative;
}
```

Result

Using mix-blend-mode with SVG

SVG

```
<svg>
  <g class="isolate">
    <circle cx="40" cy="40" r="40" fill="red" />
    <circle cx="80" cy="40" r="40" fill="lightgreen" />
    <circle cx="60" cy="80" r="40" fill="blue" />
  </g>
</svg>
```

CSS

```
circle {
  mix-blend-mode: screen;
}
.isolate {
  isolation: isolate;
} /* Without isolation, the background color will be taken into account */
```

Result

Using mix-blend-mode with text

This example uses `mix-blend-mode` to blend text color with the background color of its parent element.

HTML

```
<div class="container">
  <p>Mostly Harmless</p>
  <p class="multiply">Mostly Harmless</p>
  <p class="screen">Mostly Harmless</p>
  <p class="hard-light">Mostly Harmless</p>
</div>
```

CSS

```
@import "https://fonts.googleapis.com/css2?family=Rubik+Moonrocks&display=swap";

.container {
  background-color: blue;
}

p {
  font:
    4rem "Rubik Moonrocks",
    cursive;
  font-weight: bold;
  color: orange;
  padding: 0.5rem;
  margin: 0;
}

.multiply {
  mix-blend-mode: multiply;
}

.screen {
  mix-blend-mode: screen;
}

.hard-light {
  mix-blend-mode: hard-light;
}
```

object-fit CSS property

The **`object-fit`** CSS property sets how the content of a replaced element, such as an `<img>` or `<video>`, should be resized to fit its container.

> **Note:** The `object-fit` property has no effect on `<iframe>`, `<embed>`, and `<fencedframe>` elements.

You can alter the alignment of the replaced element's content object within the element's box using the `object-position` property.

Try it

```
object-fit: fill;
```

```
object-fit: contain;
```

```
object-fit: cover;
```

```
object-fit: none;
```

```
object-fit: scale-down;
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/plumeria-146x200.jpg" />
</section>
```

```
#example-element {
  height: 100%;
  width: 100%;
  border: 2px dotted #888888;
}
```

Syntax

```
object-fit: contain;
object-fit: cover;
object-fit: fill;
object-fit: none;
object-fit: scale-down;

/* Global values */
object-fit: inherit;
object-fit: initial;
object-fit: revert;
```

```
object-fit: revert-layer;
object-fit: unset;
```

Values

This property is specified as one of the following keyword values:

`contain`

> The replaced content is scaled to maintain its aspect ratio while fitting within the element's content box. The entire object is made to fill the box, while preserving its aspect ratio, so the object will be "letterboxed" or "pillarboxed" if its aspect ratio does not match the aspect ratio of the box.

`cover`

> The replaced content is sized to maintain its aspect ratio while filling the element's entire content box. If the object's aspect ratio does not match the aspect ratio of its box, then the object will be clipped to fit.

`fill`

> The replaced content is sized to fill the element's content box. This is the `initial` value. The entire object will completely fill the box. If the object's aspect ratio does not match the aspect ratio of its box, then the object will be stretched to fit.

`none`

> The replaced content is not resized.

`scale-down`

> The content is sized as if `none` or `contain` were specified, whichever would result in a smaller concrete object size.

Formal definition

Initial value	`fill`
Applies to	replaced elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
object-fit =
  fill                          |
  none                          |
  [ contain | cover ] || scale-down
```

This syntax reflects the latest standard as per CSS Images Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting object-fit for an image

HTML

```
<section>
  <h2>object-fit: fill</h2>
  <img class="fill" src="mdn_logo_only_color.png" alt="MDN Logo" />

  <img class="fill narrow" src="mdn_logo_only_color.png" alt="MDN Logo" />

  <h2>object-fit: contain</h2>
  <img class="contain" src="mdn_logo_only_color.png" alt="MDN Logo" />

  <img class="contain narrow" src="mdn_logo_only_color.png" alt="MDN Logo" />

  <h2>object-fit: cover</h2>
  <img class="cover" src="mdn_logo_only_color.png" alt="MDN Logo" />

  <img class="cover narrow" src="mdn_logo_only_color.png" alt="MDN Logo" />

  <h2>object-fit: none</h2>
  <img class="none" src="mdn_logo_only_color.png" alt="MDN Logo" />

  <img class="none narrow" src="mdn_logo_only_color.png" alt="MDN Logo" />

  <h2>object-fit: scale-down</h2>
  <img class="scale-down" src="mdn_logo_only_color.png" alt="MDN Logo" />

  <img class="scale-down narrow" src="mdn_logo_only_color.png" alt="MDN Logo" />
</section>
```

CSS

```
h2 {
  font-family: "Courier New", monospace;
  font-size: 1em;
  margin: 1em 0 0.3em;
}

img {
  width: 150px;
  height: 100px;
  border: 1px solid black;
  margin: 10px 0;
}

.narrow {
  width: 100px;
  height: 150px;
}
```

```
.fill {
  object-fit: fill;
}

.contain {
  object-fit: contain;
}

.cover {
  object-fit: cover;
}

.none {
  object-fit: none;
}

.scale-down {
  object-fit: scale-down;
}
```

object-position CSS property

The **`object-position`** CSS property specifies the alignment of the selected replaced element's contents within the element's box. Areas of the box which aren't covered by the replaced element's object will show the element's background.

You can adjust how the replaced element's object's intrinsic size (that is, its natural size) is adjusted to fit within the element's box using the `object-fit` property.

Try it

```
object-position: 50% 50%;
```

```
object-position: right top;
```

```
object-position: left bottom;
```

```
object-position: 250px 125px;
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/moon.jpg" />
</section>
```

```
#example-element {
  height: 250px;
  width: 250px;
  object-fit: none;
  border: 1px solid red;
}
```

Syntax

```
/* Keyword values */
object-position: top;
object-position: bottom;
object-position: left;
object-position: right;
object-position: center;

/* <percentage> values */
object-position: 25% 75%;

/* <length> values */
object-position: 0 0;
object-position: 1cm 2cm;
object-position: 10ch 8em;

/* Edge offsets values */
object-position: bottom 10px right 20px;
object-position: right 3em bottom 10px;
object-position: top 0 right 10px;

/* Global values */
object-position: inherit;
object-position: initial;
object-position: revert;
object-position: revert-layer;
object-position: unset;
```

Values

`<position>`

From one to four values that define the 2D position of the element. Relative or absolute offsets can be used.

> **Note:** The position can be set so that the replaced element is drawn outside its box.

Formal definition

Initial value	`50% 50%`
Applies to	replaced elements
Inherited	no
Percentages	refer to width and height of element itself
Computed value	as specified
Animation type	a repeatable list

Formal syntax

```
object-position =
  <position>

<position> =
  <position-one>   |
  <position-two>   |
  <position-four>

<position-one> =
  left                |
  center              |
  right               |
  top                 |
  bottom              |
  x-start             |
  x-end               |
  y-start             |
  y-end               |
  block-start         |
  block-end           |
  inline-start        |
  inline-end          |
  <length-percentage>

<position-two> =
  [ left | center | right | x-start | x-end ] && [ top | center | bottom | y-start | y-end ]  |
  [ left | center | right | x-start | x-end | <length-percentage> ] [ top | center | bottom | y-start | y-end | <length-percentage> ]  |
  [ block-start | center | block-end ] && [ inline-start | center | inline-end ]  |
  [ start | center | end ]{2}

<position-four> =
  [ [ left | right | x-start | x-end ] <length-percentage> ] && [ [ top | bottom | y-start | y-end ] <length-percentage> ]  |
  [ [ block-start | block-end ] <length-percentage> ] && [ [ inline-start | inline-end ] <length-percentage> ]  |
  [ [ start | end ] <length-percentage> ]{2}

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Images Module Level 3, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Positioning image content

HTML

Here we see HTML that includes two `<img>` elements, each displaying the MDN logo.

```
<img id="object-position-1" src="mdn.svg" alt="MDN Logo" />
<img id="object-position-2" src="mdn.svg" alt="MDN Logo" />
```

CSS

The CSS includes default styling for the `<img>` element itself, as well as separate styles for each of the two images.

```
img {
  width: 300px;
  height: 250px;
  border: 1px solid black;
  background-color: silver;
  margin-right: 1em;
  object-fit: none;
}

#object-position-1 {
  object-position: 10px;
}

#object-position-2 {
  object-position: 100% 10%;
}
```

The first image is positioned with its left edge inset 10 pixels from the left edge of the element's box. The second image is positioned with its right edge flush against the right edge of the element's box and is located 10% of the way down the height of the element's box.

object-view-box CSS property

> **Experimental: This is an experimental technology**

> Check the Browser compatibility table carefully before using this in production.

The **`object-view-box`** CSS property defines a rectangle as a viewable area (viewbox) within a replaced element, enabling the content of the replaced element to be zoomed or panned. It works similarly to the SVG `viewBox` attribute.

Try it

```
object-view-box: inset(0 0);
```

```
object-view-box: inset(20%);
```

```
object-view-box: xywh(95px 20px 60px 60px);
```

```
object-view-box: rect(110px 120px 200px 45px);
```

```
object-view-box: none;
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/plumeria-146x200.jpg"
    alt="A close-up of red flowers and buds on a branch." />
</section>
```

```
#example-element {
  height: 100%;
  width: 100%;
  border: 2px dotted #888888;
}

@supports not (object-view-box: none) {
  body::before {
    content: "Your browser does not support the 'object-view-box' property.";
    color: black;
    background-color: #ffcd33;
    display: block;
    width: 100%;
    text-align: center;
  }
}
```

Syntax

```
/* Keyword value */
object-view-box: none;

/* <basic-shape-rect> functions */
object-view-box: inset(20%);
object-view-box: inset(20% 30%);
object-view-box: inset(10px 0 25px 33px);
object-view-box: xywh(95px 20px 60px 60px);
object-view-box: rect(10px 30px 30px 10px);

/* Global values */
object-view-box: inherit;
object-view-box: initial;
object-view-box: revert;
object-view-box: revert-layer;
object-view-box: unset;
```

Values

`none`

The element does not have a view box. This is the default.

`<basic-shape-rect>`

An `inset()`, `xywh()`, or `rect()` function specifying a view box for an element with natural dimensions (replaced elements). Resolves to `none` otherwise.

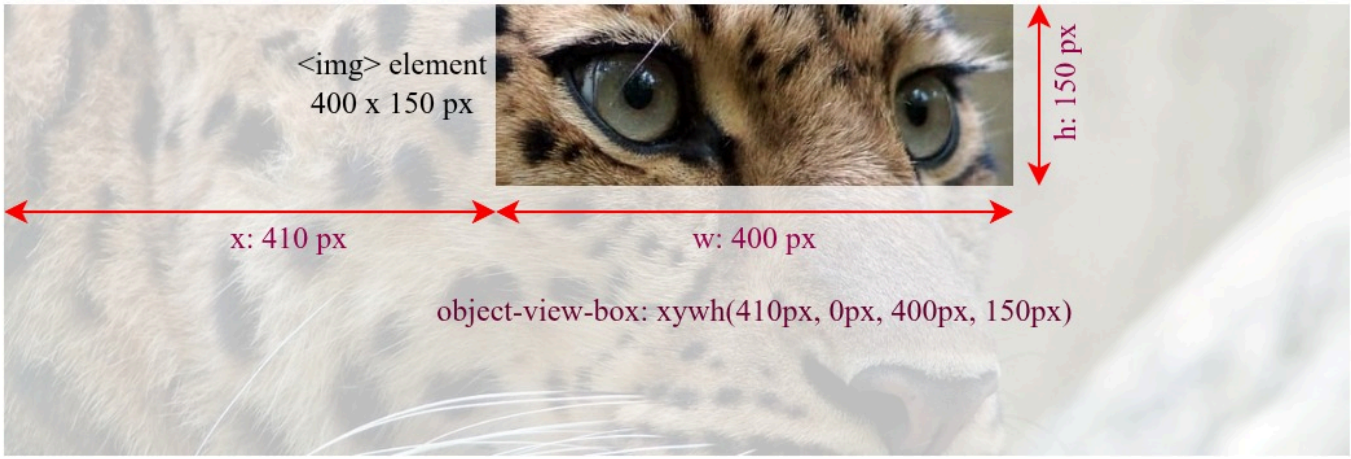
Description

The `object-view-box` property can be used to crop or resize replaced elements, including images and videos. It works by showing a section of the content of the replaced element in the available space reserved for that element. The section of the replaced element that is displayed is defined by the value of the property. The available reserved space is determined by the element's default extrinsic size. The subsection of the content displayed can be presented zoomed-in, panned-out, or at its original size, while maintaining the content's intrinsic aspect ratio.

The property value is a `<basic-shape-rect>`, one of the `<basic-shape>` functions limited to defining a rectangular shape. For example, the value can be a `xywh()` function:

```
img {
  object-view-box: xywh(410px 0 400px 150px);
}
```

In this case, the top left corner of the section of the image that will be displayed is `410px` from the left edge and `0` from the top, as defined by x and y coordinate parameters. The size of the section of the original image that will be displayed is `400px` wide by `150px` tall; the `w` and `h` components of the function. This 400x150 section of the image will be displayed in the space that was reserved for the image itself when the page was laid out. Whether the content section displayed is its original intrinsic size, zoomed in, or zoomed out depends on whether the viewbox is 400px x 150px, smaller, or larger than the image element's size, respectively.



In this case, as the rectangular viewbox defined by the `object-view-box` property and the rectangular area of the `<img>` element are the same size, i.e., 400 x 150 pixels, the replaced element is not scaled.

Decrease the `w` and `h` values to create a zoomed-in effect; as the smaller image section is stretched, it has a zoomed-in effect.

Increase the `w` and `h` argument values to create a zoomed-out effect; as the larger image section is shrunk, it has a zoomed-out effect.

Animating the `x` and `y` coordinates creates a panning effect by moving the element's viewbox while the element itself remains in its original location.

Formal definition

Initial value	none
Applies to	replaced elements
Inherited	no
Computed value	specified keyword, or computed function
Animation type	as if possible, otherwise discrete

Formal syntax

```
object-view-box =
  none                |
  <basic-shape-rect>

<basic-shape-rect> =
  <inset()>  |
  <rect()>   |
  <xywh()>

<inset()> =
  inset( <length-percentage>{1,4} [ round <'border-radius'> ]? )

<rect()> =
  rect( <top> , <right> , <bottom> , <left> )

<xywh()> =
  xywh( <length-percentage>{2} <length-percentage [0,∞]>{2} [ round <'border-radius'> ]? )

<length-percentage> =
  <length>      |
  <percentage>

<border-radius> =
  <length-percentage [0,∞]>{1,4} [ / <length-percentage [0,∞]>{1,4} ]?
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Images Module Level 5, CSS Masking Module Level 1, CSS Shapes Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates the basic usage and the effects of the `object-view-box` property, with examples using the three different `<basic-shape-rect>` functions.

HTML

We have three almost identical `<img>` elements wrapped in `<figure>` elements; the only difference is their class names.

```
<figure>
  <img
    class="intrinsic"
    src="https://mdn.github.io/shared-assets/images/examples/painted-hand.jpg"
    alt="Original scale section of a painted hand" />
  <figcaption>intrinsic</figcaption>
</figure>
<figure>
  <img
    class="zoom-in"
    src="https://mdn.github.io/shared-assets/images/examples/painted-hand.jpg"
    alt="Zoomed in section of a painted hand" />
  <figcaption>zoomed in</figcaption>
</figure>
<figure>
  <img
    class="zoom-out"
    src="https://mdn.github.io/shared-assets/images/examples/painted-hand.jpg"
    alt="Zoomed out section of a painted hand" />
```

```
  <figcaption>zoomed out</figcaption>
</figure>
```

CSS

We style all the images to have the same width and height, then set each class, and therefore each image, to have a different `object-view-box` value. The intrinsic size of the painted hand image is `298px` by `332px`. We set the `height` and `width`, setting the extrinsic size to `200px` by `200px`.

```
img {
  width: 200px;
  height: 200px;
  border: 1px solid red;
}
```

We set three different `object-view-box` property values using three different shape functions. The `intrinsic` element's `xywh()` function value displays a `200px` square section of the image content, starting from the `70px` from the left and `90px` from the top. The `zoom-in` element's `rect()` function displays a `160px` square section of the original element, going from `110px` to `270px` from the top edge and `90px` to `250px` from the left edge. The `zoom-out` replaced element's `inset()` function displays a `298px` square section of the original element; showing the entire width of the image while cutting of a 17px from the top and bottom.

```
.intrinsic {
  object-view-box: xywh(70px 90px 200px 200px);
}

.zoom-in {
  object-view-box: rect(110px 250px 270px 90px);
}

.zoom-out {
  object-view-box: inset(17px 0 17px 0);
}
```

```
@supports not (object-view-box: none) {
  body::before {
    content: "Your browser does not support the 'object-view-box' property.";
    color: black;
    background-color: #ffcd33;
    display: block;
    width: 100%;
    text-align: center;
  }
}

figure {
  display: inline-block;
  margin: 0;
}

figcaption {
  text-align: center;
}
```

Results

The `intrinsic` version is showing an unscaled section of the image. The `zoom-in` version is showing a smaller section (`160px` square) of the image, scaled up to fit `200px` square viewbox. As the section is stretched, it looks zoomed in. The `zoom-out` version is showing a larger (`298px` square) section of the image, scaled down to fit `200px` square viewbox. As the section is shrunk, it looks zoomed out.

Live zoom-in using object-view-box property

This example demonstrates using the `object-view-box` property to zoom a section of a replaced element in and out, within a statically sized HTML element. In this case, the eye of the leopard, within a very large image, serves as the focal point of the zoom effect.

HTML

We include an `<img>` element and a `range` `<input>` element, with an associated `<label>`. The natural dimensions, or intrinsic size, of the original leopard image are `1244px` wide by `416px` tall, with an aspect ratio of `3:1`.

```
<img
  src="https://mdn.github.io/shared-assets/images/examples/leopard.jpg"
  alt="leopard" />
<p>
  <label for="box-size">Zoom-in: </label>
  <input type="range" id="box-size" min="115" max="380" value="150" />
</p>
<output></output>
```

CSS

We define a `--box-size` custom property, which is used as the height and width in the `xywh()` function, creating a square viewbox with an aspect ratio of `1:1`. The view box's offset point, the focal point in our zoom effect, is set at `500px` for the `x` coordinate and `30px` for the `y` coordinate, which corresponds to the top-left corner of the leopard's right eye.

```
input {
  width: 350px;
}

output {
  text-align: center;
  background-color: #dedede;
  font-family: monospace;
  padding: 5px;
  display: block;
}

@supports not (object-view-box: none) {
  body::before {
    content: "Your browser does not support the 'object-view-box' property.";
    color: black;
    background-color: #ffcd33;
    display: block;
    width: 100%;
    text-align: center;
```

```
  }
}
```

```
img {
  width: 350px;
  height: 350px;
  border: 2px solid red;

  --box-size: 150px;
  object-view-box: xywh(500px 30px var(--box-size) var(--box-size));
}
```

JavaScript

We add an event listener to the slider that updates the value of the `--boxSize` custom property when the user interacts with it. To increase the zoom-in effect when the slider is moved to the right, the slider's value is inverted by subtracting it from `500px`, as reducing the view box size increases the zoom-in effect.

```
const img = document.querySelector("img");
const zoom = document.getElementById("box-size");
const output = document.querySelector("output");

function update() {
  const size = 500 - zoom.value;
  img.style.setProperty("--box-size", `${size}px`);
  output.innerText = `object-view-box: xywh(500px 30px ${size}px ${size}px);`;
}

zoom.addEventListener("input", update);
update();
```

Result

Move the slider to the right to increase the zoom-in effect and left to reduce it. The slider only affects the dimensions of the view box, while the x and y values, the origin point of the viewbox, remain constant. The size of the `<img>` element doesn't change either.

Panning using the object-view-box property

This example demonstrates panning an image by animating the `object-view-box` property value.

HTML

The HTML includes a single image.

```
<img
  src="https://mdn.github.io/shared-assets/images/examples/leopard.jpg"
  alt="leopard" />
```

CSS

We define an image size and keep the viewbox dimensions, the `w` and `h` components of the `xywh()` function, constant, as we animate the top and left positions, changing the position of the `x` and `y` parameters over five seconds.

```
img {
  width: 350px;
  height: 350px;

  object-view-box: xywh(0 30px 400px 400px);

  animation: panning 5s linear infinite alternate;
}

@keyframes panning {
  from {
    object-view-box: xywh(0 -50px 400px 400px);
  }
  to {
    object-view-box: xywh(800px 68px 400px 400px);
  }
}
```

```
@supports not (object-view-box: none) {
  body::before {
    content: "Your browser does not support the 'object-view-box' property.";
    color: black;
    background-color: #ffcd33;
    display: block;
    width: 100%;
    text-align: center;
  }
}
```

offset CSS property

The **`offset`** CSS shorthand property sets all the properties required for animating an element along a defined path. The offset properties together help to define an *offset transform*, a transform that aligns a point in an element (offset-anchor) to an *offset position* (offset-position) on a path (offset-path) at various points along the path (offset-distance) and optionally rotates the element (offset-rotate) to follow the direction of the path.

> **Note:** Early versions of the spec called this property `motion`.

Try it

```
offset: path("M 20 60 L 120 60 L 70 10 L 20 60") 0% auto 90deg;
```

```
offset: path(
    "M 20 210 L 74 210 L 118 140 \
 L 62 140 L 20 210"
  )
  20% auto;
```

```
<section class="default-example" id="default-example">
  <div class="wrapper">
    <div id="example-element"></div>
  </div>
  <button id="playback" type="button">Play</button>
</section>
```

```
#example-element {
  width: 24px;
  height: 24px;
  background: #2bc4a2;
  clip-path: polygon(0% 0%, 70% 0%, 100% 50%, 70% 100%, 0% 100%, 30% 50%);
  animation: distance 3000ms infinite normal ease-in-out;
  animation-play-state: paused;
}

#example-element.running {
  animation-play-state: running;
}

.wrapper {
  height: 220px;
  width: 200px;
  background:
    url('data:image/svg+xml;utf8,<svg xmlns="http://www.w3.org/2000/svg" viewBox="0 0 150 140" width="200" height="140"><path d="M 0 60 L 100 60 L 50 10 L 0 60" fill="none" stroke="lightgrey"
stroke-width="2" stroke-dasharray="4.5"/></svg>')
      no-repeat,
    url('data:image/svg+xml;utf8,<svg xmlns="http://www.w3.org/2000/svg" viewBox="0 -140 150 230" width="200" height="230"><path d="M 0 70 L 56 70 L 98 0 L 42 0 L 0 70" fill="none"
stroke="lightgrey" stroke-width="2" stroke-dasharray="4.5"/></svg>');
}

@keyframes distance {
  to {
    offset-distance: 100%;
  }
}

#playback {
  position: absolute;
  top: 0;
  left: 0;
  font-size: 1em;
}
```

```
const example = document.getElementById("example-element");
const button = document.getElementById("playback");

button.addEventListener("click", () => {
  if (example.classList.contains("running")) {
    example.classList.remove("running");
    button.textContent = "Play";
  } else {
    example.classList.add("running");
    button.textContent = "Pause";
  }
});
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `offset-anchor`
- `offset-distance`
- `offset-path`
- `offset-position`
- `offset-rotate`

Syntax

```
/* Offset position */
offset: auto;
offset: 10px 30px;
offset: none;

/* Offset path */
offset: ray(45deg closest-side);
offset: path("M 100 100 L 300 100 L 200 300 z");
offset: url("arc.svg");

/* Offset path with distance and/or rotation */
offset: url("circle.svg") 100px;
offset: url("circle.svg") 40%;
offset: url("circle.svg") 30deg;
offset: url("circle.svg") 50px 20deg;

/* Including offset anchor */
```

```
offset: ray(45deg closest-side) / 40px 20px;
offset: url("arc.svg") 2cm / 0.5cm 3cm;
offset: url("arc.svg") 30deg / 50px 100px;

/* Global values */
offset: inherit;
offset: initial;
offset: revert;
offset: revert-layer;
offset: unset;
```

Formal definition

Initial value	as each of the properties of the shorthand: • `offset-position`: `normal` • `offset-path`: `none` • `offset-distance`: `0` • `offset-anchor`: `auto` • `offset-rotate`: `auto`
Applies to	transformable elements
Inherited	no
Percentages	as each of the properties of the shorthand: • `offset-position`: refer to the size of containing block • `offset-distance`: refer to the total path length • `offset-anchor`: relative to the width and the height of the element's reference box
Computed value	as each of the properties of the shorthand: • `offset-position`: for `<length>` the absolute value, otherwise a percentage • `offset-path`: as specified • `offset-distance`: for `<length>` the absolute value, otherwise a percentage • `offset-anchor`: for `<length>` the absolute value, otherwise a percentage • `offset-rotate`: as specified
Animation type	as each of the properties of the shorthand: • `offset-position`: a position • `offset-path`: by computed value type • `offset-distance`: a length, percentage or calc(); • `offset-anchor`: a position • `offset-rotate`: as <angle>, <basic-shape> or <path()>
Creates stacking context	yes

Formal syntax

```
offset =
  [ <'offset-position'>? [ <'offset-path'> [ <'offset-distance'> || <'offset-rotate'> ]? ]! [ / <'offset-anchor'> ]?

<offset-position> =
  normal      |

Examples

Animating an element along a path

HTML

```
<div id="offsetElement"></div>
```

CSS

```
@keyframes move {
  from {
    offset-distance: 0%;
  }

  to {
    offset-distance: 100%;
  }
}

#offsetElement {
  width: 50px;
  height: 50px;
  background-color: blue;
  offset: path("M 100 100 L 300 100 L 200 300 z") auto;
  animation: move 3s linear infinite;
}
```

offset-anchor CSS property

The **`offset-anchor`** CSS property specifies the point inside the box of an element traveling along an `offset-path` that is actually moving along the path.

Try it

```
offset-anchor: auto;
```

```
offset-anchor: right top;
```

```
offset-anchor: left bottom;
```

```
offset-anchor: 20% 80%;
```

```
<section class="default-example" id="default-example">
  <div class="wrapper">
    <div id="example-element"></div>
  </div>
  <button id="playback" type="button">Play</button>
</section>
```

```
#example-element {
  offset-path: path("M 0,20 L 200,20");
  animation: distance 3000ms infinite alternate ease-in-out;
  width: 40px;
  height: 40px;
  background: cyan;
  animation-play-state: paused;
}

#example-element.running {
  animation-play-state: running;
}

.wrapper {
  background-image: linear-gradient(
    to bottom,
    transparent,
    transparent 49%,
    black 50%,
    black 51%,
    transparent 52%
  );
  border: 1px solid #cccccc;
  width: 90%;
}

@keyframes distance {
  0% {
    offset-distance: 0%;
  }
  100% {
    offset-distance: 100%;
  }
}

#playback {
  position: absolute;
  top: 0;
  left: 0;
  font-size: 1em;
}
```

```
const example = document.getElementById("example-element");
const button = document.getElementById("playback");

button.addEventListener("click", () => {
  if (example.classList.contains("running")) {
    example.classList.remove("running");
    button.textContent = "Play";
  } else {
    example.classList.add("running");
    button.textContent = "Pause";
  }
});
```

Syntax

```
/* Keyword values */
offset-anchor: top;
offset-anchor: bottom;
offset-anchor: left;
offset-anchor: right;
offset-anchor: center;
offset-anchor: auto;

/* <percentage> values */
offset-anchor: 25% 75%;

/* <length> values */
offset-anchor: 0 0;
offset-anchor: 1cm 2cm;
offset-anchor: 10ch 8em;

/* Edge offsets values */
offset-anchor: bottom 10px right 20px;
offset-anchor: right 3em bottom 10px;

/* Global values */
offset-anchor: inherit;
offset-anchor: initial;
offset-anchor: revert;
offset-anchor: revert-layer;
offset-anchor: unset;
```

Values

`auto`

`offset-anchor` is given the same value as the element's `transform-origin`, unless `offset-path` is `none`, in which case it takes its value from `offset-position`.

`<position>`

A `<position>` defines an x/y coordinate, to place an item relative to the edges of an element's box. It can be defined using one to four values. For more specifics, see the `<position>` and `background-position` reference pages. Note that the 3-value position syntax does not work for any usage of `<position>`, except for in `background(-position)`.

Formal definition

Initial value	`auto`
Applies to	transformable elements

Inherited	no
Percentages	relative to the width and the height of the element's reference box
Computed value	for `<length>` the absolute value, otherwise a percentage
Animation type	a position

Formal syntax

```
offset-anchor =
  auto        |
  <position>

<position> =
  <position-one>   |
  <position-two>   |
  <position-four>

<position-one> =
  left                |
  center              |
  right               |
  top                 |
  bottom              |
  x-start             |
  x-end               |
  y-start             |
  y-end               |
  block-start         |
  block-end           |
  inline-start        |
  inline-end          |
  <length-percentage>

<position-two> =
  [ left | center | right | x-start | x-end ] && [ top | center | bottom | y-start | y-end ]  |
  [ left | center | right | x-start | x-end | <length-percentage> ] [ top | center | bottom | y-start | y-end | <length-percentage> ]  |
  [ block-start | center | block-end ] && [ inline-start | center | inline-end ]  |
  [ start | center | end ]{2}

<position-four> =
  [ [ left | right | x-start | x-end ] <length-percentage> ] && [ [ top | bottom | y-start | y-end ] <length-percentage> ]  |
  [ [ block-start | block-end ] <length-percentage> ] && [ [ inline-start | inline-end ] <length-percentage> ]  |
  [ [ start | end ] <length-percentage> ]{2}

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4, CSS Values and Units Module Level 5, Motion Path Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting various offset-anchor values

In the following example, we have three `<div>` elements nested in `<section>` elements. Each `<div>` is given the same `offset-path` (a horizontal line 200 pixels long) and animated to move along it. The three are then given different `background-color` and `offset-anchor` values.

Each `<section>` has been styled with a linear gradient to give it a horizontal line running through its center, to give you a visual display of where the `<div>`'s offset paths are running.

This allows you to see what effect the different `offset-anchor` values have — the first one, `auto`, causes the `<div>`'s center point to move along the path. The other two cause the `<div>`'s top-right and bottom-left points to move along the path, respectively.

HTML

```
<section>
  <div class="offset-anchor1"></div>
</section>
<section>
  <div class="offset-anchor2"></div>
</section>
<section>
  <div class="offset-anchor3"></div>
</section>
```

CSS

```
div {
  offset-path: path("M 0,20 L 200,20");
  animation: move 3000ms infinite alternate ease-in-out;
  width: 40px;
  height: 40px;
}

section {
  background-image: linear-gradient(
    to bottom,
    transparent,
    transparent 49%,
    black 50%,
    black 51%,
    transparent 52%
  );
  border: 1px solid #cccccc;
  margin-bottom: 10px;
}

.offset-anchor1 {
  offset-anchor: auto;
  background: cyan;
}

.offset-anchor2 {
```

```
  offset-anchor: right top;
  background: purple;
}

.offset-anchor3 {
  offset-anchor: left bottom;
  background: magenta;
}

@keyframes move {
  0% {
    offset-distance: 0%;
  }
  100% {
    offset-distance: 100%;
  }
}
```

- SVG `<path>`

offset-distance CSS property

The **`offset-distance`** CSS property specifies a position along an `offset-path` for an element to be placed.

Try it

```
offset-distance: 0%;
```

```
offset-distance: 80%;
```

```
offset-distance: 50px;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element"></div>
</section>
```

```
#example-element {
  width: 24px;
  height: 24px;
  background: #2bc4a2;
  offset-path: path("M-70,-40 C-70,70 70,70 70,-40");
  clip-path: polygon(0% 0%, 70% 0%, 100% 50%, 70% 100%, 0% 100%, 30% 50%);
}

/* Provides a reference image of what path the element is following */
#default-example {
  background-position: calc(50% - 12px) calc(50% + 14px);
  background-repeat: no-repeat;
  background-image: url('data:image/svg+xml;utf8,<svg xmlns="http://www.w3.org/2000/svg" viewBox="-75 -45 150 140" width="150" height="140"><path d="M-70,-40 C-70,70 70,70 70,-40" fill="none"
stroke="lightgrey" stroke-width="2" stroke-dasharray="4.5"/></svg>');
}
```

Syntax

```
/* Default value */
offset-distance: 0;

/* the middle of the offset-path */
offset-distance: 50%;

/* a fixed length positioned along the path */
offset-distance: 40px;

/* Global values */
offset-distance: inherit;
offset-distance: initial;
offset-distance: revert;
offset-distance: revert-layer;
offset-distance: unset;
```

`<length-percentage>`

A length that specifies how far the element is along the path (defined with `offset-path`).

100% represents the total length of the path (when the `offset-path` is defined as a basic shape or `path()`).

Formal definition

Initial value	`0`
Applies to	transformable elements
Inherited	no
Percentages	refer to the total path length
Computed value	for `<length>` the absolute value, otherwise a percentage
Animation type	a length, percentage or calc();

Formal syntax

```
offset-distance =
  <length-percentage>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4, Motion Path Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using offset-distance in an animation

The motion aspect in CSS Motion Path typically comes from animating the `offset-distance` property. If you want to animate an element along its full path, you would define its `offset-path` and then set up an animation that takes the `offset-distance` from `0%` to `100%`.

HTML

```
<div id="motion-demo"></div>
```

CSS

```
#motion-demo {
  offset-path: path("M20,20 C20,100 200,0 200,100");
  animation: move 3000ms infinite alternate ease-in-out;
  width: 40px;
  height: 40px;
  background: cyan;
}

@keyframes move {
  0% {
    offset-distance: 0%;
  }
  100% {
    offset-distance: 100%;
  }
}
```

- `offset-position`
- `offset-rotate`

offset-path CSS property

The **`offset-path`** CSS property specifies a path for an element to follow and determines the element's positioning within the path's parent container or the SVG coordinate system. The path is a line, a curve, or a geometrical shape along which the element gets positioned or moves.

The `offset-path` property is used in combination with the `offset-distance`, `offset-rotate`, and `offset-anchor` properties to control the position and orientation of the element along a path.

Try it

```
offset-path: path("M-70,-40 C-70,70 70,70 70,-40");
```

```
offset-path: path("M0,0 L60,70 L-60,30z");
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element"></div>
  <button id="playback" type="button">Play</button>
</section>
```

```
#example-element {
  width: 24px;
  height: 24px;
  background: #2bc4a2;
  animation: distance 8000ms infinite linear;
  animation-play-state: paused;
  clip-path: polygon(0% 0%, 70% 0%, 100% 50%, 70% 100%, 0% 100%, 30% 50%);
}

#example-element.running {
  animation-play-state: running;
}

#playback {
  position: absolute;
  top: 0;
  left: 0;
  font-size: 1em;
}

@keyframes distance {
  0% {
    offset-distance: 0%;
  }
  100% {
    offset-distance: 100%;
  }
}
```

```
#default-example {
  position: relative;
}
```

```
const example = document.getElementById("example-element");
const button = document.getElementById("playback");

button.addEventListener("click", () => {
  if (example.classList.contains("running")) {
    example.classList.remove("running");
    button.textContent = "Play";
  } else {
    example.classList.add("running");
    button.textContent = "Pause";
  }
});
```

Syntax

```
/* Default */
offset-path: none;

/* Line segment */
offset-path: ray(45deg closest-side contain);
offset-path: ray(contain 150deg at center center);
offset-path: ray(45deg);

/* URL */
offset-path: url("#my-circle");

/* Basic shape */
offset-path: circle(50% at 25% 25%);
offset-path: ellipse(50% 50% at 25% 25%);
offset-path: inset(50% 50% 50% 50%);
offset-path: polygon(30% 0%, 70% 0%, 100% 50%, 30% 100%, 0% 70%, 0% 30%);
offset-path: path("M 0,200 Q 200,200 260,80 Q 290,20 400,0 Q 300,100 400,200");
offset-path: rect(5px 5px 160px 145px round 20%);
offset-path: xywh(0 5px 100% 75% round 15% 0);

/* Coordinate box */
offset-path: content-box;
offset-path: padding-box;
offset-path: border-box;
offset-path: fill-box;
offset-path: stroke-box;
offset-path: view-box;

/* Global values */
offset-path: inherit;
offset-path: initial;
offset-path: revert;
offset-path: revert-layer;
offset-path: unset;
```

Values

The `offset-path` property takes as its value an `<offset-path>` value, a `<coord-box>` value, or both, or the `none` keyword. The `<offset-path>` value is a `ray()` function, a `<url>` value, or a `<basic-shape>` value.

`none`

Specifies that the element does not follow any offset path. The `none` value is equivalent to the element not having any offset transform. The element's movement in this case is determined by its default position properties, such as `top` and `left`, instead of an offset path. This is the default value.

`<offset-path>`

A `ray()` function, a `<url>` value, or a `<basic-shape>` value that specifies the geometrical offset path. If omitted, the path shape for the `<coord-box>` value is `inset(0 round X)`, where `X` is the value of `border-radius` of the element that establishes the containing block.

`ray()`

Defines a line starting at a set position, of a set length, and extending at the specified angle. The `ray()` function accepts up to four parameters – an `<angle>`, an optional size value, the optional keyword `contain`, and an optional `at <position>`.

`<url>`

Specifies the ID of an SVG shape element. The path is the shape of the SVG `<circle>`, `<ellipse>`, `<line>`, `<path>`, `<polygon>`, `<polyline>`, or `<rect>` element referenced by its `id` in the `url()` function. If the URL does not reference a shape element or is otherwise invalid, the resolved value for the offset path is `path("M0,0")` (which is a valid `<basic-shape>` value).

`<basic-shape>`

Specifies the offset path as the equivalent path of a CSS basic shape function, such as `circle()`, `ellipse()`, `inset()`, `path()`, `polygon()`, `rect()`, or `xywh()`. For example, if the `<basic_shape>` is an `ellipse()` function, then the path is the outline of the ellipse, starting at the rightmost point of the ellipse, proceeding clockwise through a full rotation. For `ellipse()` and `circle()`, which accept the `at <position>` parameter, if the `<position>` is omitted, the position defaults to `center` unless the element has an `offset-position` specified. In this case, the `offset-position` value is used for the `at <position>` parameter. More complex shapes can be defined using the `shape()` function.

`<coord-box>`

Specifies the size information of the reference box containing the path. The reference box is derived from the element that establishes the containing block for this element. This parameter is optional. If not specified, the default value is `border-box` in CSS contexts. In SVG contexts, the value is treated as `view-box`. If `ray()` or `<basic-shape>` is used to define the offset path, the `<coord-box>` value provides the reference box for the ray or the `<basic-shape>`, respectively. If `<url>` is used to define the offset path, the `<coord-box>` value provides the viewport and user coordinate system for the shape element, with the origin (`0 0`) at the top left corner and size being `1px`.

Description

The `offset-path` property defines a path an animated element can follow. An offset path is either a specified path with one or multiple sub-paths or the geometry of a not-styled basic shape. The element's exact position on the offset path is determined by the `offset-distance` property. Each shape or path must define an initial position for the computed value of `0` for `offset-distance` and an initial direction which specifies the rotation of the object to the initial position.

Early versions of the spec called this property `motion-path`. It was changed to `offset-path` because the property describes static positions, not motion.

Formal definition

Initial value	none
Applies to	transformable elements
Inherited	no
Computed value	as specified
Animation type	by computed value type
Creates stacking context	yes

Formal syntax

```
offset-path =
  none                          |
  <offset-path> || <coord-box>

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Box Model Module Level 4, CSS Fill and Stroke Module Level 3, CSS Images Module Level 3, CSS Masking Module Level 1, CSS Shapes Module Level 1, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5, Motion Path Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Creating an offset-path using box-edge positioning

This example demonstrates using various `<coord-box>` values in the `offset-path` property.

```
<div class="box blueBox"></div>
<div class="box redBox"></div>
<div class="box greenBox"></div>
```

```
body {
  width: 300px;
  height: 200px;
  border-radius: 50px;
  border: dashed aqua;
  border-width: 25px;
  padding: 25px;
```

```
  margin: 50px;
}
```

```
.box {
  width: 40px;
  height: 20px;
  animation: move 8000ms infinite ease-in-out;
}

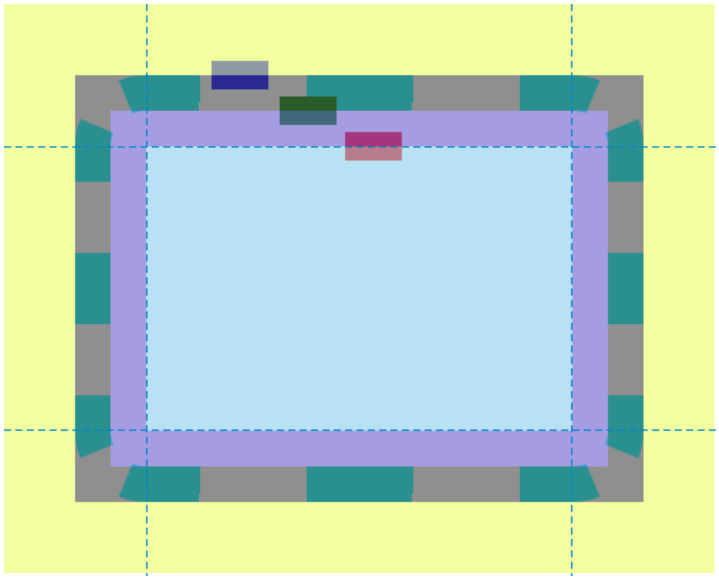
.blueBox {
  background-color: blue;
  offset-path: border-box;
  offset-distance: 5%;
}

.greenBox {
  background-color: green;
  offset-path: padding-box;
  offset-distance: 8%;
}

.redBox {
  background-color: red;
  offset-path: content-box;
  offset-distance: 12%;
}

@keyframes move {
  0%,
  20% {
    offset-distance: 0%;
  }
  80%,
  100% {
    offset-distance: 100%;
  }
}
```

In this example, the margin, border, and padding have been purposely given large values to demonstrate the placement of the blue, green, and red rectangles on their respective `<coord-box>` edges: border-box, padding-box, and content-box.



Result

Creating an offset-path using path()

In this example, the `<svg>` element creates a house with a chimney and also defines two halves of a scissor. The house and chimney are composed of rectangles and polygons, and the scissor halves are represented by two distinct path elements. In the CSS code, the `offset-path` property is used to specify a path to follow for the two scissor halves. This CSS-defined path is identical to the one represented by the `<path>` element in the SVG, which is the outline of the house including the chimney.

```
<svg
  xmlns="http://www.w3.org/2000/svg"
  width="700"
  height="450"
  viewBox="350 0 1400 900">
  <title>House and Scissors</title>
  <rect x="595" y="423" width="610" height="377" fill="blue" />
  <polygon points="506,423 900,190 1294,423" fill="yellow" />
  <polygon points="993,245 993,190 1086,190 1086,300" fill="red" />
  <path
    id="house"
    d="M900,190 L993,245 V201 A11,11 0 0,1 1004,190 H1075 A11,11 0 0,1 1086,201 V300 L1294,423 H1216 A11,11 0 0,0 1205,434 V789 A11,11 0 0,1 1194,800 H606 A11,11 0 0,1 595,789 V434 A11,11 0 0,0
584,423 H506 L900,190"
    fill="none"
    stroke="black"
    stroke-width="13"
    stroke-linejoin="round"
    stroke-linecap="round" />
  <path
    id="first-scissor-half"
    class="scissor-half"
    d="M30,0 H-10 A10,10 0 0,0 -20,10 A20,20 0 1,1 -40,-10 H20 A10,10 0 0,1 30,0 M-40,20 A10,10 1 0,0 -40,0 A10,10 1 0,0 -40,20 M0,0" />
```

```
  <path
    id="second-scissor-half"
    class="scissor-half"
    d="M30,0 H-10 A10,10 0 0,1 -20,-10 A20,20 0 1,0 -40,10 H20 A10,10 0 0,0 30,0 M-40,-20 A10,10 1 0,0 -40,0 A10,10 1 0,0 -40,-20 M0,0" />
</svg>
```

```
.scissor-half {
  offset-path: path(
    "M900,190 L993,245 V201 A11,11 0 0,1 1004,190 H1075 A11,11 0 0,1 1086,201 V300 L1294,423 H1216 A11,11 0 0,0 1205,434 V789 A11,11 0 0,1 1194,800 H606 A11,11 0 0,1 595,789 V434 A11,11 0 0,0
584,423 H506 L900,190"
  );
  transform: translate(0px, 0px);
  fill: green;
  stroke: black;
  stroke-width: 5px;
  stroke-linejoin: round;
  stroke-linecap: round;
  fill-rule: evenodd;
  offset-anchor: 0 0;
}

#first-scissor-half {
  animation:
    move 12s linear infinite,
    rotate-left 1s infinite;
}
#second-scissor-half {
  animation:
    move 12s linear infinite,
    rotate-right 1s infinite;
}

@keyframes move {
  from {
    offset-distance: 0%;
  }
  to {
    offset-distance: 100%;
  }
}

@keyframes rotate-left {
  0% {
    offset-rotate: auto 0deg;
  }
  50% {
    offset-rotate: auto -45deg;
  }
  100% {
    offset-rotate: auto 0deg;
  }
}

@keyframes rotate-right {
  0% {
    offset-rotate: auto 0deg;
  }
  50% {
    offset-rotate: auto 45deg;
  }
  100% {
    offset-rotate: auto 0deg;
  }
}
```

Result

Without the `offset-path` property, the two halves of the scissors would default to the top-left corner of the canvas. However, by using `offset-path`, the two scissor halves are aligned with the starting point of the SVG path, allowing them to move along it.

Creating an offset-path using url()

This example illustrates how to refer to an SVG shape to define the shape of the path that an element can follow. The green circle (defined by `.target`) follows the path of a rectangle, which is defined by passing the SVG shape's ID (`svgRect`) to the `offset-path` property by using `url()`.

The SVG rectangle that defines the path shape is shown here only to visually demonstrate that the green circle is indeed following the path defined by this rectangle.

```
<div class="outer">
  <div class="target"></div>
</div>
<svg width="400" height="200" xmlns="http://www.w3.org/2000/svg">
  <rect id="svgRect" x="50" y="50" width="200" height="100" />
</svg>
```

```
.outer {
  position: absolute;
}
```

```
.target {
  width: 50px;
  height: 50px;
  border-radius: 50%;
  background-color: green;
  offset-path: url("#svgRect");
  offset-anchor: auto;
  animation: move 5s linear infinite;
}

#svgRect {
  fill: antiquewhite;
  stroke: black;
```

```
  stroke-width: 2;
}

@keyframes move {
  0% {
    offset-distance: 0%;
  }
  100% {
    offset-distance: 100%;
  }
}
```

Different shapes

This example involves different `<basic-shape>` values: `circle()`, `ellipse()`, `inset()`, `polygon()`.

```
<div class="container">
  <div class="mover mover-path">path()</div>
  <div class="mover mover-circle">circle()</div>
  <div class="mover mover-ellipse">ellipse()</div>
  <div class="mover mover-inset">inset()</div>
  <div class="mover mover-polygon">polygon()</div>
</div>
```

```
.container {
  border: 1px solid black;
  width: 80vw;
  height: 80vh;
  position: relative;
  left: 10vw;
  top: 10vh;
}

.mover {
  width: 100px;
  height: 80px;
  border-radius: 50%;
  line-height: 80px;
  text-indent: 10px;
  background: url("data:image/svg+xml,%3Csvg xmlns='http://www.w3.org/2000/svg' id='e644da42-a34e-4ceb-a89a-89a4eb6dcc51' data-name='Layer 1' viewBox='0 0 71.08 54.62'%3E%3Ctitle%3Epointer-hand%3C/title%3E%3Cpath d='M43.56,49.35a5.24,5.24,0,0,0-1.27-3.43,5.26,5.26,0,0,0,1.86-9,5.26,5.26,0,0,0-.5-9.53L66.12,27c2.28-.07,5-1.57,5-4.58a5.06,5.06,0,0,0-4.58-4.83L34.08,17c3.48-2.89,6.26-6.55,6.73-11.08C41.45-.14,36.07-1.15,35,1.09,32,7.11,23,12.75,17.42,15.52,8.64,19.08,0,19.77,0,34.56,0,42.7,2.7,47.94,9.42,51c5.51,2.52,13.71,3.59,25.36,3.59H38.3A5.27,5.27,0,0,0,43.56,49.35Z'/%3E%3C/svg%3E")

offset-position CSS property

The **`offset-position`** CSS property defines the initial position of an element along a path. This property is typically used in combination with the `offset-path` property to create a motion effect. The value of `offset-position` determines where the element gets placed initially for moving along an offset path if an `offset-path` function such as `path()` does not specify its own starting position.

The `offset-position` property is part of a motion system based on `offset` constituent properties, including `offset-anchor`, `offset-distance`, and `offset-path`. These properties work together to create various motion effects along a path.

Syntax

```
/* Keyword values */
offset-position: normal;
offset-position: auto;
offset-position: top;
offset-position: bottom;
offset-position: left;
offset-position: right;
offset-position: center;

/* <percentage> values */
offset-position: 25% 75%;

/* <length> values */
offset-position: 0 0;
offset-position: 1cm 2cm;
offset-position: 10ch 8em;

/* Edge offsets values */
offset-position: bottom 10px right 20px;
offset-position: right 3em bottom 10px;
offset-position: bottom 10px right;
offset-position: top right 10px;

/* Global values */
offset-position: inherit;
offset-position: initial;
offset-position: revert;
offset-position: revert-layer;
offset-position: unset;
```

Values

`normal`

Indicates that the element does not have an offset starting position and places the element at `50% 50%` of the containing block. This is the default value.

`auto`

Indicates that the offset starting position is the top-left corner of the element's box.

`<position>`

Specifies the position as an x/y coordinate to place an element relative to its box edges. The position can be defined using one to four values. If two non-keyword values are used, the first value represents the horizontal position and the second represents the vertical position. If only one value is specified, the second value is assumed to be `center`. If three or four values are used, the `<length-percentage>` values are offsets for the preceding keyword value(s). For more explanation of these value types, see `background-position`.

Formal definition

Initial value	`normal`
Applies to	transformable elements
Inherited	no
Percentages	refer to the size of containing block
Computed value	for `<length>` the absolute value, otherwise a percentage
Animation type	a position

Formal syntax

```
offset-position =
  normal      |
  auto        |
  <position>

<position> =
  <position-one>   |
  <position-two>   |
  <position-four>

<position-one> =
  left               |
  center             |
  right              |
  top                |
  bottom             |
```

```
  x-start              |
  x-end                |
  y-start              |
  y-end                |
  block-start          |
  block-end            |
  inline-start         |
  inline-end           |
  <length-percentage>

<position-two> =
  [ left | center | right | x-start | x-end ] && [ top | center | bottom | y-start | y-end ]  |
  [ left | center | right | x-start | x-end | <length-percentage> ] [ top | center | bottom | y-start | y-end | <length-percentage> ]  |
  [ block-start | center | block-end ] && [ inline-start | center | inline-end ]  |
  [ start | center | end ]{2}

<position-four> =
  [ [ left | right | x-start | x-end ] <length-percentage> ] && [ [ top | bottom | y-start | y-end ] <length-percentage> ]  |
  [ [ block-start | block-end ] <length-percentage> ] && [ [ inline-start | inline-end ] <length-percentage> ]  |
  [ [ start | end ] <length-percentage> ]{2}

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4, CSS Values and Units Module Level 5, Motion Path Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting initial offset-position for an offset-path

In this example, the `offset-path` property is used to define the path along which the `cyan` element should move. The value of the `path()` CSS function is an SVG data path that describes a curved path. The element moves along this curved path during the `move` animation.

HTML

```
<div id="wrap">
  <div id="motion-demo"></div>
</div>
```

CSS

```
#wrap {
  width: 260px;
  height: 160px;
  border: 1px dashed black;
}
```

```
#motion-demo {
  offset-path: path("M20,20 C20,100 200,0 200,100");
  offset-position: left top;
  animation: move 3000ms infinite alternate ease-in-out;
  width: 40px;
  height: 40px;
  background: cyan;
}

@keyframes move {
  0%,
  20% {
    offset-distance: 0%;
  }
  80%,
  100% {
    offset-distance: 100%;
  }
}
```

Result

Comparing various offset starting positions

This example visually compares various initial offset starting position of an element when `ray()` is used to specify a value for the `offset-path` property. The number inside the element box indicates the element to which CSS is applied as well as the element's anchor point.

```
<div class="wrap">
  <div class="box">0</div>
  <div class="box box0">0</div>
  <pre>
    offset-position: normal;
    /* No offset-path specified */
  </pre>
</div>

<div class="wrap">
  <div class="box">0</div>
  <div class="box box1">1</div>
  <pre>
    offset-position: normal;
    offset-path: ray(0deg);
  </pre>
</div>

<div class="wrap">
  <div class="box">0</div>
  <div class="box box2">2</div>
  <pre>
    offset-position: auto;
    offset-path: ray(0deg);
  </pre>
</div>
```

```
<div class="wrap">
  <div class="box">0</div>
  <div class="box box3">3</div>
  <pre>
    offset-position: left top;
    offset-path: ray(0deg);
  </pre>
</div>

<div class="wrap">
  <div class="box">0</div>
  <div class="box box4">4</div>
  <pre>
    offset-position: 30% 70%;
    offset-path: ray(120deg);
  </pre>
</div>
```

```
.wrap {
  position: relative;
  width: 80vw;
  height: 120px;
  border: 1px solid black;
  margin: 0 2em 4em 5em;
  text-align: center;
}

pre {
  font-size: 1em;
  text-align: right;
  padding-right: 10px;
  line-height: 1em;
}

.box {
  display: flex;
  justify-content: center;
  align-items: center;
  width: 50px;
  height: 50px;
}

.box + .box {
  opacity: 1;
}
```

```
.box {
  background-color: green;
  border-top: 6px dashed white;
  background-clip: border-box;
  position: absolute;
  top: 20px;
  left: 20px;
  opacity: 20%;
  color: white;
}

.box0 {
  offset-position: normal;
}

.box1 {
  offset-position: normal;
  offset-path: ray(0deg);
}

.box2 {
  offset-position: auto;
  offset-path: ray(0deg);
}

.box3 {
  offset-position: left top;
  offset-path: ray(0deg);
}

.box4 {
  offset-position: 30% 70%;
  offset-path: ray(120deg);
}
```

Result

In `box0`, the absence of the `offset-path` property means that an `offset-position` of either `normal` or `auto` has no effect. When `offset-position` is `normal`, the ray starts at the center of the containing block (i.e., `50% 50%`). This is the default starting position of an offset path and is used when no `offset-position` is specified. Notice the difference between offset starting positions `auto` and `left top`. The value `auto` aligns the element's anchor point to its own top-left corner, whereas the value `left top` aligns the element's anchor point to the top-left corner of the containing block.

offset-rotate CSS property

The **`offset-rotate`** CSS property defines the orientation/direction of the element as it is positioned along the `offset-path`.

Try it

```
offset-rotate: auto;
```

```
offset-rotate: 90deg;
```

```
offset-rotate: auto 90deg;
```

```
offset-rotate: reverse;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element"></div>
  <button id="playback" type="button">Play</button>
</section>
```

```
#example-element {
  width: 24px;
  height: 24px;
  background: #2bc4a2;
  offset-path: path("M-70,-40 C-70,70 70,70 70,-40");
  animation: distance 8000ms infinite linear;
  animation-play-state: paused;
  clip-path: polygon(0% 0%, 70% 0%, 100% 50%, 70% 100%, 0% 100%, 30% 50%);
}

#example-element.running {
  animation-play-state: running;
}

#playback {
  position: absolute;
  top: 0;
  left: 0;
  font-size: 1em;
}

@keyframes distance {
  0% {
    offset-distance: 0%;
  }
  100% {
    offset-distance: 100%;
  }
}

/* Provides a reference image of what path the element is following */
#default-example {
  position: relative;
  background-position: calc(50% - 12px) calc(50% + 14px);
  background-repeat: no-repeat;
  background-image: url('data:image/svg+xml;utf8,<svg xmlns="http://www.w3.org/2000/svg" viewBox="-75 -45 150 140" width="150" height="140"><path d="M-70,-40 C-70,70 70,70 70,-40" fill="none"
stroke="lightgrey" stroke-width="2" stroke-dasharray="4.5"/></svg>');
}
```

```
const example = document.getElementById("example-element");
const button = document.getElementById("playback");

button.addEventListener("click", () => {
  if (example.classList.contains("running")) {
    example.classList.remove("running");
    button.textContent = "Play";
  } else {
    example.classList.add("running");
    button.textContent = "Pause";
  }
});
```

> **Note:** Early versions of the spec called this property `motion-rotation`.

Syntax

```
/* Follow the path direction, with optional additional angle */
offset-rotate: auto;
offset-rotate: auto 45deg;

/* Follow the path direction but facing the opposite direction of `auto` */
offset-rotate: reverse;

/* Keep a constant rotation regardless the position on the path */
offset-rotate: 90deg;
offset-rotate: 0.5turn;

/* Global values */
offset-rotate: inherit;
offset-rotate: initial;
offset-rotate: revert;
offset-rotate: revert-layer;
offset-rotate: unset;
```

`auto`

The element is rotated by the angle of the direction of the `offset-path`, relative to the positive x-axis. This is the default value.

`<angle>`

The element has a constant clockwise rotation transformation applied to it by the specified rotation angle.

`auto <angle>`

If `auto` is followed by an `<angle>`, the computed value of the angle is added to the computed value of `auto`.

`reverse`

The element is rotated similar to `auto`, except it faces the opposite direction. It is the same as specifying a value of `auto 180deg`.

Formal definition

Initial value	`auto`
Applies to	transformable elements
Inherited	no
Computed value	as specified
Animation type	as <angle>, <basic-shape> or <path()>

Formal syntax

```
offset-rotate =
  [ auto | reverse ]  ||
  <angle>
```

This syntax reflects the latest standard as per Motion Path Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting element orientation along its offset path

HTML

```
<div></div>
<div></div>
<div></div>
```

CSS

```
div {
  width: 40px;
  height: 40px;
  background: #2bc4a2;
  margin: 20px;
  clip-path: polygon(0% 0%, 70% 0%, 100% 50%, 70% 100%, 0% 100%, 30% 50%);
  animation: move 5000ms infinite alternate ease-in-out;

  offset-path: path("M20,20 C20,50 180,-10 180,20");
}
div:nth-child(1) {
  offset-rotate: auto;
}
div:nth-child(2) {
  offset-rotate: auto 90deg;
}
div:nth-child(3) {
  offset-rotate: 30deg;
}

@keyframes move {
  100% {
    offset-distance: 100%;
  }
}
```

- `offset-position`

opacity CSS property

The **`opacity`** CSS property sets the opacity of an element. Opacity is the degree to which content behind an element is hidden, and is the opposite of transparency.

Try it

```
opacity: 0;
```

```
opacity: 0.33;
```

```
opacity: 1;
```

```
<section class="default-example" id="default-example">
  <p id="example-element">
    London. Michaelmas term lately over, and the Lord Chancellor sitting in
    Lincoln's Inn Hall. Implacable November weather. As much mud in the streets
    as if the waters had but newly retired from the face of the earth, and it
    would not be wonderful to meet a Megalosaurus, forty feet long or so,
    waddling like an elephantine lizard up Holborn Hill.
  </p>
</section>
```

```
#example-element {
  background-color: #963770;
  color: white;
```

```
  padding: 1em;
}
```

Syntax

```
opacity: 0.9;
opacity: 90%;

/* Global values */
opacity: inherit;
opacity: initial;
opacity: revert;
opacity: revert-layer;
opacity: unset;
```

Values

`<alpha-value>`

A `<number>` in the range `0.0` to `1.0`, inclusive, or a `<percentage>` in the range `0%` to `100%`, inclusive, representing the opacity of the channel (that is, the value of its alpha channel). Any value outside the interval, though valid, is clamped to the nearest limit in the range.

Value	Meaning
`0`	The element is fully transparent (that is, invisible).
Any `<number>` strictly between `0` and `1`	The element is translucent (that is, content behind the element can be seen).
`1` (default value)	The element is fully opaque (visually solid).

Description

`opacity` applies to the element as a whole, including its contents, even though the value is not inherited by child elements. Thus, the element and its children all have the same opacity relative to the element's background, even if they have different opacities relative to one another.

To change the opacity of a background only, use the `background` property with a color value that allows for an alpha channel. For example:

```
background: rgb(0 0 0 / 40%);
```

When `opacity` value is set to `0`, the element and all of its children appear invisible, but they are still part of the DOM. That means they still register pointer events and, if the elements are in a tabbing order, they do get focus. For good usability, make sure to make such elements visible when they receive user interactions or use the CSS `pointer-events` property to disable pointer events and take the element out of the tab order by disabling with the `disabled` attribute or setting `tab-index="-1"` for non-form-related interactive elements.

Using `opacity` with a value other than `1` places the element in a new stacking context.

Opacity alone should not be used to provide information to screen readers. Use the HTML `hidden` attribute, CSS `visibility`, or CSS `display` style properties. It's best to avoid using `aria-hidden` attribute, but if the element is hidden with opacity, then hide it from screen readers as well.

Transitioning opacity

When transitioning the opacity of elements as you add them to the page when content was formerly hidden with `visibility: hidden`, `display: none`, or `content-visibility: hidden`, you need to include both a `@starting-style` and `transition-behavior: allow-discrete`:

```
.card {
  transition:
    opacity 5s,
    display 5s;
  background-color: orange;

  transition-behavior: allow-discrete;
  @starting-style {
    opacity: 0;
  }
}

.card.hidden {
  display: none;
  opacity: 0;
}
```

To enable first-style transitions, `@starting-style` rules are needed. In the above code, setting `opacity: 0` in `@starting-style` provides a starting point for the transition when the element receives its initial style update. For more details, see `@starting-style`.

Setting `transition-behavior: allow-discrete` is required to transition to `display: none`. See the `transition-behavior` property for more details.

Accessibility

If text opacity is adjusted, it is important to ensure that the contrast ratio between the color of the text and the background the text is placed over is high enough that people experiencing low vision conditions will be able to read the content of the page.

Color contrast ratio is determined by comparing the luminosity of the opacity-adjusted text and background color values. In order to meet current Web Content Accessibility Guidelines (WCAG), a ratio of 4.5:1 is required for text content and 3:1 for larger text such as headings. Large text is defined as 18.66px and bold or larger, or 24px or larger.

- WebAIM: Color Contrast Checker
- MDN Understanding WCAG, Guideline 1.4 explanations
- Understanding Success Criterion 1.4.3 | W3C Understanding WCAG 2.0

Various operating systems provide a preference for reducing transparency. To set the `opacity` based on the user's operating systems transparency preferences, use the `prefers-reduced-transparency` media query.

Formal definition

Initial value	`1`
Applies to	all elements
Inherited	no
Percentages	map to the range `[0,1]`
Computed value	The same as the specified value after clipping the `<number>` to the range [0.0, 1.0].

Animation type	by computed value type

Formal syntax

```
opacity =
  <opacity-value>

<opacity-value> =
  <number>     |
  <percentage>
```

This syntax reflects the latest standard as per CSS Color Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting opacity

The following example demonstrates how the `opacity` property changes the opacity of the entire element and content, thus making the text very hard to read.

HTML

```
<div class="light">You can barely see this.</div>
<div class="medium">This is easier to see.</div>
<div class="heavy">This is very easy to see.</div>
```

CSS

```
div {
  background-color: yellow;
  font-weight: bold;
  font-size: 130%;
}
.light {
  opacity: 0.2; /* Barely see the text over the background */
}
.medium {
  opacity: 0.5; /* See the text more clearly over the background */
}
.heavy {
  opacity: 0.9; /* See the text very clearly over the background */
}
```

Result

Setting opacity on hover

In the following example opacity is changed on hover, so the striped background image on the parent element shows through the image.

HTML

```
<div class="wrapper">
  <img
    src="/shared-assets/images/examples/dino.svg"
    alt="MDN Dino"
    width="128"
    height="146"
    class="opacity" />
</div>
```

CSS

```
img.opacity {
  opacity: 1;
}

img.opacity:hover {
  opacity: 0.5;
}

.wrapper {
  width: 200px;
  height: 160px;
  background-color: #f03cc3;
  background-image: linear-gradient(
    90deg,
    transparent 50%,
    rgb(255 255 255 / 50%) 50%
  );
  background-size: 20px 20px;
}
```

Result

Styling based on user preferences

To style elements based on user's operating systems transparency preferences, use the `prefers-reduced-transparency` media query. The following example demonstrates how to use the `prefers-color-scheme` media query to specify the desired `opacity` based on the user's preferences.

```
.element {
  opacity: 0.5;
}

@media (prefers-reduced-transparency) {
  .element {
    opacity: 1;
  }
}
```

- `prefers-reduced-transparency` media query

- CSS color module
- SVG `opacity` attribute

order CSS property

The **`order`** CSS property sets the order to lay out an item in a flex or grid container. Items in a container are sorted by ascending `order` value and then by their source code order. Items not given an explicit `order` value are assigned the default value of `0`.

Try it

```
order: 0;
```

```
order: 3;
```

```
order: -1;
```

```
order: 2;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">Box 1:</div>
  <div style="order: 1">Box 2: <code>order: 1;</code></div>
  <div style="order: 2">Box 3: <code>order: 2;</code></div>
  <div style="order: 2">Box 4: <code>order: 2;</code></div>
  <div style="order: 3">Box 5: <code>order: 3;</code></div>
</section>
```

```
.default-example {
  max-height: 300px;
  display: flex;
  flex-flow: column;
}

.default-example > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
  margin: 0.5rem;
  padding: 0.5rem;
  flex: 1;
}

#example-element {
  background-color: rgb(255 0 200 / 0.2);
  border: 3px solid rebeccapurple;
}

#example-element::after {
  content: attr(style);
  outline: 2px dashed;
  font-family: monospace;
}
```

In the above demo, select the options on the left-hand side to change the value of the pink box's `order` property. The light blue boxes have been given fixed `order` values.

Bear in mind the effect of source order. For example, when `order: 2;` is selected, the pink box is placed before the two blue boxes with `order: 2;`. This is because the pink box appears before the blue boxes in the source code.

Syntax

```
/* <integer> values */
order: 5;
order: -5;

/* Global values */
order: inherit;
order: initial;
order: revert;
order: revert-layer;
order: unset;
```

Since `order` is only meant to affect the *visual order* of elements and not their logical or tab order, it must not be used on non-visual media such as speech.

Defined in the CSS display module, this property impacts only grid and flex items. When `order` is set on an element whose parent's `display` property is not creating a flex or grid container, it has no effect.

Values

`<integer>`

Represents the ordinal group to be used by the item.

Accessibility

Using the `order` property will create a disconnect between the visual presentation of content and DOM order. This will adversely affect low vision users navigating with the aid of assistive technology such as a screen reader. If the visual order differs from the DOM order, your users will have different experiences depending on how they access your content.

- Flexbox & the keyboard navigation disconnect via Tink (2016)
- Source Order Matters via Adrian Roselli (2015)
- Understanding WCAG, Guideline 1.3 explanations
- Understanding Success Criterion 1.3.2 | W3C Understanding WCAG 2.0

Formal definition

Initial value	`0`
Applies to	Flex items, grid items, and absolutely-positioned flex and grid container children
Inherited	no
Computed value	as specified

Animation type	an integer

Formal syntax

```
order =
  <integer>

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Display Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Ordering items in a flex container

In this example, we create a classic two-sidebar layout.

HTML

We include a header, a footer, and a main content area. The main content includes an article and two side bars. Note their order! We'll use the CSS `order` property to change their visual order.

```
<header>Header</header>
<main>
  <article>Article</article>
  <nav>Nav</nav>
  <aside>Aside</aside>
</main>
<footer>Footer</footer>
```

CSS

We style the main area using flexible box layout module features; by setting `display` to `flex`, the `<main>` element becomes a flex container. By default, this creates flex items of equal vertical size. The sidebars are both given an absolute `width`, while the `<article>` will consume all the positive free space with a `flex-grow` factor set via the `flex` shorthand.

We then set different `order` property values on each of the flex container's three children; this means the CSS is defining that component's visual order rather than it appearing in the order declared in the HTML.

```
main {
  display: flex;
  text-align: center;
}
main > article {
  flex: 1;
  order: 2;
}
main > nav {
  width: 200px;
  order: 1;
}
main > aside {
  width: 200px;
  order: 3;
}
```

Result

The `<article>` appears first in the source order but visually rendered in the center.

- Reading order

orphans CSS property

The **`orphans`** CSS property sets the minimum number of lines in a block container that must be shown at the *bottom* of a page, region, or column.

In typography, an *orphan* is the first line of a paragraph that appears alone at the bottom of a page. (The paragraph continues on a following page.)

Syntax

```
/* <integer> values */
orphans: 2;
orphans: 3;

/* Global values */
orphans: inherit;
orphans: initial;
orphans: revert;
orphans: revert-layer;
orphans: unset;
```

Values

`<integer>`

The minimum number of lines that can stay by themselves at the bottom of a fragment before a fragmentation break. The value must be positive.

Formal definition

Initial value	2
Applies to	block container elements
Inherited	yes

Computed value	as specified
Animation type	by computed value type

Formal syntax

```
orphans =
  <integer [1,∞]>

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Fragmentation Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Controlling column orphans

This example uses a checkbox to switch `orphans` between `2` and `1`. With `orphans: 2`, at least two lines of a paragraph must appear at the bottom of a column. With `orphans: 1`, the paragraph can be broken anywhere.

HTML

```
<div>
  <p>This is the first paragraph containing some text.</p>
  <p>
    This is the second paragraph containing some more text than the first one.
    It is used to demonstrate how orphans work.
  </p>
  <p>
    This is the third paragraph. It has a little bit more text than the first
    one.
  </p>
</div>
<form>
  <input type="checkbox" id="orphans" checked />
  <label for="orphans">Apply orphans: 2</label>
</form>
```

CSS

```
div {
  background-color: #8cffa0;
  width: 420px;
  height: 120px;
  columns: 3;
  column-fill: auto;
  orphans: 1;
  widows: 1;
}

div:has(~ form input:checked) {
  orphans: 2;
}

p {
  background-color: #8ca0ff;
}

p:first-child {
  margin-top: 0;
}
```

Result

In Firefox, which does not support `orphans`, the behavior in this example is essentially equivalent to `orphans: 1`, regardless of the checkbox state. The following screenshot shows the result with `orphans: 2` in a supporting browser:

outline CSS property

The **`outline`** CSS shorthand property sets the style, color, and width of an element's outline.

Try it

```
outline: solid;
```

```
outline: dashed red;
```

```
outline: 1rem solid;
```

```
outline: thick double #32a1ce;
```

```
outline: 8px ridge rgb(170 50 220 / 0.6);
border-radius: 2rem;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with an outline around it.
  </div>
</section>
```

```
#example-element {
  padding: 0.75rem;
  width: 80%;
  height: 100px;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `outline-width`
- `outline-style`
- `outline-color`

Syntax

```
/* style */
outline: solid;

/* style | color */
outline: dashed #ff6666;

/* width | style */
outline: thick inset;

/* width | style | color*/
outline: 3px solid green;

/* Global values */
outline: inherit;
outline: initial;
outline: revert;
outline: revert-layer;
outline: unset;
```

Values

This property is specified as one, two, or three values from the following list:

`<'outline-width'>`

A `<line-width>` value setting the thickness of the outline. Defaults to `medium` if absent. See `outline-width`.

`<'outline-style'>`

Sets the style of the outline. Defaults to `none` if absent. See `outline-style`.

`<'outline-color'>`

Sets the color of the outline. Defaults to `invert` for browsers supporting it, `currentColor` for the others. See `outline-color`.

Description

The `outline` shorthand property sets the style, color, and width of an element's outline. It can be specified using one, two, or three values. The order of the values does not matter. Any omitted sub-values are set to their initial value.

The outline will be invisible for many elements if its style is not defined. This is because the style defaults to `none`. A notable exception is `input` elements, which are given default styling by browsers.

Outline is a line outside of the element's border. Unlike other areas of the box, outlines don't take up space, so they don't affect the layout of the document in any way.

There are a few properties that affect an outline's appearance. It is possible to change the style, color, and width using the `outline` property, the distance from the border using the `outline-offset` property, and corner angles using the `border-radius` property.

An outline is not required to be rectangular: While dealing with multiline text, some browsers will draw an outline for each line box separately, while others will wrap the whole text with a single outline.

Accessibility

Assigning `outline` a value of `0` or `none` will remove the browser's default focus style. If an element can be interacted with it must have a visible focus indicator. Provide obvious focus styling if the default focus style is removed.

- How to Design Useful and Usable Focus Indicators
- WCAG 2.1: Understanding Success Criterion 2.4.7: Focus Visible

Formal definition

Initial value	as each of the properties of the shorthand: • `outline-width`: `medium` • `outline-style`: none • `outline-color`: `auto`
Applies to	all elements
Inherited	no
Computed value	as each of the properties of the shorthand: • `outline-width`: the absolute `<length>`, snapped as a line width • `outline-style`: as specified • `outline-color`: For the keyword `auto`, the computed value is `currentcolor`. For the color value, if the value is translucent, the computed value will be the `rgba()` corresponding one. If it isn't, it will be the `rgb()` corresponding one. The `transparent` keyword maps to `rgba(0,0,0,0)`.
Animation type	as each of the properties of the shorthand: • `outline-width`: a length • `outline-style`: by computed value type • `outline-color`: a color

Formal syntax

```
outline =
  <'outline-width'>  ||
  <'outline-style'>  ||
  <'outline-color'>

<outline-width> =
  <line-width>

<outline-style> =
  auto                  |
  <outline-line-style>

<outline-color> =
  auto                  |
  <'border-top-color'>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick

<outline-line-style> =
  none    |
  auto    |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset

<border-top-color> =
  <color>     |
  <image-1D>

<image-1D> =
  <stripes()>

<stripes()> =
  stripes( <color-stripe># )

<color-stripe> =
  <color>                           &&
  [ <length-percentage> | <flex> ]?

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Basic User Interface Module Level 4, CSS Borders and Box Decorations Module Level 4, CSS Images Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using outline to set a focus style

HTML

```
<a href="#">This link has a special focus style.</a>
```

CSS

```
a {
  border: 1px solid;
  border-radius: 3px;
  display: inline-block;
  margin: 10px;
  padding: 5px;
}

a:focus {
  outline: 4px dotted #ee7733;
```

```
  outline-offset: 4px;
  background: #ffffaa;
}
```

Result

See also

- outline-width
- outline-style
- outline-color
- border

outline-color CSS property

The **outline-color** CSS property sets the color of an element's outline.

Try it

```
outline-color: red;
```

```
outline-color: #32a1ce;
```

```
outline-color: rgb(170 50 220 / 0.6);
```

```
outline-color: hsl(60 90% 50% / 0.8);
```

```
outline-color: currentColor;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with an outline around it.
  </div>
</section>
```

```
#example-element {
  outline: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}
```

Syntax

```
/* <color> values */
outline-color: #f92525;
outline-color: rgb(30 222 121);
outline-color: blue;

/* Global values */
outline-color: inherit;
outline-color: initial;
outline-color: revert;
outline-color: revert-layer;
outline-color: unset;
```

The `outline-color` property is specified as any one of the values listed below.

Values

`<color>`

The color of the outline, specified as a `<color>`.

The specification also lists an additional value, `auto`, which is not currently supported in any browsers. When implemented, `auto` will compute to `currentColor` unless `outline-style` is set to `auto` then it will compute to the accent color.

Description

An outline is a line that is drawn around an element, outside the `border`. Unlike the element's border, the outline is drawn outside the element's frame, and may overlap other content. The border, on the other hand, will actually alter the page's layout to ensure that it fits without overlapping anything else (unless you explicitly set it to overlap).

It is often more convenient to use the shorthand property `outline` when defining the appearance of an outline.

Accessibility

Custom focus styles commonly involve making adjustments to the `outline` property. If the color of the outline is adjusted, it is important to ensure that the contrast ratio between it and the background the outline is placed over is high enough that people experiencing low vision conditions will be able to perceive it.

An outline is a visual indicator. In order to meet current Web Content Accessibility Guidelines (WCAG), Success Criterion 1.4.11 Non-text Contrast requires a contrast ratio of at least 3:1 between the outline and the adjacent colors it sits against. Note that when the outline is used as a focus indicator, the adjacent colors include both the background outside the element and the element's own background when the outline borders both.

- WebAIM: Color Contrast Checker
- MDN Understanding WCAG, Guideline 1.4 explanations
- Understanding Success Criterion 1.4.11: Non-text Contrast | W3C Understanding WCAG 2.2

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	no
Computed value	For the keyword `auto`, the computed value is `currentcolor`. For the color value, if the value is translucent, the computed value will be the `rgba()` corresponding one. If it isn't, it will be the `rgb()` corresponding one. The `transparent` keyword maps to `rgba(0,0,0,0)`.

Animation type	a color

Formal syntax

```
outline-color =
  auto                |
  <'border-top-color'>

<border-top-color> =
  <color>     |
  <image-1D>

<image-1D> =
  <stripes()>

<stripes()> =
  stripes( <color-stripe># )

<color-stripe> =
  <color>                          &&
  [ <length-percentage> | <flex> ]?

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Basic User Interface Module Level 4, CSS Borders and Box Decorations Module Level 4, CSS Images Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting a solid blue outline

HTML

```
<p>My outline is blue, as you can see.</p>
```

CSS

```
p {
  outline: 2px solid; /* Set the outline width and style */
  outline-color: blue; /* Set the outline color */
  margin: 5px;
}
```

Result

See also

- `outline`
- `outline-width`
- `outline-style`
- The `<color>` data type
- Other color-related properties: `color`, `background-color`, `border-color`, `text-decoration-color`, `text-emphasis-color`, `text-shadow`, `caret-color`, and `column-rule-color`

outline-offset CSS property

The **`outline-offset`** CSS property sets the amount of space between an outline and the edge or border of an element.

Try it

```
outline-offset: 4px;
```

```
outline-offset: 0.6rem;
```

```
outline-offset: 12px;
outline: 5px dashed blue;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with an outline around it.
  </div>
</section>
```

```
#example-element {
  border: 2px solid crimson;
  outline: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}
```

Syntax

```
/* <length> values */
outline-offset: 3px;
outline-offset: 0.2em;

/* Global values */
outline-offset: inherit;
outline-offset: initial;
outline-offset: revert;
outline-offset: revert-layer;
outline-offset: unset;
```

Values

`<length>`

The width of the space between the element and its outline. A negative value places the outline inside the element. A value of `0` places the outline so that there is no space between it and the element.

Description

An outline is a line that is drawn around an element, outside the border edge. The space between an element and its outline is transparent. In other words, it is the same as the parent element's background.

Formal definition

Initial value	`0`
Applies to	all elements
Inherited	no
Computed value	the absolute `<length>`, snapped as a line width
Animation type	a length

Formal syntax

```
outline-offset =
  <length>
```

This syntax reflects the latest standard as per CSS Basic User Interface Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting outline offset in pixels

HTML

```
<p>Gallia est omnis divisa in partes tres.</p>
```

CSS

```
p {
  outline: 1px dashed red;
  outline-offset: 10px;
  background: yellow;
  border: 1px solid blue;
  margin: 15px;
}
```

Result

See also

- `outline`
- `outline-width`
- `outline-style`
- `outline-color`

outline-style CSS property

The **`outline-style`** CSS property sets the style of an element's outline. An outline is a line that is drawn around an element, outside the `border`.

It is often more convenient to use the shorthand property `outline` when defining the appearance of an outline.

Try it

```
outline-style: none;
```

```
outline-style: dotted;
```

```
outline-style: solid;
```

```
outline-style: groove;
```

```
outline-style: inset;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with an outline around it.
  </div>
</section>
```

```
#example-element {
  outline: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}
```

Syntax

```
/* Keyword values */
outline-style: auto;
outline-style: none;
outline-style: dotted;
outline-style: dashed;
outline-style: solid;
outline-style: double;
outline-style: groove;
outline-style: ridge;
outline-style: inset;
outline-style: outset;

/* Global values */
outline-style: inherit;
```

```
outline-style: initial;
outline-style: revert;
outline-style: revert-layer;
outline-style: unset;
```

Values

This property is specified as one of the following values:

`auto`

Permits the user agent to render a custom outline style.

`none`

No outline is used.

`dotted`

The outline is a series of dots.

`dashed`

The outline is a series of short line segments.

`solid`

The outline is a single line.

`double`

The outline is two single lines. The `outline-width` is the sum of the two lines and the space between them.

`groove`

The outline looks as though it were carved into the page.

`ridge`

The opposite of `groove`: the outline looks as though it were extruded from the page.

`inset`

The outline makes the box look as though it were embedded in the page.

`outset`

The opposite of `inset`: the outline makes the box look as though it were coming out of the page.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
outline-style =
  auto                 |
  <outline-line-style>

<outline-line-style> =
  none    |
  auto    |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset
```

This syntax reflects the latest standard as per CSS Basic User Interface Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting outline style to auto

The `auto` value indicates a custom outline style, described in the specification as "typically a style [that] is either a user interface default for the platform, or perhaps a style that is richer than can be described in detail in CSS, e.g., a rounded edge outline with semi-translucent outer pixels that appears to glow".

HTML

```
<div>
  <p class="auto">Outline Demo</p>
</div>
```

CSS

```
.auto {
  outline-style: auto; /* same result as "outline: auto" */
}

/* To make the Demo clearer */
* {
  outline-width: 10px;
```

```
  padding: 15px;
}
```

Result

Setting outline style to dashed and dotted

HTML

```
<div>
  <div class="dotted">
    <p class="dashed">Outline Demo</p>
  </div>
</div>
```

CSS

```
.dotted {
  outline-style: dotted; /* same result as "outline: dotted" */
}
.dashed {
  outline-style: dashed;
}

/* To make the Demo clearer */
* {
  outline-width: 10px;
  padding: 15px;
}
```

Result

Setting outline style to solid and double

HTML

```
<div>
  <div class="solid">
    <p class="double">Outline Demo</p>
  </div>
</div>
```

CSS

```
.solid {
  outline-style: solid;
}
.double {
  outline-style: double;
}

/* To make the Demo clearer */
* {
  outline-width: 10px;
  padding: 15px;
}
```

Result

Setting outline style to groove and ridge

HTML

```
<div>
  <div class="groove">
    <p class="ridge">Outline Demo</p>
  </div>
</div>
```

CSS

```
.groove {
  outline-style: groove;
}
.ridge {
  outline-style: ridge;
}

/* To make the Demo clearer */
* {
  outline-width: 10px;
  padding: 15px;
}
```

Result

Setting outline style to inset and outset

HTML

```
<div>
  <div class="inset">
    <p class="outset">Outline Demo</p>
  </div>
</div>
```

CSS

```
.inset {
  outline-style: inset;
}
```

```
.outset {
  outline-style: outset;
}

/* To make the Demo clearer */
* {
  outline-width: 10px;
  padding: 15px;
}
```

Result

outline-width CSS property

The CSS **`outline-width`** property sets the thickness of an element's outline. An outline is a line that is drawn around an element, outside the `border`.

It is often more convenient to use the shorthand property `outline` when defining the appearance of an outline.

Try it

```
outline-width: 12px;
```

```
outline-width: thin;
```

```
outline-width: medium;
```

```
outline-width: thick;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with an outline around it.
  </div>
</section>
```

```
#example-element {
  outline: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}
```

Syntax

```
/* Keyword values */
outline-width: thin;
outline-width: medium;
outline-width: thick;

/* <length> values */
outline-width: 1px;
outline-width: 0.1em;

/* Global values */
outline-width: inherit;
outline-width: initial;
outline-width: revert;
outline-width: revert-layer;
outline-width: unset;
```

Values

This property is specified as one `<line-width>` value.

`<line-width>`

Defines the width of the outline, either as an explicit non-negative `<length>` or the keywords: `thin`, `medium`, or `thick`. The default is `medium`.

Formal definition

Initial value	`medium`
Applies to	all elements
Inherited	no
Computed value	the absolute `<length>`, snapped as a line width
Animation type	a length

Formal syntax

```
outline-width =
  <line-width>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

This syntax reflects the latest standard as per CSS Basic User Interface Module Level 4, CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting an element's outline width

HTML

```
<span id="thin">thin</span>
<span id="medium">medium</span>
<span id="thick">thick</span>
<span id="twopixels">2px</span>
<span id="oneex">1ex</span>
<span id="em">1.2em</span>
```

CSS

```
span {
  outline-style: solid;
  display: inline-block;
  margin: 20px;
}

#thin {
  outline-width: thin;
}

#medium {
  outline-width: medium;
}

#thick {
  outline-width: thick;
}

#twopixels {
  outline-width: 2px;
}

#oneex {
  outline-width: 1ex;
}

#em {
  outline-width: 1.2em;
}
```

Result

- outline-color

overflow CSS property

The **overflow** CSS shorthand property sets the desired behavior when content does not fit in the element's padding box (overflows) in the horizontal and/or vertical direction.

Try it

```
overflow: visible;
```

```
overflow: hidden;
```

```
overflow: clip;
```

```
overflow: scroll;
```

```
overflow: auto;
```

```
<section class="default-example" id="default-example">
  <p id="example-element">
    Michaelmas term lately over, and the Lord Chancellor sitting in Lincoln's
    Inn Hall. Implacable November weather. As much mud in the streets as if the
    waters had but newly retired from the face of the earth.
  </p>
</section>
```

```
#example-element {
  width: 15em;
  height: 9em;
  border: medium dotted;
  padding: 0.75em;
  text-align: left;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- overflow-x
- overflow-y

Syntax

```
/* Keyword values */
overflow: visible;
overflow: hidden;
overflow: clip;
```

```
overflow: scroll;
overflow: auto;

/* Two-value syntax: horizontal | vertical */
overflow: hidden visible;

/* Global values */
overflow: inherit;
overflow: initial;
overflow: revert;
overflow: revert-layer;
overflow: unset;
```

Values

This property is specified as one or two space-separated `<overflow>` keyword values:

`visible`

> Overflow content is not clipped and may be visible outside the element's padding box. The element box is not a scroll container. This is the default value.

`hidden`

> Overflow content is clipped at the element's padding box, hiding the clipped content. When overflowing, the element box is a scroll container with no scroll bars; scrolling is still possible via other methods including tabbing to hidden focusable elements, properties such as `scrollLeft` property, and methods like `scrollTo()`.

`clip`

> Overflow content is clipped at the element's *overflow clip edge* defined by the `overflow-clip-margin` property. The element box is not a scroll container, clipped content is not visible, and programmatic scrolling is not supported.

`scroll`

> Overflow content is clipped at the element's padding box. Whether overflowing or not, the element box is always a scroll container displaying scroll bars.

`auto`

> Overflow content is clipped at the element's padding box. When overflowing, the element box is a scroll container displaying scroll bars.

Non-standard values

Some non-standard values are also supported in some browsers:

`overlay`

> A legacy alias for `auto`, defined in the specification for web compatibility. Originally implemented as a non-standard value to render scrollbars on top of content rather than taking up space. Its use in new code is discouraged.

Description

By default, block-level elements grow to fit their content. If the size of a container is constrained, the content will overflow. The `overflow` property determines how a container handles content that overflows its edges.

The `overflow` property is shorthand for the horizontal `overflow-x` and vertical `overflow-y` properties. If only one keyword is specified, both `overflow-x` and `overflow-y` are set to the same value. If two keywords are specified, the first value applies to `overflow-x` in the horizontal direction and the second one applies to `overflow-y` in the vertical direction.

Overflow options include hiding overflow content, enabling scroll bars to view overflow content or displaying the content flowing out of an element box into the surrounding area, and combinations there of.

All values, except `visible` and `clip`, create a new block formatting context. The new block formatting context is necessary for scroll containers because if a float were to intersect with a scrolling element, it would forcibly rewrap the content after each scroll step, leading to a slow scrolling experience.

What creates overflow

Overflow occurs when a block-level element has content that overflows its constrained space. The allotted space may be constrained by a height (`height` or `max-height`) for vertical overflow, a width (`width` or `max-width`) for horizontal overflow, a block-size (`block-size` or `max-block-size`) for block direction overflow, or an inline-size (`inline-size`, `max-inline-size`, or `white-space` set to `nowrap`) for inline direction overflow.

The following CSS limits the size of the container, defining box model property values that limit the container's size. A background color, clipped to the `content-box`, is also added to help demonstrate how overflowing content overflows the content box in the explanations that follow.

```
div {
  height: 10em;
  width: 15em;
  border: 3px solid;
  padding: 10px;

  background-color: #ededed;
  background-clip: content-box;
}
```

Understanding overflow values

The different `overflow` values define whether an element has scrollbars, whether it is user and programmatically scrollable, and whether it is a scroll container (which creates a new block formatting context) when that element's contents overflow and, in the case of `scroll`, even when they don't.

The `visible` value

The default value is `visible`. By default, if content overflows a container's constraints, the contents are not contained to the container. An element that defaults or is explicitly set to `visible` doesn't have scrollbars, is not user or programmatically scrollable, and is not a scroll container. This value does not create a new block formatting context.

```
div {
  overflow: visible;
}
```

```
<div>
  <h2>overflow: visible;</h2>
</div>
<div>
  <p>
    The <code>overflow</code> property in this example is set to
    <code>visible</code>. No scroll container is created; the content just
```

```
    overflows the container.
  </p>
</div>
```

With `visible`, no clipping occurs, so the overflowing content is visible outside the element's padding box, potentially overlapping adjacent content.

The `scroll` value

With `scroll`, content is clipped at the element's padding box and can be scrolled into view. User agents display scroll bars in both directions, whether or not any content is overflowing, which prevents scroll bars from appearing and disappearing as content changes. Printers may still print overflow content.

The element is always a scroll container — even when there is no overflowing content — and is both user-scrollable and programmatically scrollable.

```
div {
  overflow: scroll;
}
```

```
<div>
  <h2>overflow: scroll;</h2>
</div>
<div>
  <p>
    The <code>overflow</code> property in this example is set to
    <code>scroll</code>. A scroll container is created; a scrollbar is always
    visible, even if not needed.
  </p>
</div>
```

In the first example, even though the content is not overflowing, a scroll container is still created. In the second example, the content is clipped to the padding box, with a scroll bar enabling scrolling to the overflowing content.

The `auto` value

With `auto`, whether the element has scrollbars and is a scroll container depends on whether the element has overflowing content. When the element contains overflowing content, it behaves like `scroll`: the overflowing content is clipped at the element's padding box, and overflow content can be scrolled into view using scroll bars. Unlike `scroll`, user agents display scroll bars *only if* the content is overflowing. If content fits inside the element's padding box, it looks the same as with `visible`, but still establishes a new formatting context. The element box is a scroll container only when there is overflowing content.

```
div {
  overflow: auto;
}
```

```
<div>
  <h2>overflow: auto;</h2>
</div>
<div>
  <p>
    The <code>overflow</code> property in this example is set to
    <code>auto</code>. Because there is overflowing content, a scroll container
    is created. The content is clipped to the padding box and a scroll bar
    enables scrolling to the overflowing content.
  </p>
</div>
```

When using the two value syntax, if one value is set to `visible`, that `visible` overflow direction will behave as `auto` if the other value is not `visible` or `clip`.

The `hidden` value

With `hidden`, overflowing content is clipped at the element's padding box. There are no scroll bars and the clipped content is not visible (i.e., it's "hidden").

If there is overflowing content, the element is a scroll container. While there are no scroll bars and the user cannot view the content outside the clipped region by actions such as dragging on a touch screen or using the scroll wheel on a mouse, the hidden overflow content can be scrolled into view.

If the content contains focusable elements, tabbing brings the currently focused element into view. Content can also be scrolled to programmatically. Setting a value for the `scrollLeft` or `scrollTop` property scrolls that distance from the left or top edge, respectively. You can also scroll using the `scrollTo()` method.

```
div {
  overflow: hidden;
}
```

```
<div>
  <h2>overflow: hidden;</h2>
</div>
<div>
  <p>
    The <code>overflow</code> property in this example is set to
    <code>hidden</code>. While hidden,
    <a
      href="https://developer.mozilla.org/en-US/docs/Web/HTML/Guides/Content_categories#interactive_content"
      >interactive content</a
    >
    can be scrolled into view when focused. Because content overflows, the
    element is a scroll container, even though no scroll bars are present.
    Tabbing will give this
    <input aria-label="input" placeholder="input" /> focus and scroll it into
    view. This content is also programmatically scrollable.
  </p>
</div>
```

The first example does not have overflowing content and is not a scroll container. The second example has overflowing content that is clipped to the padding box. Even though there is no scroll bar enabling scrolling to the overflowing content, the content can be scrolled into view, such as by tabbing to the `<input>` in the hidden content. The second example is a scroll container.

The `clip` value

With `clip`, content that overflows is by default hidden, there are no scroll bars, and programmatic scrolling is not possible. The element is not a scroll container and no new formatting context is created. If the clipped content includes interactive content, hidden focusable content still receives keyboard focus, but that content will not scroll into view, making it inaccessible to keyboard users.

With `clip`, overflow content is clipped at the element's *overflow clip edge* that is defined using the `overflow-clip-margin` property. The clipped content overflows the element's padding box by the `<length>` value of `overflow-clip-margin`, which defaults to `0px`.

```
div {
  overflow: clip;
}
```

```
<div>
  <h2>overflow: clip;</h2>
</div>
<div>
  <p>
    The <code>overflow</code> property in this example is set to
    <code>clip</code>. When hidden,
    <a
      href="https://developer.mozilla.org/en-US/docs/Web/HTML/Guides/Content_categories#interactive_content"
      >interactive content</a
    >
    can NOT be scrolled into view when focused. Overflowing content is clipped
    to the container. No scroll container is created. Tabbing will give this
    <input aria-label="input" placeholder="input" /> focus but will not scroll
    it into view. Keyboard users will not be able to reach this content. This
    content is also not programmatically scrollable.
  </p>
</div>
<fieldset>
  <legend>Select a <code>overflow-clip-margin</code> value</legend>
  <ul>
    <li>
      <label
        ><input type="radio" name="overflow" value="0" /> overflow-clip-margin:
        0;</label
      >
    </li>
    <li>
      <label
        ><input type="radio" name="overflow" value="3em" />
        overflow-clip-margin: 3em;</label
      >
    </li>
  </ul>
</fieldset>
```

The second example's overflowing content is clipped. Tabbing to the `<input>` in the hidden content gives the element focus, but does not scroll it into view, making that content inaccessible to keyboard users.

When using the two value syntax, if one value is set to `clip`, that `clip` overflow direction will behave as `hidden` if the other value is not set to `visible` or `clip`.

```
ul {
  list-style-type: none;
}
label {
  font-family: monospace;
}
:has([value="0"]:checked) div {
  overflow-clip-margin: 0;
}
:has([value="3em"]:checked) div {
  overflow-clip-margin: 3em;
}

@supports not (overflow-clip-margin: 0) {
  body::before {
    content: "Your browser doesn't support overflow-clip-margin yet.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;

    width: 100%;
  }
}
```

With scroll-driven animations

When creating scroll-driven animations using the `scroll()` function, consider using `clip` instead of `hidden` if there is no interactive content within the clipped area, unless you explicitly want to create a scroll container.

With both `hidden` and `clip`, the overflow gets clipped, but `overflow: clip` doesn't create a scroll container, so clipped elements are skipped when the user agent goes up the DOM tree looking for the nearest ancestor scroll container.

Because `overflow: hidden` creates a scroll container when there is overflowing content, you might accidentally create a scrolling-ancestor that doesn't scroll. But only use `clip` if you are certain you won't clip any interactive content.

```
div {
  height: 10em;
  width: 15em;
  border: 3px solid;
  padding: 10px;
  background-color: #ededed;
  background-clip: content-box;
}
p {
  font-size: 1.5rem;
  line-height: 1.6;
  font-family: sans-serif;
}
h2 {
  font-family: monospace;
}
body {
  height: 98vh;
  overflow: clip;
  display: flex;
```

```
  flex-flow: row wrap;
  gap: 3em;
}
```

Overflowing replaced elements

Setting `overflow` on images and other replaced elements works as expected in browsers that support CSS Overflow Module Level 4; in previous versions of the specification, replaced elements were always clipped to the bounding container.

See the browser compatibility chart for current browser support information.

Formal definition

Initial value	`visible`
Applies to	Block-containers, flex containers, and grid containers
Inherited	no
Computed value	as each of the properties of the shorthand: • `overflow-x`: as specified, except with `visible`/`clip` computing to `auto`/`hidden` respectively if one of `overflow-x` or `overflow-y` is neither `visible` nor clip • `overflow-y`: as specified, except with `visible`/`clip` computing to `auto`/`hidden` respectively if one of `overflow-x` or `overflow-y` is neither `visible` nor clip
Animation type	discrete

Formal syntax

```
overflow =
  <'overflow-block'>{1,2}

<overflow-block> =
  visible  |
  hidden   |
  clip     |
  scroll   |
  auto
```

This syntax reflects the latest standard as per CSS Overflow Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Accessibility

In some browsers, scrolling content areas are not keyboard-focusable, so they cannot be scrolled by a keyboard-only user. To ensure all keyboard-only users can scroll the container, enable the element to receive focus by setting `tabindex="0"` on the container. To give screen reader users context when the container receives focus, set an appropriate WAI-ARIA role on the container, such as `role="region"`, and an accessible name using the `aria-label` or `aria-labelledby` attribute.

Examples

Demonstrating results of various overflow keywords

HTML

```
<div>
  <code>visible</code>
  <p class="visible">
    Maya Angelou: "I've learned that people will forget what you said, people
    will forget what you did, but people will never forget how you made them
    feel."
  </p>
</div>

<div>
  <code>hidden</code>
  <p class="hidden">
    Maya Angelou: "I've learned that people will forget what you said, people
    will forget what you did, but people will never forget how you made them
    feel."
  </p>
</div>

<div>
  <code>clip</code>
  <p class="clip">
    Maya Angelou: "I've learned that people will forget what you said, people
    will forget what you did, but people will never forget how you made them
    feel."
  </p>
</div>

<div>
  <code>scroll</code>
  <p class="scroll">
    Maya Angelou: "I've learned that people will forget what you said, people
    will forget what you did, but people will never forget how you made them
    feel."
  </p>
</div>

<div>
  <code>auto</code>
  <p class="auto">
    Maya Angelou: "I've learned that people will forget what you said, people
    will forget what you did, but people will never forget how you made them
    feel."
  </p>
</div>
```

CSS

```
body {
  display: flex;
  flex-wrap: wrap;
```

```
  justify-content: start;
}

div {
  margin: 2em;
  font-size: 1.2em;
}

p {
  width: 5em;
  height: 5em;
  border: dotted;
  margin-top: 0.5em;
}

div:nth-of-type(5),
div:nth-of-type(6) {
  margin-top: 200px;
}
```

```
p.visible {
  overflow: visible;
}

p.hidden {
  overflow: hidden;
}

p.clip {
  overflow: clip;
  overflow-clip-margin: 1em;
}

p.scroll {
  overflow: scroll;
}

p.auto {
  overflow: auto;
}
```

overflow-anchor CSS property

The **`overflow-anchor`** CSS property provides a way to opt out of the browser's scroll anchoring behavior, which adjusts scroll position to minimize content shifts.

Scroll anchoring behavior is enabled by default in any browser that supports it. Therefore, changing the value of this property is typically only required if you are experiencing problems with scroll anchoring in a document or part of a document and need to turn the behavior off.

Try it

```
overflow-anchor: auto;
```

```
overflow-anchor: none;
```

```
<section class="default-example" id="default-example">
  <div class="whole-content-wrapper">
    <button id="playback" type="button">Start lottery</button>
    <p>Magic numbers for today are:</p>
    <div id="example-element"></div>
  </div>
</section>
```

```
.whole-content-wrapper {
  display: flex;
  flex-direction: column;
  height: 100%;
  width: 100%;
}

#example-element {
  height: 100%;
  border: 2px dashed dodgerblue;
  padding: 0.75em;
  text-align: left;
  overflow: scroll;
}

#playback {
  font-size: 1em;
  width: 10em;
  height: 4em;
  font-weight: bold;
  margin: 1em auto;
  background-color: aliceblue;
  border: solid 2px dodgerblue;
  border-radius: 5px;
```

```
}

#playback:hover {
  border-color: lightseagreen;
}

#playback:active {
  filter: brightness(0.9);
}
```

```
const example = document.getElementById("example-element");
const button = document.getElementById("playback");
let intervalId;

function setInitialState() {
  example.innerHTML = "";
  Array.from({ length: 10 }, (_, i) => i).forEach(addContent);
  example.scrollTop = example.scrollHeight;
}

function addContent() {
  console.log("adding content");
  const magicNumber = Math.floor(Math.random() * 10000);
  example.insertAdjacentHTML(
    "afterbegin",
    `<div class="new-content-container">New Magic Number: ${magicNumber}</div>`,
  );
}

button.addEventListener("click", () => {
  if (example.classList.contains("running")) {
    example.classList.remove("running");
    button.textContent = "Start lottery";
    clearInterval(intervalId);
  } else {
    example.classList.add("running");
    button.textContent = "Stop lottery";
    setInitialState();
    intervalId = setInterval(addContent, 1000);
  }
});
```

Syntax

```
/* Keyword values */
overflow-anchor: auto;
overflow-anchor: none;

/* Global values */
overflow-anchor: inherit;
overflow-anchor: initial;
overflow-anchor: revert;
overflow-anchor: revert-layer;
overflow-anchor: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

: The element becomes a potential anchor when adjusting scroll position.

`none`

: The element won't be selected as a potential anchor.

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
overflow-anchor =
  auto  |
  none
```

This syntax reflects the latest standard as per CSS Scroll Anchoring Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Prevent scroll anchoring

To prevent scroll anchoring in a document, use the `overflow-anchor` property.

```
* {
  overflow-anchor: none;
}
```

- Overview of scroll anchoring
- CSS scroll anchoring module

overflow-block CSS property

The **`overflow-block`** CSS property sets what shows when content overflows the block start and block end edges of a box. This may be nothing, a scroll bar, or the overflow content.

> **Note:** The `overflow-block` property maps to `overflow-y` or `overflow-x` depending on the writing mode of the document.

Syntax

```
/* Keyword values */
overflow-block: visible;
overflow-block: hidden;
overflow-block: clip;
overflow-block: scroll;
overflow-block: auto;

/* Global values */
overflow-block: inherit;
overflow-block: initial;
overflow-block: revert;
overflow-block: revert-layer;
overflow-block: unset;
```

The `overflow-block` property is specified as a single `<overflow>` keyword value:

Values

`visible`

Content is not clipped and may be rendered outside the padding box's block start and block end edges.

`hidden`

Content is clipped if necessary to fit the block dimension in the padding box. No scrollbars are provided.

`clip`

Overflow content is clipped at the element's overflow clip edge that is defined using the `overflow-clip-margin` property.

`scroll`

Content is clipped if necessary to fit in the block dimension in the padding box. Browsers display scrollbars whether or not any content is actually clipped. (This prevents scrollbars from appearing or disappearing when the content changes.) Printers may still print overflowing content.

`auto`

Depends on the user agent. If content fits inside the padding box, it looks the same as `visible`, but still establishes a new block-formatting context.

Formal definition

Initial value	`auto`
Applies to	Block-containers, flex containers, and grid containers
Inherited	no
Computed value	as specified, except with `visible`/`clip` computing to `auto`/`hidden` respectively if one of `overflow-x` or `overflow-y` is neither `visible` nor clip
Animation type	discrete

Formal syntax

```
overflow-block =
  visible  |
  hidden   |
  clip     |
  scroll   |
  auto
```

This syntax reflects the latest standard as per CSS Overflow Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<ul>
  <li>
    <code>overflow-block: hidden</code> (hides the text outside the box)
    <div id="hidden">
      Lorem ipsum dolor sit amet, consectetur adipisicing elit, sed do eiusmod
      tempor incididunt ut labore et dolore magna aliqua. Ut enim ad minim
      veniam, quis nostrud exercitation ullamco laboris nisi ut aliquip ex ea
      commodo consequat. Duis aute irure dolor in reprehenderit in voluptate
      velit esse cillum dolore eu fugiat nulla pariatur.
    </div>
  </li>

  <li>
    <code>overflow-block: scroll</code> (always adds a scrollbar)
    <div id="scroll">
      Lorem ipsum dolor sit amet, consectetur adipisicing elit, sed do eiusmod
      tempor incididunt ut labore et dolore magna aliqua. Ut enim ad minim
      veniam, quis nostrud exercitation ullamco laboris nisi ut aliquip ex ea
      commodo consequat. Duis aute irure dolor in reprehenderit in voluptate
      velit esse cillum dolore eu fugiat nulla pariatur.
    </div>
  </li>

  <li>
    <code>overflow-block: clip</code> (hides the text outside the box beyond the
    overflow clip edge)
    <div id="clip">
      Lorem ipsum dolor sit amet, consectetur adipisicing elit, sed do eiusmod
```

```
      tempor incididunt ut labore et dolore magna aliqua. Ut enim ad minim
      veniam, quis nostrud exercitation ullamco laboris nisi ut aliquip ex ea
      commodo consequat. Duis aute irure dolor in reprehenderit in voluptate
      velit esse cillum dolore eu fugiat nulla pariatur.
    </div>
  </li>

  <li>
    <code>overflow-block: visible</code> (displays the text outside the box if
    needed)
    <div id="visible">
      Lorem ipsum dolor sit amet, consectetur adipisicing elit, sed do eiusmod
      tempor incididunt ut labore et dolore magna aliqua. Ut enim ad minim
      veniam, quis nostrud exercitation ullamco laboris nisi ut aliquip ex ea
      commodo consequat. Duis aute irure dolor in reprehenderit in voluptate
      velit esse cillum dolore eu fugiat nulla pariatur.
    </div>
  </li>

  <li>
    <code>overflow-block: auto</code> (on most browsers, equivalent to
    <code>scroll</code>)
    <div id="auto">
      Lorem ipsum dolor sit amet, consectetur adipisicing elit, sed do eiusmod
      tempor incididunt ut labore et dolore magna aliqua. Ut enim ad minim
      veniam, quis nostrud exercitation ullamco laboris nisi ut aliquip ex ea
      commodo consequat. Duis aute irure dolor in reprehenderit in voluptate
      velit esse cillum dolore eu fugiat nulla pariatur.
    </div>
  </li>
</ul>
```

CSS

```
div {
  border: 1px solid black;
  width: 250px;
  height: 100px;
  margin-bottom: 120px;
}

#hidden {
  overflow-block: hidden;
}
#scroll {
  overflow-block: scroll;
}
#clip {
  overflow-block: clip;
}
#visible {
  overflow-block: visible;
}
#auto {
  overflow-block: auto;
}
```

overflow-clip-margin CSS property

The **`overflow-clip-margin`** CSS property determines how far outside its bounds an element with `overflow: clip` may be painted before being clipped. The bound defined by this property is called the *overflow clip edge* of the box.

Syntax

```
/* <length> values */
overflow-clip-margin: 20px;
overflow-clip-margin: 1em;

/* <visual-box> | <length> */
overflow-clip-margin: content-box 5px;

/* Global values */
overflow-clip-margin: inherit;
overflow-clip-margin: initial;
overflow-clip-margin: revert;
overflow-clip-margin: revert-layer;
overflow-clip-margin: unset;
```

The `<visual-box>` value, which defaults to `padding-box`, specifies the box edge to use as the overflow clip edge origin. The `<length>` value specified in `overflow-clip-margin` must be non-negative.

> **Note:** If the element does not have `overflow: clip` then this property will be ignored.

Formal definition

Initial value	`0px`
Applies to	all elements

Inherited	no
Computed value	the computed <length> and a <visual-box> keyword
Animation type	discrete

Formal syntax

```
overflow-clip-margin =
  <visual-box>  ||
  <length>

<visual-box> =
  content-box  |
  padding-box  |
  border-box
```

This syntax reflects the latest standard as per CSS Box Model Module Level 4, CSS Overflow Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<div class="box">
  Lorem ipsum dolor sit amet, consectetur adipisicing elit, sed do eiusmod
  tempor incididunt ut labore et dolore magna aliqua. Ut enim ad minim veniam,
  quis nostrud exercitation ullamco laboris nisi ut aliquip ex ea commodo
  consequat. Duis aute irure dolor in reprehenderit in voluptate velit esse
  cillum dolore eu fugiat nulla pariatur.
</div>
```

CSS

```
.box {
  border: 3px solid black;
  width: 250px;
  height: 100px;
  overflow: clip;
  overflow-clip-margin: 20px;
}
```

Result

overflow-inline CSS property

The **`overflow-inline`** CSS property sets what shows when content overflows the inline start and end edges of a box. This may be nothing, a scroll bar, or the overflow content.

> **Note:** The `overflow-inline` property maps to `overflow-y` or `overflow-x` depending on the writing mode of the document.

Syntax

```
/* Keyword values */
overflow-inline: visible;
overflow-inline: hidden;
overflow-inline: clip;
overflow-inline: scroll;
overflow-inline: auto;

/* Global values */
overflow-inline: inherit;
overflow-inline: initial;
overflow-inline: revert;
overflow-inline: revert-layer;
overflow-inline: unset;
```

Values

This property is specified as one of the following `<overflow>` keyword values:

`visible`

Content is not clipped and may be rendered outside the padding box's inline start and end edges.

`hidden`

Content is clipped if necessary to fit the inline dimension in the padding box. No scrollbars are provided.

`clip`

Overflow content is clipped at the element's overflow clip edge that is defined using the `overflow-clip-margin` property.

`scroll`

Content is clipped if necessary to fit in the padding box in the inline dimension. Browsers display scrollbars whether or not any content is actually clipped. (This prevents scrollbars from appearing or disappearing when the content changes.) Printers may still print overflowing content.

`auto`

Depends on the user agent. If content fits inside the padding box, it looks the same as `visible`, but still establishes a new block-formatting context. Desktop browsers provide scrollbars if content overflows.

Formal definition

Initial value	`auto`

Applies to	Block-containers, flex containers, and grid containers
Inherited	no
Computed value	as specified, except with `visible`/`clip` computing to `auto`/`hidden` respectively if one of `overflow-x` or `overflow-y` is neither `visible` nor clip
Animation type	discrete

Formal syntax

```
overflow-inline =
  visible  |
  hidden   |
  clip     |
  scroll   |
  auto
```

This syntax reflects the latest standard as per CSS Overflow Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting inline overflow behavior

HTML

```
<ul>
  <li>
    <code>overflow-inline: hidden</code> (hides the text outside the box)
    <div id="div1">ABCDEFGHIJKLMOPQRSTUVWXYZABCDEFGHIJKLMOPQRSTUVWXYZ</div>
  </li>

  <li>
    <code>overflow-inline: scroll</code> (always adds a scrollbar)
    <div id="div2">ABCDEFGHIJKLMOPQRSTUVWXYZABCDEFGHIJKLMOPQRSTUVWXYZ</div>
  </li>

  <li>
    <code>overflow-inline: visible</code> (displays the text outside the box if
    needed)
    <div id="div3">ABCDEFGHIJKLMOPQRSTUVWXYZABCDEFGHIJKLMOPQRSTUVWXYZ</div>
  </li>

  <li>
    <code>overflow-inline: auto</code> (equivalent to <code>scroll</code>
    in most browsers)
    <div id="div4">ABCDEFGHIJKLMOPQRSTUVWXYZABCDEFGHIJKLMOPQRSTUVWXYZ</div>
  </li>

  <li>
    <code>overflow-inline: clip</code> (hides the text outside the box beyond
    the overflow clip edge)
    <code>clip</code>
    <div id="div5">ABCDEFGHIJKLMOPQRSTUVWXYZABCDEFGHIJKLMOPQRSTUVWXYZ</div>
  </li>
</ul>
```

CSS

```
div {
  border: 1px solid black;
  width: 250px;
  margin-bottom: 12px;
}

#div1 {
  overflow-inline: hidden;
}
#div2 {
  overflow-inline: scroll;
}
#div3 {
  overflow-inline: visible;
}
#div4 {
  overflow-inline: auto;
}
#div5 {
  overflow-inline: clip;
  overflow-clip-margin: 2em;
}
```

Result

See also

overflow-wrap CSS property

The **`overflow-wrap`** CSS property applies to text, setting whether the browser should insert line breaks within an otherwise unbreakable string to prevent text from overflowing its line box.

> **Note:** The property was originally a nonstandard and unprefixed Microsoft extension called `word-wrap`, and was implemented by most browsers with the same name. It has since been renamed to `overflow-wrap`, with `word-wrap` being an alias.

Try it

```
overflow-wrap: normal;
```

```
overflow-wrap: anywhere;
```

```
overflow-wrap: break-word;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    Most words are short &amp; don't need to break. But
    <strong class="transition-all" id="example-element"
      >Antidisestablishmentarianism</strong
    >
    is long. The width is set to min-content, with a max-width of 11em.
  </div>
</section>
```

```
.example-container {
  background-color: rgb(255 0 200 / 0.2);
  border: 3px solid rebeccapurple;
  padding: 0.75em;
  width: min-content;
  max-width: 11em;
  height: 200px;
}
```

> **Note:** In contrast to `word-break`, `overflow-wrap` will only create a break if an entire word cannot be placed on its own line without overflowing.

Syntax

```
/* Keyword values */
overflow-wrap: normal;
overflow-wrap: break-word;
overflow-wrap: anywhere;

/* Global values */
overflow-wrap: inherit;
overflow-wrap: initial;
overflow-wrap: revert;
overflow-wrap: revert-layer;
overflow-wrap: unset;
```

Values

This property is specified as one of the following keyword values:

`normal`

Lines may only break at normal word break points (such as a space between two words).

`anywhere`

To prevent overflow, an otherwise unbreakable string of characters — like a long word or URL — may be broken at any point if there are no otherwise-acceptable break points in the line. No hyphenation character is inserted at the break point. Soft wrap opportunities introduced by the word break are considered when calculating min-content intrinsic sizes.

`break-word`

The same as the `anywhere` value, with normally unbreakable words allowed to be broken at arbitrary points if there are no otherwise acceptable break points in the line, but soft wrap opportunities introduced by the word break are NOT considered when calculating min-content intrinsic sizes.

Formal definition

Initial value	`normal`
Applies to	text elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
overflow-wrap =
  normal      |
  break-word  |
  anywhere
```

This syntax reflects the latest standard as per CSS Text Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Comparing overflow-wrap, word-break, and hyphens

This example compares the results of `overflow-wrap`, `word-break`, and `hyphens` when breaking up a long word.

HTML

```
<p>
  They say the fishing is excellent at Lake
  <em class="normal">Chargoggagoggmanchauggagoggchaubunagungamaugg</em>, though
  I've never been there myself. (<code>normal</code>)
</p>
<p>
  They say the fishing is excellent at Lake
  <em class="ow-anywhere">Chargoggagoggmanchauggagoggchaubunagungamaugg</em>,
  though I've never been there myself. (<code>overflow-wrap: anywhere</code>)
</p>
```

```
<p>
  They say the fishing is excellent at Lake
  <em class="ow-break-word">Chargoggagoggmanchauggagoggchaubunagungamaugg</em>,
  though I've never been there myself. (<code>overflow-wrap: break-word</code>)
</p>
<p>
  They say the fishing is excellent at Lake
  <em class="word-break">Chargoggagoggmanchauggagoggchaubunagungamaugg</em>,
  though I've never been there myself. (<code>word-break</code>)
</p>
<p>
  They say the fishing is excellent at Lake
  <em class="hyphens">Chargoggagoggmanchauggagoggchaubunagungamaugg</em>, though
  I've never been there myself. (<code>hyphens</code>, without
  <code>lang</code> attribute)
</p>
<p lang="en">
  They say the fishing is excellent at Lake
  <em class="hyphens">Chargoggagoggmanchauggagoggchaubunagungamaugg</em>, though
  I've never been there myself. (<code>hyphens</code>, English rules)
</p>
<p class="hyphens" lang="de">
  They say the fishing is excellent at Lake
  <em class="hyphens">Chargoggagoggmanchauggagoggchaubunagungamaugg</em>, though
  I've never been there myself. (<code>hyphens</code>, German rules)
</p>
```

CSS

```
p {
  width: 13em;
  margin: 2px;
  background: gold;
}

.ow-anywhere {
  overflow-wrap: anywhere;
}

.ow-break-word {
  overflow-wrap: break-word;
}

.word-break {
  word-break: break-all;
}

.hyphens {
  hyphens: auto;
}
```

Result

- `white-space`
- `hyphens`
- `text-overflow`
- Guide to wrapping and breaking text

overflow-x CSS property

The **`overflow-x`** CSS property sets what shows when content overflows a block-level element's left and right edges. This may be nothing, a scroll bar, or the overflow content. This property may also be set by using the `overflow` shorthand property.

Try it

```
overflow-x: visible;
```

```
overflow-x: hidden;
```

```
overflow-x: clip;
```

```
overflow-x: scroll;
```

```
overflow-x: auto;
```

```
<section class="default-example" id="default-example">
  <div id="example-element">
    The value of Pi is 3.14159265358979323846264338327950 29. The value of e is
    2.71828182845904523536028747135266 25.
  </div>
</section>
```

```
#example-element {
  width: 15em;
  height: 9em;
  border: medium dotted;
  padding: 0.75em;
  text-align: left;
}
```

Syntax

```
/* Keyword values */
overflow-x: visible;
overflow-x: hidden;
```

```
overflow-x: clip;
overflow-x: scroll;
overflow-x: auto;

/* Global values */
overflow-x: inherit;
overflow-x: initial;
overflow-x: revert;
overflow-x: revert-layer;
overflow-x: unset;
```

The `overflow-x` property is specified as a single `<overflow>` keyword value.

If `overflow-y` is `hidden`, `scroll`, or `auto`, and the `overflow-x` property is `visible` (default), the value will be implicitly computed as `auto`.

Values

`visible`

Overflow content is not clipped and may be visible outside the element's padding box on left and right edges. The element box is not a scroll container.

`hidden`

Overflow content is clipped if necessary to fit horizontally in the elements' padding box. No scroll bars are provided.

`clip`

Overflow content is clipped at the element's *overflow clip edge* that is defined using the `overflow-clip-margin` property. As a result, content overflows the element's padding box by the `<length>` value of `overflow-clip-margin` or by `0px` if not set. The difference between `clip` and `hidden` is that the `clip` keyword also forbids all scrolling, including programmatic scrolling. No new formatting context is created. To establish a formatting context, use `overflow: clip` along with `display: flow-root`. The element box is not a scroll container.

`scroll`

Overflow content is clipped if necessary to fit horizontally inside the element's padding box. Browsers display scroll bars in the horizontal direction whether or not any content is actually clipped. (This prevents scroll bars from appearing or disappearing when the content changes.) Printers may still print overflowing content.

`auto`

Overflow content is clipped at the element's padding box, and overflow content can be scrolled into view. Unlike `scroll`, user agents display scroll bars *only if* the content is overflowing and hide scroll bars by default. If content fits inside the element's padding box, it looks the same as with `visible`, but still establishes a new block-formatting context. Desktop browsers provide scroll bars if content overflows.

> **Note:** The keyword value `overlay` is a legacy value alias for `auto`. With `overlay`, the scroll bars are drawn on top of the content instead of taking up space.

Formal definition

Initial value	`visible`
Applies to	Block-containers, flex containers, and grid containers
Inherited	no
Computed value	as specified, except with `visible`/`clip` computing to `auto`/`hidden` respectively if one of `overflow-x` or `overflow-y` is neither `visible` nor clip
Animation type	discrete

Formal syntax

```
overflow-x =
  visible  |
  hidden   |
  clip     |
  scroll   |
  auto
```

This syntax reflects the latest standard as per CSS Overflow Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<ul>
  <li>
    <code>overflow-x:hidden</code> — hides the text outside the box
    <div id="div1">ABCDEFGHIJKLMOPQRSTUVWXYZABCDEFGHIJKLMOPQRSTUVWXYZ</div>
  </li>

  <li>
    <code>overflow-x:scroll</code> — always adds a scrollbar
    <div id="div2">ABCDEFGHIJKLMOPQRSTUVWXYZABCDEFGHIJKLMOPQRSTUVWXYZ</div>
  </li>

  <li>
    <code>overflow-x:visible</code> — displays the text outside the box if
    needed
    <div id="div3">ABCDEFGHIJKLMOPQRSTUVWXYZABCDEFGHIJKLMOPQRSTUVWXYZ</div>
  </li>

  <li>
    <code>overflow-x:auto</code> — on most browsers, equivalent to
    <code>scroll</code>
    <div id="div4">ABCDEFGHIJKLMOPQRSTUVWXYZABCDEFGHIJKLMOPQRSTUVWXYZ</div>
  </li>
</ul>
```

CSS

```
#div1,
#div2,
#div3,
#div4 {
  border: 1px solid black;
```

```
  width: 250px;
  margin-bottom: 12px;
}

#div1 {
  overflow-x: hidden;
}
#div2 {
  overflow-x: scroll;
}
#div3 {
  overflow-x: visible;
}
#div4 {
  overflow-x: auto;
}
```

overflow-y CSS property

The **`overflow-y`** CSS property sets what shows when content overflows a block-level element's top and bottom edges. This may be nothing, a scroll bar, or the overflow content. This property may also be set by using the `overflow` shorthand property.

Try it

```
overflow-y: visible;
```

```
overflow-y: hidden;
```

```
overflow-y: clip;
```

```
overflow-y: scroll;
```

```
overflow-y: auto;
```

```
<section class="default-example" id="default-example">
  <p id="example-element">
    Michaelmas term lately over, and the Lord Chancellor sitting in Lincoln's
    Inn Hall. Implacable November weather. As much mud in the streets as if the
    waters had but newly retired from the face of the earth.
  </p>
</section>
```

```
#example-element {
  width: 15em;
  height: 9em;
  border: medium dotted;
  padding: 0.75em;
  text-align: left;
}
```

Syntax

```
/* Keyword values */
overflow-y: visible;
overflow-y: hidden;
overflow-y: clip;
overflow-y: scroll;
overflow-y: auto;

/* Global values */
overflow-y: inherit;
overflow-y: initial;
overflow-y: revert;
overflow-y: revert-layer;
overflow-y: unset;
```

The `overflow-y` property is specified as a single `<overflow>` keyword value.

If `overflow-x` is `hidden`, `scroll`, or `auto` and the `overflow-y` property is `visible` (default), the value will be implicitly computed as `auto`.

Values

`visible`

Overflow content is not clipped and may be visible outside the element's padding box at the top and bottom edges. The element box is not a scroll container.

`hidden`

Overflow content is clipped if necessary to fit vertically in the elements' padding box. No scroll bars are provided.

`clip`

Overflow content is clipped at the element's *overflow clip edge* that is defined using the `overflow-clip-margin` property. As a result, content overflows the element's padding box by the `<length>` value of `overflow-clip-margin` or by `0px` if not set. The difference between `clip` and `hidden` is that the `clip` keyword also forbids all scrolling, including programmatic scrolling. No new formatting context is created. To establish a formatting context, use `overflow: clip` along with `display: flow-root`. The element box is not a scroll container.

`scroll`

Overflow content is clipped if necessary to fit vertically inside the element's padding box. Browsers display scroll bars in the vertical direction whether or not any content is actually clipped. (This prevents scroll bars from appearing or disappearing when the content changes.) Printers may still print overflowing content.

`auto`

Overflow content is clipped at the element's padding box, and overflow content can be scrolled into view. Unlike `scroll`, user agents display scroll bars *only if* the content is overflowing, hiding scroll bars by default. If content fits inside the element's padding box, it looks the same as with `visible`, but still establishes a new block-formatting context.

> **Note:** The keyword value `overlay` is a legacy value alias for `auto`. With `overlay`, the scroll bars are drawn on top of the content instead of taking up space.

Formal definition

Initial value	`visible`
Applies to	Block-containers, flex containers, and grid containers
Inherited	no
Computed value	as specified, except with `visible`/`clip` computing to `auto`/`hidden` respectively if one of `overflow-x` or `overflow-y` is neither `visible` nor clip
Animation type	discrete

Formal syntax

```
overflow-y =
  visible  |
  hidden   |
  clip     |
  scroll   |
  auto
```

This syntax reflects the latest standard as per CSS Overflow Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting overflow-y behavior

HTML

```
<ul>
  <li>
    <code>overflow-y:hidden</code> – hides the text outside the box
    <div id="div1">
      Lorem ipsum dolor sit amet, consectetur adipisicing elit, sed do eiusmod
      tempor incididunt ut labore et dolore magna aliqua. Ut enim ad minim
      veniam, quis nostrud exercitation ullamco laboris nisi ut aliquip ex ea
      commodo consequat. Duis aute irure dolor in reprehenderit in voluptate
      velit esse cillum dolore eu fugiat nulla pariatur.
    </div>
  </li>

  <li>
    <code>overflow-y:scroll</code> – always adds a scrollbar
    <div id="div2">
      Lorem ipsum dolor sit amet, consectetur adipisicing elit, sed do eiusmod
      tempor incididunt ut labore et dolore magna aliqua. Ut enim ad minim
      veniam, quis nostrud exercitation ullamco laboris nisi ut aliquip ex ea
      commodo consequat. Duis aute irure dolor in reprehenderit in voluptate
      velit esse cillum dolore eu fugiat nulla pariatur.
    </div>
  </li>

  <li>
    <code>overflow-y:visible</code> – displays the text outside the box if
    needed
    <div id="div3">
      Lorem ipsum dolor sit amet, consectetur adipisicing elit, sed do eiusmod
      tempor incididunt ut labore et dolore magna aliqua. Ut enim ad minim
      veniam, quis nostrud exercitation ullamco laboris nisi ut aliquip ex ea
      commodo consequat. Duis aute irure dolor in reprehenderit in voluptate
      velit esse cillum dolore eu fugiat nulla pariatur.
    </div>
  </li>

  <li>
    <code>overflow-y:auto</code> – equivalent to <code>scroll</code>
    on most browsers
    <div id="div4">
      Lorem ipsum dolor sit amet, consectetur adipisicing elit, sed do eiusmod
      tempor incididunt ut labore et dolore magna aliqua. Ut enim ad minim
      veniam, quis nostrud exercitation ullamco laboris nisi ut aliquip ex ea
      commodo consequat. Duis aute irure dolor in reprehenderit in voluptate
      velit esse cillum dolore eu fugiat nulla pariatur.
    </div>
  </li>
</ul>
```

CSS

```
div {
  border: 1px solid black;
  width: 250px;
  height: 100px;
}

#div1 {
  overflow-y: hidden;
  margin-bottom: 12px;
}
#div2 {
  overflow-y: scroll;
  margin-bottom: 12px;
}
#div3 {
```

```
  overflow-y: visible;
  margin-bottom: 120px;
}
#div4 {
  overflow-y: auto;
  margin-bottom: 120px;
}
```

overlay CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`overlay`** CSS property specifies whether an element appearing in the top layer (for example, a shown popover or modal `<dialog>` element) is actually rendered in the top layer. This property is only relevant within a list of `transition-property` values, and only if `allow-discrete` is set as the `transition-behavior`.

It is important to note that `overlay` can *only* be set by the browser — author styles cannot change the `overlay` value of any element. You can, however, add `overlay` to the list of transition properties set on an element. This causes its removal from the top layer to be deferred so it can be animated instead of disappearing immediately.

> **Note:** When transitioning `overlay`, you need to set `transition-behavior: allow-discrete` on the transition so that it will animate. `overlay` animations differ from normal discrete animations in that the visible (i.e., `auto`) state will always be shown for the full duration of the transition, regardless of whether it is the start or end state.

Syntax

```
/* Keyword values */
overlay: auto;
overlay: none;

/* Global values */
overlay: inherit;
overlay: initial;
overlay: revert;
overlay: revert-layer;
overlay: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

The element is rendered in the top layer if it is promoted to the top layer.

`none`

The element is not rendered in the top layer.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	Discrete behavior except when animating to or from `none` is visible for the entire duration

Formal syntax

```
overlay =
  none  |
  auto
```

This syntax reflects the latest standard as per CSS Positioned Layout Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Transitioning a popover

In this example, a popover is animated as it transitions from hidden to shown and back again.

HTML

The HTML contains a `<div>` element declared as a popover using the popover attribute, and a `<button>` element designated as the popover's display control using its popovertarget attribute.

```
<button popovertarget="mypopover">Show the popover</button>
<div popover="auto" id="mypopover">I'm a Popover! I should animate.</div>
```

CSS

The `overlay` property is only present in the list of transitioned properties. As `overlay` is a user-agent controlled property, it is not declared in the pre-transition or post-transition states.

```
html {
  font-family: "Helvetica", "Arial", sans-serif;
}

[popover]:popover-open {
```

```
  opacity: 1;
  transform: scaleX(1);
}

[popover] {
  font-size: 1.2rem;
  padding: 10px;

  /* Final state of the exit animation */
  opacity: 0;
  transform: scaleX(0);

  transition:
    opacity 0.7s,
    transform 0.7s,
    overlay 0.7s allow-discrete,
    display 0.7s allow-discrete;
  /* Equivalent to
  transition: all 0.7s allow-discrete; */
}

/* Needs to be included after the previous [popover]:popover-open
   rule to take effect, as the specificity is the same */
@starting-style {
  [popover]:popover-open {
    opacity: 0;
    transform: scaleX(0);
  }
}

/* Transition for the popover's backdrop */

[popover]::backdrop {
  background-color: transparent;
  transition:
    display 0.7s allow-discrete,
    overlay 0.7s allow-discrete,
    background-color 0.7s;
  /* Equivalent to
  transition: all 0.7s allow-discrete; */
}

[popover]:popover-open::backdrop {
  background-color: rgb(0 0 0 / 25%);
}

/* Nesting selectors (&) cannot represent pseudo-elements, so this
   starting-style rule cannot be nested. */

@starting-style {
  [popover]:popover-open::backdrop {
    background-color: transparent;
  }
}
```

The two properties we want to animate are `opacity` and `transform`: we want the popover to fade in and out while growing and shrinking in the horizontal direction. We set a starting state for these properties on the default hidden state of the popover element (selected via `[popover]`), and an end state on the open state of the popover (selected via the `:popover-open` pseudo-class). We then set a `transition` property to animate between the two.

Because the animated element is being promoted to the top layer when shown and removed from the top layer when hidden, `overlay` is added to the list of transitioned elements. This ensures that the removal of the element from the top layer is deferred until the animation has ended. This doesn't make a huge difference for basic animations such as this one, but in more complex cases not doing this can result in the element being removed from the overlay too quickly, meaning the animation is not smooth or effective. Note that the `transition-behavior: allow-discrete` value is also set in the shorthand to enable discrete transitions.

The following steps are also required to get the animation working in both directions:

- A starting state for the animation is set inside the `@starting-style` at-rule. This is needed to avoid unexpected behavior. By default transitions are not triggered on elements' first style updates, or when the `display` type changes from `none` to another type. `@starting-style` allows you to override that default in a specific controlled fashion. Without this, the entry animation would not occur and the popover would just appear.
- `display` is also added to the list of transitioned elements so that the animated element is visible (set to `display: block`) throughout both the entry and exit animation. Without this, the exit animation would not be visible; in effect, the popover would just disappear. Again, `transition-behavior: allow-discrete` is required in this case for the animation to occur.

You'll note that we've also included a transition on the `::backdrop` that appears behind the popover when it opens, to provide a nice darkening animation. `[popover]:popover-open::backdrop` is needed to select the backdrop when the popover is open.

Result

The code renders as follows:

> **Note:** Because popovers change from `display: none` to `display: block` each time they are shown, the popover transitions from its `@starting-style` styles to its `[popover]:popover-open` styles every time the entry transition occurs. When the popover closes, it transitions from its `[popover]:popover-open` state to the default `[popover]` state.
>
> It is possible for the style transition on entry and exit to be different in such cases. See our Demonstration of when starting styles are used example for a proof of this.

overscroll-behavior CSS property

The **`overscroll-behavior`** CSS property controls what happens when scrolling reaches the edge of a scroll container.

Try it

```
overscroll-behavior: auto;
```

```
overscroll-behavior: contain;
```

```
overscroll-behavior: chain;
```

```
overscroll-behavior: none;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="box">
      This is a scrollable container. Michaelmas term lately over, and the Lord
      Chancellor sitting in Lincoln's Inn Hall. Implacable November weather. As
      much mud in the streets as if the waters had but newly retired from the
      face of the earth.
      <br /><br />
      Lorem Ipsum has been the industry's standard dummy text ever since the
      1500s, when an unknown printer took a galley of type and scrambled it to
      make a type specimen book. It has survived not only five centuries, but
      also the leap into electronic typesetting, remaining essentially
      unchanged.
    </div>
    <div id="example-element">
      This is the inner container. Focus on this container, scroll to the bottom
      and when you reach the bottom keep scrolling.
      <p>
        If you have
        <code class="language-css">overscroll-behavior: auto;</code> selected
        the outer container will start to scroll.
      </p>
      If you have
      <code class="language-css">overscroll-behavior: contain;</code> selected,
      the outer container will not scroll unless you move your cursor out of the
      inner container and try to perform scroll on the outer container.
    </div>
  </div>
</section>
```

```
.example-container {
  width: 35em;
  height: 18em;
  border: medium dotted;
  padding: 0.75em;
  text-align: left;
  overflow: auto;
  display: flex;
}

.box {
  width: 50%;
}

#example-element {
  width: 50%;
  height: 12em;
  border: medium dotted #1b76c4;
  padding: 0.3em;
  margin: 0 0.3em;
  text-align: left;
  overflow: auto;
  overscroll-behavior: contain;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `overscroll-behavior-x`
- `overscroll-behavior-y`

Syntax

```
/* Keyword values */
overscroll-behavior: auto; /* default */
overscroll-behavior: chain;
overscroll-behavior: contain;
overscroll-behavior: none;

/* Two values */
overscroll-behavior: auto contain;

/* Global values */
overscroll-behavior: inherit;
overscroll-behavior: initial;
overscroll-behavior: revert;
overscroll-behavior: revert-layer;
overscroll-behavior: unset;
```

Values

The `overscroll-behavior` property is specified as one or two keywords chosen from the list of values below.

Two keywords specifies the `overscroll-behavior` value on the `x` and `y` axes respectively. If only one value is specified, both x and y are assumed to have the same value.

`auto`

Allows the default behavior at a scroll boundary. Scrolling may continue in another scroll container.

`chain`

Allows scrolling to continue outside the scroll container, but prevents overscroll "bounce" effects.

`contain`

Prevents scrolling from continuing outside the scroll container. "Bounce" effects may still occur.

`none`

Prevents scrolling from continuing outside the scroll container and also prevents overscroll "bounce" effects.

Description

By default, mobile browsers tend to provide a "bounce" effect or even a page refresh when the top or bottom of a page (or other scroll area) is reached. You may also have noticed that when you have a dialog box with scrolling content at the top of a page that also has scrolling content, once the dialog box's scroll boundary is reached, the underlying page will then start to scroll — this is called scroll chaining.

In some cases, these behaviors are not desirable. You can use `overscroll-behavior` to get rid of unwanted scroll chaining and the browser's "pull to refresh"-type behavior.

Note that this property applies only to scroll containers. In particular, since an `<iframe>` is not a scroll container, setting this property on an iframe has no effect. To control scroll chaining from an iframe, set `overscroll-behavior` on both the `<html>` and the `<body>` elements of the iframe's document.

A scroll container that has no scrollable overflow, such as an element with `overflow: hidden`, is always considered to be at its scroll boundary. So setting a non-default `overscroll-behavior` such as `contain` or `none` on it will prevent scroll chaining to ancestor scroll containers. This can be used to prevent background scrolling while a dialog or overlay is open.

Formal definition

Initial value	`auto`
Applies to	non-replaced block-level elements and non-replaced inline-block elements
Inherited	no
Computed value	as each of the properties of the shorthand: • `overscroll-behavior-x`: as specified • `overscroll-behavior-y`: as specified
Animation type	discrete

Formal syntax

```
overscroll-behavior =
  [ contain | none | auto | chain ]{1,2}
```

This syntax reflects the latest standard as per CSS Overscroll Behavior Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

<code>overscroll-behavior</code> on <code><dialog></code> elements

In this example there are 4 buttons that launch a dialog, each dialog has a different `overscroll-behavior` value. There is also a `<div>` that forces the content to be larger than the container so that the scroll effect of the page can be seen.

HTML

```
<div class="buttons">
  <button popovertarget="dialog-auto"><code>auto</code></button>
  <button popovertarget="dialog-contain"><code>contain</code></button>
  <button popovertarget="dialog-chain"><code>chain</code></button>
  <button popovertarget="dialog-none"><code>none</code></button>
</div>
<div class="force-scroll"></div>
<dialog id="dialog-auto" popover>
  <code>overscroll-behavior: auto;</code>
  <p>
    Lorem ipsum dolor sit amet consectetur adipisicing elit. Ipsa odio
    voluptatum minus dolorem assumenda nemo quos autem culpa, pariatur illo
    deserunt ea nam commodi fugiat ipsum quam alias suscipit facilis?
  </p>
</dialog>
<dialog id="dialog-contain" popover>
  <code>overscroll-behavior: contain;</code>
  <p>
    Lorem ipsum dolor sit amet consectetur adipisicing elit. Ipsa odio
    voluptatum minus dolorem assumenda nemo quos autem culpa, pariatur illo
    deserunt ea nam commodi fugiat ipsum quam alias suscipit facilis?
  </p>
</dialog>
<dialog id="dialog-chain" popover>
  <code>overscroll-behavior: chain;</code>
  <p>
    Lorem ipsum dolor sit amet consectetur adipisicing elit. Ipsa odio
    voluptatum minus dolorem assumenda nemo quos autem culpa, pariatur illo
    deserunt ea nam commodi fugiat ipsum quam alias suscipit facilis?
  </p>
</dialog>
<dialog id="dialog-none" popover>
  <code>overscroll-behavior: none;</code>
  <p>
    Lorem ipsum dolor sit amet consectetur adipisicing elit. Ipsa odio
    voluptatum minus dolorem assumenda nemo quos autem culpa, pariatur illo
    deserunt ea nam commodi fugiat ipsum quam alias suscipit facilis?
  </p>
</dialog>
```

CSS

```
::backdrop {
  backdrop-filter: blur(0.5rem);
}
.buttons {
```

```
  display: flex;
  flex-direction: row;
  justify-content: space-around;
  margin: 2vb;
}
.force-scroll {
  width: 20vi;
  height: 200vb;
  margin-inline: auto;
  border: solid 1px black;
  background: linear-gradient(45deg, tomato, olivedrab);
}
```

```
[popover] {
  width: 30vi;
  height: 10vi;
}
#dialog-auto {
  overscroll-behavior: auto;
}
#dialog-contain {
  overscroll-behavior: contain;
}
#dialog-chain {
  overscroll-behavior: chain;
}
#dialog-none {
  overscroll-behavior: none;
}
```

Result

Click one of the buttons to see that behavior applied to the dialog that appears, when you scroll within the dialog:

- `auto`: if you overscroll the dialog you will see the content "bounce" and if you then continue to scroll you will see the background scroll too.
- `contain`: if you overscroll the dialog you will see the content "bounce" and if you then continue to scroll you will see the background does not scroll.
- `chain`: if you overscroll the dialog you will see that the content does not "bounce" and if you then continue to scroll you will see the background scroll too.
- `none`: if you overscroll the dialog you will see that the content does not "bounce" and if you then continue to scroll you will see the background does not scroll.

An alternate example of controlling scroll of "chat" window can be seen on the `overscroll-behavior-y` property.

overscroll-behavior-block CSS property

The **`overscroll-behavior-block`** CSS property sets the browser's behavior when the block direction boundary of a scrolling area is reached.

See `overscroll-behavior` for a full explanation.

Syntax

```
/* Keyword values */
overscroll-behavior-block: auto; /* default */
overscroll-behavior-block: chain;
overscroll-behavior-block: contain;
overscroll-behavior-block: none;

/* Global values */
overscroll-behavior-block: inherit;
overscroll-behavior-block: initial;
overscroll-behavior-block: revert;
overscroll-behavior-block: revert-layer;
overscroll-behavior-block: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

Allows the default behavior at a scroll boundary. Scrolling may continue in another scroll container.

`chain`

Allows scrolling to continue outside the scroll container, but prevents overscroll "bounce" effects.

`contain`

Prevents scrolling from continuing outside the scroll container. "Bounce" effects may still occur.

`none`

Prevents scrolling from continuing outside the scroll container and also prevents overscroll "bounce" effects.

Formal definition

Initial value	`auto`
Applies to	non-replaced block-level elements and non-replaced inline-block elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
overscroll-behavior-block =
  contain |
  none    |
  auto    |
  chain
```

This syntax reflects the latest standard as per CSS Overscroll Behavior Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Preventing block overscrolling

In this demo we have two block-level boxes, one inside the other. The outer box has a large `height` set on it so the page will scroll vertically. The inner box has a small `width` (and `height`) set on it so it sits comfortably inside the viewport, but its content is given a large `height` so it will also scroll vertically.

By default, when the inner box is scrolled and a scroll boundary is reached, the whole page will begin to scroll, which is probably not what we want. To avoid this happening in the block direction, we've set `overscroll-behavior-block: contain` on the inner box.

HTML

```
<main>
  <div>
    <div>
      <p>
        <code>overscroll-behavior-block</code> has been used to make it so that
        when the scroll boundaries of the yellow inner box are reached, the
        whole page does not begin to scroll.
      </p>
    </div>
  </div>
</main>
```

CSS

```
main {
  height: 3000px;
  width: 500px;
  background-color: white;
  background-image: repeating-linear-gradient(
    to bottom,
    transparent 0px,
    transparent 19px,
    rgb(0 0 0 / 50%) 20px
  );
}

main > div {
  height: 300px;
  width: 400px;
  overflow: auto;
  position: relative;
  top: 50px;
  left: 50px;
  overscroll-behavior-block: contain;
}

div > div {
  height: 1500px;
  width: 100%;
  background-color: yellow;
  background-image: repeating-linear-gradient(
    to bottom,
    transparent 0px,
    transparent 19px,
    rgb(0 0 0 / 50%) 20px
  );
}

p {
  padding: 10px;
  background-color: rgb(255 0 0 / 50%);
  margin: 0;
  width: 340px;
  position: relative;
  top: 10px;
  left: 10px;
}
```

Result

- CSS overscroll behavior module

overscroll-behavior-inline CSS property

The **`overscroll-behavior-inline`** CSS property sets the browser's behavior when the inline direction boundary of a scrolling area is reached.

See `overscroll-behavior` for a full explanation.

Syntax

```
/* Keyword values */
overscroll-behavior-inline: auto; /* default */
overscroll-behavior-inline: chain;
```

```
overscroll-behavior-inline: contain;
overscroll-behavior-inline: none;

/* Global values */
overscroll-behavior-inline: inherit;
overscroll-behavior-inline: initial;
overscroll-behavior-inline: revert;
overscroll-behavior-inline: revert-layer;
overscroll-behavior-inline: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

Allows the default behavior at a scroll boundary. Scrolling may continue in another scroll container.

`chain`

Allows scrolling to continue outside the scroll container, but prevents overscroll "bounce" effects.

`contain`

Prevents scrolling from continuing outside the scroll container. "Bounce" effects may still occur.

`none`

Prevents scrolling from continuing outside the scroll container and also prevents overscroll "bounce" effects.

Formal definition

Initial value	`auto`
Applies to	non-replaced block-level elements and non-replaced inline-block elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
overscroll-behavior-inline =
  contain  |
  none     |
  auto     |
  chain
```

This syntax reflects the latest standard as per CSS Overscroll Behavior Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Preventing inline overscrolling

In this demo we have two block-level boxes, one inside the other. The outer box has a large `width` set on it so the page will scroll horizontally. The inner box has a small width (and `height`) set on it so it sits comfortably inside the viewport, but its content is given a large width so it will also scroll horizontally.

By default, when the inner box is scrolled and a scroll boundary is reached, the whole page will begin to scroll, which is probably not what we want. To avoid this happening in the inline direction, we've set `overscroll-behavior-inline: contain` on the inner box.

HTML

```
<main>
  <div>
    <div>
      <p>
        <code>overscroll-behavior-inline</code> has been used to make it so that
        when the scroll boundaries of the yellow inner box are reached, the
        whole page does not begin to scroll.
      </p>
    </div>
  </div>
</main>
```

CSS

```
main {
  height: 400px;
  width: 3000px;
  background-color: white;
  background-image: repeating-linear-gradient(
    to right,
    transparent 0px,
    transparent 19px,
    rgb(0 0 0 / 50%) 20px
  );
}

main > div {
  height: 300px;
  width: 400px;
  overflow: auto;
  position: relative;
  top: 50px;
  left: 50px;
  overscroll-behavior-inline: contain;
}

div > div {
  height: 100%;
  width: 1500px;
  background-color: yellow;
```

```
  background-image: repeating-linear-gradient(
    to right,
    transparent 0px,
    transparent 19px,
    rgb(0 0 0 / 50%) 20px
  );
}

p {
  padding: 10px;
  background-color: rgb(255 0 0 / 50%);
  margin: 0;
  width: 360px;
  position: relative;
  top: 10px;
  left: 10px;
}
```

Result

overscroll-behavior-x CSS property

The **`overscroll-behavior-x`** CSS property sets the browser's behavior when the horizontal boundary of a scrolling area is reached.

See `overscroll-behavior` for a full explanation.

Syntax

```
/* Keyword values */
overscroll-behavior-x: auto; /* default */
overscroll-behavior-x: chain;
overscroll-behavior-x: contain;
overscroll-behavior-x: none;

/* Global values */
overscroll-behavior-x: inherit;
overscroll-behavior-x: initial;
overscroll-behavior-x: revert;
overscroll-behavior-x: revert-layer;
overscroll-behavior-x: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

Allows the default behavior at a scroll boundary. Scrolling may continue in another scroll container.

`chain`

Allows scrolling to continue outside the scroll container, but prevents overscroll "bounce" effects.

`contain`

Prevents scrolling from continuing outside the scroll container. "Bounce" effects may still occur.

`none`

Prevents scrolling from continuing outside the scroll container and also prevents overscroll "bounce" effects.

Formal definition

Initial value	`auto`
Applies to	non-replaced block-level elements and non-replaced inline-block elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
overscroll-behavior-x =
  contain  |
  none     |
  auto     |
  chain
```

This syntax reflects the latest standard as per CSS Overscroll Behavior Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Preventing an underlying element from scrolling horizontally

In our overscroll-behavior-x example (see source code also), we have two block-level boxes, one inside the other. The outer box has a large `width` set on it so the page will scroll horizontally. The inner box has a small width (and `height`) set on it so it sits comfortably inside the viewport, but its content is given a large `width` so it will scroll horizontally.

By default, when the inner box is scrolled and a scroll boundary is reached, the whole page will begin to scroll, which is probably not what we want. To avoid this, you can set `overscroll-behavior-x: contain` on the inner box:

```
main > div {
  height: 300px;
  width: 500px;
  overflow: auto;
  position: relative;
  top: 100px;
  left: 100px;
  overscroll-behavior-x: contain;
}
```

- `overscroll-behavior`
- `overscroll-behavior-y`
- `overscroll-behavior-inline`
- `overscroll-behavior-block`
- CSS overscroll behavior module

overscroll-behavior-y CSS property

The **`overscroll-behavior-y`** CSS property sets the browser's behavior when the vertical boundary of a scrolling area is reached.

See `overscroll-behavior` for a full explanation.

Syntax

```
/* Keyword values */
overscroll-behavior-y: auto; /* default */
overscroll-behavior-y: chain;
overscroll-behavior-y: contain;
overscroll-behavior-y: none;

/* Global values */
overscroll-behavior-y: inherit;
overscroll-behavior-y: initial;
overscroll-behavior-y: revert;
overscroll-behavior-y: revert-layer;
overscroll-behavior-y: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

Allows the default behavior at a scroll boundary. Scrolling may continue in another scroll container.

`chain`

Allows scrolling to continue outside the scroll container, but prevents overscroll "bounce" effects.

`contain`

Prevents scrolling from continuing outside the scroll container. "Bounce" effects may still occur.

`none`

Prevents scrolling from continuing outside the scroll container and also prevents overscroll "bounce" effects.

Formal definition

Initial value	`auto`
Applies to	non-replaced block-level elements and non-replaced inline-block elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

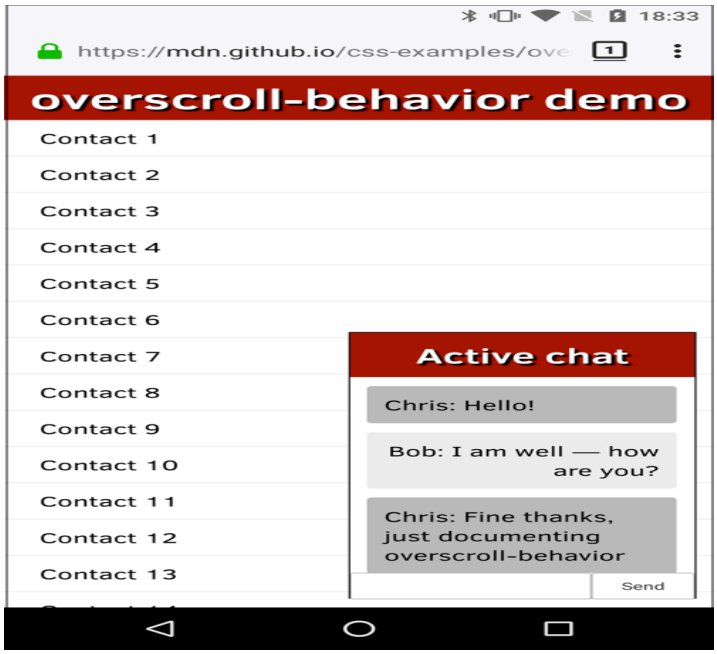
```
overscroll-behavior-y =
  contain  |
  none     |
  auto     |
  chain
```

This syntax reflects the latest standard as per CSS Overscroll Behavior Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Preventing an underlying element from scrolling

In our overscroll-behavior example (see the source code also), we present a full-page list of fake contacts, and a dialog box containing a chat window.



Both of these areas scroll; normally if you scrolled the chat window until you hit a scroll boundary, the underlying contacts window would start to scroll too, which is not desirable. This can be stopped using `overscroll-behavior-y` (`overscroll-behavior` would also work) on the chat window, like this:

```
.messages {
  height: 220px;
  overflow: auto;
  overscroll-behavior-y: contain;
}
```

We also wanted to get rid of the standard overscroll effects when the contacts are scrolled to the top or bottom (e.g., Chrome on Android refreshes the page when you scroll past the top boundary). This can be prevented by setting `overscroll-behavior-y: none` on the `<html>` element:

```
html {
  margin: 0;
  overscroll-behavior-y: none;
}
```

- `overscroll-behavior-inline`
- `overscroll-behavior-block`
- CSS overscroll behavior module

padding CSS property

The **`padding`** CSS shorthand property sets the padding area on all four sides of an element at once.

Try it

```
padding: 1em;
```

```
padding: 10% 0;
```

```
padding: 10px 50px 20px;
```

```
padding: 10px 50px 30px 0;
```

```
padding: 0;
```

```
<section id="default-example">
  <div class="transition-all" id="example-element">
    <div class="box">
      Far out in the uncharted backwaters of the unfashionable end of the
      western spiral arm of the Galaxy lies a small unregarded yellow sun.
    </div>
  </div>
</section>
```

```
#example-element {
  border: 10px solid #ffc129;
  overflow: hidden;
  text-align: left;
}

.box {
  border: dashed 1px;
}
```

An element's padding area is the space between its content and its border.

> **Note:** Padding creates extra space within an element. In contrast, `margin` creates extra space *around* an element.

Constituent properties

This property is a shorthand for the following CSS properties:

- `padding-top`
- `padding-right`
- `padding-bottom`
- `padding-left`

Syntax

```
/* Apply to all four sides */
padding: 1em;

/* top and bottom | left and right */
padding: 5% 10%;

/* top | left and right | bottom */
padding: 1em 2em 2em;

/* top | right | bottom | left */
padding: 5px 1em 0 2em;

/* Global values */
padding: inherit;
padding: initial;
padding: revert;
padding: revert-layer;
padding: unset;
```

The `padding` property may be specified using one, two, three, or four values. Each value is a `<length>` or a `<percentage>`. Negative values are invalid.

- When **one** value is specified, it applies the same padding to **all four sides**.
- When **two** values are specified, the first padding applies to the **top and bottom**, the second to the **left and right**.
- When **three** values are specified, the first padding applies to the **top**, the second to the **right and left**, the third to the **bottom**.
- When **four** values are specified, the paddings apply to the **top**, **right**, **bottom**, and **left** in that order (clockwise).

Values

`<length>`

The size of the padding as a fixed value.

`<percentage>`

The size of the padding as a percentage, relative to the inline size (*width* in a horizontal language, defined by `writing-mode`) of the containing block.

Formal definition

Initial value	as each of the properties of the shorthand: • `padding-bottom`: `0` • `padding-left`: `0` • `padding-right`: `0` • `padding-top`: `0`
Applies to	all elements, except `table-row-group`, `table-header-group`, `table-footer-group`, `table-row`, `table-column-group` and `table-column`. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Percentages	refer to the width of the containing block
Computed value	as each of the properties of the shorthand: • `padding-bottom`: the percentage as specified or the absolute length • `padding-left`: the percentage as specified or the absolute length • `padding-right`: the percentage as specified or the absolute length • `padding-top`: the percentage as specified or the absolute length
Animation type	a length

Formal syntax

```
padding =
  <'padding-top'>{1,4}

<padding-top> =
  <length-percentage [0,∞]>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Box Model Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting padding with pixels

HTML

```
<h4>This element has moderate padding.</h4>
<h3>The padding is huge in this element!</h3>
```

CSS

```
h4 {
  background-color: lime;
  padding: 20px 50px;
}

h3 {
  background-color: cyan;
  padding: 110px 50px 50px 110px;
}
```

Result

Setting padding with pixels and percentages

```
padding: 5%; /* All sides: 5% padding */

padding: 10px; /* All sides: 10px padding */

padding: 10px 20px; /* top and bottom: 10px padding */
/* left and right: 20px padding */

padding: 10px 3% 20px; /* top:           10px padding */
/* left and right: 3% padding   */
/* bottom:         20px padding */

padding: 1em 3px 30px 5px; /* top:    1em padding  */
/* right:  3px padding  */
/* bottom: 30px padding */
/* left:   5px padding  */
```

- CSS box model module

padding-block CSS property

The **`padding-block`** CSS shorthand property defines the logical block start and end padding of an element, which maps to physical padding properties depending on the element's writing mode, directionality, and text orientation.

Try it

```
padding-block: 10px 20px;
writing-mode: horizontal-tb;
```

```
padding-block: 20px 40px;
writing-mode: vertical-rl;
```

```
padding-block: 5% 10%;
writing-mode: horizontal-tb;
```

```
padding-block: 2em 4em;
writing-mode: vertical-lr;
```

```
<section id="default-example">
  <div class="transition-all" id="example-element">
    <div class="box">
      Far out in the uncharted backwaters of the unfashionable end of the
      western spiral arm of the Galaxy lies a small unregarded yellow sun.
    </div>
  </div>
</section>
```

```
#example-element {
  border: 10px solid #ffc129;
  overflow: hidden;
  text-align: left;
}

.box {
  border: dashed 1px;
  unicode-bidi: bidi-override;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `padding-block-start`
- `padding-block-end`

Syntax

```
/* <length> values */
padding-block: 10px 20px; /* An absolute length */
padding-block: 1em 2em; /* relative to the text size */
padding-block: 10px; /* sets both start and end values */

/* <percentage> values */
padding-block: 5% 2%; /* relative to the nearest block container's width */

/* Global values */
padding-block: inherit;
```

```
padding-block: initial;
padding-block: revert;
padding-block: revert-layer;
padding-block: unset;
```

The `padding-block` property may be specified with one or two values. If one value is given, it is used as the value for both `padding-block-start` and `padding-block-end`. If two values are given, the first is used for `padding-block-start` and the second for `padding-block-end`.

Values

The `padding-block` property takes the same values as the `padding-top` property.

Description

The padding values specified by `padding-block` can be equivalent to the `padding-top` and `padding-bottom` properties or the `padding-right` and `padding-left` properties, depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

Formal definition

Initial value	as each of the properties of the shorthand: • `padding-block-start`: `0` • `padding-block-end`: `0`
Applies to	all elements, except `table-row-group`, `table-header-group`, `table-footer-group`, `table-row`, `table-column-group` and `table-column`
Inherited	no
Percentages	logical-width of containing block
Computed value	as each of the properties of the shorthand: • `padding-block-start`: as `<length>` • `padding-block-end`: as `<length>`
Animation type	a length

Formal syntax

```
padding-block =
  <'padding-top'>{1,2}

<padding-top> =
  <length-percentage [0,∞]>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Box Model Module Level 4, CSS Logical Properties and Values Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting block padding for vertical text

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-rl;
  padding-block: 20px 40px;
  background-color: #c8c800;
}
```

Result

See also

- CSS Logical Properties and Values
- The mapped physical properties: `padding-top`, `padding-right`, `padding-bottom`, and `padding-left`
- `writing-mode`, `direction`, `text-orientation`

padding-block-end CSS property

The **`padding-block-end`** CSS property defines the logical block end padding of an element, which maps to a physical padding depending on the element's writing mode, directionality, and text orientation.

Try it

```
padding-block-end: 20px;
writing-mode: horizontal-tb;
```

```
padding-block-end: 20px;
writing-mode: vertical-rl;
```

```
padding-block-end: 5em;
writing-mode: horizontal-tb;
```

```
padding-block-end: 5em;
writing-mode: vertical-lr;
```

```
<section id="default-example">
  <div class="transition-all" id="example-element">
    <div class="box">
      Far out in the uncharted backwaters of the unfashionable end of the
      western spiral arm of the Galaxy lies a small unregarded yellow sun.
    </div>
  </div>
</section>
```

```
#example-element {
  border: 10px solid #ffc129;
  overflow: hidden;
  text-align: left;
}

.box {
  border: dashed 1px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
/* <length> values */
padding-block-end: 10px; /* An absolute length */
padding-block-end: 1em; /* A length relative to the text size */

/* <percentage> value */
padding-block-end: 5%; /* A padding relative to the block container's width */

/* Global values */
padding-block-end: inherit;
padding-block-end: initial;
padding-block-end: revert;
padding-block-end: revert-layer;
padding-block-end: unset;
```

Values

`<length>`

The size of the padding as a fixed value. Must be non-negative.

`<percentage>`

The size of the padding as a percentage, relative to the inline size (*width* in a horizontal language, defined by `writing-mode`) of the containing block. Must be non-negative.

Description

The `padding-block-end` property takes the same values as physical padding properties such as `padding-top`. However, it can be equivalent to `padding-bottom`, `padding-top`, `padding-left`, or `padding-right` depending on the values set for `writing-mode`, `direction`, and `text-orientation`.

It relates to `padding-block-start`, `padding-inline-start`, and `padding-inline-end`, which define the other padding values of the element.

Formal definition

Initial value	`0`
Applies to	all elements, except `table-row-group`, `table-header-group`, `table-footer-group`, `table-row`, `table-column-group` and `table-column`
Inherited	no
Percentages	logical-width of containing block
Computed value	as `<length>`
Animation type	a length

Formal syntax

```
padding-block-end =
  <'padding-top'>

<padding-top> =
  <length-percentage [0,∞]>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Box Model Module Level 4, CSS Logical Properties and Values Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting block end padding for vertical text

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}
```

```
.exampleText {
  writing-mode: vertical-lr;
  padding-block-end: 20px;
  background-color: #c8c800;
}
```

Result

See also

- CSS Logical Properties and Values
- The mapped physical properties: `padding-top`, `padding-right`, `padding-bottom`, and `padding-left`
- `writing-mode`, `direction`, `text-orientation`

padding-block-start CSS property

The **`padding-block-start`** CSS property defines the logical block start padding of an element, which maps to a physical padding depending on the element's writing mode, directionality, and text orientation.

Try it

```
padding-block-start: 20px;
writing-mode: horizontal-tb;
```

```
padding-block-start: 20px;
writing-mode: vertical-rl;
```

```
padding-block-start: 5em;
writing-mode: horizontal-tb;
```

```
padding-block-start: 5em;
writing-mode: vertical-lr;
```

```
<section id="default-example">
  <div class="transition-all" id="example-element">
    <div class="box">
      Far out in the uncharted backwaters of the unfashionable end of the
      western spiral arm of the Galaxy lies a small unregarded yellow sun.
    </div>
  </div>
</section>
```

```
#example-element {
  border: 10px solid #ffc129;
  overflow: hidden;
  text-align: left;
}

.box {
  border: dashed 1px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
/* <length> values */
padding-block-start: 10px; /* An absolute length */
padding-block-start: 1em; /* A length relative to the text size */

/* <percentage> value */
padding-block-start: 5%; /* A padding relative to the block container's width */

/* Global values */
padding-block-start: inherit;
padding-block-start: initial;
padding-block-start: revert;
padding-block-start: revert-layer;
padding-block-start: unset;
```

Values

`<length>`

The size of the padding as a fixed value. Must be non-negative.

`<percentage>`

The size of the padding as a percentage, relative to the inline-size (*width* in a horizontal language) of the containing block. Must be non-negative.

Description

The `padding-block-start` property takes the same values as physical padding properties such as `padding-top`. However, it can be equivalent to `padding-top`, `padding-bottom`, `padding-left`, or `padding-right` depending on the values set for `writing-mode`, `direction`, and `text-orientation`.

It relates to `padding-block-end`, `padding-inline-start`, and `padding-inline-end`, which define the other padding values of the element.

Formal definition

Initial value	`0`
Applies to	all elements, except `table-row-group`, `table-header-group`, `table-footer-group`, `table-row`, `table-column-group` and `table-column`
Inherited	no
Percentages	logical-width of containing block
Computed value	as `<length>`
Animation type	a length

Formal syntax

```
padding-block-start =
  <'padding-top'>

<padding-top> =
  <length-percentage [0,∞]>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Box Model Module Level 4, CSS Logical Properties and Values Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting block start padding for vertical text

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  padding-block-start: 20px;
  background-color: #c8c800;
}
```

Result

See also

- CSS Logical Properties and Values
- The mapped physical properties: `padding-top`, `padding-right`, `padding-bottom`, and `padding-left`
- `writing-mode`, `direction`, `text-orientation`

padding-bottom CSS property

The **`padding-bottom`** CSS property sets the height of the padding area on the bottom of an element.

Try it

```
padding-bottom: 1em;
```

```
padding-bottom: 10%;
```

```
padding-bottom: 20px;
```

```
padding-bottom: 1ch;
```

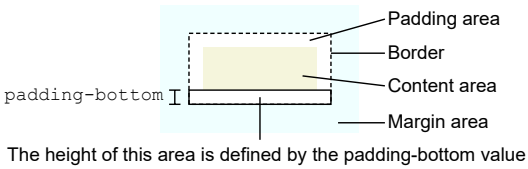
```
padding-bottom: 0;
```

```
<section id="default-example">
  <div class="transition-all" id="example-element">
    <div class="box">
      Far out in the uncharted backwaters of the unfashionable end of the
      western spiral arm of the Galaxy lies a small unregarded yellow sun.
    </div>
  </div>
</section>
```

```
#example-element {
  border: 10px solid #ffc129;
  overflow: hidden;
  text-align: left;
}

.box {
  border: dashed 1px;
}
```

An element's padding area is the space between its content and its border.



> **Note:** The `padding` property can be used to set paddings on all four sides of an element with a single declaration.

Syntax

```
/* <length> values */
padding-bottom: 0.5em;
padding-bottom: 0;
padding-bottom: 2cm;

/* <percentage> value */
padding-bottom: 10%;

/* Global values */
padding-bottom: inherit;
padding-bottom: initial;
padding-bottom: revert;
padding-bottom: revert-layer;
padding-bottom: unset;
```

The `padding-bottom` property is specified as a single value chosen from the list below. Unlike margins, negative values are not allowed for padding.

Values

`<length>`

The size of the padding as a fixed value. Must be non-negative.

`<percentage>`

The size of the padding as a percentage, relative to the inline size (*width* in a horizontal language, defined by `writing-mode`) of the containing block. Must be non-negative.

Formal definition

Initial value	`0`
Applies to	all elements, except `table-row-group`, `table-header-group`, `table-footer-group`, `table-row`, `table-column-group` and `table-column`. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Percentages	refer to the width of the containing block
Computed value	the percentage as specified or the absolute length
Animation type	a length

Formal syntax

```
padding-bottom =
  <length-percentage [0,∞]>

<length-percentage> =
  <length>     |
  <percentage>
```

This syntax reflects the latest standard as per CSS Box Model Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting padding bottom with pixels and percentages

```
.content {
  padding-bottom: 5%;
}
.side-box {
  padding-bottom: 10px;
}
```

padding-inline CSS property

The **`padding-inline`** CSS shorthand property defines the logical inline start and end padding of an element, which maps to physical padding properties depending on the element's writing mode, directionality, and text orientation.

Try it

```
padding-inline: 5% 10%;
writing-mode: horizontal-tb;
```

```
padding-inline: 15px 40px;
writing-mode: vertical-rl;
```

```
padding-inline: 5% 20%;
writing-mode: horizontal-tb;
direction: rtl;
```

```
<section id="default-example">
  <div class="transition-all" id="example-element">
    <div class="box">
      Far out in the uncharted backwaters of the unfashionable end of the
      western spiral arm of the Galaxy lies a small unregarded yellow sun.
    </div>
```

```
  </div>
</section>
```

```
#example-element {
  border: 10px solid #ffc129;
  overflow: hidden;
  text-align: left;
}

.box {
  border: dashed 1px;
  unicode-bidi: bidi-override;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `padding-inline-end`
- `padding-inline-start`

Syntax

```
/* <length> values */
padding-inline: 10px 20px; /* An absolute length */
padding-inline: 1em 2em; /* relative to the text size */
padding-inline: 10px; /* sets both start and end values */

/* <percentage> values */
padding-inline: 5% 2%; /* relative to the nearest block container's width */

/* Global values */
padding-inline: inherit;
padding-inline: initial;
padding-inline: revert;
padding-inline: revert-layer;
padding-inline: unset;
```

The `padding-inline` property may be specified with one or two values. If one value is given, it is used as the value for both `padding-inline-start` and `padding-inline-end`. If two values are given, the first is used for `padding-inline-start` and the second for `padding-inline-end`.

Values

`<length>`

The size of the padding as a fixed value. Must be non-negative.

`<percentage>`

The size of the padding as a percentage, relative to the inline size (*width* in a horizontal language, defined by `writing-mode`) of the containing block. Must be non-negative.

Description

The padding values specified by `padding-inline` can be equivalent to the `padding-top` and `padding-bottom` properties or the `padding-right` and `padding-left` properties, depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

Formal definition

Initial value	as each of the properties of the shorthand: • `padding-inline-start`: `0` • `padding-inline-end`: `0`
Applies to	all elements, except `table-row-group`, `table-header-group`, `table-footer-group`, `table-row`, `table-column-group` and `table-column`
Inherited	no
Percentages	logical-width of containing block
Computed value	as each of the properties of the shorthand: • `padding-inline-start`: as `<length>` • `padding-inline-end`: as `<length>`
Animation type	a length

Formal syntax

```
padding-inline =
  <'padding-top'>{1,2}

<padding-top> =
  <length-percentage [0,∞]>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Box Model Module Level 4, CSS Logical Properties and Values Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting inline padding for vertical text

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-rl;
  padding-inline: 20px 40px;
  background-color: #c8c800;
}
```

Result

See also

- CSS Logical Properties and Values
- The mapped physical properties: `padding-top`, `padding-right`, `padding-bottom`, and `padding-left`
- `writing-mode`, `direction`, `text-orientation`

padding-inline-end CSS property

The **`padding-inline-end`** CSS property defines the logical inline end padding of an element, which maps to a physical padding depending on the element's writing mode, directionality, and text orientation.

Try it

```
padding-inline-end: 20px;
writing-mode: horizontal-tb;
```

```
padding-inline-end: 20px;
writing-mode: vertical-rl;
```

```
padding-inline-end: 5em;
writing-mode: horizontal-tb;
direction: rtl;
```

```
<section id="default-example">
  <div class="transition-all" id="example-element">
    <div class="box">
      Far out in the uncharted backwaters of the unfashionable end of the
      western spiral arm of the Galaxy lies a small unregarded yellow sun.
    </div>
  </div>
</section>
```

```
#example-element {
  border: 10px solid #ffc129;
  overflow: hidden;
  text-align: left;
}

.box {
  border: dashed 1px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
/* <length> values */
padding-inline-end: 10px; /* An absolute length */
padding-inline-end: 1em; /* A length relative to the text size */

/* <percentage> value */
padding-inline-end: 5%; /* A padding relative to the block container's width */

/* Global values */
padding-inline-end: inherit;
padding-inline-end: initial;
padding-inline-end: revert;
padding-inline-end: revert-layer;
padding-inline-end: unset;
```

Values

`<length>`

The size of the padding as a fixed value. Must be non-negative.

`<percentage>`

The size of the padding as a percentage, relative to the inline-size (*width* in a horizontal language) of the containing block. Must be non-negative.

Description

The `padding-inline-end` property takes the same values as physical padding properties such as `padding-top`. However, it can be equivalent to `padding-right`, `padding-left`, `padding-top`, or `padding-bottom` depending on the values set for `writing-mode`, `direction`, and `text-orientation`.

It relates to `padding-block-start`, `padding-block-end`, and `padding-inline-start`, which define the other padding values of the element.

Formal definition

Initial value	`0`
Applies to	all elements, except `table-row-group`, `table-header-group`, `table-footer-group`, `table-row`, `table-column-group` and `table-column`
Inherited	no

Percentages	logical-width of containing block
Computed value	as `<length>`
Animation type	a length

Formal syntax

```
padding-inline-end =
  <'padding-top'>

<padding-top> =
  <length-percentage [0,∞]>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Box Model Module Level 4, CSS Logical Properties and Values Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting inline end padding for vertical text

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  padding-inline-end: 20px;
  background-color: #c8c800;
}
```

Result

See also

- CSS Logical Properties and Values
- The mapped physical properties: `padding-top`, `padding-right`, `padding-bottom`, and `padding-left`
- `writing-mode`, `direction`, `text-orientation`

padding-inline-start CSS property

The **`padding-inline-start`** CSS property defines the logical inline start padding of an element, which maps to a physical padding depending on the element's writing mode, directionality, and text orientation.

Try it

```
padding-inline-start: 20px;
writing-mode: horizontal-tb;
```

```
padding-inline-start: 20px;
writing-mode: vertical-rl;
```

```
padding-inline-start: 5em;
writing-mode: horizontal-tb;
direction: rtl;
```

```
<section id="default-example">
  <div class="transition-all" id="example-element">
    <div class="box">
      Far out in the uncharted backwaters of the unfashionable end of the
      western spiral arm of the Galaxy lies a small unregarded yellow sun.
    </div>
  </div>
</section>
```

```
#example-element {
  border: 10px solid #ffc129;
  overflow: hidden;
  text-align: left;
}

.box {
  border: dashed 1px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
/* <length> values */
padding-inline-start: 10px; /* An absolute length */
padding-inline-start: 1em; /* A length relative to the text size */

/* <percentage> value */
padding-inline-start: 5%; /* A padding relative to the block container's width */

/* Global values */
padding-inline-start: inherit;
```

```
padding-inline-start: initial;
padding-inline-start: revert;
padding-inline-start: revert-layer;
padding-inline-start: unset;
```

Values

`<length>`

The size of the padding as a fixed value. Must be non-negative.

`<percentage>`

The size of the padding as a percentage, relative to the inline size (*width* in a horizontal language, defined by `writing-mode`) of the containing block. Must be non-negative.

Description

The `padding-inline-start` property takes the same values as physical properties such as `padding-top`. However, it can be equivalent to `padding-left`, `padding-right`, `padding-top`, or `padding-bottom` depending on the values set for `writing-mode`, `direction`, and `text-orientation`.

It relates to `padding-block-start`, `padding-block-end`, and `padding-inline-end`, which define the other padding values of the element.

Formal definition

Initial value	`0`
Applies to	all elements, except `table-row-group`, `table-header-group`, `table-footer-group`, `table-row`, `table-column-group` and `table-column`
Inherited	no
Percentages	logical-width of containing block
Computed value	as `<length>`
Animation type	a length

Formal syntax

```
padding-inline-start =
  <'padding-top'>

<padding-top> =
  <length-percentage [0,∞]>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Box Model Module Level 4, CSS Logical Properties and Values Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting inline start padding for vertical text

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  padding-inline-start: 20px;
  background-color: #c8c800;
}
```

Result

See also

- CSS Logical Properties and Values
- The mapped physical properties: `padding-top`, `padding-right`, `padding-bottom`, and `padding-left`
- `writing-mode`, `direction`, `text-orientation`

padding-left CSS property

The **`padding-left`** CSS property sets the width of the padding area to the left of an element.

Try it

```
padding-left: 1.5em;
```

```
padding-left: 10%;
```

```
padding-left: 20px;
```

```
padding-left: 1ch;
```

```
padding-left: 0;
```

```
<section id="default-example">
  <div class="transition-all" id="example-element">
    <div class="box">
      Far out in the uncharted backwaters of the unfashionable end of the
      western spiral arm of the Galaxy lies a small unregarded yellow sun.
    </div>
  </div>
</section>
```

```
#example-element {
  border: 10px solid #ffc129;
  overflow: hidden;
  text-align: left;
}

.box {
  border: dashed 1px;
}
```

An element's padding area is the space between its content and its border.

> **Note:** The `padding` property can be used to set paddings on all four sides of an element with a single declaration.

Syntax

```
/* <length> values */
padding-left: 0.5em;
padding-left: 0;
padding-left: 2cm;

/* <percentage> value */
padding-left: 10%;

/* Global values */
padding-left: inherit;
padding-left: initial;
padding-left: revert;
padding-left: revert-layer;
padding-left: unset;
```

The `padding-left` property is specified as a single value chosen from the list below. Unlike margins, negative values are not allowed for padding.

Values

`<length>`

The size of the padding as a fixed value. Must be non-negative.

`<percentage>`

The size of the padding as a percentage, relative to the inline size (*width* in a horizontal language, defined by `writing-mode`) of the containing block. Must be non-negative.

Formal definition

Initial value	`0`
Applies to	all elements, except `table-row-group`, `table-header-group`, `table-footer-group`, `table-row`, `table-column-group` and `table-column`. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Percentages	refer to the width of the containing block
Computed value	the percentage as specified or the absolute length
Animation type	a length

Formal syntax

```
padding-left =
  <length-percentage [0,∞]>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Box Model Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting left padding using pixels and percentages

```
.content {
  padding-left: 5%;
}
.side-box {
  padding-left: 10px;
}
```

padding-right CSS property

The **`padding-right`** CSS property sets the width of the padding area on the right of an element.

Try it

```
padding-right: 1.5em;
```

```
padding-right: 10%;
```

```
padding-right: 20px;
```

```
padding-right: 1ch;
```

```
padding-right: 0;
```

```
<section id="default-example">
  <div class="transition-all" id="example-element">
    <div class="box">
      Far out in the uncharted backwaters of the unfashionable end of the
      western spiral arm of the Galaxy lies a small unregarded yellow sun.
    </div>
  </div>
</section>
```

```
#example-element {
  border: 10px solid #ffc129;
  overflow: hidden;
  text-align: left;
}

.box {
  border: dashed 1px;
}
```

An element's padding area is the space between its content and its border.

> **Note:** The `padding` property can be used to set paddings on all four sides of an element with a single declaration.

Syntax

```
/* <length> values */
padding-right: 0.5em;
padding-right: 0;
padding-right: 2cm;

/* <percentage> value */
padding-right: 10%;

/* Global values */
padding-right: inherit;
padding-right: initial;
padding-right: revert;
padding-right: revert-layer;
padding-right: unset;
```

The `padding-right` property is specified as a single value chosen from the list below. Unlike margins, negative values are not allowed for padding.

Values

`<length>`

The size of the padding as a fixed value. Must be non-negative.

`<percentage>`

The size of the padding as a percentage, relative to the inline size (*width* in a horizontal language, defined by `writing-mode`) of the containing block. Must be non-negative.

Formal definition

Initial value	`0`
Applies to	all elements, except `table-row-group`, `table-header-group`, `table-footer-group`, `table-row`, `table-column-group` and `table-column`. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Percentages	refer to the width of the containing block
Computed value	the percentage as specified or the absolute length
Animation type	a length

Formal syntax

```
padding-right =
  <length-percentage [0,∞]>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Box Model Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting right padding using pixels and percentages

```
.content {
  padding-right: 5%;
}
.side-box {
  padding-right: 10px;
}
```

padding-top CSS property

The **`padding-top`** CSS property sets the height of the padding area on the top of an element.

Try it

```
padding-top: 1em;
```

```
padding-top: 10%;
```

```
padding-top: 20px;
```

```
padding-top: 1ch;
```

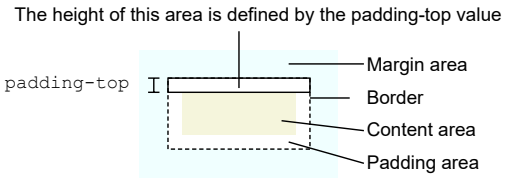
```
padding-top: 0;
```

```
<section id="default-example">
  <div class="transition-all" id="example-element">
    <div class="box">
      Far out in the uncharted backwaters of the unfashionable end of the
      western spiral arm of the Galaxy lies a small unregarded yellow sun.
    </div>
  </div>
</section>
```

```
#example-element {
  border: 10px solid #ffc129;
  overflow: hidden;
  text-align: left;
}

.box {
  border: dashed 1px;
}
```

An element's padding area is the space between its content and its border.



> **Note:** The `padding` property can be used to set paddings on all four sides of an element with a single declaration.

Syntax

```
/* <length> values */
padding-top: 0.5em;
padding-top: 0;
padding-top: 2cm;

/* <percentage> value */
padding-top: 10%;

/* Global values */
padding-top: inherit;
padding-top: initial;
padding-top: revert;
padding-top: revert-layer;
padding-top: unset;
```

The `padding-top` property is specified as a single value chosen from the list below. Unlike margins, negative values are not allowed for padding.

Values

`<length>`

The size of the padding as a fixed value. Must be non-negative.

`<percentage>`

The size of the padding as a percentage, relative to the inline size (*width* in a horizontal language, defined by `writing-mode`) of the containing block. Must be non-negative.

Formal definition

Initial value	`0`
Applies to	all elements, except `table-row-group`, `table-header-group`, `table-footer-group`, `table-row`, `table-column-group` and `table-column`. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Percentages	refer to the width of the containing block
Computed value	the percentage as specified or the absolute length
Animation type	a length

Formal syntax

```
padding-top =
  <length-percentage [0,∞]>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Box Model Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting top padding using pixels and percentages

```
.content {
  padding-top: 5%;
}
.side-box {
  padding-top: 10px;
}
```

page CSS property

The **page** CSS property is used to specify the named page, a specific type of page defined by the `@page` at-rule.

If there are multiple selectors that are using a named page consecutively then a forced page break using `break-after` may be needed.

Syntax

```
/* set a named page */
page: exampleName;
page: chapterIntro;

/* Use ancestors named page */
page: auto; /* default value */

/* Global values */
page: inherit;
page: initial;
page: revert;
page: revert-layer;
page: unset;
```

Values

`auto`

Default value. Use the value of the nearest ancestor with a non-`auto` value. If no ancestor has a named page value set, the used value for auto is the empty string.

`<custom-ident>`

Case-sensitive name defined in a `@page` at-rule.

Formal definition

Initial value	`auto`
Applies to	block-level elements in the normal flow of the root element. User agents may also apply it to other elements like `table-row` elements.
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
page =
  auto           |
  <custom-ident>
```

This syntax reflects the latest standard as per CSS Paged Media Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Named page example

In this example, there are two parts to this HTML; print controls and the content to be printed. The print controls allow the user to select how the `sections` in the `article` will be printed.

```
<!-- print options in a fieldset -->
<fieldset id="printStyle">
  <legend>How would you like to print</legend>
  <label for="single">
    <input type="radio" id="single" name="type" value="single" checked />
    No Pages
  </label>
  <label for="grouped">
    <input type="radio" id="grouped" name="type" value="grouped" />Pages with
    Grouped Chapters
  </label>
  <label for="paged">
    <input type="radio" id="paged" name="type" value="paged" />
    Chapters Paged
  </label>
  <button id="print">Print</button>
</fieldset>

<!-- Content to be printed -->
<article id="print-area" data-print="single">
  <section id="toc">
    <h2>Table of contents</h2>
    <ul>
      <li>Foreword</li>
      <li>Introduction</li>
      <li>Chapter One - named pages</li>
      <li>Chapter Two - page orientation</li>
      <li>Chapter Three - page margins</li>
      <li>Conclusion</li>
    </ul>
  </section>
  <section id="foreword">
    <h2>Foreword</h2>
    <p>
      This book is all about how the CSS <code>@page</code> at-rule can help
      with printing HTML books.
    </p>
  </section>
  <section id="introduction">
    <h2>Introduction</h2>
    <p>
      This book is a concept to show how an <em>HTML</em> document can easily be
      printed out in pages.
    </p>
  </section>
  <section id="chapter1" class="chapter">
    <h2>Named pages</h2>
    <p>Lorem ipsum</p>
  </section>
  <section id="chapter2" class="chapter">
    <h2>Page Orientation</h2>
    <p>Lorem ipsum</p>
  </section>
  <section id="chapter3" class="chapter">
    <h2>Page Margins</h2>
    <p>There are 16 page margins that can be set:</p>
    <ul>
      <li>@top-left-corner</li>
      <li>@top-left</li>
      <li>@top-center</li>
      <li>@top-right</li>
      <li>@top-right-corner</li>
      <li>@left-top</li>
      <li>@left-middle</li>
      <li>@left-bottom</li>
      <li>@right-top</li>
      <li>@right-middle</li>
      <li>@right-bottom</li>
      <li>@bottom-left-corner</li>
      <li>@bottom-left</li>
      <li>@bottom-center</li>
      <li>@bottom-right</li>
      <li>@bottom-right-corner</li>
    </ul>
    <p>They can be used to show what appears in these parts of the margin</p>
  </section>
  <section id="conclusion">
    <h2>Conclusion</h2>
    <p>Now go ahead and write books.</p>
  </section>
</article>
```

The first part of the CSS sets up the **named** pages, these include the size and orientation and also some content to go in the `@top-center` margin of the printed pages.

```
@page toc {
  size: a4 portrait;
  @top-center {
    content: "Table of contents";
  }
}

@page foreword {
  size: a4 portrait;
  @top-center {
    content: "Foreword";
  }
```

```
}

@page introduction {
  size: a4 portrait;
  @top-center {
    content: "Introduction";
  }
}

@page conclusion {
  size: a4 portrait;
  @top-center {
    content: "Conclusion";
  }
}

@page chapter {
  size: a4 landscape;
  @top-center {
    content: "Chapter";
  }
}
```

```
fieldset {
  display: flex;
  flex-direction: row;
  justify-content: space-between;
  gap: 1rem;
  width: fit-content;
}
body {
  font: 1.1em sans-serif;
}
```

The next part of the CSS uses attribute selectors to apply the print dimensions, orientation, and margins defined in the named `@page` rules defined in the previous CSS section to elements using the `page` property. The sections with `class="chapter"` are concurrent and appear as one page. The `break-after: page;` is used to split them up, which splits each chapter into a separately printed page.

```
@media print {
  fieldset {
    display: none;
  }
  section {
    font-size: 2rem;
    font-family: "Roboto", sans-serif;
  }
  .chapter {
    border: tomato 2px solid;
  }
  [data-print="grouped"] > #toc,
  [data-print="paged"] > #toc {
    page: toc;
    font-family: "Courier New";
  }
  [data-print="grouped"] > #foreword,
  [data-print="paged"] > #foreword {
    page: foreword;
    font-family: "Courier New";
  }
  [data-print="grouped"] > #introduction,
  [data-print="paged"] > #introduction {
    page: introduction;
    font-family: "Courier New";
  }
  [data-print="grouped"] > #conclusion,
  [data-print="paged"] > #conclusion {
    page: conclusion;
    font-family: "Courier New";
  }
  [data-print="grouped"] > .chapter,
  [data-print="paged"] > .chapter {
    page: chapter;
  }
  [data-print="paged"] > .chapter {
    border: none;
    break-after: page;
  }
  .chapter > ul {
    columns: 2;
  }
}
```

The JavaScript updates the value of the `data-print` attribute, which is the attribute on which the named page is applied, when you select a different printing option:

```
const printArea = document.querySelector("#print-area");
const printButton = document.querySelector("#print");
const printOption = document.querySelector("#printStyle");

printOption.addEventListener("change", (event) => {
  if (event.target.value === "single") {
    printArea.dataset.print = "single";
  } else if (event.target.value === "grouped") {
    printArea.dataset.print = "grouped";
  } else {
    printArea.dataset.print = "paged";
  }
});

printButton.addEventListener("click", () => {
  window.print();
});
```

What is printed, and what is shown in the print preview dialog, will change depending on which print style radio button is selected:

page-break-after CSS property

> **Warning:** This property has been replaced by the `break-after` property.

The **`page-break-after`** CSS property adjusts page breaks *after* the current element.

Try it

```
page-break-after: auto;
```

```
page-break-after: always;
```

```
<div>
  <p>
    The effect of this property can be noticed when the document is being
    printed or a preview of a print is displayed.
  </p>
  <button id="print-btn">Show Print Preview</button>
  <div class="box-container">
    <div class="box">Content before the property</div>
    <div class="box" id="example-element">Content with 'page-break-after'</div>
    <div class="box">Content after the property</div>
  </div>
</div>
```

```
.box {
  border: solid #5b6dcd 5px;
  background-color: #5b6dcd;
  margin: 10px 0;
  padding: 5px;
}

#example-element {
  border: solid 5px #ffc129;
  background-color: #ffc129;
  color: black;
}
```

```
const btn = document.getElementById("print-btn");

btn.addEventListener("click", () => {
  window.print();
});
```

Syntax

```
/* Keyword values */
page-break-after: auto;
page-break-after: always;
page-break-after: avoid;
page-break-after: left;
page-break-after: right;
page-break-after: recto;
page-break-after: verso;

/* Global values */
page-break-after: inherit;
page-break-after: initial;
page-break-after: revert;
page-break-after: revert-layer;
page-break-after: unset;
```

This property applies to block elements that generate a box. It won't apply on an empty `<div>` that won't generate a box.

Values

`auto`

Initial value. Automatic page breaks (neither forced nor forbidden).

`always`

Always force page breaks after the element.

`avoid`

Avoid page breaks after the element.

`left`

Force page breaks after the element so that the next page is formatted as a left page. It's the page placed on the left side of the spine of the book or the back side of the page in duplex printing.

`right`

Force page breaks after the element so that the next page is formatted as a right page. It's the page placed on the right side of the spine of the book or the front side of the page in duplex printing.

`recto`

If pages progress left-to-right, then this acts like `right`. If pages progress right-to-left, then this acts like `left`.

`verso`

If pages progress left-to-right, then this acts like `left`. If pages progress right-to-left, then this acts like `right`.

Page break aliases

The `page-break-after` property is now a legacy property, replaced by `break-after`.

For compatibility reasons, `page-break-after` should be treated by browsers as an alias of `break-after`. This ensures that sites using `page-break-after` continue to work as designed. A subset of values should be aliased as follows:

page-break-after	break-after
auto	auto
left	left
right	right
avoid	avoid
always	page

Formal definition

Initial value	auto
Applies to	block-level elements in the normal flow of the root element. User agents may also apply it to other elements like `table-row` elements.
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
page-break-after =
  auto     |
  always   |
  avoid    |
  left     |
  right    |
  inherit
```

This syntax reflects the latest standard as per Cascading Style Sheets Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting a page break after footnotes

```
/* move to a new page after footnotes */
div.footnotes {
  page-break-after: always;
}
```

page-break-before CSS property

> **Warning:** This property has been replaced by the `break-before` property.

The **`page-break-before`** CSS property adjusts page breaks *before* the current element.

This property applies to block elements that generate a box. It won't apply on an empty `<div>` that won't generate a box.

Try it

```
page-break-before: auto;
```

```
page-break-before: always;
```

```
<div>
  <p>
    The effect of this property can be noticed when the document is being
    printed or a preview of a print is displayed.
  </p>
  <button id="print-btn">Show Print Preview</button>
  <div class="box-container">
    <div class="box">Content before the property</div>
    <div class="box" id="example-element">Content with 'page-break-before'</div>
    <div class="box">Content after the property</div>
  </div>
</div>
```

```
.box {
  border: solid #5b6dcd 5px;
  background-color: #5b6dcd;
  margin: 10px 0;
  padding: 5px;
}

#example-element {
  border: solid 5px #ffc129;
  background-color: #ffc129;
  color: black;
}
```

```
const btn = document.getElementById("print-btn");

btn.addEventListener("click", () => {
  window.print();
});
```

Syntax

```
/* Keyword values */
page-break-before: auto;
page-break-before: always;
page-break-before: avoid;
page-break-before: left;
page-break-before: right;
page-break-before: recto;
page-break-before: verso;

/* Global values */
page-break-before: inherit;
page-break-before: initial;
page-break-before: revert;
page-break-before: revert-layer;
page-break-before: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

Initial value. Automatic page breaks (neither forced nor forbidden).

`always`

Always force page breaks before the element.

`avoid`

Avoid page breaks before the element.

`left`

Force page breaks before the element so that the next page is formatted as a left page. It's the page placed on the left side of the spine of the book or the back side of the page in duplex printing.

`right`

Force page breaks before the element so that the next page is formatted as a right page. It's the page placed on the right side of the spine of the book or the front side of the page in duplex printing.

`recto`

If pages progress left-to-right, then this acts like `right`. If pages progress right-to-left, then this acts like `left`.

`verso`

If pages progress left-to-right, then this acts like `left`. If pages progress right-to-left, then this acts like `right`.

Page break aliases

The `page-break-before` property is now a legacy property, replaced by `break-before`.

For compatibility reasons, `page-break-before` should be treated by browsers as an alias of `break-before`. This ensures that sites using `page-break-before` continue to work as designed. A subset of values should be aliased as follows:

page-break-before	break-before
`auto`	`auto`
`left`	`left`
`right`	`right`
`avoid`	`avoid`
`always`	`page`

Formal definition

Initial value	`auto`
Applies to	block-level elements in the normal flow of the root element. User agents may also apply it to other elements like `table-row` elements.
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
page-break-before =
  auto    |
  always  |
  avoid   |
  left    |
  right   |
  inherit
```

This syntax reflects the latest standard as per Cascading Style Sheets Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Avoid a page break before an element

```
/* Avoid page break before div elements of class note */
div.note {
  page-break-before: avoid;
}
```

page-break-inside CSS property

> **Warning:** This property has been replaced by the break-inside property.

The **page-break-inside** CSS property adjusts page breaks *inside* the current element.

Try it

```
page-break-inside: auto;
```

```
page-break-inside: avoid;
```

```
<div>
  <p>
    The effect of this property can be noticed when the document is being
    printed or a preview of a print is displayed.
  </p>
  <button id="print-btn">Show Print Preview</button>
  <div class="box-container">
    <div class="box">Content before the property</div>
    <div class="box" id="example-element">Content with 'page-break-inside'</div>
    <div class="box">Content after the property</div>
  </div>
</div>
```

```
.box {
  border: solid #5b6dcd 5px;
  background-color: #5b6dcd;
  margin: 10px 0;
  padding: 5px;
}

#example-element {
  border: solid 5px #ffc129;
  background-color: #ffc129;
  color: black;
}

@media print {
  #example-element {
    height: 25cm;
  }
}
```

```
const btn = document.getElementById("print-btn");

btn.addEventListener("click", () => {
  window.print();
});
```

Syntax

```
/* Keyword values */
page-break-inside: auto;
page-break-inside: avoid;

/* Global values */
page-break-inside: inherit;
page-break-inside: initial;
page-break-inside: revert;
page-break-inside: revert-layer;
page-break-inside: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

Initial value. Automatic page breaks (neither forced nor forbidden).

`avoid`

Avoid page breaks inside the element.

Page break aliases

The `page-break-inside` property is now a legacy property, replaced by `break-inside`.

For compatibility reasons, `page-break-inside` should be treated by browsers as an alias of `break-inside`. This ensures that sites using `page-break-inside` continue to work as designed. A subset of values should be aliased as follows:

page-break-inside	break-inside
auto	auto
avoid	avoid

Formal definition

Initial value	auto
Applies to	block-level elements in the normal flow of the root element. User agents may also apply it to other elements like `table-row` elements.
Inherited	no

Computed value	as specified
Animation type	discrete

Formal syntax

```
page-break-inside =
  avoid    |
  auto     |
  inherit
```

This syntax reflects the latest standard as per Cascading Style Sheets Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Avoiding page breaks inside elements

HTML

```
<div class="page">
  <p>This is the first paragraph.</p>
  <section class="list">
    <span>A list</span>
    <ol>
      <li>one</li>
      <!-- <li>two</li> -->
    </ol>
  </section>
  <ul>
    <li>one</li>
    <!-- <li>two</li> -->
  </ul>
  <p>This is the second paragraph.</p>
  <p>This is the third paragraph, it contains more text.</p>
  <p>
    This is the fourth paragraph. It has a little bit more text than the third
    one.
  </p>
</div>
```

CSS

```
.page {
  background-color: #8cffa0;
  height: 90px;
  width: 200px;
  columns: 1;
  column-width: 100px;
}

.list,
ol,
ul,
p {
  break-inside: avoid;
}

p {
  background-color: #8ca0ff;
}

ol,
ul,
.list {
  margin: 0.5em 0;
  display: block;
  background-color: orange;
}

p:first-child {
  margin-top: 0;
}
```

- orphans, widows

paint-order CSS property

The **`paint-order`** CSS property lets you control the order in which the fill and stroke (and painting markers) of text content and shapes are drawn.

Syntax

```
/* Normal */
paint-order: normal;

/* Single values */
paint-order: stroke; /* draw the stroke first, then fill and markers */
paint-order: markers; /* draw the markers first, then fill and stroke */

/* Multiple values */
paint-order: stroke fill; /* draw the stroke first, then the fill, then the markers */
paint-order: markers stroke fill; /* draw markers, then stroke, then fill */

/* Global values */
paint-order: inherit;
paint-order: initial;
```

```
paint-order: revert;
paint-order: revert-layer;
paint-order: unset;
```

If no value is specified, the default paint order is `fill`, `stroke`, `markers`.

When one value is specified, that one is painted first, followed by the other two in their default order relative to one another. When two values are specified, they will be painted in the order they are specified in, followed by the unspecified one.

> **Note:** In the case of this property, markers are only appropriate when drawing SVG shapes involving the use of the `marker-*` properties (e.g., `marker-start`) and `<marker>` element. They do not apply to HTML text, so in that case, you can only determine the order of `stroke` and `fill`.

Values

`normal`

Paint the different items in normal paint order.

`stroke`, `fill`, `markers`

Specify some or all of these values in the order you want them to be painted in.

Formal definition

Initial value	`normal`
Applies to	text elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
paint-order =
  normal                        |
  [ fill || stroke || markers ]
```

This syntax reflects the latest standard as per CSS Specification. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Reversing the paint order of stroke and fill

SVG

```
<svg xmlns="http://www.w3.org/2000/svg" width="400" height="200">
  <text x="10" y="75">stroke in front</text>
  <text x="10" y="150" class="stroke-behind">stroke behind</text>
</svg>
```

CSS

```
text {
  font-family: sans-serif;
  font-size: 50px;
  font-weight: bold;
  fill: black;
  stroke: red;
  stroke-width: 4px;
}

.stroke-behind {
  paint-order: stroke fill;
}
```

Result

Reversing the paint order of stroke and fill using HTML

To control the fill and stroke order in HTML, you can use the `-webkit-text-stroke-color` and `-webkit-text-stroke-width` CSS properties.

HTML

```
<div>stroke in front</div>
<div class="stroke-behind">stroke behind</div>
```

CSS

```
div {
  font-family: sans-serif;
  font-size: 50px;
  font-weight: bold;
  fill: black;
  padding-top: 10px;
  padding-bottom: 10px;
  -webkit-text-stroke-color: red;
  -webkit-text-stroke-width: 4px;
}

.stroke-behind {
  paint-order: stroke fill;
}
```

Result

path-length CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`path-length`** CSS property specifies a total path length, in user units. All path computations are then scaled using the ratio `path-length` / *(computed value of path length)* — this includes text paths, animation paths, and various stroke operations.

The `path-length` property only applies to `<circle>`, `<ellipse>`, `<line>`, `<path>`, `<polygon>`, `<polyline>`, and `<rect>` elements nested in an `<svg>`.

> **Note:** If present, the `path-length` CSS property overrides an SVG element's `pathLength` attribute. This property doesn't apply to SVG, HTML, or pseudo-elements other than those listed above.

Syntax

```
/* Keyword value */
path-length: none;

/* <length> values */
path-length: 0;
path-length: 70px;
path-length: 500px;

/* Global values */
path-length: inherit;
path-length: initial;
path-length: revert;
path-length: revert-layer;
path-length: unset;
```

Values

`none`

No author path length is specified and the user agent's own computed path length is used for all path-related calculations.

`<length>`

A non-negative `<length>` representing an author-defined total path length.

Formal definition

Initial value	none
Applies to	The SVG `<path>`, `<circle>`, `<ellipse>`, `<line>`, `<polygon>`, `<polyline>`, and `<rect>` elements.
Inherited	no
Computed value	The keyword `none` or an absolute length.
Animation type	by computed value

Formal syntax

```
path-length =
  none                |
  <length> [ 0 , ∞ ]
```

This syntax reflects the latest standard as per CSS Specification. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example defines a path and shows how to apply a path length to it using the `path-length` CSS property.

SVG

Our SVG defines a single curved `<path>` element with a colored `stroke`. It includes a `stroke-dasharray` attribute that defines a regular dashed pattern for the stroke.

```
<svg viewBox="0 0 600 200">
  <path
    d="M 30 100 C 150 20, 250 180, 380 100 S 520 20, 570 100"
    fill="none"
    stroke="#D85A30"
    stroke-width="4"
    stroke-dasharray="24 24"></path>
</svg>
```

CSS

We set a `path-length` value on the `<path>`:

```
path {
  path-length: 500px;
}
```

Results

Setting a large `path-length` value results in the dashes becoming smaller and more frequent.

Animating <code>path-length</code>

One major advantage of making `path-length` available as a CSS property is that you can apply standard CSS functionality such as animations and transitions to it. This example builds on the previous one, showing how to animate a `path-length` with a CSS animation.

HTML and SVG

This example includes the same SVG `<path>` as the previous one. In addition, it includes an `<input type="range">` element that can be used to change the value of `path-length` applied to the `<path>` at runtime. We also include an `<output>` element to display the current slider value.

```
<div>
  <label for="path-slider">Adjust path-length</label>
  <input type="range" id="path-slider" min="0" max="800" value="200" />
  <output>200</output>
</div>
```

CSS

On the `:root` element, we define a CSS custom property called `--path-length` and give it an initial value of `200px`. We then set the `<path>` element's `path-length` value to the `--path-length` property, and set an `animation` on it that runs an infinite number of times and alternates between forwards and backwards.

```
:root {
  --path-length: 200px;
}

path {
  path-length: var(--path-length);
  animation: path-length-anim 2s alternate infinite ease-in-out;
}
```

```
div {
  position: fixed;
  bottom: 0;
  left: 0;
  display: flex;
  align-items: center;
}
```

Next, we define the `@keyframes` block for the animation — it animates the `path-length` property between the `--path-length` value and the `--path-length` value multiplied by `1.5`.

```
@keyframes path-length-anim {
  from {
    path-length: var(--path-length);
  }

  to {
    path-length: calc(var(--path-length) * 1.5);
  }
}
```

JavaScript

We start our script by grabbing references to the `<input type="range">`, `<output>`, and `:root` elements.

```
const slider = document.querySelector("input");
const output = document.querySelector("output");
const rootElem = document.querySelector(":root");
```

Next, we add an `input` event handler to the range slider so that, when its value is changed, the `<output>` element's `textContent` and the value of the `--path-length` custom property are set to equal the slider's new value.

```
slider.addEventListener("input", () => {
  output.textContent = `${slider.value}px`;
  rootElem.style.setProperty("--path-length", `${slider.value}px`);
});
```

Results

Adjust the slider, and note how larger values result in a smaller dash size.

- SVG `pathLength` attribute

perspective CSS property

The **`perspective`** CSS property determines the distance between the z=0 plane and the user in order to give a 3D-positioned element some perspective.

Try it

```
perspective: none;
```

```
perspective: 800px;
```

```
perspective: 23rem;
```

```
perspective: 5.5cm;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    <div class="face front">1</div>
    <div class="face back">2</div>
    <div class="face right">3</div>
    <div class="face left">4</div>
    <div class="face top">5</div>
    <div class="face bottom">6</div>
```

```
  </div>
</section>
```

```
#default-example {
  background: linear-gradient(skyblue, khaki);
  perspective: 800px;
  perspective-origin: 150% 150%;
}

#example-element {
  width: 100px;
  height: 100px;
  perspective: 550px;
  transform-style: preserve-3d;
}

.face {
  display: flex;
  align-items: center;
  justify-content: center;
  width: 100%;
  height: 100%;
  position: absolute;
  backface-visibility: inherit;
  font-size: 60px;
  color: white;
}

.front {
  background: rgb(90 90 90 / 0.7);
  transform: translateZ(50px);
}

.back {
  background: rgb(0 210 0 / 0.7);
  transform: rotateY(180deg) translateZ(50px);
}

.right {
  background: rgb(210 0 0 / 0.7);
  transform: rotateY(90deg) translateZ(50px);
}

.left {
  background: rgb(0 0 210 / 0.7);
  transform: rotateY(-90deg) translateZ(50px);
}

.top {
  background: rgb(210 210 0 / 0.7);
  transform: rotateX(90deg) translateZ(50px);
}

.bottom {
  background: rgb(210 0 210 / 0.7);
  transform: rotateX(-90deg) translateZ(50px);
}
```

Syntax

```
/* Keyword value */
perspective: none;

/* <length> values */
perspective: 20px;
perspective: 3.5em;

/* Global values */
perspective: inherit;
perspective: initial;
perspective: revert;
perspective: revert-layer;
perspective: unset;
```

Values

`none`

Indicates that no perspective transform is to be applied.

`<length>`

A `<length>` giving the distance from the user to the z=0 plane. It is used to apply a perspective transform to the children of the element. Negative values are syntax errors. If the value is smaller than `1px`, it is clamped to `1px`.

Description

Each 3D element with z>0 becomes larger; each 3D-element with z<0 becomes smaller. The strength of the effect is determined by the value of this property. Large values of `perspective` cause a small transformation; small values of `perspective` cause a large transformation.

The parts of the 3D elements that are behind the user — i.e., their z-axis coordinates are greater than the value of the `perspective` CSS property — are not drawn.

The *vanishing point* is by default placed at the center of the element, but its position can be changed using the `perspective-origin` property.

Using this property with a value other than `none` creates a new stacking context. Also, in that case, the object will act as a containing block for `position: fixed` elements that it contains.

Formal definition

Initial value	none
Applies to	transformable elements

Inherited	no
Computed value	the absolute length or none
Animation type	a length
Creates stacking context	yes

Formal syntax

```
perspective =
  none            |
  <length [0,∞]>
```

This syntax reflects the latest standard as per CSS Transforms Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting perspective

An example showing how a cube varies if the `perspective` is set at different positions is given in Using CSS transforms > Setting perspective.

See also

- Using CSS Transforms

perspective-origin CSS property

The **`perspective-origin`** CSS property determines the position at which the viewer is looking. It is used as the *vanishing point* by the `perspective` property.

The **`perspective-origin`** and `perspective` properties are attached to the parent of a child transformed in 3-dimensional space, unlike the `perspective()` transform function which is placed on the element being transformed.

Try it

```
perspective-origin: center;
```

```
perspective-origin: top;
```

```
perspective-origin: bottom right;
```

```
perspective-origin: -170%;
```

```
perspective-origin: 500% 200%;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    <div class="face front">1</div>
    <div class="face back">2</div>
    <div class="face right">3</div>
    <div class="face left">4</div>
    <div class="face top">5</div>
    <div class="face bottom">6</div>
  </div>
</section>
```

```
#default-example {
  background: linear-gradient(skyblue, khaki);
  perspective: 550px;
}

#example-element {
  width: 100px;
  height: 100px;
  transform-style: preserve-3d;
  perspective: 250px;
}

.face {
  display: flex;
  align-items: center;
  justify-content: center;
  width: 100%;
  height: 100%;
  position: absolute;
  backface-visibility: inherit;
  font-size: 60px;
  color: white;
}

.front {
  background: rgb(90 90 90 / 0.7);
  transform: translateZ(50px);
}

.back {
  background: rgb(0 210 0 / 0.7);
  transform: rotateY(180deg) translateZ(50px);
}

.right {
  background: rgb(210 0 0 / 0.7);
  transform: rotateY(90deg) translateZ(50px);
}

.left {
  background: rgb(0 0 210 / 0.7);
  transform: rotateY(-90deg) translateZ(50px);
}
```

```
.top {
  background: rgb(210 210 0 / 0.7);
  transform: rotateX(90deg) translateZ(50px);
}

.bottom {
  background: rgb(210 0 210 / 0.7);
  transform: rotateX(-90deg) translateZ(50px);
}
```

Syntax

```
/* One-value syntax */
perspective-origin: x-position;

/* Two-value syntax */
perspective-origin: x-position y-position;

/* When both x-position and y-position are keywords,
   the following is also valid */
perspective-origin: y-position x-position;

/* Global values */
perspective-origin: inherit;
perspective-origin: initial;
perspective-origin: revert;
perspective-origin: revert-layer;
perspective-origin: unset;
```

Values

x-position

Indicates the position of the abscissa of the *vanishing point*. It can have one of the following values:

- `<length-percentage>` indicating the position as an absolute length value or relative to the width of the element. The value may be negative.
- `left`, a keyword being a shortcut for the `0` length value.
- `center`, a keyword being a shortcut for the `50%` percentage value.
- `right`, a keyword being a shortcut for the `100%` percentage value.

y-position

Indicates the position of the ordinate of the *vanishing point*. It can have one of the following values:

- `<length-percentage>` indicating the position as an absolute length value or relative to the height of the element. The value may be negative.
- `top`, a keyword being a shortcut for the `0` length value.
- `center`, a keyword being a shortcut for the `50%` percentage value.
- `bottom`, a keyword being a shortcut for the `100%` percentage value.

Formal definition

Initial value	`50% 50%`
Applies to	transformable elements
Inherited	no
Percentages	refer to the size of bounding box
Computed value	for `<length>` the absolute value, otherwise a percentage
Animation type	simple list of length, percentage, or calc

Formal syntax

```
perspective-origin =
  <position>

<position> =
  <position-one>   |
  <position-two>   |
  <position-four>

<position-one> =
  left                |
  center              |
  right               |
  top                 |
  bottom              |
  x-start             |
  x-end               |
  y-start             |
  y-end               |
  block-start         |
  block-end           |
  inline-start        |
  inline-end          |
  <length-percentage>

<position-two> =
  [ left | center | right | x-start | x-end ] && [ top | center | bottom | y-start | y-end ]  |
  [ left | center | right | x-start | x-end | <length-percentage> ] [ top | center | bottom | y-start | y-end | <length-percentage> ]  |
  [ block-start | center | block-end ] && [ inline-start | center | inline-end ]  |
  [ start | center | end ]{2}

<position-four> =
  [ [ left | right | x-start | x-end ] <length-percentage> ] && [ [ top | bottom | y-start | y-end ] <length-percentage> ]  |
  [ [ block-start | block-end ] <length-percentage> ] && [ [ inline-start | inline-end ] <length-percentage> ]  |
  [ [ start | end ] <length-percentage> ]{2}

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Transforms Module Level 2, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Changing the perspective origin

An example showing how to change `perspective-origin` is given in Using CSS transforms > Changing the perspective origin.

- `<transform-function>`
- `perspective`
- `transform: perspective()` function

place-content CSS property

The **`place-content`** CSS shorthand property allows you to align content along both the block and inline directions at once (i.e., the `align-content` and `justify-content` properties) in a relevant layout system such as Grid or Flexbox.

Try it

```
place-content: end space-between;
```

```
place-content: space-around start;
```

```
place-content: start space-evenly;
```

```
place-content: end center;
```

```
place-content: end;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">
      <div>One</div>
      <div>Two</div>
      <div>Three</div>
    </div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-template-columns: 60px 60px;
  grid-auto-rows: 40px;
  height: 180px;
  width: 220px;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `align-content`
- `justify-content`

Syntax

```
/* Positional alignment */
/* align-content does not take left and right values */
place-content: center start;
place-content: start center;
place-content: end left;
place-content: flex-start center;
place-content: flex-end center;

/* Baseline alignment */
/* justify-content does not take baseline values */
place-content: baseline center;
place-content: first baseline space-evenly;
place-content: last baseline right;

/* Distributed alignment */
place-content: space-between space-evenly;
place-content: space-around space-evenly;
place-content: space-evenly stretch;
place-content: stretch space-evenly;

/* Global values */
place-content: inherit;
place-content: initial;
place-content: revert;
place-content: revert-layer;
place-content: unset;
```

The first value is the `align-content` property value, the second the `justify-content` one.

> **Note:** If the second value is not present, the first value is used for both, provided it is a valid value for both. If it is invalid for one or the other, the whole value will be invalid.

Values

`start`

The items are packed flush to each other toward the start edge of the alignment container in the appropriate axis.

`end`

The items are packed flush to each other toward the end edge of the alignment container in the appropriate axis.

`flex-start`

The items are packed flush to each other toward the edge of the alignment container depending on the flex container's main-start or cross-start side. This only applies to flex layout items. For items that are not children of a flex container, this value is treated like `start`.

`flex-end`

The items are packed flush to each other toward the edge of the alignment container depending on the flex container's main-end or cross-end side. This only applies to flex layout items. For items that are not children of a flex container, this value is treated like `end`.

`center`

The items are packed flush to each other toward the center of the alignment container.

`left`

The items are packed flush to each other toward the left edge of the alignment container. If the property's axis is not parallel with the inline axis, this value behaves like `start`.

`right`

The items are packed flush to each other toward the right edge of the alignment container in the appropriate axis. If the property's axis is not parallel with the inline axis, this value behaves like `start`.

`space-between`

The items are evenly distributed within the alignment container. The spacing between each pair of adjacent items is the same. The first item is flush with the main-start edge, and the last item is flush with the main-end edge.

`baseline`, `first baseline`, `last baseline`

Specifies participation in first- or last-baseline alignment: aligns the alignment baseline of the box's first or last baseline set with the corresponding baseline in the shared first or last baseline set of all the boxes in its baseline-sharing group. The fallback alignment for `first baseline` is `start`, the one for `last baseline` is `end`.

`space-around`

The items are evenly distributed within the alignment container. The spacing between each pair of adjacent items is the same. The empty space before the first and after the last item equals half of the space between each pair of adjacent items.

`space-evenly`

The items are evenly distributed within the alignment container. The spacing between each pair of adjacent items, the main-start edge and the first item, and the main-end edge and the last item, are all exactly the same.

`stretch`

If the combined size of the items is less than the size of the alignment container, any `auto`-sized items have their size increased equally (not proportionally), while still respecting the constraints imposed by `max-height`/`max-width` (or equivalent functionality), so that the combined size exactly fills the alignment container

`safe`

Used alongside an alignment keyword. If the chosen keyword means that the item overflows the alignment container causing data loss, the item is instead aligned as if the alignment mode were `start`.

`unsafe`

Used alongside an alignment keyword. Regardless of the relative sizes of the item and alignment container, and regardless of whether overflow which causes data loss might happen, the given alignment value is honored.

Formal definition

Initial value	as each of the properties of the shorthand: • `align-content`: `normal` • `justify-content`: `normal`
Applies to	multi-line flex containers
Inherited	no
Computed value	as each of the properties of the shorthand: • `align-content`: as specified • `justify-content`: as specified
Animation type	discrete

Formal syntax

```
place-content =
  <'align-content'> <'justify-content'>?

<align-content> =
  normal                                |
  <baseline-position>                   |
  <content-distribution>                |
  <overflow-position>? <content-position>

<justify-content> =
  normal                                          |
  <content-distribution>                          |
```

```
  <overflow-position>? [ <content-position> | left | right ]

<baseline-position> =
  [ first | last ]?  &&
  baseline

<content-distribution> =
  space-between  |
  space-around   |
  space-evenly   |
  stretch

<overflow-position> =
  unsafe  |
  safe

<content-position> =
  center      |
  start       |
  end         |
  flex-start  |
  flex-end
```

This syntax reflects the latest standard as per CSS Box Alignment Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Placing content in a flex container

HTML

```
<div id="container">
  <div class="small">Lorem</div>
  <div class="small">Lorem<br />ipsum</div>
  <div class="large">Lorem</div>
  <div class="large">Lorem<br />ipsum</div>
  <div class="large"></div>
  <div class="large"></div>
</div>
```

```
<code>writing-mode:</code
><select id="writingMode">
  <option value="horizontal-tb" selected>horizontal-tb</option>
  <option value="vertical-rl">vertical-rl</option>
  <option value="vertical-lr">vertical-lr</option>
  <option value="sideways-rl">sideways-rl</option>
  <option value="sideways-lr">sideways-lr</option></select
><code>;</code><br />

<code>direction:</code
><select id="direction">
  <option value="ltr" selected>ltr</option>
  <option value="rtl">rtl</option></select
><code>;</code><br />

<code>place-content:</code
><select id="alignContentAlignment">
  <option value="normal">normal</option>
  <option value="first baseline">first baseline</option>
  <option value="last baseline">last baseline</option>
  <option value="baseline">baseline</option>
  <option value="space-between">space-between</option>
  <option value="space-around">space-around</option>
  <option value="space-evenly" selected>space-evenly</option>
  <option value="stretch">stretch</option>
  <option value="center">center</option>
  <option value="start">start</option>
  <option value="end">end</option>
  <option value="flex-start">flex-start</option>
  <option value="flex-end">flex-end</option>
  <option value="safe">safe</option>
  <option value="unsafe">unsafe</option>
</select>
<select id="justifyContentAlignment">
  <option value="normal">normal</option>
  <option value="space-between">space-between</option>
  <option value="space-around">space-around</option>
  <option value="space-evenly">space-evenly</option>
  <option value="stretch">stretch</option>
  <option value="center" selected>center</option>
  <option value="start">start</option>
  <option value="end">end</option>
  <option value="flex-start">flex-start</option>
  <option value="flex-end">flex-end</option>
  <option value="left">left</option>
  <option value="right">right</option>
  <option value="safe">safe</option>
  <option value="unsafe">unsafe</option></select
><code>;</code>
```

```
function update() {
  document.getElementById("container").style.placeContent =
    `${document.getElementById("alignContentAlignment").value} ` +
    `${document.getElementById("justifyContentAlignment").value}`;
}

const alignContentAlignment = document.getElementById("alignContentAlignment");
alignContentAlignment.addEventListener("change", update);

const justifyContentAlignment = document.getElementById(
  "justifyContentAlignment",
);
justifyContentAlignment.addEventListener("change", update);
```

```
const writingM = document.getElementById("writingMode");
writingM.addEventListener("change", (evt) => {
  document.getElementById("container").style.writingMode = evt.target.value;
});

const direction = document.getElementById("direction");
direction.addEventListener("change", (evt) => {
  document.getElementById("container").style.direction = evt.target.value;
});
```

CSS

```
#container {
  display: flex;
  height: 240px;
  width: 240px;
  flex-wrap: wrap;
  background-color: #8c8c8c;
  writing-mode: horizontal-tb; /* Can be changed in the live sample */
  direction: ltr; /* Can be changed in the live sample */
  place-content: flex-end center; /* Can be changed in the live sample */
}

div > div {
  border: 2px solid #8c8c8c;
  width: 50px;
  background-color: #a0c8ff;
}

.small {
  font-size: 12px;
  height: 40px;
}

.large {
  font-size: 14px;
  height: 50px;
}
```

Result

- Aligning items in a flex container
- Box alignment in grid layout
- CSS box alignment module

place-items CSS property

The **`place-items`** CSS shorthand property aligns items along both block and inline directions at the same time.

Try it

```
place-items: center stretch;
```

```
place-items: center start;
```

```
place-items: start end;
```

```
place-items: end center;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">
      <div>One</div>
      <div>Two</div>
      <div>Three</div>
    </div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-template-columns: 1fr 1fr;
  grid-auto-rows: 80px;
  grid-gap: 10px;
  width: 220px;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `align-items`
- `justify-items`

Syntax

```
/* Positional alignment */
place-items: center;
place-items: normal start;
place-items: center normal;
place-items: start legacy;
place-items: end normal;
place-items: self-start legacy;
place-items: self-end normal;
place-items: flex-start legacy;
place-items: flex-end normal;
place-items: anchor-center;

/* Baseline alignment */
place-items: baseline normal;
place-items: first baseline legacy;
place-items: last baseline normal;
place-items: stretch legacy;

/* Global values */
place-items: inherit;
place-items: initial;
place-items: revert;
place-items: revert-layer;
place-items: unset;
```

Values

This property is specified as one or two space-separated values of the following types, in the order listed:

`align-items`

Specifies the alignment in the block direction.

`justify-items` Optional

Specifies the alignment in the inline direction. If omitted, the `align-items` value is used.

Description

The `place-items` shorthand property sets `align-items` and `justify-items` in a single declaration, aligning items along both the block and inline directions.

If only one value is provided, the value is used to set alignment in both block and inline directions. If two values are provided, the first value is the `align-items` value, setting the alignment in the block direction, and the second value is the `justify-items` value, setting alignment in the inline direction.

Formal definition

Initial value	as each of the properties of the shorthand: • `align-items`: `normal` • `justify-items`: `legacy`
Applies to	all elements
Inherited	no
Computed value	as each of the properties of the shorthand: • `align-items`: as specified • `justify-items`: as specified
Animation type	discrete

Formal syntax

```
place-items =
  <'align-items'> <'justify-items'>?

<align-items> =
  normal                                |
  stretch                               |
  <baseline-position>                   |
  <overflow-position>? <self-position>

<justify-items> =
  normal                                            |
  stretch                                           |
  <baseline-position>                               |
  <overflow-position>? [ <self-position> | left | right ]  |
  legacy                                            |
  legacy && [ left | right | center ]

<baseline-position> =
  [ first | last ]?  &&
  baseline

<overflow-position> =
  unsafe  |
  safe

<self-position> =
  center      |
  start       |
  end         |
  self-start  |
  self-end    |
  flex-start  |
  flex-end
```

This syntax reflects the latest standard as per CSS Box Alignment Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Placing items in a flex container

In flexbox `justify-self` or `justify-items` do not apply, as on the main axis items are treated as a group. Therefore, the second value will be ignored.

```
div > div {
  box-sizing: border-box;
  border: 2px solid #8c8c8c;
  width: 50px;
  display: flex;
  align-items: center;
  justify-content: center;
}

#item1 {
  background-color: #8cffa0;
  min-height: 30px;
  font-size: 2em;
}

#item2 {
  background-color: #a0c8ff;
  min-height: 50px;
}

#item3 {
  background-color: #ffa08c;
  min-height: 40px;
}

#item4 {
  background-color: #ffff8c;
  min-height: 60px;
}

#item5 {
  background-color: #ff8cff;
  min-height: 70px;
}

#item6 {
  background-color: #8cffff;
  min-height: 50px;
}

select {
  font-size: 16px;
}

.row {
  margin-top: 10px;
}
```

```
<div id="container">
  <div id="item1">1</div>
  <div id="item2">2</div>
  <div id="item3">3</div>
</div>

<div class="row">
  <label for="values">place-items: </label>
  <select id="values">
    <option value="stretch">stretch</option>
    <option value="start">start</option>
    <option value="center">center</option>
    <option value="end">end</option>
    <option value="left">left</option>
    <option value="right">right</option>
    <option value="auto center">auto center</option>
    <option value="normal start">normal start</option>
    <option value="center normal">center normal</option>
    <option value="start auto">start auto</option>
    <option value="end normal">end normal</option>
    <option value="self-start auto">self-start auto</option>
    <option value="self-end normal">self-end normal</option>
    <option value="flex-start auto">flex-start auto</option>
    <option value="flex-end normal">flex-end normal</option>
    <option value="left auto">left auto</option>
    <option value="right normal">right normal</option>
    <option value="baseline normal">baseline normal</option>
    <option value="first baseline auto">first baseline auto</option>
    <option value="last baseline normal">last baseline normal</option>
    <option value="stretch auto">stretch auto</option>
  </select>
</div>
```

```
const values = document.getElementById("values");
const container = document.getElementById("container");

values.addEventListener("change", (evt) => {
  container.style.placeItems = evt.target.value;
});
```

CSS

```
#container {
  height: 200px;
  width: 240px;
  place-items: stretch; /* You can change this value by selecting another option in the list */
  background-color: #8c8c8c;
```

```
  display: flex;
}
```

Result

Placing items in a grid container

The following grid container has items which are smaller than the grid areas they are placed in, therefore `place-items` will move them in the block and inline dimensions.

```
div > div {
  box-sizing: border-box;
  border: 2px solid #8c8c8c;
}

#item1 {
  background-color: #8cffa0;
  min-height: 30px;
  font-size: 2em;
}

#item2 {
  background-color: #a0c8ff;
  min-height: 50px;
}

#item3 {
  background-color: #ffa08c;
  min-height: 40px;
}

#item4 {
  background-color: #ffff8c;
  min-height: 60px;
}

#item5 {
  background-color: #ff8cff;
  min-height: 70px;
}

#item6 {
  background-color: #8cffff;
  min-height: 50px;
}

select {
  font-size: 16px;
}

.row {
  margin-top: 10px;
}
```

```
<div id="grid-container">
  <div id="item1">1</div>
  <div id="item2">2</div>
  <div id="item3">3</div>
  <div id="item4">4</div>
  <div id="item5">5</div>
</div>

<div class="row">
  <label for="grid-values">place-items: </label>
  <select id="grid-values">
    <option value="stretch">stretch</option>
    <option value="start">start</option>
    <option value="center">center</option>
    <option value="end">end</option>
    <option value="left">left</option>
    <option value="right">right</option>
    <option value="auto center">auto center</option>
    <option value="normal start">normal start</option>
    <option value="center normal">center normal</option>
    <option value="start auto">start auto</option>
    <option value="end normal">end normal</option>
    <option value="self-start auto">self-start auto</option>
    <option value="self-end normal">self-end normal</option>
    <option value="flex-start auto">flex-start auto</option>
    <option value="flex-end normal">flex-end normal</option>
    <option value="left auto">left auto</option>
    <option value="right normal">right normal</option>
    <option value="baseline normal">baseline normal</option>
    <option value="first baseline auto">first baseline auto</option>
    <option value="last baseline normal">last baseline normal</option>
    <option value="stretch auto">stretch auto</option>
  </select>
</div>
```

```
const values = document.getElementById("grid-values");
const container = document.getElementById("grid-container");

values.addEventListener("change", (evt) => {
  container.style.placeItems = evt.target.value;
});
```

CSS

```
#grid-container {
  height: 200px;
  width: 240px;
  place-items: stretch; /* You can change this value by selecting another option in the list */
```

```
  background-color: #8c8c8c;
  display: grid;
  grid-template-columns: repeat(3, 1fr);
}

#grid-container > div {
  width: 50px;
}
```

place-self CSS property

The **`place-self`** CSS shorthand property allows you to align an individual item in both the block and inline directions at once (i.e., the `align-self` and `justify-self` properties). This property applies to block-level boxes, absolutely-positioned boxes, and grid items. If the second value is not present, the first value is also used for it.

Try it

```
place-self: stretch center;
```

```
place-self: center start;
```

```
place-self: start end;
```

```
place-self: end center;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">One</div>
    <div>Two</div>
    <div>Three</div>
  </div>
</section>
```

```
.example-container {
  border: 1px solid #c5c5c5;
  display: grid;
  width: 220px;
  grid-template-columns: 1fr 1fr;
  grid-auto-rows: 80px;
  grid-gap: 10px;
}

.example-container > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `align-self`
- `justify-self`

Syntax

```
/* Positional alignment */
place-self: auto center;
place-self: normal start;
place-self: center normal;
place-self: start auto;
place-self: end normal;
place-self: self-start auto;
place-self: self-end normal;
place-self: flex-start auto;
place-self: flex-end normal;
place-self: anchor-center;

/* Baseline alignment */
place-self: baseline normal;
place-self: first baseline auto;
place-self: last baseline normal;
place-self: stretch auto;

/* Global values */
place-self: inherit;
place-self: initial;
place-self: revert;
place-self: revert-layer;
place-self: unset;
```

Values

This property is specified as one or two of the following keyword values:

`auto`

Computes to the parent's `align-items` value.

`normal`

The effect of this keyword is dependent of the layout mode we are in:

- In absolutely-positioned layouts, the keyword behaves like `start` on *replaced* absolutely-positioned boxes, and as `stretch` on *all other* absolutely-positioned boxes.
- In static position of absolutely-positioned layouts, the keyword behaves as `stretch`.
- For flex items, the keyword behaves as `stretch`.
- For grid items, this keyword leads to a behavior similar to the one of `stretch`, except for boxes with an aspect ratio or an intrinsic size where it behaves like `start`.
- The property doesn't apply to block-level boxes, and to table cells.

`self-start`

Aligns the items to be flush with the edge of the alignment container corresponding to the item's start side in the cross axis.

`self-end`

Aligns the items to be flush with the edge of the alignment container corresponding to the item's end side in the cross axis.

`flex-start`

The cross-start margin edge of the flex item is flushed with the cross-start edge of the line.

`flex-end`

The cross-end margin edge of the flex item is flushed with the cross-end edge of the line.

`center`

The flex item's margin box is centered within the line on the cross-axis. If the cross-size of the item is larger than the flex container, it will overflow equally in both directions.

`baseline`, `first baseline`. `last baseline`

Specifies participation in first- or last-baseline alignment: aligns the alignment baseline of the box's first or last baseline set with the corresponding baseline in the shared first or last baseline set of all the boxes in its baseline-sharing group. The fallback alignment for `first baseline` is `start`, the one for `last baseline` is `end`.

`stretch`

If the combined size of the items along the cross axis is less than the size of the alignment container and the item is `auto`-sized, its size is increased equally (not proportionally), while still respecting the constraints imposed by `max-height`/`max-width` (or equivalent functionality), so that the combined size of all `auto`-sized items exactly fills the alignment container along the cross axis.

`anchor-center`

In the case of anchor-positioned elements, aligns the item to the center of the associated anchor element in the block and inline direction. See Centering on the anchor using `anchor-center`.

Formal definition

Initial value	as each of the properties of the shorthand: • `align-self`: `auto` • `justify-self`: `auto`
Applies to	block-level boxes, absolutely-positioned boxes, and grid items
Inherited	no
Computed value	as each of the properties of the shorthand: • `align-self`: `auto` computes to itself on absolutely-positioned elements, and to the computed value of `align-items` on the parent (minus any legacy keywords) on all other boxes, or `start` if the box has no parent. Its behavior depends on the layout model, as described for `justify-self`. Otherwise the specified value. • `justify-self`: as specified
Animation type	discrete

Formal syntax

```
place-self =
  <'align-self'> <'justify-self'>?

<align-self> =
  auto                                          |
  <overflow-position>? [ normal | <self-position> ]  |
  stretch                                       |
  <baseline-position>                           |
  anchor-center

<justify-self> =
  auto                                           |
  <overflow-position>? [ normal | <self-position> | left | right ]  |
  stretch                                        |
  <baseline-position>                            |
  anchor-center

<overflow-position> =
  unsafe  |
  safe

<self-position> =
  center      |
  start       |
  end         |
  self-start  |
  self-end    |
  flex-start  |
  flex-end

<baseline-position> =
  [ first | last ]?  &&
  baseline
```

This syntax reflects the latest standard as per CSS Box Alignment Module Level 3, CSS Specification. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic demonstration

In the following example we have a 2 x 2 grid layout. Initially the grid container has `justify-items` and `align-items` values of `stretch` — the defaults — which causes the grid items to stretch across the entire width of their cells.

The second, third, and fourth grid items are then given different values of `place-self`, to show how these override the default placements. These values cause the grid items to span only as wide/tall as their content width/height, and align in different positions across their cells, in the block and inline directions.

HTML

```
<article class="container">
  <span>First</span>
  <span>Second</span>
  <span>Third</span>
  <span>Fourth</span>
</article>
```

CSS

```
html {
  font-family: "Helvetica", "Arial", sans-serif;
  letter-spacing: 1px;
}

article {
  background-color: red;
  display: grid;
  grid-template-columns: 1fr 1fr;
  grid-auto-rows: 80px;
  grid-gap: 10px;
  margin: 20px;
  width: 300px;
}

span:nth-child(2) {
  place-self: start center;
}

span:nth-child(3) {
  place-self: center start;
}

span:nth-child(4) {
  place-self: end;
}

article span {
  background-color: black;
  color: white;
  margin: 1px;
  text-align: center;
}

article,
span {
  padding: 10px;
  border-radius: 7px;
}
```

pointer-events CSS property

The **`pointer-events`** CSS property sets under what circumstances (if any) a particular graphic element can become the target of pointer events.

Try it

```
pointer-events: auto;
```

```
pointer-events: none;
```

```
pointer-events: stroke; /* SVG-only */
```

```
pointer-events: fill; /* SVG-only */
```

```
<section class="flex-column" id="default-example">
  <div id="example-element">
    <p>
      <a href="#">example link</a>
    </p>
    <p>
      <svg viewBox="0 0 100 100" xmlns="http://www.w3.org/2000/svg">
        <a xlink:href="#">
          <circle
            cx="50"
            cy="50"
```

```
            fill="#3E6E84"
            r="40"
            stroke="#ffb500"
            stroke-width="5"></circle>
          <text fill="white" text-anchor="middle" x="50" y="55">SVG</text>
        </a>
      </svg>
    </p>
  </div>
</section>
```

```
#example-element {
  font-weight: bold;
}

#example-element a {
  color: #009e5f;
}

#example-element svg {
  width: 10em;
  height: 10em;
}
```

Syntax

```
/* Keyword values */
pointer-events: auto;
pointer-events: none;

/* Values used in SVGs */
pointer-events: visiblePainted;
pointer-events: visibleFill;
pointer-events: visibleStroke;
pointer-events: visible;
pointer-events: painted;
pointer-events: fill;
pointer-events: stroke;
pointer-events: bounding-box;
pointer-events: all;

/* Global values */
pointer-events: inherit;
pointer-events: initial;
pointer-events: revert;
pointer-events: revert-layer;
pointer-events: unset;
```

The `pointer-events` property is specified as a single keyword chosen from the list of values below.

Values

`auto`

The element behaves as it would if the `pointer-events` property were not specified. In SVG content, this value and the value `visiblePainted` have the same effect.

`none`

The element is generally not the target of pointer events, with the exception of `pointerenter` and `pointerleave` events fired at the element or its descendants. Note that pointer events targeted at descendants (that don't set `pointer-events` to `none`) will still trigger event listeners on this parent element during the event capture and bubble phases.

> **Note:** The `pointerenter` and `pointerleave` events are fired when a pointing device is moved into an element or one of its descendants. So, even if `pointer-events: none` is set on the parent and not set on children, the events are triggered on the parent after the pointer is moved in or out of a descendant.

SVG only (experimental for HTML)

`visiblePainted`

SVG only (experimental for HTML). The element can only be the target of a pointer event when the `visibility` property is set to `visible` and e.g., when a mouse cursor is over the interior (i.e., 'fill') of the element and the `fill` property is set to a value other than `none`, or when a mouse cursor is over the perimeter (i.e., 'stroke') of the element and the `stroke` property is set to a value other than `none`.

`visibleFill`

SVG only. The element can only be the target of a pointer event when the `visibility` property is set to `visible` and when e.g., a mouse cursor is over the interior (i.e., fill) of the element. The value of the `fill` property does not affect event processing.

`visibleStroke`

SVG only. The element can only be the target of a pointer event when the `visibility` property is set to `visible` and e.g., when the mouse cursor is over the perimeter (i.e., stroke) of the element. The value of the `stroke` property does not affect event processing.

`visible`

SVG only (experimental for HTML). The element can be the target of a pointer event when the `visibility` property is set to `visible` and e.g., the mouse cursor is over either the interior (i.e., fill) or the perimeter (i.e., stroke) of the element. The values of the `fill` and `stroke` do not affect event processing.

`painted`

SVG only (experimental for HTML). The element can only be the target of a pointer event when e.g., the mouse cursor is over the interior (i.e., 'fill') of the element and the `fill` property is set to a value other than `none`, or when the mouse cursor is over the perimeter (i.e., 'stroke') of the element and the `stroke` property is set to a value other than `none`. The value of the `visibility` property does not affect event processing.

`fill`

SVG only. The element can only be the target of a pointer event when the pointer is over the interior (i.e., fill) of the element. The values of the `fill` and `visibility` properties do not affect event processing.

`stroke`

SVG only. The element can only be the target of a pointer event when the pointer is over the perimeter (i.e., stroke) of the element. The values of the `stroke` and `visibility` properties do not affect event processing.

`bounding-box`

SVG only. The element can only be the target of a pointer event when the pointer is over the bounding box of the element.

`all`

SVG only (experimental for HTML). The element can only be the target of a pointer event when the pointer is over the interior (i.e., fill) or the perimeter (i.e., stroke) of the element. The values of the `fill`, `stroke`, and `visibility` properties do not affect event processing.

Description

When this property is unspecified, the same characteristics of the `visiblePainted` value apply to SVG content.

In addition to indicating that the element is not the target of pointer events, the value `none` instructs the pointer event to go "through" the element and target whatever is "underneath" that element instead.

Note that preventing an element from being the target of pointer events by using `pointer-events` does *not* necessarily mean that pointer event listeners on that element *cannot* or *will not* be triggered. If one of the element's children has `pointer-events` explicitly set to *allow* that child to be the target of pointer events, then any events targeting that child will pass through the parent as the event travels along the parent chain, and trigger event listeners on the parent as appropriate. Of course any pointer activity at a point on the screen that is covered by the parent but not by the child will not be caught by either the child or the parent (it will go "through" the parent and target whatever is underneath).

Elements with `pointer-events: none` will still receive focus through sequential keyboard navigation using the `Tab` key.

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
pointer-events =
  auto            |
  bounding-box    |
  visiblePainted  |
  visibleFill     |
  visibleStroke   |
  visible         |
  painted         |
  fill            |
  stroke          |
  all             |
  none
```

This syntax reflects the latest standard as per CSS Specification. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Disabling pointer events on all images

This example disables pointer events (clicking, dragging, hovering, etc.) on all images.

```
img {
  pointer-events: none;
}
```

Disabling pointer events on a single link

This example disables pointer events on the link to `http://example.com`.

HTML

```
<ul>
  <li><a href="https://developer.mozilla.org">MDN</a></li>
  <li><a href="http://example.com">example.com</a></li>
</ul>
```

CSS

```
a[href="http://example.com"] {
  pointer-events: none;
}
```

- SVG `visibility` attribute
- `PointerEvent`

position CSS property

The **`position`** CSS property sets how an element is positioned in a document. The `top`, `right`, `bottom`, and `left` physical properties and the `inset-block-start`, `inset-block-end`, `inset-inline-start`, and `inset-inline-end` flow-relative logical properties can be used to determine the final location of positioned elements.

Try it

```
position: static;
```

```
position: relative;
top: 40px;
left: 40px;
```

```
position: absolute;
inset-inline-start: 40px;
inset-block-start: 40px;
```

```
position: sticky;
top: 20px;
```

```
<section class="default-example" id="default-example">
  <div id="example-element-container">
    <p>
      In this demo you can control the <code>position</code> property for the
      yellow box.
    </p>
    <div class="box"></div>
    <div class="box" id="example-element"></div>
    <div class="box"></div>
    <p class="clear">
      To see the effect of <code>sticky</code> positioning, select the
      <code>position: sticky</code> option and scroll this container.
    </p>
    <p>
      The element will scroll along with its container, until it is at the top
      of the container (or reaches the offset specified in <code>top</code>),
      and will then stop scrolling, so it stays visible.
    </p>
    <p>
      The rest of this text is only supplied to make sure the container
      overflows, so as to enable you to scroll it and see the effect.
    </p>
    <hr />
    <p>
      Far out in the uncharted backwaters of the unfashionable end of the
      western spiral arm of the Galaxy lies a small unregarded yellow sun.
      Orbiting this at a distance of roughly ninety-two million miles is an
      utterly insignificant little blue green planet whose ape-descended life
      forms are so amazingly primitive that they still think digital watches are
      a pretty neat idea.
    </p>
  </div>
</section>
```

```
section {
  align-items: flex-start;
  overflow: auto;
}

.box {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
  float: left;
  width: 65px;
  height: 65px;
}

.box + .box {
  margin-left: 10px;
}

.clear {
  clear: both;
  padding-top: 1em;
}

#example-element-container {
  position: relative;
  text-align: left;
}

#example-element {
  background-color: yellow;
  border: 3px solid red;
  z-index: 1;
}
```

Syntax

```
position: static;
position: relative;
position: absolute;
position: fixed;
position: sticky;

/* Global values */
position: inherit;
position: initial;
position: revert;
position: revert-layer;
position: unset;
```

Values

This property is specified as one of the following keyword values:

`static`

The element is positioned according to the Normal Flow of the document. The `top`, `right`, `bottom`, `left`, and `z-index` properties have *no effect*. This is the default value.

`relative`

The element is positioned according to the normal flow of the document, and then offset *relative to itself* based on the values of `top`, `right`, `bottom`, and `left`. The offset does not affect the position of any other elements; thus, the space given for the element in the page layout is the same as if position were `static`.

This value creates a new stacking context when the value of `z-index` is not `auto`. Its effect on `table-*-group`, `table-row`, `table-column`, `table-cell`, and `table-caption` elements is undefined.

`absolute`

The element is removed from the normal document flow, and no space is created for the element in the page layout. The element is positioned relative to its closest positioned ancestor (if any) or to the initial containing block. Its final position is determined by the values of `top`, `right`, `bottom`, and `left`.

This value creates a new stacking context when the value of `z-index` is not `auto`. The margins of absolutely positioned boxes do not collapse with other margins.

`fixed`

The element is removed from the normal document flow, and no space is created for the element in the page layout. The element is positioned relative to its initial containing block, which is the viewport in the case of visual media. Its final position is determined by the values of `top`, `right`, `bottom`, and `left`.

This value always creates a new stacking context. In printed documents, the element is placed in the same position on *every page*.

`sticky`

The element is positioned according to the normal flow of the document, and then offset relative to its *nearest scrolling ancestor* and containing block (nearest block-level ancestor), including table-related elements, based on the values of `top`, `right`, `bottom`, and `left`. The offset does not affect the position of any other elements.

This value always creates a new stacking context. Note that a sticky element "sticks" to its nearest ancestor that has a "scrolling mechanism" (created when `overflow` is `hidden`, `scroll`, `auto`, or `overlay`), even if that ancestor isn't the nearest actually scrolling ancestor.

> **Note:** At least one inset property (`top`, `inset-block-start`, `right`, `inset-inline-end`, etc.) needs to be set to a non-`auto` value for the axis on which the element needs to be made sticky. If both `inset` properties for an axis are set to `auto`, on that axis the `sticky` value will behave as `relative`.

Description

Types of positioning

- A **positioned element** is an element whose computed `position` value is either `relative`, `absolute`, `fixed`, or `sticky`. (In other words, it's anything except `static`.)
- A **relatively positioned element** is an element whose computed `position` value is `relative`. The `top` and `bottom` properties specify the vertical offset from its normal position; the `left` and `right` properties specify the horizontal offset.
- An **absolutely positioned element** is an element whose computed `position` value is `absolute` or `fixed`. The `top`, `right`, `bottom`, and `left` properties specify offsets from the edges of the element's containing block. (The containing block is the ancestor relative to which the element is positioned.) If the element has margins, they are added to the offset. The element establishes a new block formatting context (BFC) for its contents.
- A **stickily positioned element** is an element whose computed `position` value is `sticky`. It's treated as relatively positioned until its containing block crosses a specified threshold (such as setting `top` to value other than auto) within its flow root (or the container it scrolls within), at which point it is treated as "stuck" until meeting the opposite edge of its containing block.

Most of the time, absolutely positioned elements that have `height` and `width` set to `auto` are sized so as to fit their contents. However, non-replaced, absolutely positioned elements can be made to fill the available vertical space by specifying both `top` and `bottom` and leaving `height` unspecified (that is, `auto`). They can likewise be made to fill the available horizontal space by specifying both `left` and `right` and leaving `width` as `auto`.

Except for the case just described (of absolutely positioned elements filling the available space):

- If both `top` and `bottom` are specified (technically, not `auto`), `top` wins.
- If both `left` and `right` are specified, `left` wins when `direction` is `ltr` (English, horizontal Japanese, etc.) and `right` wins when `direction` is `rtl` (Persian, Arabic, Hebrew, etc.).

Accessibility

Ensure that elements positioned with an `absolute` or `fixed` value do not obscure other content when the page is zoomed to increase text size.

- MDN Understanding WCAG, Guideline 1.4 explanations
- Visual Presentation: Understanding SC 1.4.8 | Understanding WCAG 2.0

Performance & Accessibility

Scrolling elements containing `fixed` or `sticky` content can cause performance and accessibility issues. As a user scrolls, the browser must repaint the sticky or fixed content in a new location. Depending on the content needing to be repainted, the browser performance, and the device's processing speed, the browser may not be able to manage repaints at 60 fps. Such a scenario can lead to jank and, more importantly, accessibility concerns for people with sensitivities. One solution is to add `will-change: transform` to the positioned elements to render the element in its own layer, improving repaint speed and therefore improving performance and accessibility.

Formal definition

Initial value	`static`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete
Creates stacking context	yes

Formal syntax

```
position =
  static       |
  relative     |
  absolute     |
  sticky       |
  fixed        |
  <running()>

<running()> =
  running( <custom-ident> )
```

This syntax reflects the latest standard as per CSS Generated Content for Paged Media Module, CSS Positioned Layout Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Relative positioning

Relatively positioned elements are offset a given amount from their normal position within the document, but without the offset affecting other elements. In the example below, note how the other elements are placed as if "Two" were taking up the space of its normal location.

HTML

```
<div class="box" id="one">One</div>
<div class="box" id="two">Two</div>
<div class="box" id="three">Three</div>
<div class="box" id="four">Four</div>
```

CSS

```
* {
  box-sizing: border-box;
}

.box {
  display: inline-block;
  width: 100px;
  height: 100px;
  background: red;
  color: white;
}

#two {
  position: relative;
  top: 20px;
  left: 20px;
  background: blue;
}
```

Absolute positioning

Elements that are relatively positioned remain in the normal flow of the document. In contrast, an element that is absolutely positioned is taken out of the flow; thus, other elements are positioned as if it did not exist. The absolutely positioned element is positioned relative to its *nearest positioned ancestor* (i.e., the nearest ancestor that is not `static`). If a positioned ancestor doesn't exist, it is positioned relative to the ICB (initial containing block), which is the containing block of the document's root element.

HTML

```
<h1>Absolute positioning</h1>

<p>
  I am a basic block level element. My adjacent block level elements sit on new
  lines below me.
</p>

<p class="positioned">
  By default we span 100% of the width of our parent element, and we are as tall
  as our child content. Our total width and height is our content + padding +
  border width/height.
</p>

<p>
  We are separated by our margins. Because of margin collapsing, we are
  separated by the width of one of our margins, not both.
</p>

<p>
  inline elements <span>like this one</span> and <span>this one</span> sit on
  the same line as one another, and adjacent text nodes, if there is space on
  the same line. Overflowing inline elements
  <span>wrap onto a new line if possible — like this one containing text</span>,
  or just go on to a new line if not, much like this image will do:
  <img src="https://mdn.github.io/shared-assets/images/examples/long.jpg" />
</p>
```

CSS

```
* {
  box-sizing: border-box;
}

body {
  width: 500px;
  margin: 0 auto;
}

p {
  background: aqua;
  border: 3px solid blue;
  padding: 10px;
  margin: 10px;
}

span {
  background: red;
  border: 1px solid black;
}

.positioned {
  position: absolute;
  background: yellow;
  inset-block-start: 30px;
  inset-inline-start: 30px;
}
```

Result

Fixed positioning

Fixed positioning is similar to absolute positioning, with the exception that the element's containing block is the initial containing block established by the *viewport*, unless any ancestor has `transform`, `perspective`, or `filter` property set to something other than `none` (see fixed positioning containing block), which then causes that ancestor to take the place of the elements containing block. This can be used to create a "floating" element that stays in the same position regardless of scrolling. In the example below, box "One" is fixed at 80 pixels from the top of the page and 10 pixels from the left. Even after scrolling, it remains in the same place relative to the viewport. Also, when the `will-change` property is set to `transform`, a new containing block is established.

HTML

```
<div class="outer">
  <p>
    Lorem ipsum dolor sit amet, consectetur adipiscing elit. Nam congue tortor
    eget pulvinar lobortis. Vestibulum ante ipsum primis in faucibus orci luctus
    et ultrices posuere cubilia Curae; Nam ac dolor augue. Pellentesque mi mi,
    laoreet et dolor sit amet, ultrices varius risus. Nam vitae iaculis elit.
    Aliquam mollis interdum libero. Sed sodales placerat egestas. Vestibulum ut
    arcu aliquam purus viverra dictum vel sit amet mi. Duis nisl mauris, aliquam
    sit amet luctus eget, dapibus in enim. Sed velit augue, pretium a sem
    aliquam, congue porttitor tortor. Sed tempor nisl a lorem consequat, id
    maximus erat aliquet. Sed sagittis porta libero sed condimentum. Aliquam
    finibus lectus nec ante congue rutrum. Curabitur quam quam, accumsan id
    ultrices ultrices, tempor et tellus.
  </p>
  <p>
    Lorem ipsum dolor sit amet, consectetur adipiscing elit. Nam congue tortor
    eget pulvinar lobortis. Vestibulum ante ipsum primis in faucibus orci luctus
    et ultrices posuere cubilia Curae; Nam ac dolor augue. Pellentesque mi mi,
    laoreet et dolor sit amet, ultrices varius risus. Nam vitae iaculis elit.
    Aliquam mollis interdum libero. Sed sodales placerat egestas. Vestibulum ut

  </p>
  <div class="box" id="one">One</div>
</div>
```

CSS

```
* {
  box-sizing: border-box;
}

.box {
  width: 100px;
  height: 100px;
  background: red;
  color: white;
}

#one {
  position: fixed;
  top: 80px;
  left: 10px;
  background: blue;
}

.outer {
  width: 500px;
  height: 300px;
  overflow: scroll;
  padding-left: 150px;
}
```

Result

Sticky positioning

The following CSS rule positions the element with id `one` relatively until the viewport is scrolled such that the element is 10 pixels from the top. Beyond that threshold, the element is fixed to 10 pixels from the top.

```
#one {
  position: sticky;
  top: 10px;
}
```

List with sticky headings

A common use for sticky positioning is for the headings in an alphabetized list. The "B" heading will appear just below the items that begin with "A" until they are scrolled offscreen. Rather than sliding offscreen with the rest of the content, the "B" heading will then remain fixed to the top of the viewport until all the "B" items have scrolled offscreen, at which point it will be covered up by the "C" heading, and so on.

You must specify a threshold with at least one of `top`, `right`, `bottom`, or `left` for sticky positioning to behave as expected. Otherwise, it will be indistinguishable from relative positioning.

HTML

```
<dl>
  <div>
    <dt>A</dt>
    <dd>Andrew W.K.</dd>
    <dd>Apparat</dd>
    <dd>Arcade Fire</dd>
    <dd>At The Drive-In</dd>
    <dd>Aziz Ansari</dd>
  </div>
  <div>
    <dt>C</dt>
    <dd>Chromeo</dd>
    <dd>Common</dd>
    <dd>Converge</dd>
```

```
    <dd>Crystal Castles</dd>
    <dd>Cursive</dd>
  </div>
  <div>
    <dt>E</dt>
    <dd>Explosions In The Sky</dd>
  </div>
  <div>
    <dt>T</dt>
    <dd>Ted Leo &amp;amp; The Pharmacists</dd>
    <dd>T-Pain</dd>
    <dd>Thrice</dd>
    <dd>TV On The Radio</dd>
    <dd>Two Gallants</dd>
  </div>
</dl>
```

CSS

```
* {
  box-sizing: border-box;
}

dl > div {
  background: white;
  padding-top: 24px;
}

dt {
  background: #b8c1c8;
  border-bottom: 1px solid #989ea4;
  border-top: 1px solid #717d85;
  color: white;
  font:
    bold 18px/21px "Helvetica",
    "Arial",
    sans-serif;
  margin: 0;
  padding: 2px 0 0 12px;
  position: -webkit-sticky;
  position: sticky;
  top: -1px;
}

dd {
  font:
    bold 20px/45px "Helvetica",
    "Arial",
    sans-serif;
  margin: 0;
  padding-left: 12px;
  white-space: nowrap;
}

dd + dd {
  border-top: 1px solid #cccccc;
}
```

Result

Sticky position with all the inset boundaries set

The following example demonstrates an element's behavior when all inset boundaries are set. Here, we have two light bulb emojis in a paragraph. The light bulbs use sticky positioning, and the inset boundaries are specified as 50px from the top and bottom, and 100px from the left and right. A gray background on the parent div element marks the inset area.

HTML

```
Use scrollbars to put the light bulbs(💡) in the right place in the following
text:
<div>
  <p>
    The representation of an idea by a light bulb(<span class="bulb">💡</span>)
    is a commonly used metaphor that symbolizes the moment of inspiration or the
    birth of a new idea. The association between a light bulb and an idea can be
    traced back to the invention of the incandescent light bulb(<span
      class="bulb"
      >💡</span
    >) by Thomas Edison in the late 19th century. The light bulb is a powerful
    symbol because it represents illumination, clarity, and the sudden
    brightening of one's thoughts or understanding. When someone has an idea, it
    is often described as a light bulb turning on in their mind, signifying a
    moment of insight or creativity. The image of a light bulb also suggests the
    idea of energy, power, and the potential for growth and development.
  </p>
</div>
```

CSS

```
div {
  width: 400px;
  height: 200px;
  overflow: scroll;
  scrollbar-width: thin;
  font-size: 16px;
  font-family: "Verdana";
  border: 1px solid;
}

p {
  width: 600px;
  user-select: none;
  margin: 0;
```

```
  border: 110px solid transparent;
}
```

```
.bulb {
  position: sticky;
  inset: 50px 100px;
}

div {
  /* mark area defined by the inset boundaries using gray color */
  background: linear-gradient(#99999999, #99999999) 100px 50px / 192px 100px
    no-repeat;
}
```

Result

When you put both bulbs in their proper place, you'll notice that they are relatively positioned inside the inset area. When you move them out of the inset area, they are fixed (sticky) to the inset boundary in that direction.

position-anchor CSS property

The **`position-anchor`** CSS property specifies the default **anchor element** for a positioned element. This default is used by `position-area` and `position-try`, and by anchor functions (`anchor()` and `anchor-size()`) when no `<anchor-name>` argument is provided to those functions.

Syntax

```
/* Single values */
position-anchor: normal;
position-anchor: auto;
position-anchor: none;
position-anchor: --anchor-name;
position-anchor: match-parent;

/* Global values */
position-anchor: inherit;
position-anchor: initial;
position-anchor: revert;
position-anchor: revert-layer;
position-anchor: unset;
```

Values

`normal`

If `position-area` is `none`, it behaves as `none`. Otherwise it behaves as `auto`.

`auto`

Associates a positioned element with its implicit anchor element, if it has one — for example as set by the non-standard HTML `anchor` attribute.

`none`

The positioned element is not associated with an anchor element.

`<dashed-ident>`

The name of the anchor element to associate the positioned element with, as listed in the anchor element's `anchor-name` property. This is known as the **default anchor specifier**.

`match-parent`

Uses the same default anchor element as the parent element, or the originating element if this is a pseudo-element, provided that would be an acceptable anchor element (that is part of the tree). Otherwise, it has no default anchor element.

Description

This property is only relevant to "positioned" elements — elements and pseudo-elements that have a `position` of `absolute` or `fixed` set.

To position an element relative to an anchor element, the positioned element requires three features: an association, a position, and a location. The `position-anchor` and `anchor-name` properties provide an explicit association.

The anchor element accepts one or more `<dashed-ident>` anchor names set on it via the `anchor-name` property. When one of those names is then set as the value of the positioned element's `position-anchor` property, the two elements are associated.

If there are multiple anchor elements with the anchor name listed in the `position-anchor` property, the positioned element will be associated with the last anchor element in the source order with that anchor name.

To cancel a previously-made association between an anchor-positioned element and an anchor, you can set the anchor-positioned element's `position-anchor` value to `none`.

To tether a positioned element to its anchor, it must be placed relative to an anchor element using an anchor positioning feature, such as the `anchor()` function (set as a value on inset properties) or the `position-area` property.

If the associated anchor is hidden, for example with `display: none` or `visibility: hidden`, or if it is part of the skipped contents of another element due to it having `content-visibility: hidden` set on it, the anchor positioned element will not be displayed.

The `position-anchor` property is supported on all elements that are positioned, including pseudo-elements like `::before` and `::after`. Pseudo elements are implicitly anchored to the same element as the pseudo-element's originating element, unless otherwise specified.

For more information on anchor features and usage, see the CSS anchor positioning module and the Using CSS anchor positioning guide.

Formal definition

Initial value	`normal`

Applies to	absolutely positioned elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
position-anchor =
  normal         |
  none           |
  auto           |
  <anchor-name>  |
  match-parent

<anchor-name> =
  <dashed-ident>
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

See the `anchor-name` documentation for basic usage and additional `position-anchor` examples.

Multiple positioned elements and anchors

In this example, you can move multiple positioned elements around, associating them with different anchors. This example demonstrates how an anchor can be associated with multiple positioned elements, but an anchor-positioned element can only be associated with a single anchor at a time, the anchor defined by the `anchor-position` property.

HTML

We have four anchors and two positioned elements, distinguished with different `id` values. The positioned elements contain `<select>` boxes that allow you to choose which anchor you want to associate them with.

```
<div id="anchor-container">
  <div class="anchor" id="anchor1">⚓</div>
  <div class="anchor" id="anchor2">⚓</div>
  <div class="anchor" id="anchor3">⚓</div>
  <div class="anchor" id="anchor4">⚓</div>
</div>

<div class="infobox" id="infobox1">
  <form>
    <label for="anchor1-anchor-select">Place infobox on:</label>
    <select id="anchor1-anchor-select">
      <option value="1">Anchor 1</option>
      <option value="2">Anchor 2</option>
      <option value="3">Anchor 3</option>
      <option value="4">Anchor 4</option>
    </select>
  </form>
</div>

<div class="infobox" id="infobox2">
  <form>
    <label for="anchor2-anchor-select">Place infobox on:</label>
    <select id="anchor2-anchor-select">
      <option value="1">Anchor 1</option>
      <option value="2">Anchor 2</option>
      <option value="3">Anchor 3</option>
      <option value="4">Anchor 4</option>
    </select>
  </form>
</div>
```

CSS

We declare the first `anchor <div>` as an anchor using the `anchor-name` property, which is given two comma-separated anchor names, one for each positioned element. This is the initial state of the demo — both positioned elements will be tethered to the first anchor.

```
body {
  height: 100vh;
}

#anchor-container {
  display: grid;
  height: 100%;
  grid-template-columns: 1fr 1fr;
  grid-auto-rows: 1fr 1fr;
  justify-items: center;
  align-items: center;
}

.anchor {
  font-size: 1.8rem;
  color: white;
  text-shadow: 1px 1px 1px black;
  background-color: hsl(240 100% 75%);
  width: fit-content;
  border-radius: 10px;
  border: 1px solid black;
  padding: 3px;
}
```

```
#anchor1 {
  anchor-name: --my-anchor1, --my-anchor2;
}
```

Each of the positioned elements is given a `position-anchor` property with a value matching one of the two anchor names. The positioned elements are then given anchor-relative positioning information using a combination of inset, alignment, and margin properties.

```
.infobox {
  color: darkblue;
  background-color: azure;
  border: 1px solid #dddddd;
  padding: 10px;
  border-radius: 10px;
  font-size: 1rem;
  width: 120px;
}
```

```
#infobox1 {
  position-anchor: --my-anchor1;
  position: fixed;
  left: anchor(right);
  align-self: anchor-center;
  margin-left: 10px;
}

#infobox2 {
  position-anchor: --my-anchor2;
  position: fixed;
  bottom: anchor(top);
  justify-self: anchor-center;
  margin-bottom: 15px;
}
```

JavaScript

We dynamically change which anchor elements the `anchor-name` values are set on in response to different anchors being selected in the positioned elements' `<select>` menus. The key functionality here is the `change` event handler, `updateAnchorNames()`. It sets both anchor names on one anchor, if the anchors chosen in the two `<select>` menus are the same. Otherwise, it sets a single anchor name on two separate anchors as appropriate.

```
// Get references to the two select menus
const select1 = document.querySelector("#anchor1-anchor-select");
const select2 = document.querySelector("#anchor2-anchor-select");
// Store references to all the anchors in a NodeList (array-like)
const anchors = document.querySelectorAll("#anchor-container > div");

// Set the same change event handler on both select menus
select1.addEventListener("change", updateAnchorNames);
select2.addEventListener("change", updateAnchorNames);

function updateAnchorNames() {
  // Remove all anchor names from all anchors
  for (const anchor of anchors) {
    anchor.style.anchorName = "none";
  }

  // convert the select menu values to numbers, and remove one to
  // make them match the selected anchors' index positions in the NodeList
  const value1 = Number(select1.value) - 1;
  const value2 = Number(select2.value) - 1;

  if (value1 === value2) {
    // If the chosen anchors are both the same, set both anchor
    // names on the same anchor
    anchors[value1].style.anchorName = "--my-anchor1, --my-anchor2";
  } else {
    // If they are not the same, set the anchor names separately
    // on each selected anchor
    anchors[value1].style.anchorName = "--my-anchor1";
    anchors[value2].style.anchorName = "--my-anchor2";
  }
}
```

Result

Select different values from the drop-down menus to change the anchors that the elements are positioned relative to.

Using a slider thumb as an anchor

In this example, an `<output>` is positioned relative to an anchor that is the thumb of a range slider.

HTML

We include an `<input type="range">` element and an `<output>` element to display the value of the range. The value displayed in the `<output>` element is updated via JavaScript as the slider value changes.

```
<label for="slider">Change the value:</label>
<input type="range" min="0" max="100" value="25" id="slider" />
<output>25</output>
```

CSS

We give the thumb, represented by the `::-webkit-slider-thumb` and `::-moz-range-thumb` pseudo-elements, an anchor name of `--thumb`. We then set that name as the value of the `<output>` element's `position-anchor` property, and give it a `position` value of `fixed`. These steps associated the `<output>` with the thumb.

Finally, we use `left` and `top` properties with `anchor()` values to position the `<output>` relative to the thumb.

```
body {
  display: grid;
  place-items: center;
  height: 100vh;
  font-size: 1.4rem;
  font-family: sans-serif;
}
input {
  width: 33vw;
```

```
}
output {
  background: cyan;
  border: 2px solid darkblue;
  padding: 3px 6px;
  border-radius: 10px;
  font-size: 1.2rem;
}
```

```
input::-webkit-slider-thumb {
  anchor-name: --thumb;
}

input::-moz-range-thumb {
  anchor-name: --thumb;
}

output {
  position-anchor: --thumb;
  position: absolute;
  left: anchor(right);
  bottom: anchor(top);
}
```

JavaScript

We include an event listener that updates the content of the `<output>` element when the value of the `<input>` changes:

```
const input = document.querySelector("input");
const output = document.querySelector("output");

input.addEventListener("input", (event) => {
  output.innerText = `${input.value}`;
});
```

Results

The output is anchored to the thumb. Change the value and the output will remain above and to the right of the thumb, no matter where it is along the slider.

> **Note:** The anchor positioning CSS for this demo currently doesn't work in Firefox. The slider's thumb can be targeted via the `::-moz-range-thumb` pseudo-element in Firefox, but it is currently not available as an anchor (see Firefox bug 1993699).

position-area CSS property

The **`position-area`** CSS property enables an anchor-positioned element to be positioned relative to the edges of its associated anchor element by placing the positioned element on one or more tiles of an implicit 3x3 grid, where the anchoring element is the center cell.

`position-area` provides a convenient alternative to tethering and positioning an element relative to its anchor via inset properties and the `anchor()` function. The grid-based concept solves the common use-case of positioning the edges of the positioned element's containing block relative to the edges of its default anchor element.

If an element does not have a default anchor element, or is not an absolutely-positioned element, this property has no effect.

> **Note:** This property was originally named and supported in Chromium browsers as `inset-area`, with the same property values. Both property names will be supported for a short while, for backwards compatibility purposes.

Syntax

```
/* Default value */
position-area: none;

/* Two <position-area> keywords defining a single specific tile */
position-area: top left;
position-area: start end;
position-area: block-start center;
position-area: inline-start block-end;
position-area: x-start y-end;
position-area: center self-y-end;

/* Two <position-area> keywords spanning two tiles */
position-area: top span-left;
position-area: center span-start;
position-area: inline-start span-block-end;
position-area: y-start span-x-end;

/* Two <position-area> keywords spanning three tiles */
position-area: top span-all;
position-area: block-end span-all;
position-area: self-x-start span-all;

/* One <position-area> keyword with an implicit second <position-area> keyword  */
position-area: top; /* equiv: top span-all */
position-area: inline-start; /* equiv: inline-start span-all */
position-area: center; /* equiv: center center */
position-area: span-all; /* equiv: span-all span-all */
position-area: end; /* equiv: end end */

/* Global values */
position-area: inherit;
```

```
position-area: initial;
position-area: revert;
position-area: revert-layer;
position-area: unset;
```

Values

The property value is two `<position-area>` keyterms, or the keyword `none`. If only one `<position-area>` keyterm is provided, the second keyterm is implied.

`<position-area>`

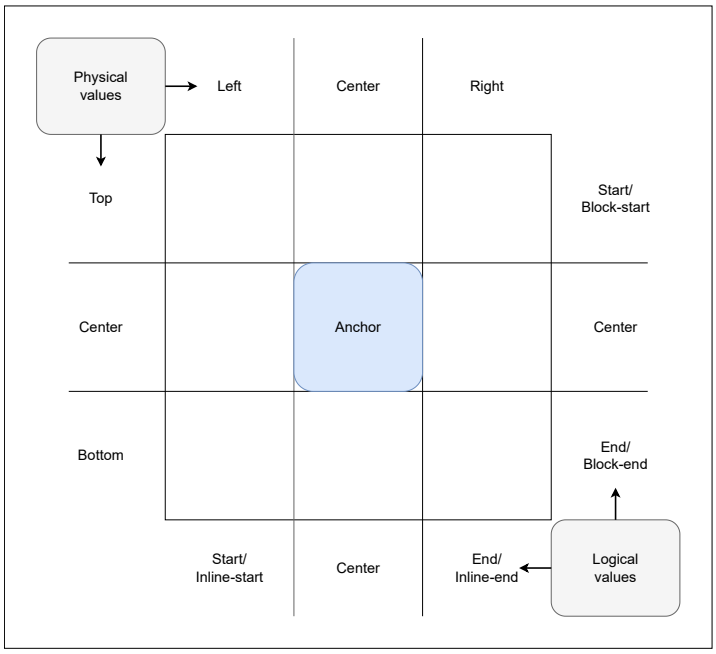
Specifies the area of the position area grid on which to place selected positioned elements.

`none`

No position area is set.

Description

The `position-area` property provides an alternative to the `anchor()` function for positioning elements relative to anchors. `position-area` works on the concept of a 3x3 grid of tiles, called the **position-area grid**, with the anchor element being the center tile:



The grid tiles are broken up into rows and columns:

- The three rows are represented by the physical values `top`, `center`, and `bottom`. They also have logical equivalents such as `block-start`, `center`, and `block-end`, and coordinate equivalents — `y-start`, `center`, and `y-end`.
- The three columns are represented by the physical values `left`, `center`, and `right`. They also have logical equivalents such as `inline-start`, `center`, and `inline-end`, and coordinate equivalents — `x-start`, `center`, and `x-end`.

The dimensions of the center tile are defined by the containing block of the anchor element, while the dimensions of the grid's outer edge are defined by the positioned element's containing block.

The `<position-area>` value is composed of one or two keywords, which define the region of the grid the positioned element should be placed inside. To be exact, the containing block of the positioned element is set to the grid area.

For example:

- You can specify a row value and a column value to place the positioned element in a single, specific grid square — for example, `top left` (logical equivalent `start start`) or `bottom center` (logical equivalent `end center`) will place the positioned element in the top-right or bottom-center square.
- You can specify a row or column value plus a `span-*` value to span two or three cells. The first value specifies the row or column to place the positioned element in, placing it initially in the center, and the other one specifies the other tiles of that row or column to span. For example:
  - `top span-left` causes the positioned element to be placed in the center of the top row, and span across the center and left tiles of that row.
  - `block-end span-inline-end` causes the positioned element to be placed in the center of the block end row, and span across the center and inline end tiles of that row.
  - `bottom span-all` and `y-end span-all` cause the positioned element to be placed in the center of the bottom row, and span across three cells, in this case the left, center, and right tiles of the bottom row.

For detailed information on anchor features, usage, and the `position-area` property, see the CSS anchor positioning module and the Using CSS anchor positioning guide, specifically the section on setting a `position-area`.

Adjusted default behavior

When a `<position-area>` value is set on a positioned element, some of its properties will have their default behavior adjusted to provide a good default alignment.

Self-alignment property `normal` value

The `normal` value of the self-alignment properties, including `align-items`, `align-self`, `justify-items`, and `justify-self`, behaves as either `start`, `end`, or `anchor-center`. Which value a self-alignment property defaults to depends on the positioning of the element:

- If the `position-area` value specifies the center region in an axis, the default alignment in that axis is `anchor-center`.
- Otherwise, the behavior is the opposite of the region specified by the `position-area` property. For example, if the `position-area` value specifies the start region of its axis, the default alignment in that axis is `end`.

For example, if the `writing-mode` is set to `horizontal-tb`, `position-area: top span-x-start` causes the positioned element to be placed in the center of the top row, and span across the center and start tiles of that row. In this case, the self-alignment properties will default to `align-self: end` and `justify-self: anchor-center`.

inset properties and values

When an anchor-positioned element is positioned using the `position-area` property, any inset properties set, such as `top` or `inset-inline-end`, specify offsets from the position-area. Some other property values, like `max-block-size: 100%`, will also be relative to the position-area. Any inset properties set or defaulting to `auto` will behave as if their value was set to `0`.

An aside on positioned element width

If the positioned element does not have a specific size set on it, its size will default to its intrinsic size, but it will also be affected by the size of the position-area grid.

If the positioned element is placed in a single top-center, bottom-center, or center-center cell, its block size will be the same as the anchor's containing block size, growing up, down, or in both directions respectively. The positioned element will align with the specified grid square but adopt the same width as the anchor element. However, it won't allow its content to overflow — its minimum `width` will be its `min-content` (as defined by the width of its longest word).

If the positioned element is placed in any other single grid square (say with `position-area: top left`) or is set to span two or more grid squares (for example using `position-area: bottom span-all`), it will align with the specified grid area but behave as if it has a `width` of `max-content` set on it. It is being sized according to its containing block size, which is the size imposed on it when it was set to `position: fixed`. It will stretch as wide as the text content, although it may also be constrained by the edge of the `<body>`.

Using <code>position-area</code> to position popovers

When using `position-area` to position popovers, be aware that the default styles for popovers may conflict with the position you're trying to achieve. The usual culprits are the default styles for `margin` and `inset`, so it's advisable to reset those:

```
.my-popover {
  margin: 0;
  inset: auto;
}
```

The CSS working group is looking at ways to avoid requiring this workaround.

Formal definition

Initial value	none
Applies to	Positioned elements with a default anchor element
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
position-area =
  none              |
  <position-area>

<position-area> =
  [ left | center | right | span-left | span-right | x-start | x-end | span-x-start | span-x-end | self-x-start | self-x-end | span-self-x-start | span-self-x-end | span-all ] || [ top | center | bottom |
span-top | span-bottom | y-start | y-end | span-y-start | span-y-end | self-y-start | self-y-end | span-self-y-start | span-self-y-end | span-all ]  |
  [ block-start | center | block-end | span-block-start | span-block-end | span-all ] || [ inline-start | center | inline-end | span-inline-start | span-inline-end | span-all ]  |
  [ self-block-start | center | self-block-end | span-self-block-start | span-self-block-end | span-all ] || [ self-inline-start | center | self-inline-end | span-self-inline-start | span-self-inline-end
| span-all ]  |
  [ start | center | end | span-start | span-end | span-all ]{1,2}  |
  [ self-start | center | self-end | span-self-start | span-self-end | span-all ]{1,2}
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

In this example, a positioned element is tethered and positioned relative to its associated anchor using the `position-area` property.

HTML

The HTML includes a `<div>` and a `<p>`. The `<p>` will be positioned relative to the `<div>` with CSS. We also include a style block that will be made visible. All elements are set to be directly editable via the `contenteditable` attribute.

```
<div class="anchor" contenteditable="true">⚓</div>

<p class="positionedElement" contenteditable="true">This can be edited.</p>

<style contenteditable="true">.positionedElement {
    position-area: top center;
  }
</style>
```

CSS

We convert the `<div>` to an anchor element with the `anchor-name` property. We then associate the absolutely-positioned `<p>` with it by setting its `position-anchor` value to the same anchor name.

We set the initial `position-area` value to `top center`. This value is set on a `p` selector, so the value has less specificity than any value added to the `<style>` block's `.positionedElement` class selector. As a result, you can override the initial `position-area` value by setting a `position-area` value inside the style block.

```
.anchor {
  anchor-name: --infobox;
  background: palegoldenrod;
  font-size: 3em;
  width: fit-content;
  border: 1px solid goldenrod;
  margin: 100px auto;
}

p {
  position: absolute;
  position-anchor: --infobox;
  position-area: top center;
  margin: 0;
  background-color: darkkhaki;
  border: 1px solid darkolivegreen;
```

```
}

style {
  display: block;
  white-space: pre;
  font-family: monospace;
  background-color: #ededed;
  -webkit-user-modify: read-write-plaintext-only;
  line-height: 1.5;
  padding: 10px;
}
```

Results

Try changing the amount of text in the anchor-positioned element to see how it grows. Also, try changing the value of the `position-area` property to something else, like `center`.

<code>position-area</code> value comparison

This demo creates an anchor and tethers a positioned element to it. It also provides a drop-down menu allowing you to choose various `position-area` values to apply to the positioned element, to see their effect. One of the options causes a text field to appear that enables you to enter a custom value. Finally, a checkbox is provided to turn `writing-mode: vertical-lr` on and off, allowing you to observe how `position-area` value effects differ across different writing modes.

HTML

In the HTML, we specify two `<div>` elements, one with a class of `anchor` and one with a class of `infobox`. These are intended to be the anchor element and the positioned element we will associate with it, respectively. We've included the `contenteditable` attribute on both, making them directly editable.

We've also included two forms that contain the `<select>` and `<input type="text">` elements for setting different `position-area` values, and the `<input type="checkbox">` element for toggling the vertical `writing-mode` on and off. The code for these, along with the JavaScript, has been hidden for the sake of brevity.

```
<div class="anchor" contenteditable>⚓</div>

<div class="infobox">
  <p contenteditable>You can edit this text.</p>
</div>
```

```
<form id="position-area-form">
  <div>
    <label for="position-area-select">Choose a position-area:</label>
    <select id="position-area-select" name="position-area-select">
      <optgroup label="Enter custom value">
        <option>Custom</option>
      </optgroup>
      <optgroup label="Physical, single tile">
        <option selected>top left</option>
        <option>bottom right</option>
      </optgroup>
      <optgroup label="Physical, span two">
        <option>bottom span-right</option>
        <option>left span-top</option>
      </optgroup>
      <optgroup label="Physical, span all">
        <option>top</option>
        <option>left</option>
      </optgroup>
      <optgroup label="Logical, single tile">
        <option>start center</option>
        <option>inline-start block-end</option>
      </optgroup>
      <optgroup label="Logical, span two">
        <option>start span-end</option>
        <option>center span-start</option>
        <option>inline-start span-block-end</option>
        <option>span-block-start center</option>
      </optgroup>
      <optgroup label="Logical, span all">
        <option>start span-all</option>
        <option>block-end</option>
      </optgroup>
      <optgroup label="Coordinates, single tile">
        <option>x-start center</option>
        <option>x-end y-end</option>
      </optgroup>
      <optgroup label="Coordinates, span two">
        <option>center span-y-start</option>
        <option>y-start span-x-end</option>
      </optgroup>
      <optgroup label="Coordinates, span all">
        <option>x-start span-all</option>
        <option>y-end</option>
      </optgroup>
    </select>
  </div>
  <div id="position-area-custom-container">
    <label for="position-area-custom">Enter a custom position-area:</label
    ><br />
    <input type="text" id="position-area-custom" name="position-area-custom" />
  </div>
</form>

<form id="writing-mode-form">
  <label for="writing-mode-checkbox">writing-mode: vertical-lr</label><br />
  <input
    type="checkbox"
    id="writing-mode-checkbox"
    name="writing-mode-checkbox" />
</form>
```

CSS

In the CSS, we first declare the `anchor` `<div>` as an anchor element by setting an anchor name on it via the `anchor-name` property.

The positioned element is associated with the anchor element by setting its anchor name as the value of the positioned element's `position-anchor` property. We also give it an initial position with `position-area: top left`; this will be overridden when new values are selected from the `<select>` menu. Finally, we set its `opacity` to `0.8`, so that when the positioned element is given a `position-area` value that places it over the top of the anchor, you can still see the elements' position relative to one another.

```
.anchor {
  font-size: 1.8rem;
  text-align: center;
  color: white;
  text-shadow: 1px 1px 1px black;
  background-color: hsl(240 100% 75%);
  min-width: 50px;
  min-height: 50px;
  line-height: 50px;
  border-radius: 10px;
  border: 1px solid black;
  padding: 3px;
}

html {
  height: 100%;
}

body {
  margin: 0;
  width: 100vw;
  height: 100vh;
  display: flex;
  justify-content: center;
  align-items: center;
}

form {
  background: white;
  border: 1px solid black;
  padding: 5px;
  position: fixed;
}

#position-area-form {
  top: 0;
  right: 2px;
}

#position-area-form div:last-child {
  margin-top: 10px;
}

#position-area-form div :last-child {
  margin-top: 5px;
}

#writing-mode-form {
  bottom: 0;
  left: 2px;
  writing-mode: horizontal-tb;
}

#position-area-custom-container {
  display: none;
}

.infobox {
  color: darkblue;
  background-color: azure;
  border: 1px solid #dddddd;
  padding: 5px 2px;
  border-radius: 5px;
  font-size: 1rem;
  box-sizing: border-box;
}
```

```
.anchor {
  anchor-name: --my-anchor;
}

.infobox {
  position-anchor: --my-anchor;
  position: fixed;
  opacity: 0.8;
  position-area: top left;
}
```

```
const anchorContainer = document.querySelector("body");
const infobox = document.querySelector(".infobox");

const positionAreaForm = document.querySelector("#position-area-form");
const selectElem = document.querySelector("select");
const inputElemContainer = document.querySelector(
  "#position-area-custom-container",
);
const inputElem = document.querySelector("#position-area-custom");
const checkboxElem = document.querySelector("#writing-mode-checkbox");

// Stop form from submitting when enter is pressed on it
positionAreaForm.addEventListener("submit", (e) => {
  e.preventDefault();
});

// Update positioned element position-area to value selected in drop-down
selectElem.addEventListener("change", () => {
  const area = selectElem.value;
```

```
  if (area === "Custom") {
    // Show the custom value input field
    inputElemContainer.style.display = "block";
  } else {
    // Hide the custom value input field
    inputElemContainer.style.display = "none";
    // Set the position-area to the value chosen in the select box
    infobox.style.positionArea = area;
  }
});

// Update positioned element position-area to entered custom value
inputElem.addEventListener("change", () => {
  const customArea = inputElem.value;

  // Set the position-area to the value in the input box
  infobox.style.positionArea = customArea;
});

// Change writing-mode to match checkbox setting
checkboxElem.addEventListener("change", () => {
  if (checkboxElem.checked) {
    anchorContainer.style.writingMode = "vertical-lr";
  } else {
    anchorContainer.style.writingMode = "horizontal-tb";
  }
});
```

Result

The result is as follows:

Try selecting new `position-area` values from the `<select>` menu to see the effect they have on the position of the infobox. Select the "Custom" value and try entering some custom `position-area` values into the text input to see their effect. Add text to the anchor and the anchor positioned elements to see how the anchor positioned element grows based on the `position-area` value. Finally, check the checkbox and then experiment with different `position-area` values to see which ones give the same result across different writing modes, and which ones give different results.

position-try CSS property

The **`position-try`** CSS shorthand property corresponds to the `position-try-order` and `position-try-fallbacks` properties.

Constituent properties

This property is a shorthand for the following CSS properties:

- `position-try-order`
- `position-try-fallbacks`

Syntax

```
/* position-try-fallbacks only */
position-try: normal flip-block;
position-try: top;
position-try: --custom-try-option;
position-try: flip-block flip-inline;
position-try: top, right, bottom;
position-try: --custom-try-option1, --custom-try-option2;
position-try:
  normal flip-block,
  right,
  --custom-try-option;

/* position-try-order and position-try-fallbacks */
position-try: normal none;
position-try:
  most-width --custom-try-option1,
  --custom-try-option2;
position-try:
  most-height flip-block,
  right,
  --custom-try-option;

/* Global values */
position-try: inherit;
position-try: initial;
position-try: revert;
position-try: revert-layer;
position-try: unset;
```

Values

This property is specified as one or both of the following values:

`position-try-order` Optional

A keyword specifying the priority order of the position-try fallback options. If omitted, defaults to `normal`.

`position-try-fallbacks`

The keyword `none`, or a comma-separated list of `<position-area>` values, `<try-tactic>` options, and custom positions.

Description

The `position-try` shorthand property can be used to specify the `position-try-order` and `position-try-fallbacks` properties in a single declaration. It specifies the `position-try-order` and `position-try-fallbacks`, in that order. If the `position-try-order` component is omitted, it defaults to `normal`.

The `position-try-fallbacks` is a comma-separated list of one or more alternative position try fallback options for anchor-positioned elements to be placed relative to their associated anchor elements. When the element would otherwise overflow its inset-modified containing block, the browser will try placing the positioned element in these different fallback positions, in the order provided, until it finds a value that stops it from overflowing its container or the viewport.

The `position-try-order` prioritizes the `position-try-fallbacks` option applied to an anchor-positioned element when it first renders, based on which option creates the most space around the element in the given direction. If omitted, it is set to the property's initial value, which is `normal`, meaning the position-try fallback options are tried in the order they appear in the property.

Formal definition

Initial value	as each of the properties of the shorthand: • `position-try-fallbacks`: `none` • `position-try-order`: `normal`
Applies to	absolutely positioned elements
Inherited	no
Percentages	as each of the properties of the shorthand: • `position-try-fallbacks`: no • `position-try-order`: no
Computed value	as each of the properties of the shorthand: • `position-try-fallbacks`: as specified • `position-try-order`: as specified
Animation type	as each of the properties of the shorthand: • `position-try-fallbacks`: discrete • `position-try-order`: discrete

Formal syntax

```
position-try =
  <'position-try-order'>? <'position-try-fallbacks'>

<position-try-order> =
  normal      |
  <try-size>

<position-try-fallbacks> =
  none                                          |
  [ [ <dashed-ident> || <try-tactic> ] | <position-area> ]#

<try-size> =
  most-width       |
  most-height      |
  most-block-size  |
  most-inline-size

<try-tactic> =
  flip-block   ||
  flip-inline  ||
  flip-start   ||
  flip-x       ||
  flip-y

<position-area> =
  [ left | center | right | span-left | span-right | x-start | x-end | span-x-start | span-x-end | self-x-start | self-x-end | span-self-x-start | span-self-x-end | span-all ] || [ top | center | bottom |
span-top | span-bottom | y-start | y-end | span-y-start | span-y-end | self-y-start | self-y-end | span-self-y-start | span-self-y-end | span-all ]  |
  [ block-start | center | block-end | span-block-start | span-block-end | span-all ] || [ inline-start | center | inline-end | span-inline-start | span-inline-end | span-all ]  |
  [ self-block-start | center | self-block-end | span-self-block-start | span-self-block-end | span-all ] || [ self-inline-start | center | self-inline-end | span-self-inline-start | span-self-inline-end
| span-all ]  |
  [ start | center | end | span-start | span-end | span-all ]{1,2}  |
  [ self-start | center | self-end | span-self-start | span-self-end | span-all ]{1,2}
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic <code>position-try</code> usage

This demo shows the effect of `position-try`.

HTML

The HTML includes two `<div>` elements that will become an anchor and an anchor-positioned element.

```
<div class="anchor">⚓</div>

<div class="infobox">
  <p>This is an information box.</p>
</div>
```

CSS

In the CSS, the anchor is given an `anchor-name` and has a `position` value of `absolute` set on it. We position it in the top-half of the viewport using `top` and `left` values:

```
.anchor {
  font-size: 1.8rem;
  color: white;
  text-shadow: 1px 1px 1px black;
```

```
  background-color: hsl(240 100% 75%);
  width: fit-content;
  border-radius: 10px;
  border: 1px solid black;
  padding: 3px;
}
```

```
.anchor {
  anchor-name: --my-anchor;
  position: absolute;
  top: 100px;
  left: 45%;
}
```

```
.infobox {
  color: darkblue;
  background-color: azure;
  border: 1px solid #dddddd;
  padding: 10px;
  border-radius: 10px;
  font-size: 1rem;
  text-align: center;
}

form {
  position: fixed;
  bottom: 2px;
  right: 2px;
}
```

We then include a custom position option — `--custom-bottom` — which positions the element below the anchor and gives it an appropriate margin:

```
@position-try --custom-bottom {
  top: anchor(bottom);
  bottom: unset;
  margin-top: 10px;
}
```

We initially position the element above its anchor, and then set a `position-try` value on it that gives it a `position-try-order` of `most-height`, and a `position-try-fallbacks` list that just includes our custom fallback option:

```
.infobox {
  position: fixed;
  position-anchor: --my-anchor;

  bottom: anchor(top);
  margin-bottom: 10px;
  justify-self: anchor-center;

  position-try: most-height --custom-bottom;
}
```

Result

The element appears below its anchor, even though it is initially positioned above it. This occurs because there is more vertical space below the anchor than there is above it. The `most-height` try order causes the `--custom-bottom` try fallback option to be applied, placing the positioned element in the position that gives its containing block the most height.

position-try-fallbacks CSS property

The **`position-try-fallbacks`** CSS property enables you to specify a list of one or more alternative **position try fallback options** for anchor-positioned elements to be placed relative to their associated anchor elements. When the element would otherwise overflow its inset-modified containing block, the browser will try placing the positioned element in these different fallback positions, in the order provided, until it finds a value that stops it from overflowing its container or the viewport.

Syntax

```
/* Default value: no try fallback options */
position-try-fallbacks: none;

/* Single try option */
position-try-fallbacks: flip-block;
position-try-fallbacks: top;
position-try-fallbacks: --custom-try-option;

/* Multiple value combination option */
position-try-fallbacks: flip-block flip-inline;

/* Multiple values */
position-try-fallbacks: flip-block, flip-inline;
position-try-fallbacks: top, right, bottom;
position-try-fallbacks: --custom-try-option1, --custom-try-option2;
position-try-fallbacks:
  flip-block,
  flip-inline,
  flip-block flip-inline;
position-try-fallbacks:
  flip-block,
  --custom-try-option,
```

```
  --custom-try-option flip-inline,
  right;

/* Global values */
position-try-fallbacks: inherit;
position-try-fallbacks: initial;
position-try-fallbacks: revert;
position-try-fallbacks: revert-layer;
position-try-fallbacks: unset;
```

The `position-try-fallbacks` property may be specified as either the keyword value `none` or as a comma-separated list of one or more space-separated custom position option names or `<try-tactic>`s or a `position-area` value.

Values

This property is specified as the keyword `none` or a comma-separated list of the following values:

`none`

The default value. There are no position try fallback options set.

`<try-tactic>`

Predefined fallback options move the positioned element by taking its computed position and transforming it across a particular axis of the anchor, mirroring any margin offsets. Possible values are:

`flip-block`

Flips the element's position along the block axis.

`flip-inline`

Flips the element's position along the inline axis.

`flip-start`

Flips both the inline and block axis values, swapping the `start` properties with each other, and the `end` properties with each other.

`position-area` value

Positions the element relative to the edges of its associated anchor element by placing the positioned element on one or more tiles of an implicit 3x3 position area grid based on the specified `<position-area>` value; the effect is the same as a custom `@position-try` fallback option containing only a `position-area` descriptor.

`<dashed-ident>`

Adds a custom `@position-try` option to the fallback options list, the identifying name of which matches the specified `dashed-ident`. If no custom position option exists with that name, the option is ignored.

Description

Anchor-positioned elements should always appear in a convenient place for the user to interact with, if at all possible, regardless of where their anchor is positioned. To stop the positioned element from overflowing the viewport, it is often necessary to change its location when its anchor gets close to the edge of its containing element or the viewport.

This is achieved by providing one or more position-try fallback options in the `position-try-fallbacks` property. If the positioned element's initial position would overflow, the browser will try each fallback position option; the first fallback option that doesn't cause the element to overflow its containing block is applied. By default, the browser will try them in the order they appear in the list, applying the first one it finds that will stop the positioned element from overflowing.

If no option can be found that will place the positioned element completely on-screen, the browser will revert to displaying the positioned element at its default position before any try fallback options were applied.

> **Note:** In some situations you might want to just hide overflowing positioned elements, which can be achieved using the `position-visibility` property. In most cases however it is better to keep them on-screen and usable.

The `position-try-fallbacks` property, along with the `position-try-order` property, can also be set by using the `position-try` shorthand.

For detailed information on anchor features and position try fallback usage, see the CSS anchor positioning module and the Fallback options and conditional hiding for overflow guide.

Predefined <try-tactic> values

Referred to as a `<try-tactic>` in the specification, the predefined values move the positioned element by taking its computed position and transforming it across a particular axis of the anchor. The predefined values are:

`flip-block`

Flips the element's position along the block axis so that it appears the same distance away from the anchor but on the opposite side of it. To put it another way, it mirrors the element's position across an inline axis drawn through the center of the anchor. As an example, if the positioned element started to overflow at the top of the anchor, this value would flip the position to the bottom.

`flip-inline`

Flips the element's position along the inline axis so that it appears the same distance away from the anchor but on the opposite side of it. To put it another way, it mirrors the element's position across a block axis drawn through the center of the anchor. As an example, if the positioned element started to overflow at the left of the anchor, this value would flip the position to the right.

`flip-start`

Mirrors the element's position across an axis drawn diagonally through the center of the anchor, passing through the point at the intersection of the block axis start and the inline axis start, and the point at the intersection of the block axis end and the inline axis end. As an example, if the positioned element started to overflow at the left of the anchor, this value would flip the positioned element to the top.

Combination options

A single position-try fallback option can include more than one `<try-tactic>` or `dashed-ident` options, or a combination of both by declaring them as a single space-separated option:

- In the case of multiple predefined `<try-tactic>` options, their transformations are composed together.
- In the case of declaring a predefined `<try-tactic>` and a `<dashed-ident>` named `@position-try` option, the custom position option is applied first, then the `<try-tactic>` transformation is applied.

`position-area` values cannot be combined like this.

Formal definition

Initial value	none
Applies to	absolutely positioned elements

Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
position-try-fallbacks =
  none                                          |
  [ [ <dashed-ident> || <try-tactic> ] | <position-area> ]#

<try-tactic> =
  flip-block   ||
  flip-inline  ||
  flip-start   ||
  flip-x       ||
  flip-y

<position-area> =
  [ left | center | right | span-left | span-right | x-start | x-end | span-x-start | span-x-end | self-x-start | self-x-end | span-self-x-start | span-self-x-end | span-all ] || [ top | center | bottom |
span-top | span-bottom | y-start | y-end | span-y-start | span-y-end | self-y-start | self-y-end | span-self-y-start | span-self-y-end | span-all ]  |
  [ block-start | center | block-end | span-block-start | span-block-end | span-all ] || [ inline-start | center | inline-end | span-inline-start | span-inline-end | span-all ]  |
  [ self-block-start | center | self-block-end | span-self-block-start | span-self-block-end | span-all ] || [ self-inline-start | center | self-inline-end | span-self-inline-start | span-self-inline-end
| span-all ]  |
  [ start | center | end | span-start | span-end | span-all ]{1,2}  |
  [ self-start | center | self-end | span-self-start | span-self-end | span-all ]{1,2}
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example shows the basic usage of a couple of predefined `<try-tactic>` fallback options.

HTML

The HTML includes two `<div>` elements that will become an anchor and an anchor-positioned element:

```
<div class="anchor">⚓</div>

<div class="infobox">
  <p>This is an information box.</p>
</div>
```

CSS

We style the `<body>` element to be very large, to enable both horizontal and vertical scrolling.

The anchor is given an `anchor-name` and large margins to place it somewhere near the center of the visible section of the `<body>`:

```
.anchor {
  font-size: 1.8rem;
  color: white;
  text-shadow: 1px 1px 1px black;
  background-color: hsl(240 100% 75%);
  width: fit-content;
  border-radius: 10px;
  border: 1px solid black;
  padding: 3px;
}
```

```
body {
  width: 1500px;
  height: 500px;
}

.anchor {
  anchor-name: --my-anchor;
  margin: 100px 350px;
}
```

The infobox is given fixed positioning, a `position-anchor` property that references the anchor's `anchor-name`, to associate the two together, and it is tethered to the anchor's top-left corner using a `position-area`.

We include a `position-try-fallbacks` list (and re-declare it with the `position-try` shorthand in case the longhand property name is not yet supported), providing two predefined position-try fallback options to prevent it from overflowing when the anchor gets near the edge of the viewport, by flipping it along the inline or block axis of the anchor.

```
.infobox {
  color: darkblue;
  background-color: azure;
  border: 1px solid #dddddd;
  padding: 10px;
  border-radius: 10px;
  font-size: 1rem;
}
```

```
.infobox {
  position: fixed;
  position-anchor: --my-anchor;
  position-area: top left;

  position-try-fallbacks: flip-block, flip-inline;
  position-try: flip-block, flip-inline;
}
```

Result

This gives us the following result:

Try scrolling so the anchor nears the edges:

- If you move the anchor near the top of the viewport, you will see the positioned element flip to the bottom-left of the anchor to avoid overflowing.
- If you move the anchor near the left of the viewport, you will see the positioned element flip to the top-right of the anchor to avoid overflowing.

Depending on the browser, once the positioned element moves to the fallback position, it may remain in the fallback position even if the fallback positioning is no longer necessary, such as when the space allows it to return to the position defined by the `position-area`.

However, if you move the anchor towards the top-left corner of the viewport, you'll notice a problem — as the positioned element starts to overflow in the block and inline direction, it flips back to its default top-left position and overflows in both directions, which is not what we want.

This is because we only gave the browser position options of `flip-block` *or* `flip-inline`. We didn't give it the option of trying both at the same time. The next example will show you how to fix this issue.

Combining multiple values into one option

Let's use a combined try fallback option to fix the problem we found with the previous demo.

HTML and CSS

All of the HTML and CSS in this demo is the same, except for the positioned element code. In this case, it is given a third position try fallback option: `flip-block flip-inline`:

```
<div class="anchor">⚓</div>

<div class="infobox">
  <p>This is an information box.</p>
</div>
```

```
body {
  width: 1500px;
  height: 500px;
}

.anchor {
  font-size: 1.8rem;
  color: white;
  text-shadow: 1px 1px 1px black;
  background-color: hsl(240 100% 75%);
  width: fit-content;
  border-radius: 10px;
  border: 1px solid black;
  padding: 3px;
}

.anchor {
  anchor-name: --my-anchor;
  margin: 100px 350px;
}

.infobox {
  color: darkblue;
  background-color: azure;
  border: 1px solid #dddddd;
  padding: 10px;
  border-radius: 10px;
  font-size: 1rem;
}
```

```
.infobox {
  position: fixed;
  position-anchor: --my-anchor;
  position-area: top left;

  position-try:
    flip-block,
    flip-inline,
    flip-block flip-inline;
  position-try-fallbacks:
    flip-block,
    flip-inline,
    flip-block flip-inline;
}
```

Result

The third position-try fallback option means that the browser will try `flip-block` then `flip-inline` to avoid overflow, and if those fallbacks fail, it will combine the two, flipping the element's position in the block and inline directions at the same time. Now when you scroll the anchor towards the top *and* left edges of the viewport, the positioned element will flip over to the bottom-right.

<code>position-area</code> try fallback options

This example shows some `position-area` position-try fallback options in action.

HTML and CSS

All of the HTML and CSS in this demo is the same, except for the positioned element code. In this case, our position try fallback options are all `position-area` values — `top`, `top right`, `right`, `bottom right`, `bottom`, `bottom left`, and `left`.

This means that the positioned element will find a reasonable position to display in, whatever viewport edges the anchor is near. This approach is a bit more longwinded than the predefined values approach, but it is also more granular and flexible.

```
<div class="anchor">⚓</div>

<div class="infobox">
  <p>This is an information box.</p>
</div>
```

```
body {
  width: 1500px;
  height: 500px;
}

.anchor {
  font-size: 1.8rem;
```

```
  color: white;
  text-shadow: 1px 1px 1px black;
  background-color: hsl(240 100% 75%);
  width: fit-content;
  border-radius: 10px;
  border: 1px solid black;
  padding: 3px;
}

.anchor {
  anchor-name: --my-anchor;
  margin: 100px 350px;
}

.infobox {
  color: darkblue;
  background-color: azure;
  border: 1px solid #dddddd;
  padding: 10px;
  border-radius: 10px;
  font-size: 1rem;
}
```

```
.infobox {
  position: fixed;
  position-anchor: --my-anchor;
  position-area: top left;

  position-try:
    top, top right, right,
    bottom right, bottom,
    bottom left, left;

  position-try-fallbacks:
    top, top right, right,
    bottom right, bottom,
    bottom left, left;
}
```

Result

Scroll the page and check out the effect of these position-try fallback options as the anchor nears the edge of the viewport.

Custom try option examples

See the `@position-try` reference page.

position-try-order CSS property

The **`position-try-order`** CSS property allows you to prioritize the `position-try-fallbacks` option applied to an anchor-positioned element when it first renders, based on which option creates the most space around the element in the given direction.

Syntax

```
/* Keyword values */
position-try-order: normal;
position-try-order: most-height;
position-try-order: most-width;
position-try-order: most-block-size;
position-try-order: most-inline-size;

/* Global values */
position-try-order: inherit;
position-try-order: initial;
position-try-order: revert;
position-try-order: revert-layer;
position-try-order: unset;
```

Values

The `position-try-order` property may be specified as either the keyword value `normal` or a `<try-size>`.

`normal`

The default. No position-try fallback options will be tried when the element is first rendered.

`<try-size>`

Defines which criteria will be used to determine what try fallback should be applied to the anchor-positioned element when it initially renders. Available values are:

`most-height`

Applies the position try fallback option that gives the element the most vertical space.

`most-width`

Applies the position try fallback option that gives the element the most horizontal space.

`most-block-size`

Applies the position try fallback option that gives the element the most space in the block direction.

`most-inline-size`

Applies the position try fallback option that gives the element the most space in the inline direction.

Description

The `position-try-order` property has a slightly different focus from the rest of the position-try features, in that it influences which position-try fallback option is applied when the positioned element is first displayed, rather than when it is being scrolled. For example, you might want to initially display the element in a space that has more available height or width than the default initial position.

The browser tests the available `position-try-fallbacks` to find which one gives the anchor-positioned element the most space in the specified direction. It will then apply that option, overriding the element's initial styling when the page first renders.

If no position try fallback option is available that provides more width/height than the initial positioning assigned to the element, no position try option will be applied, the same as if `position-try-order` were set to `normal`.

For detailed information on anchor features and position try option usage, see the CSS anchor positioning module and the Fallback options and conditional hiding for overflow guide.

The `position-try-order` property, along with the `position-try-fallbacks` property, can also be set by using the `position-try` shorthand.

Formal definition

Initial value	`normal`
Applies to	absolutely positioned elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
position-try-order =
  normal      |
  <try-size>

<try-size> =
  most-width       |
  most-height      |
  most-block-size  |
  most-inline-size
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example shows the effect of `position-try-order`.

HTML

The HTML includes two `<div>` elements that will become an anchor and an anchor-positioned element.

```
<div class="anchor">⚓</div>

<div class="infobox">
  <p>This is an information box.</p>
</div>
```

CSS

In the CSS, we start by setting a `position-try-order` value of `normal` on the anchor-positioned element, so it is easier to find when we ask you to edit it later on:

```
.infobox {
  position-try-order: normal;
}
```

The anchor is given an `anchor-name` and a large `margin` to position it near center of the viewport:

```
.anchor {
  font-size: 1.8rem;
  color: white;
  text-shadow: 1px 1px 1px black;
  background-color: hsl(240 100% 75%);
  width: fit-content;
  border-radius: 10px;
  border: 1px solid black;
  padding: 3px;
}
```

```
.anchor {
  anchor-name: --my-anchor;
  margin: 90px auto;
}
```

```
.infobox {
  color: darkblue;
  background-color: azure;
  border: 1px solid #dddddd;
  padding: 10px;
  border-radius: 10px;
  font-size: 1rem;
  text-align: center;
}
```

We include a custom position option named `--custom-bottom`, which will positions the anchor-positioned element below the anchor and give it an appropriate margin:

```
@position-try --custom-bottom {
  top: anchor(bottom);
  bottom: unset;
  margin-top: 10px;
}
```

We initially position the anchor-positioned element above its anchor, and then give it our custom position option using the `position-try-fallbacks` property.

```
.infobox {
  position: fixed;
  position-anchor: --my-anchor;

  bottom: anchor(top);
  margin-bottom: 10px;
  justify-self: anchor-center;

  position-try-fallbacks: --custom-bottom;
}
```

Result

Initially, the anchor-positioned element is positioned above its anchor, which is the default position we've given it.

Now open the example in the MDN Playground by pressing the **Play** button, run the example, then change the `position-try-order` to `most-height` or `most-block-size`. When the example re-renders, the anchor-positioned element is positioned below its anchor: `--custom-bottom` fallback is applied because it gives the positioned element more surrounding height than the default position.

position-visibility CSS property

The **`position-visibility`** CSS property enables conditionally hiding an anchor-positioned element depending on, for example, whether it is overflowing its containing element or the viewport.

Syntax

```
/* Single values */
position-visibility: always;
position-visibility: anchors-valid;
position-visibility: anchors-visible;
position-visibility: no-overflow;

/* Global values */
position-visibility: inherit;
position-visibility: initial;
position-visibility: revert;
position-visibility: revert-layer;
position-visibility: unset;
```

Values

This property is specified as one of the following keyword values:

`always`

The positioned element is always displayed.

`anchors-valid`

If the positioned element's `position-anchor` value doesn't point to a valid anchor element, the positioned element will be strongly hidden.

`anchors-visible`

If the anchor is completely hidden, either by overflowing its containing element (or the viewport) or being covered by other elements, the positioned element will be strongly hidden.

`no-overflow`

If the positioned element starts to overflow its containing element or the viewport, it will be strongly hidden.

Description

In some situations, you might not want to display an anchor-positioned element. For example, if its associated anchor has been scrolled offscreen but the anchor-positioned element would otherwise still be partially or fully visible, it might be unclear what it refers to and take up space unnecessarily, so you may want to hide it altogether.

The `position-visibility` property can be used to `always` show the anchor-positioned element, or conditionally hide it in certain situations:

- `anchors-visible`: The associated anchor element is completely hidden.
- `anchors-valid`: The anchor-positioned element's `position-anchor` property doesn't reference a valid `anchor-name` set on an anchor element in the same document.
- `no-overflow`: The anchor-positioned element is partially or completely hidden.

When an element is hidden due to `position-visibility`, it is referred to as **strongly hidden**. This means that it will act as though it and its descendant elements have a `visibility` value of `hidden` set, regardless of what their actual visibility value is.

`position-visibility` should only be used in situations in which hiding the positioned element altogether is preferred. In most cases, it makes more sense to attempt to change the placement of positioned elements when they start to overflow, to keep them on-screen and usable. This can be done with the `position-try-fallbacks` property and `@position-try` at-rule. See the Fallback options and conditional hiding for overflow guide for more information.

Formal definition

Initial value	`anchors-visible`
Applies to	absolutely positioned elements
Inherited	no

Computed value	as specified
Animation type	discrete

Formal syntax

```
position-visibility =
  always                                          |
  [ anchor-valid || anchor-visible || no-overflow ]
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example enables changing the value of an anchor positioned element's `position-visibility` property to demonstrate the effects of each value.

HTML

We specify two `<div>` elements: an anchor element with a class of `anchor` and a positioned element with a class of `infobox`.

```
<p>
  Malesuada nunc vel risus commodo viverra maecenas accumsan lacus. Vel elit
  scelerisque mauris pellentesque pulvinar pellentesque habitant morbi
  tristique.
</p>

<p>
  Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod tempor
  incididunt ut labore et dolore magna aliqua. Dui nunc mattis enim ut tellus
  elementum sagittis vitae et.
</p>

<p>
  Malesuada nunc vel risus commodo viverra maecenas accumsan lacus. Vel elit
  scelerisque mauris pellentesque pulvinar pellentesque habitant morbi
  tristique. Porta lorem mollis aliquam ut porttitor. Turpis cursus in hac
  habitasse platea dictumst quisque.
</p>
```

```
<div class="anchor">⚓</div>

<div class="infobox">
  <p>This is an information box.</p>
</div>
```

```
<p>
  Nisi quis eleifend quam adipiscing vitae proin sagittis nisl rhoncus. In arcu
  cursus euismod quis viverra nibh cras pulvinar. Vulputate ut pharetra sit amet
  aliquam.
</p>

<p>
  Malesuada nunc vel risus commodo viverra maecenas accumsan lacus. Vel elit
  scelerisque mauris pellentesque pulvinar pellentesque habitant morbi
  tristique. Porta lorem mollis aliquam ut porttitor. Turpis cursus in hac
  habitasse platea dictumst quisque. Dolor sit amet consectetur adipiscing elit.
  Ornare lectus sit amet est placerat. Nulla aliquet porttitor lacus luctus
  accumsan.
</p>

<form>
  <fieldset>
    <legend>Choose position visibility</legend>
    <div>
      <label for="radio-always">always</label>
      <input
        type="radio"
        id="radio-always"
        name="position-visibility"
        value="always"
        checked />
    </div>
    <div>
      <label for="radio-anchors-visible">anchors-visible</label>
      <input
        type="radio"
        id="radio-anchors-visible"
        name="position-visibility"
        value="anchors-visible" />
    </div>
    <div>
      <label for="radio-no-overflow">no-overflow</label>
      <input
        type="radio"
        id="radio-no-overflow"
        name="position-visibility"
        value="no-overflow" />
    </div>
  </fieldset>
</form>
```

The HTML also includes filler text to make the content taller than the viewport so scrolling is required. We've also included a `<fieldset>` with a group of radio inputs with different `position-visibility` values. The markup for these is not shown for the sake of brevity.

CSS

We style an `anchor` `<div>` as an anchor element and tether the `infobox` `<div>` to it. The relevant CSS is as follows:

```
body {
  width: 50%;
  margin: 0 auto;
}

.anchor {
  font-size: 1.8rem;
  color: white;
  text-shadow: 1px 1px 1px black;
  background-color: hsl(240 100% 75%);
  width: fit-content;
  border-radius: 10px;
  border: 1px solid black;
  padding: 3px;
}

form {
  position: fixed;
  background: white;
  bottom: 2px;
  right: 2px;
}

.infobox {
  color: darkblue;
  background-color: azure;
  border: 1px solid #dddddd;
  padding: 10px;
  border-radius: 10px;
  font-size: 1rem;
}
```

```
.anchor {
  anchor-name: --my-anchor;
}

.infobox {
  position-anchor: --my-anchor;
  position: fixed;
  position-area: top span-all;
  margin-bottom: 5px;
  position-visibility: always;
}
```

JavaScript

We include a change event handler on the radio buttons so that, when a new value is selected, we update the infobox's `position-visibility` property value.

```
const infobox = document.querySelector(".infobox");
const radios = document.querySelectorAll('[name="position-visibility"]');

for (const radio of radios) {
  radio.addEventListener("change", setPositionVisibility);
}

function setPositionVisibility(e) {
  infobox.style.positionVisibility = e.target.value;
}
```

Result

Select different `position-visibility` values and then scroll the page up and down to see their effects. With `position-visibility: always` set, the positioned element will not be hidden. With `position-visibility: anchors-visible` set, the positioned element will only be visible when the anchor is partially or fully on-screen. With `position-visibility: no-overflow` set, the positioned element will be hidden as soon as it starts to overflow the viewport.

print-color-adjust CSS property

The **`print-color-adjust`** CSS property sets what, if anything, the user agent may do to optimize the appearance of the element on the output device. By default, the browser is allowed to make any adjustments to the element's appearance it determines to be necessary and prudent given the type and capabilities of the output device.

Syntax

```
print-color-adjust: economy;
print-color-adjust: exact;

/* Global values */
print-color-adjust: inherit;
print-color-adjust: initial;
print-color-adjust: revert;
print-color-adjust: revert-layer;
print-color-adjust: unset;
```

Values

This property is specified as one of the following keyword values:

`economy`

The user agent is allowed to make adjustments to the element as it deems appropriate and prudent in order to optimize the output for the device it's being rendered for. For example, when printing, a browser might opt to leave out all background images and to adjust text colors to be sure the contrast is optimized for reading on white paper. This is the default.

`exact`

The element's content has been specifically and carefully crafted to use colors, images, and styles in a thoughtful and/or important way, such that being altered by the browser might actually make things worse rather than better. The appearance of the content should not be changed except by the user's request. For example, a page might include a list of information with rows whose background colors alternate between white and a light gray. Removing the background color would decrease the legibility of the content.

Usage notes

There are a number of reasons a browser might wish to deviate from the specified appearance, such as:

- The content uses text and background colors that will be too similar on the output device for legibility purposes.
- If the output device is a printer, and to save ink, dark or extremely dense background images might be removed.
- When printing a page, the browser might want to replace light-colored text on a dark background with dark text on a white background.

Any options the user agent offers the user to allow them to control the use of color and images will take priority over the value of `print-color-adjust`. In other words, there isn't any guarantee that `print-color-adjust` will do anything. Not only can the user override the behavior, but each user agent is allowed to decide for itself how to handle `print-color-adjust` in any given situation.

Formal definition

Initial value	`economy`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
print-color-adjust =
  economy  |
  exact
```

This syntax reflects the latest standard as per CSS Color Adjustment Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Preserving low contrast

In this example, a box is shown which uses a `background-image` and a translucent `linear-gradient()` function atop a black background color to have a dark blue gradient behind medium red text. For whatever reason, this is the desired appearance in any rendering environment, including on paper, so we also use `print-color-adjust: exact` to tell the browser not to make color or style adjustments to the box when rendering it.

CSS

```
.my-box {
  background-color: black;
  background-image: linear-gradient(rgb(0 0 180 / 50%), rgb(70 140 220 / 50%));
  color: #990000;
  width: 15rem;
  height: 6rem;
  text-align: center;
  font:
    24px "Helvetica",
    sans-serif;
  display: flex;
  align-items: center;
  justify-content: center;
  print-color-adjust: exact;
}
```

HTML

```
<div class="my-box">
  <p>Need more contrast!</p>
</div>
```

Result

See also

- Other color-related properties: `color`, `background-color`, `border-color`, `outline-color`, `text-decoration-color`, `text-emphasis-color`, `text-shadow`, `caret-color`, and `column-rule-color`
- `background-image`

quotes CSS property

The CSS **`quotes`** property sets how the browser should render quotation marks that are automatically added to the HTML `<q>` element or added using the `open-quotes` or `close-quotes` (or omitted using the `no-open-quote` and `no-close-quote`) values of the of the CSS `content` property.

Browsers insert quotation marks at the opening and closing of `<q>` elements and for the `open-quote` and `close-quote` values of the `content` property. Each opening or closing quote is replaced by one of the strings from the value of `quotes`, based on the depth of nesting, or, if `quotes` is explicitly set to or otherwise resolves to `auto`, the quotation marks used are language dependent.

Try it

```

<section id="default-example">
  <q id="example-element"
    >Show us the wonder-working <q>Brothers,</q> let them come out publicly—and
    we will believe in them!</q
  >
</section>
```

```
q {
  font-size: 1.2rem;
}
```

Syntax

```
/* Keyword values */
quotes: none;
quotes: auto;

/* <string> values */
quotes: "«" "»"; /* Set open-quote and close-quote to use French quotation marks */
quotes: "«" "»" "‹" "›"; /* Set two levels of quotation marks */

/* Global values */
quotes: inherit;
quotes: initial;
quotes: revert;
quotes: revert-layer;
quotes: unset;
```

Values

`none`

The `open-quote` and `close-quote` values of the `content` property produce no quotation marks, as if `no-open-quote` and `no-close-quote` were set, respectively.

`auto`

Quotation marks that are typographically appropriate for the inherited language (i.e., via the `lang` attribute set on the parent or other ancestor).

`<string>`

Defines one or more pairs of quotation mark values for opening and closing quotes. In each pair, the first of each pair of quotes are used as the values for the `open-quote` and the second of each pair is the `close-quote`.

The first pair represents the quotation's outer level. The second pair, if present, represents the first nested level. The next pair is used for doubly nested levels, and so on. If the depth of quote nesting is greater than the number of pairs, the last pair in the `quotes` value is repeated.

Which pair of quotes is used depends on the depth, or nesting level, of quotes: the number of occurrences of `<q>` quotes or `open-quote` (or `no-open-quote`) in all generated text before the current occurrence, minus the number of occurrences of closing quotes, either as `</q>`, `close-quote`, or `no-close-quote`. If the depth is 0, the first pair is used, if the depth is 1, the second pair is used, etc.

> **Note:** The CSS `content` property value `no-open-quote` increments and `no-close-quote` decrements the quoting level, but they do not insert quotation marks.

Formal definition

Initial value	depends on user agent
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
quotes =
  auto                  |
  none                  |
  bikeshed-this         |
  [ <string> <string> ]+
```

This syntax reflects the latest standard as per CSS Generated Content Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Default quotes and overrides

This example compares the default quotes provided by the semantic HTML `<q>` element to those we define using the CSS `quotes` property.

The default value of `quotes` is `auto`. In this example, the first list item has `quotes: auto` set, so gets the default quotes for the language specified; the same as if no `quotes` property was set. The second list item defines which quotation marks to use for quotes and nested quotes; these quotation marks will be used for descendants of an element with `specialQuotes` class regardless of the language (like any `lang` attribute values set).

HTML

```
<ul>
  <li>
    Default quotes:
    <p lang="ru">
      <q
        >Митч Макконнелл - это человек, который знает о России и ее влиянии
        меньше, чем даже Дональд Трамп, и <q>я ничего не знаю</q>, сказал
        Трамп</q
      >, - писал Раджу.
    </p>
  </li>
  <li class="specialQuotes">
    Defined by <code>quotes</code> property :
    <p lang="ru">
      <q
```

```
        >Митч Макконнелл - это человек, который знает о России и ее влиянии
        меньше, чем даже Дональд Трамп, и <q>я ничего не знаю</q>, сказал
        Трамп</q
      >, - писал Раджу.
    </p>
  </li>
</ul>
```

CSS

```
li {
  quotes: auto;
}

.specialQuotes {
  quotes: "“" "”" "‘" "’";
}
```

Result

By default, browser provide language specific quotation marks when the `<q>` element is used. If the `quotes` property is defined, the values provided override the browser defaults. Note the `quotes` property is inherited. The `quotes` property is set on the `<li>` with the `specialQuotes` class, but the quotes are applied the `<q>` elements.

Note that each open-quote and close-quote is replaced by one of the strings from the value of quotes, based on the depth of nesting.

Auto quotes

The default value of `quotes` is `auto`. This example works without it being explicitly being set.

HTML

```
<ul>
  <li lang="fr">
    <q>Ceci est une citation française.</q>
  </li>
  <li lang="ru">
    <q>Это русская цитата</q>
  </li>
  <li lang="de">
    <q>Dies ist ein deutsches Zitat</q>
  </li>
  <li lang="en">
    <q>This is an English quote.</q>
  </li>
</ul>
```

CSS

```
q {
  quotes: auto;
}
li:not(:last-of-type) {
  border-bottom: 1px solid;
}
```

```
li {
  padding: 0.5em 0;
}
```

Result

Note that the `lang` attribute was placed on an ancestor of the `<q>`, not the `<q>` itself. If a quotation is in a different language than the surrounding text, it is customary to quote the text with the quote marks of the language of the surrounding text, not the language of the quotation itself.

With generated content

In this example, instead of using the `<q>` element, we are adding quotation marks to the `::before` and `::after` pseudo-elements before and after the content of each element with a specific class name.

HTML

```
<p>
  <span class="quote">I should be using quotes</span>, I thought,
  <span class="quote"
    >But why use semantic HTML elements when I can add classes to
    <span class="quote">ALL THE THINGS!</span>?
  </span>
</p>
```

CSS

```
.quote {
  quotes: '"' '"' "'" "'";
}
.quote::before {
  content: open-quote;
}
.quote::after {
  content: close-quote;
}
```

Result

Text as quotes and empty quotes

This example demonstrates using something other than quotation marks as the `<string>` values. The open-quote indicates the speaker and, as there is no opening quotation mark, the close-quote is empty. (Mixing a `<string>` with an enumerated keyword to create a pair is not supported). We set `auto` for the nested quotes. These nested quotes will be book-ended by whatever the language dictates is normal for nested quotes.

HTML

```
<ul>
  <li><q data-speaker="karen">Hello</q></li>
  <li><q data-speaker="chad">Hi</q></li>
  <li><q data-speaker="karen">this conversation is not interesting</q></li>
  <li>
    <q data-speaker="pat"
      >OMG! <q>Hi</q>? Seriously? at least <q>hello</q> is five letters long.</q
    >
  </li>
</ul>
```

CSS

```
[data-speaker="karen" i] {
  quotes: "She said: " "";
}
[data-speaker="chad" i] {
  quotes: "He said: " "";
}
[data-speaker="pat" i] {
  quotes: "They said: " "";
}
[data-speaker] q {
  quotes: auto;
}
```

```
li {
  padding: 0.5em 0;
}
```

r CSS property

The **`r`** CSS property defines the radius of a circle. It can only be used with the SVG `<circle>` element. If present, it overrides the circle's `r` attribute.

> **Note:** The `r` property only applies to `<circle>` elements nested in an `<svg>`. It doesn't apply to other SVG elements or HTML elements or pseudo-elements.

Syntax

```
/* Length and percentage values */
r: 3px;
r: 20%;

/* Global values */
r: inherit;
r: initial;
r: revert;
r: revert-layer;
r: unset;
```

Values

The `<length>` and `<percentage>` values define the radius of the circle.

`<length>`

Absolute or relative lengths can be expressed in any unit allowed by the CSS `<length>` data type. Negative values are invalid.

`<percentage>`

Percentages refer to the normalized diagonal of the current SVG viewport, which is calculated as $\frac{\sqrt{<\text{width}>^2 + <\text{height}>^2}}{\sqrt{2}}$.

Formal definition

Initial value	`0`
Applies to	`<circle>` element in `<svg>`
Inherited	no
Percentages	refer to the normalized diagonal of the current SVG viewport
Computed value	the percentage as specified or the absolute length
Animation type	by computed value type

Formal syntax

```
r =
  <length-percentage>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Specification, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Defining the radius of a circle

In this example, we have two identical `<circle>` elements in an SVG, each with a `10` radius and the same `x`- and `y`-axis coordinates for their center points.

```
<svg xmlns="http://www.w3.org/2000/svg">
  <circle cx="50" cy="50" r="10" />
  <circle cx="50" cy="50" r="10" />
</svg>
```

With CSS, we style only the first circle, allowing the second circle to use default styles (with `fill` defaulting to black). We use the `r` property to override the value of the SVG `r` attribute, giving it a `fill` and `stroke`. The default size of an SVG is `300px` wide and `150px` tall.

```
svg {
  border: 1px solid black;
}

circle:first-of-type {
  r: 30px;
  fill: lightgreen;
  stroke: black;
}
```

ViewBox versus viewport pixels

This example contains two SVGs, each with two `<circle>` elements. The second SVG includes a `viewBox` attribute to demonstrate the difference between SVG viewBox and SVG viewports.

```
<svg xmlns="http://www.w3.org/2000/svg">
  <circle cx="50" cy="50" r="10" />
  <circle cx="50" cy="50" r="10" />
</svg>
<svg viewBox="0 0 200 100" xmlns="http://www.w3.org/2000/svg">
  <circle cx="50" cy="50" r="10" />
  <circle cx="50" cy="50" r="10" />
</svg>
```

The CSS is similar to the previous example, with `r: 30px` set, but we set a `width` to ensure the images are both `300px` wide:

```
svg {
  border: 1px solid black;
  width: 300px;
}

circle:first-of-type {
  r: 30px;
  fill: lightgreen;
  stroke: black;
}
```

Because the `viewBox` attribute defines the SVG as 200 SVG coordinate system pixels wide, and the image is scaled up to `300px`, the `30` SVG coordinate pixels are scaled to be rendered as `45` CSS pixels.

Defining the radius of a circle using percentages

In this example, we use the same markup as the previous example. The only difference is the `r` value; in this case, we use a percentage value.

```
<svg xmlns="http://www.w3.org/2000/svg">
  <circle cx="50" cy="50" r="10" />
  <circle cx="50" cy="50" r="10" />
</svg>
<svg viewBox="0 0 200 100" xmlns="http://www.w3.org/2000/svg">
  <circle cx="50" cy="50" r="10" />
  <circle cx="50" cy="50" r="10" />
</svg>
```

```
svg {
  border: 1px solid black;
  width: 300px;
}

circle:first-of-type {
  r: 30%;
  fill: lightgreen;
  stroke: black;
}
```

In both cases, the circle radius is `30%` of the normalized diagonal of the SVG viewport. The radius `r` is equal to $0.3 \times \frac{\sqrt{\text{<width>}^2 + \text{<height>}^2}}{\sqrt{2}}$. While the first image is using `300` and `150` CSS pixels and the second is using `200` and `100` SVG view box units, 30% is a proportional value. As a result, the `r` value is the same: `47.43` viewBox units, which resolves to `71.15` CSS pixels.

While the `r` is the same, the center points differ because the second SVG is scaled up by 50%, pushing its center down and to the right by 50%.

reading-flow CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`reading-flow`** CSS property enables modifying the reading order of child elements of a block, flex, or grid layout. This affects the order in which they are rendered to speech and navigated to when using sequential navigation such as tabbing to links or buttons.

Syntax

```
/* Keyword values */
reading-flow: normal;
reading-flow: flex-visual;
reading-flow: flex-flow;
reading-flow: grid-columns;
reading-flow: grid-rows;
reading-flow: grid-order;
reading-flow: source-order;

/* Global values */
reading-flow: inherit;
reading-flow: initial;
reading-flow: revert;
reading-flow: revert-layer;
reading-flow: unset;
```

Value

The `reading-flow` property takes one of the following keywords as its value:

`normal`

The default value. The reading order follows the order of elements in the DOM.

`flex-visual`

Only affects flex containers. The reading order follows the visual order of the `flex` items, taking the `writing-mode` into account. Therefore, a document in English with `flex-direction: row-reverse` and `reading-flow: flex-visual` set would have a reading order of left-to-right.

`flex-flow`

Only affects flex containers. The reading order follows the `flex-flow` direction.

`grid-columns`

Only affects grid containers. The reading order follows the visual order of grid items, column by column, taking the writing mode into account.

`grid-rows`

Only affects grid containers. The reading order follows the visual order of grid items, row by row, taking the writing mode into account.

`grid-order`

Only affects grid containers. if the `order` property is applied to any of the container's children, the reading order follows the modified item order. If the `order` property is not applied to the grid items, `grid-order` behaves as `normal`.

`source-order`

Affects grid, flex, and block containers. Has no effect on its own — the container's reading order continues to follow the order of elements in the DOM — but allows the reading order to be modified by setting the `reading-order` property on the container's children.

Description

The `reading-flow` property modifies the reading order of elements within a block, flex, or grid container when set to a value other than `normal`. Such a container is referred to as a reading flow container.

By default, web content is read out in DOM source order. Generally, the source order should express a sensible reading order for the content, and this should also be reflected by the visual order in the content layout. However, sometimes the visual order or tab order differs from the source order. For example, when applying multiple flexbox or grid layouts to a document via media queries to suit different device or user requirements, the content order may differ based on the viewport width. In such a case, the `reading-flow` can be used to ensure the reading and tabbing order reflect the visual order.

In some cases you may wish to further fine-tune the reading order within a reading flow container. You can use `reading-order` property values on the container's children, putting them into ordinal groups which are then read out in numerical order.

Interaction with <code>tabindex</code>

If a set of reading flow container child elements that are not normally focusable are made focusable with `tabindex="0"` attributes, their reading order will be modified as expected by the `reading-flow` and `reading-order` properties, in just the same way as interactive elements such as `<a>` or `<button>`.

However, any attempt to modify the tabbing order of a reading flow container's content using positive `tabindex` values will be ignored — overridden by the effects of `reading-flow` and `reading-order`. You generally shouldn't be using these anyway; see Don't Use Tabindex Greater than 0. The `reading-flow` and `reading-order` properties provide a much better way to modify tabbing order if required.

Formal definition

Initial value	`normal`
Applies to	Block-containers, flex containers, and grid containers
Inherited	no
Computed value	as specified
Animation type	Not animatable

Examples

Flex value comparison

In this example, we demonstrate the effects of different `reading-flow` values on a flex container with reversed flex items.

HTML

The markup includes a `<select>` element for selecting different `reading-flow` values, and a wrapper `<div>` containing three `<a>` elements.

```
<form>
  <label for="reading-flow">Choose reading flow:</label>
  <select id="reading-flow">
    <option>normal</option>
    <option>flex-visual</option>
    <option>flex-flow</option>
  </select>
</form>
<div class="wrapper">
  <a href="#">Item 1</a>
  <a href="#">Item 2</a>
  <a href="#">Item 3</a>
</div>
```

CSS

We use a `display` value of `flex` to turn the `<div>` into a flex container, and display the flex items in a row in reverse DOM order with a `flex-direction` value of `row-reverse`. Initially, we set a `reading-flow` of `normal` so the items are read or tabbed through in DOM source order.

We also set an `order` value of `1` on the first `<a>` element to cause it to display after the second and third item in the flex flow. The resulting visual order of the flex items from left to right is "Item 1", "Item 3", then "Item 2", but the DOM order remains unchanged.

```
.wrapper {
  display: flex;
  flex-direction: row-reverse;
  reading-flow: normal;
  gap: 1em;
}

a:first-child {
  order: 1;
}
```

JavaScript

In our script, we grab references to the `<select>` element and wrapper `<div>`, then add a `change` event listener to the `<select>` element. When a new value is selected, it is set as a `reading-flow` property value on the wrapper.

```
const selectElem = document.getElementById("reading-flow");
const wrapperElem = document.querySelector(".wrapper");

selectElem.addEventListener("change", () => {
  wrapperElem.style.readingFlow = selectElem.value;
});
```

Result

The demo renders like this:

First, try tabbing through the links with `reading-flow: normal` set. The tabbing order is "Item 1", "Item 2", then "Item 3", as that is the order of the elements in the DOM.

Now try changing the `reading-flow` value and tabbing through the links again:

- A value of `flex-visual` causes the items to be tabbed through in the order "Item 1", "Item 3", then "Item 2", which is the visual display order resulting from the applied flexbox properties.
- A value of `flex-flow` causes the items to be tabbed through in the order "Item 2", "Item 3", then "Item 1", which matches the direction of the `flex-flow` — in this case, `row-reverse`. Here, the tabbing order is the reverse of the display order.

Grid value comparison

In this example, we demonstrate the effects of different `reading-flow` values on a grid container.

HTML

The markup includes a `<select>` element for selecting different `reading-flow` values, and a wrapper `<div>` containing four `<a>` elements.

```
<form>
  <label for="reading-flow">Choose reading flow:</label>
  <select id="reading-flow">
    <option>normal</option>
    <option>grid-rows</option>
    <option>grid-columns</option>
    <option>grid-order</option>
  </select>
</form>
<div class="wrapper">
  <a class="a" href="#">Item A</a>
  <a class="b" href="#">Item B</a>
  <a class="c" href="#">Item C</a>
  <a class="d" href="#">Item D</a>
</div>
```

CSS

We use a `display` value of `grid` to turn the `<div>` into a grid container, and display the grid items in three columns using `grid-template-columns`. We also set `grid-template-areas` to describe different placement areas in those columns, and place the `<a>` elements in those areas using `grid-area`. Initially, we set a `reading-flow` of `normal` so the items are read or tabbed through in the default DOM source order.

Finally, we set an `order` value of `1` on the first `<a>` element; this has no effect on the layout because it does not override the grid area placement, but it does have an effect when a certain `reading-flow` value is set, as you'll se later on.

Reading from left to right, the resulting display order of the grid items is "Item D", "Item B", "Item C", then "Item A".

```
.wrapper {
  display: grid;
  grid-template-columns: repeat(3, 150px);
  grid-template-areas:
```

```
    "d b b"
    "c c a";
  reading-flow: normal;
}

.a {
  grid-area: a;
}
.b {
  grid-area: b;
}
.c {
  grid-area: c;
}
.d {
  grid-area: d;
}

a:first-child {
  order: 1;
}
```

JavaScript

In our script, we grab references to the `<select>` element and wrapper `<div>`, then add a `change` event listener to the `<select>` element. When a new value is selected, it is set as a `reading-flow` property value on the wrapper.

```
const selectElem = document.getElementById("reading-flow");
const wrapperElem = document.querySelector(".wrapper");

selectElem.addEventListener("change", () => {
  wrapperElem.style.readingFlow = selectElem.value;
});
```

Result

The demo renders like this:

First, try tabbing through the links with `reading-flow: normal` set. The tabbing order is "Item A", "Item B", "Item C", and "Item D", as that is the order of the elements in the DOM.

Now change the `reading-flow` value and then try tabbing through the links again:

- A value of `grid-rows` causes the items to be tabbed through in the visual display order by row. This is "Item D", "Item B", "Item C", then "Item A".
- A value of `grid-columns` causes the items to be tabbed through in the visual display order by column. This is "Item D", "Item C", "Item B", then "Item A".
- A value of `grid-order` causes the items to be tabbed through in DOM order, but takes into account any `order` value changes. Since we have `order: 1;` set on the first `<a>` element, the tabbing order is "Item B", "Item C", "Item D", then "Item A".

Reading order adjustment on block containers

In this example, we demonstrate the effects of the `reading-flow: source-order` value on a block container.

HTML

The markup includes a wrapper `<div>` containing four `<a>` elements.

```
<div class="wrapper">
  <a class="a" href="#">Item A</a>
  <a class="b" href="#">Item B</a>
  <a class="c" href="#">Item C</a>
  <a class="d" href="#">Item D</a>
</div>
```

CSS

We set a `reading-flow` of `source-order` so the items are read or tabbed through in DOM source order, but modifications are allowed to the reading order via `reading-order`. We set a `reading-order` value of `1` on the first `<a>` element.

```
.wrapper {
  reading-flow: source-order;
}

a:first-child {
  reading-order: 1;
}
```

Result

The demo renders like this:

Try tabbing through the links: the tabbing order is "Item B", "Item C", "Item D", then "Item A" — the order of the elements in the DOM is followed, but Item A has been put in a higher reading order ordinal group than the others (the default `reading-order` value is `0`), therefore it is tabbed to last.

reading-order CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`reading-order`** CSS property enables changing the order in which a child of a reading flow container is read relative to its element siblings.

Syntax

```
/* <integer> values */
reading-order: 1;
reading-order: -1;

/* Global values */
reading-order: inherit;
reading-order: initial;
reading-order: revert;
reading-order: revert-layer;
reading-order: unset;
```

Value

`<integer>`

Represents the ordinal group the element belongs to.

Description

When an element's block, flex, or grid parent container has a `reading-flow` property set to a value other than `normal`, the `reading-order` property can be used to set the element's reading flow position relative to that of its siblings.

For reading and navigation, elements inside a block, flex, or grid container are sorted by ascending `reading-order` value. If multiple siblings have the same `reading-order` value, those items are sorted according to the container's `reading-flow`. Siblings not given an explicit `reading-order` value are assigned the default value of `0`, which puts all the children of a reading flow container in the same ordinal group by default.

Sibling elements are ordered starting from the lowest numbered ordinal group to the highest. Therefore, to cause an element to be read out after its siblings, you could set a `reading-order` value or `1` or more on it. To cause an element to be read out before its siblings, you could set a `reading-order` value or `-1` or less on it.

The `reading-order` defines the reading and tabbing order, but has no effect on visual order.

Interaction with <code>tabindex</code>

If a set of reading flow container child elements that are not normally focusable are made focusable with `tabindex="0"` attributes, their reading order will be modified as expected by the `reading-flow` and `reading-order` properties, in just the same way as interactive elements such as `<a>` or `<button>`.

However, any attempt to modify the tabbing order of a reading flow container's content using positive `tabindex` values will be ignored — overridden by the effects of `reading-flow` and `reading-order`. You generally shouldn't be using these anyway; see Don't Use Tabindex Greater than 0. The `reading-flow` and `reading-order` properties provide a much better way to modify tabbing order if required.

Formal definition

Initial value	`0`
Applies to	Block-containers, flex containers, and grid containers
Inherited	no
Computed value	The specified integer
Animation type	by computed value type

Examples

Grid row order

This example demonstrates using `reading-order` to control the positions of individual grid items within a grid container's reading order. One grid item has a `reading-order` value that is lower than the default `0`, so will be read out before its sibling elements. Another has a higher `reading-order` value set, so will be read out after the others, regardless of source or display order.

HTML

In our markup we have six `<a>` elements contained inside a wrapper `<div>`.

```
<div class="wrapper">
  <a href="#">Item 1</a>
  <a class="bottom" href="#">Item 2</a>
  <a href="#">Item 3</a>
  <a class="top" href="#">Item 4</a>
  <a href="#">Item 5</a>
  <a href="#">Item 6</a>
</div>
```

CSS

On the `<div>`, we set the grid-auto-flow property to `dense`, therefore items may display out of source order. The `reading-order` property on the `<a>` element with a class of `top` is set to `-1`, therefore "Item 4" will be the first item in reading flow. The `reading-order` property on the `<a>` element with a class of `bottom` is set to `21`, therefore "Item 4" will be the last item in the reading order. The remaining items will be visited in between, in grid row order, as the `<div>` element's `reading-flow` property is set to grid-rows.

```
.wrapper {
  display: grid;
  grid-template-columns: repeat(3, 150px);
  grid-auto-flow: dense;
  reading-flow: grid-rows;
}

.top {
  reading-order: -1;
}

.bottom {
  reading-order: 21;
}
```

Result

The above demo renders as follows:

Try tabbing through the links. Note how "Item 4" is tabbed to first and "Item 2" is tabbed to last because of their modified `reading-order` values. In between, the items are tabbed to in grid row order.

Source order override

In this example, the odd-numbered items have a lower `reading-order` value set, so will be read out before the others in a group, regardless of source or display order.

HTML

In our markup, we have five `<a>` elements contained inside a wrapper `<div>`.

```
<div class="wrapper">
  <a href="#">Item 1</a>
  <a href="#">Item 2</a>
  <a href="#">Item 3</a>
  <a href="#">Item 4</a>
  <a href="#">Item 5</a>
</div>
```

CSS

The `<div>` element's `reading-flow` property is set to `source-order`, which allows `reading-order` to be used to override the default source reading order. The odd-numbered `<a>` elements have a `reading-order` value of `-1`, therefore they are read out before the even-numbered items.

```
.wrapper {
  reading-flow: source-order;
}

.wrapper > a {
  display: block;
}

.wrapper a:nth-child(odd) {
  reading-order: -1;
}
```

Result

The above demo renders as follows:

Try tabbing through the links, and note how "Item 1", "Item 3", and "Item 5" are tabbed to first because of their modified `reading-order`. After that, the items are tabbed to in source order.

resize CSS property

The **`resize`** CSS property sets whether an element is resizable, and if so, in which directions.

Try it

```
resize: both;
```

```
resize: horizontal;
```

```
resize: vertical;
```

```
resize: none;
```

```
<section class="default-example" id="default-example">
  <div id="example-element">Try resizing this element.</div>
</section>
```

```
#example-element {
  background: linear-gradient(135deg, cyan 0%, cyan 94%, white 95%);
  border: 3px solid #c5c5c5;
  overflow: auto;
  width: 250px;
  height: 250px;
  font-weight: bold;
  color: black;
  display: flex;
  align-items: center;
  justify-content: center;
  padding: 10px;
}
```

`resize` does not apply to the following:

- Inline elements
- Block elements for which the `overflow` property is set to `visible` or `clip`

Syntax

```
/* Keyword values */
resize: none;
resize: both;
resize: horizontal;
resize: vertical;
resize: block;
resize: inline;

/* Global values */
resize: inherit;
resize: initial;
resize: revert;
resize: revert-layer;
resize: unset;
```

Values

This property is specified as one of the following keyword values:

`none`

The element offers no user-controllable method for resizing it.

`both`

The element displays a mechanism for allowing the user to resize it, which may be resized both horizontally and vertically.

`horizontal`

The element displays a mechanism for allowing the user to resize it in the *horizontal* direction.

`vertical`

The element displays a mechanism for allowing the user to resize it in the *vertical* direction.

`block`

The element displays a mechanism for allowing the user to resize it in the *block* direction (either horizontally or vertically, depending on the `writing-mode` and `direction` value).

`inline`

The element displays a mechanism for allowing the user to resize it in the *inline* direction (either horizontally or vertically, depending on the `writing-mode` and `direction` value).

Formal definition

Initial value	none
Applies to	elements with `overflow` other than `visible`, and optionally replaced elements representing images or videos, and iframes
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
resize =
  none        |
  both        |
  horizontal  |
  vertical    |
  block       |
  inline
```

This syntax reflects the latest standard as per CSS Basic User Interface Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Disabling resizability of text areas

In many browsers, `<textarea>` elements are resizable by default. You may override this behavior with the `resize` property.

HTML

```
<textarea>Type some text here.</textarea>
```

CSS

```
textarea {
  resize: none; /* Disables resizability */
}
```

Result

Using resize with arbitrary elements

You can use the `resize` property to make any element resizable. In the example below, a resizable `<div>` contains a resizable paragraph (`<p>` element).

HTML

```
<div class="resizable">
  <p class="resizable">
    This paragraph is resizable in all directions, because the CSS `resize`
    property is set to `both` on this element.
  </p>
</div>
```

CSS

```
.resizable {
  resize: both;
  overflow: scroll;
  border: 1px solid black;
}

div {
  height: 300px;
  width: 300px;
}

p {
  height: 200px;
  width: 200px;
}
```

Result

- `<textarea>`

right CSS property

The **`right`** CSS property participates in specifying the horizontal position of a positioned element. This inset property has no effect on non-positioned elements.

Try it

```
right: 0;
```

```
right: 4em;
```

```
right: 10%;
```

```
right: 20px;
```

```
<section id="default-example">
  <div class="example-container">
    <div id="example-element">I am absolutely positioned.</div>
    <p>
      As much mud in the streets as if the waters had but newly retired from the
      face of the earth, and it would not be wonderful to meet a Megalosaurus,
      forty feet long or so, waddling like an elephantine lizard up Holborn
      Hill.
    </p>
  </div>
</section>
```

```
.example-container {
  border: 0.75em solid;
  padding: 0.75em;
  text-align: left;
  position: relative;
  width: 100%;
  min-height: 200px;
}

#example-element {
  background-color: #264653;
  border: 4px solid #ffb500;
  color: white;
  position: absolute;
  width: 140px;
  height: 60px;
}
```

Syntax

```
/* <length> values */
right: 3px;
right: 2.4em;
right: anchor(--my-anchor 50%);
right: anchor-size(--my-anchor height, 65px);

/* <percentage>s of the width of the containing block */
right: 10%;

/* Keyword value */
right: auto;

/* Global values */
right: inherit;
right: initial;
right: revert;
right: revert-layer;
right: unset;
```

Values

`<length>`

A negative, null, or positive `<length>`:

- for *absolutely positioned elements*, it represents the distance to the right edge of the containing block.
- for *anchor-positioned elements*, the `anchor()` function resolves to a `<length>` value relative to the position of the associated *anchor element*'s left or right edge (see Using inset properties with `anchor()` function values), and the `anchor-size()` function resolves to a `<length>` value relative to the associated anchor element's width or height (see Setting element position based on anchor size).
- for *relatively positioned elements*, it represents the distance that the element is moved to the left of its normal position.

`<percentage>`

A `<percentage>` of the containing block's width.

`auto`

Specifies that:

- for *absolutely positioned elements*, the position of the element is based on the `left` property, while `width: auto` is treated as a width based on the content; or if `left` is also `auto`, the element is positioned where it should horizontally be positioned if it were a static element.
- for *relatively positioned elements*, the distance of the element from its normal position is based on the `left` property; or if `left` is also `auto`, the element is not moved horizontally at all.

Description

The effect of `right` depends on how the element is positioned (i.e., the value of the `position` property):

- When `position` is set to `absolute` or `fixed`, the `right` property specifies the distance between the element's outer margin of right edge and the inner border of the right edge of its containing block. If the positioned element has an associated *anchor element*, and the property value includes an `anchor()` function, `right` positions the right edge of the positioned element relative to the specified `<anchor-side>` edge. The `right` property is compatible with the `left`, `right`, `start`, `end`, `self-start`, `self-end`, `center`, and `<percentage>` values.
- When `position` is set to `relative`, the `right` property specifies the distance the element's right edge is moved to the left from its normal position.
- When `position` is set to `sticky`, the `right` property is used to compute the sticky-constraint rectangle.
- When `position` is set to `static`, the `right` property has *no effect*.

When both `left` and `right` are defined, if not prevented from doing so by other properties, the element will stretch to satisfy both. If the element cannot stretch to satisfy both — for example, if a `width` is declared — the position of the element is *over-constrained*. When this is the case, the `left` value has precedence when the container is left-to-right; the `right` value has precedence when the container is right-to-left.

Formal definition

Initial value	`auto`
Applies to	positioned elements
Inherited	no
Percentages	refer to the width of the containing block
Computed value	if specified as a length, the corresponding absolute length; if specified as a percentage, the specified value; otherwise, `auto`
Animation type	a length, percentage or calc();

Formal syntax

```
right =
  auto                |
  <length-percentage>  |
  <anchor()>           |
  <anchor-size()>

<length-percentage> =
  <length>     |
  <percentage>

<anchor()> =
  anchor( <anchor-name>?                 &&
  <anchor-side> , <length-percentage>? )

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<anchor-name> =
  <dashed-ident>

<anchor-side> =
  inside       |
  outside      |
  top          |
  left         |
  right        |
  bottom       |
  start        |
  end          |
  self-start   |
  self-end     |
  <percentage>  |
  center

<anchor-size> =
  width       |
  height      |
  block       |
  inline      |
  self-block  |
  self-inline
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Positioned Layout Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Absolute and relative positioning using right

HTML

```
<div id="relative">Relatively positioned</div>
<div id="absolute">Absolutely positioned</div>
```

CSS

```
#relative {
  width: 100px;
  height: 100px;
  background-color: #ffc7e4;
  position: relative;
  top: 20px;
  left: 20px;
}

#absolute {
  width: 100px;
  height: 100px;
  background-color: #ffd7c2;
  position: absolute;
  bottom: 10px;
  right: 20px;
}
```

Result

Declaring both left and right

When both `left` and `right` are declared, the element will stretch to meet both, unless other constraints prevent it from doing so. If the element will not stretch or shrink to meet both. When the position of the element is *overspecified*, the precedence is based on the container's direction: The `left` will take precedence if the container's direction is left-to-right. The `right` will take precedence if the container's direction is right-to-left.

HTML

```
<div id="parent">
  Parent
  <div id="noWidth">No width</div>
  <div id="width">width: 100px</div>
</div>
```

CSS

```
div {
  outline: 1px solid #cccccc;
}
#parent {
  width: 200px;
  height: 200px;
  background-color: #ffc7e4;
  position: relative;
}
/* declare both a left and a right */
#width,
#noWidth {
  background-color: #c2ffd7;
  position: absolute;
  left: 0;
  right: 0;
}
/* declare a width */
#width {
  width: 100px;
  top: 60px;
}
```

rotate CSS property

The **`rotate`** CSS property allows you to specify rotation transforms individually and independently of the `transform` property. This maps better to typical user interface usage, and saves having to remember the exact order of transform functions to specify in the `transform` property.

Try it

```
rotate: none;
```

```
rotate: -45deg;
```

```
rotate: z 45deg;
```

```
rotate: x 45deg;
```

```
rotate: y 45deg;
```

```
rotate: 3 0.5 2 45deg;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    <div class="face front">1</div>
    <div class="face back">2</div>
    <div class="face right">3</div>
    <div class="face left">4</div>
    <div class="face top">5</div>
    <div class="face bottom">6</div>
  </div>
</section>
```

```
#default-example {
  background: linear-gradient(skyblue, khaki);
  perspective: 550px;
}

#example-element {
  width: 100px;
  height: 100px;
  transform-style: preserve-3d;
}

.face {
  display: flex;
  align-items: center;
  justify-content: center;
  width: 100%;
  height: 100%;
```

```
  position: absolute;
  backface-visibility: inherit;
  font-size: 60px;
  color: white;
}

.front {
  background: rgb(90 90 90 / 0.7);
  transform: translateZ(50px);
}

.back {
  background: rgb(0 210 0 / 0.7);
  transform: rotateY(180deg) translateZ(50px);
}

.right {
  background: rgb(210 0 0 / 0.7);
  transform: rotateY(90deg) translateZ(50px);
}

.left {
  background: rgb(0 0 210 / 0.7);
  transform: rotateY(-90deg) translateZ(50px);
}

.top {
  background: rgb(210 210 0 / 0.7);
  transform: rotateX(90deg) translateZ(50px);
}

.bottom {
  background: rgb(210 0 210 / 0.7);
  transform: rotateX(-90deg) translateZ(50px);
}
```

Syntax

```
/* Keyword value */
rotate: none;

/* Angle value */
rotate: 90deg;
rotate: 0.25turn;
rotate: 1.57rad;

/* x, y, or z axis name plus angle */
rotate: x 90deg;
rotate: y 0.25turn;
rotate: z 1.57rad;

/* Vector plus angle value */
rotate: 1 1 1 90deg;

/* Global values */
rotate: inherit;
rotate: initial;
rotate: revert;
rotate: revert-layer;
rotate: unset;
```

Values

angle value

An `<angle>` specifying the angle to rotate the affected element through, around the Z axis. Equivalent to a `rotate()` (2D rotation) function.

x, y, or z axis name plus angle value

The name of the axis you want to rotate the affected element around (`x`, `y`, or `z`), plus an `<angle>` specifying the angle to rotate the element through. Equivalent to a `rotateX()`/`rotateY()`/`rotateZ()` (3D rotation) function.

vector plus angle value

Three `<number>`s representing an origin-centered vector that defines a line around which you want to rotate the element, plus an `<angle>` specifying the angle to rotate the element through. Equivalent to a `rotate3d()` (3D rotation) function.

none

Specifies that no rotation should be applied.

Formal definition

Initial value	none
Applies to	transformable elements
Inherited	no
Computed value	as specified
Animation type	a transform
Creates stacking context	yes

Formal syntax

```
rotate =
  none                                  |
  <angle>                               |
  [ x | y | z | <number>{3} ] && <angle>
```

This syntax reflects the latest standard as per CSS Transforms Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Rotating an element on hover

The following example shows how to use the `rotate` property to rotate an element along various axes on hover. The first box rotates 90 degrees on the Z axis hover, the second rotates 180 degrees on the Y axis on hover, and the third rotates 360 degrees on hover around a vector defined by coordinates.

HTML

```
<div class="box" id="box1">rotate Z</div>
<div class="box" id="box2">rotate Y</div>
<div class="box" id="box3">vector & angle</div>
```

CSS

```
.box {
  display: inline-block;
  margin: 1em;
  min-width: 6.5em;
  line-height: 6.5em;
  text-align: center;
  transition: 1s ease-in-out;
  border: 0.25em dotted;
}

#box1:hover {
  rotate: 90deg;
}

#box2:hover {
  rotate: y 180deg;
}

#box3:hover {
  rotate: 1 2 1 360deg;
}
```

Result

- `translate`
- `scale`
- `transform`

Note: `skew` is not an independent `transform` value

row-gap CSS property

The **`row-gap`** CSS property sets the size of the gap (gutter) between an element's rows in multi-column, flexible box, and grid layouts.

Try it

```
row-gap: 0;
```

```
row-gap: 1ch;
```

```
row-gap: 1em;
```

```
row-gap: 20px;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">
      <div>One</div>
      <div>Two</div>
      <div>Three</div>
      <div>Four</div>
      <div>Five</div>
    </div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-template-columns: 1fr 1fr;
  width: 200px;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}
```

Syntax

```
/* Keyword value */
row-gap: normal;

/* <length-percentage> value */
row-gap: 20px;
row-gap: 1em;
row-gap: 3vmin;
row-gap: 0.5cm;
row-gap: 10%;
row-gap: calc(10% - 6px);

/* <line-width> values */
```

```
row-gap: thin;
row-gap: medium;
row-gap: thick;

/* Global values */
row-gap: inherit;
row-gap: initial;
row-gap: revert;
row-gap: revert-layer;
row-gap: unset;
```

Values

This property is specified as a single value from the following list:

`normal`

For multi-column layout, resolves to `1em`; otherwise `0`. This is the default value.

`<line-width>`

Sets the size of the gap using the keywords `thin`, `medium`, or `thick`, or a positive `<length>` value.

`<length-percentage>`

Sets a non-negative `<length>` or `<percentage>` value. Percentages are relative to the block-size of the content box or `0`.

Description

The `row-gap` property sets the size of the gap between an element's rows. This gap may contain a visible separator as a gap decoration. If there is a rule between rows, it will appear in the middle of the gap, but has no impact on the gap size. These decorative lines can be added to the otherwise "empty space" by using the `row-rule` property or `rule` shorthand.

Defined in CSS gaps, the property can be used in multi-column, flexible box, and grid layouts. The `row-gap`, along with the `column-gap` property, can also be set using the `gap` shorthand property, in that order. The `row-gap` property replaced the `grid-row-gap` property, which was limited to CSS grid layouts. Now `grid-row-gap` is an alias for `row-gap`.

The property specifies a fixed-length gutter between items in a container, separating boxes in the container's block axis. Negative values are invalid. The default value `normal` resolves to `1em` on multi-column containers, and `0` everywhere else. See Defining CSS gaps for more information about gaps by layout type.

Percentages resolve against the content box size of the container element's block axis when this size is definite, against `0` otherwise, except in grid layout, for which cyclic percentage sizes resolve against zero for determining intrinsic size contributions but resolve against the element's content box when laying out the contents. See Specifying gap values as percentages for more information.

In grid layouts, the effect of the gap is as though the grid lines between grid rows acquired the thickness of the property's value: the grid track between two rows is the space between the gutters that represent them. When it comes to track sizing, each gutter is treated as an extra, empty, fixed-size track of the specified size, which is spanned by any grid items that spans across more than one row. While treated as empty for sizing, the gap created may contain a `row-rule`.

Formal definition

Initial value	`normal`
Applies to	multi-column elements, flex containers, grid containers
Inherited	no
Percentages	refer to corresponding dimension of the content area
Computed value	as specified, with <length>s made absolute, and normal computing to zero except on multi-column elements
Animation type	a length, percentage or calc();

Formal syntax

```
row-gap =
  normal                    |
  <length-percentage [0,∞]>  |
  <line-width>

<length-percentage> =
  <length>      |
  <percentage>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Flex layout

This example demonstrates using the `row-gap` property to create horizontal space between adjacent rows of flex items. It also demonstrates how the `row-gap` size is not affected by the size of the row rule.

HTML

We include six items in a container element:

```
<div id="flexbox">
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
</div>
```

CSS

We set the `display` to `flex`, set the `flex-flow` to `row wrap` to create a flex container with rows of flex items that flow onto new lines as needed, and limit the `width` to `300px`. We also add a `row-rule`, which will draw a 30px-wide, dashed, magenta line in the middle of the gap.

The `row-gap` value is set as `20px` on the flex container to create a `20px` gap between the adjacent flex rows.

We also set a background color on the flex items, with most being semi-opaque, to demonstrate how the rule is visible under the flex items when it is wider than the gap.

```
#flexbox {
  display: flex;
  flex-flow: row wrap;
  width: 300px;
  row-rule: 30px dashed magenta;

  row-gap: 20px;
}

#flexbox > div {
  border: 1px solid green;
  background-color: #00ff0033;
  flex: 1 1 100px;
  height: 50px;
}
#flexbox > div:nth-of-type(3n-1) {
  background-color: lime;
}
```

Result

To set vertical space between flex items, specify a non-zero value for the `column-gap` property, optionally setting both `row-gap` and `column-gap` by using the `gap` shorthand.

Grid layout

This example demonstrates using the `row-gap` property with a `<percentage>` value in a grid layout.

HTML

We include five items in a container element:

```
<div id="grid">
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
</div>
```

CSS

We set the `display` property to `grid`, the `height` to `240px`, the `width` to `350px` and `grid-template-rows` to `repeat(3, 1fr)` to create a 350px-wide grid container with three columns and as many rows as needed. Each row is `100px` tall, as defined by the `grid-template-rows` property.

The `row-gap` is set to `5%`. The container height is `240px`. The `5%` value creates a row gap that is `12px` tall, leaving `216px` for three rows of grid items, meaning each row is `72px` tall.

```
#grid {
  display: grid;
  height: 240px;
  width: 350px;
  grid-template-rows: repeat(3, 1fr);
  grid-template-columns: 150px 1fr;

  row-gap: 5%;
}
```

```
body {
  padding: 1em;
}

#grid > div {
  outline: 1px solid green;
  background-color: lime;
}
@layer no-support {
  @supports not (row-gap: 5%) {
    body::before {
      content: "Your browser doesn't support percent values";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

Result

row-rule CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`row-rule`** CSS shorthand property sets the width, style, and color of the line drawn between rows in multi-row grid, flex, and multi-col layouts.

Try it

```
row-rule: solid;
```

```
row-rule: dotted medium blue;
```

```
row-rule:
  dotted medium blue,
  repeat(3, dashed magenta 1px, outset green 5px);
```

```
row-rule:
  dotted medium blue,
  repeat(auto, dashed magenta 1px, dashed magenta 5px),
  dotted medium blue;
```

```
row-rule:
  dotted medium blue,
  repeat(auto, dashed magenta 1px),
  outset green 5px;
```

```
<section id="default-example">
  <ul id="example-element">
    <li>One fish</li>
    <li>Two fish</li>
    <li>Red fish</li>
    <li>Blue fish</li>
  </ul>
</section>
```

```
#example-element {
  display: flex;
  flex-flow: column;
  gap: 7px;
  text-align: left;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `row-rule-color`
- `row-rule-style`
- `row-rule-width`

Syntax

```
/* One value */
row-rule: dotted;
row-rule: solid 8px;
row-rule: solid blue;
row-rule: thick inset blue;

/* Multiple values */
row-rule: groove, dashed, solid;
row-rule:
  dotted medium blue,
  dashed magenta 1px,
  outset green 5px;
row-rule:
  solid #0ff,
  repeat(3, dashed magenta 1px, outset green 5px);
row-rule:
  inset 3px yellow,
  repeat(auto, dashed magenta 1px, groove green 5px);

/* Global values */
row-rule: inherit;
row-rule: initial;
row-rule: revert;
row-rule: revert-layer;
row-rule: unset;
```

Values

This property is specified as a comma-separated list of values. Each value can be one of the following value types:

`<gap-rule>`

Specified as one, two, or three of the values listed below, in any order.

`<'line-width'>`

A `<line-width>`: a positive `<length>` or one of the three keywords, `thin`, `medium`, or `thick`. The default value is `medium`. See `row-rule-width`.

`<'line-style'>`

A `<line-style>`: one of `none`, `hidden`, `dotted`, `dashed`, `solid`, `double`, `groove`, `ridge`, `inset`, or `outset`. The default value is `none`. See `row-rule-style`.

`<'color'>`

A `<color>` value representing the color of the line. The default value is `currentcolor`. See `row-rule-color`.

`<gap-repeat-rule>`

A `repeat()` function, with an `<integer>` of `1` or more as the first argument and one or more `<gap-rule>` values as subsequent arguments. The `<integer>` specifies how many times the list of `<gap-rule>` values should be repeated.

`<gap-auto-repeat-rule>`

A `repeat()` function, with `auto` as the first argument and one or more `<gap-rule>` values as subsequent arguments. The provided list of `<gap-rule>` values is repeated as many times as needed to fill in values for any row-rules that are not explicitly specified by other components of the property value.

Description

The `row-rule` property defines the line style of any rule lines drawn in the gaps between rows in multi-column, flex, and grid containers with more than one row.

The `row-rule` is shorthand for `row-rule-color`, `row-rule-style`, and `row-rule-width`. The `row-rule`, along with the `column-rule` shorthand property, can also be set using the `rule` shorthand.

The property value is a comma-separated list of components, which can include `<gap-rule>`, `<gap-repeat-rule>`, and `<gap-auto-repeat-rule>` types. Each `<gap-rule>` defines the width, color, and style of one or more rule lines.

If the property value consists of only one `<gap-rule>`, all the row rules will be that style. If we declare the following, all row rules will be `dashed red 3px`:

```
row-rule: dashed red 3px;
```

When more than one `<gap-rule>` is declared, they will be applied to row-rules in the order specified. If there are more gutters between rows than `<gap-rule>` values, the list of values is repeated until every row rule has a gap line. If we declare the following, for example, every odd rule will be `dashed red 3px`, and every even rule will be `dotted blue 5px`.

```
row-rule:
  dashed red 3px,
  dotted blue 5px;
```

Repeated line styles

The `repeat()` function, with an integer of `1` or greater as the first argument, can be used to repeat a valid list of CSS `<gap-rule>` values passed as subsequent arguments the specified number of times. This allows the same `<gap-rule>` to be repeated a set number of times without repeating the same CSS multiple times. The following declarations are equivalent:

```
row-rule:
  solid red 5px,
  outset blue 10px,
  inset green 1px,
  outset blue 10px,
  inset green 1px,
  outset blue 10px,
  inset green 1px;
row-rule:
  solid red 5px,
  repeat(3, outset blue 10px, inset green 1px);
```

This creates a list of seven rules. If the number of styles in the `row-rule` value's style list exceeds the number of gaps between rows, the excess style values are ignored. If the container on which this is applied has three rows, the rule in the first gutter will be `solid red 5px` and the second `outset blue 10px`.

If there are more gutters than styles, the list of styles is repeated. If the container has 8, 15, 22, or 29 rows, this sequence of styles will be repeated one, two, three, or four times, respectively, with the last rule being `inset green 1px`.

Auto-repeating line styles

The `repeat()` function also accepts `auto` as the first argument instead of a positive integer. With `auto` as the first argument, the `<gap-rule>` values passed as subsequent arguments will be repeated as many times as needed to fill in values for any rules that are not explicitly specified by other components of the property value.

```
row-rule:
  solid red 5px,
  repeat(auto, dotted green 1px, dashed blue 1px),
  solid red 5px;
```

In this case, the first and last row rules will be `solid red 5px`, and all others will alternate between `dotted green 1px` and `dashed blue 1px`. It doesn't matter if the container has 3, 6, 11, 16, or 21 rows; the first and last gutters will always have a thick solid red line painted between them (unless `row-rule-visibility-items` leads to no line being drawn), and all the other row rules will be thin, dotted green or dashed blue lines. If there are only 2 or 3 rows, there will be no dotted or dashed lines.

The `auto` keyword within the `repeat()` function creates an auto-repeater that fills in values for row rules that would not otherwise receive values from other parts of the list, preventing the list from being cycled. At most, only one `repeat(auto, <gap-rule>)` can be present in a `row-rule` value.

Formal definition

Value not found in DB!

Formal syntax

```
row-rule =
  <gap-rule-list>       |
  <gap-auto-rule-list>

<gap-rule-list> =
  <gap-rule-or-repeat>#

<gap-auto-rule-list> =
  <gap-rule-or-repeat>#? , <gap-auto-repeat-rule> , <gap-rule-or-repeat>#?

<gap-rule-or-repeat> =
  <gap-rule>         |
  <gap-repeat-rule>

<gap-auto-repeat-rule> =
  repeat( auto , <gap-rule># )

<gap-rule> =
  <line-width>  ||
  <line-style>  ||
  <color>

<gap-repeat-rule> =
  repeat( <integer [1,∞]> , <gap-rule># )

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
```

```
  thick

<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

In this example, we define a single rule for the lines drawn between flex items.

HTML

We include a list of dynamic sports duos:

```
<ul>
  <li>Simone Biles + Jonathan Owens</li>
  <li>Serena Williams + Venus Williams</li>
  <li>Aaron Judge + Giancarlo Stanton</li>
  <li>LeBron James + Dwyane Wade</li>
  <li>Xavi Hernandez + Andres Iniesta</li>
  <li>Kerri Walsh + Misty May Treanor</li>
</ul>
```

CSS

We define the list to be a flex container, creating rows by setting the `flex-direction` to `column` using the `flex-flow` shorthand. We include a `gap` of `5px` to provide enough room between the rows to fit our `3px dashed red` rule:

```
ul {
  display: flex;
  flex-flow: column;
  gap: 5px;

  row-rule: 3px red dashed;
}
```

Result

Repeating values

This example demonstrates how the values are repeated when there are fewer values in the list of styles than row rules. It also demonstrates the default values for the width, color, and style of `medium`, `currentcolor` and `none`, respectively.

CSS

Using the same HTML and CSS as in the previous example, we include four comma-separated `<gap-rule>` values as the `row-rule` value, omitting the width in the first `<gap-rule>`, the color in the second, and the style from the third, with the fourth including all three components:

```
ul {
  row-rule:
    red dashed,
    1px dotted,
    5px blue,
    10px magenta solid;
}
```

Result

The red line is `3px` wide, the dotted line is the same color as the text, and there is no `5px`-wide blue line, as the style of the third `<gap-rule>` defaults to `none`, so no line is painted.

Using the <code>repeat()</code> function

This example demonstrates using the `repeat()` function within the `row-rule` property value.

CSS

We use the same HTML and CSS as in the previous examples. We include a `repeat()` function, setting the list of two `<gap-rule>` values to repeat 3 times.

```
ul {
  row-rule:
    3px red dashed,
    repeat(3, dotted green 1px, dashed blue 1px),
    3px red dashed;
}
```

Result

The flex container has six rows, so five gutters. The `repeat()` function repeats two style values three times, creating a list of eight style values. As there are fewer row gutters than total gap-rules, the last three values in the list are discarded.

Using <code>auto</code> within <code>repeat()</code>

This example demonstrates using the `auto` argument instead of an integer in the `repeat()` function.

CSS

Using `repeat(auto, <gap-rule>)`, we set all row rules to `1px dotted` and default to the current color, except the first and last, which we set to `3px solid red`.

```
ul {
  row-rule:
    3px red solid,
    repeat(auto, 1px dotted),
    3px red solid;
}
```

Result

```
@layer no-support {
  @supports not (row-rule: thin, thick) {
    body::before {
      content: "Your browser doesn't support the row-rule property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

row-rule-break CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`row-rule-break`** CSS property sets the behavior for breaking row rules into segments where row rules intersect column gaps.

Try it

```
row-rule-break: none;
```

```
row-rule-break: normal;
```

```
row-rule-break: intersection;
```

```
<section id="default-example">
  <div id="example-element">
    <i>A</i>
    <i>B</i>
    <i>C</i>
    <i>D</i>
    <i>E</i>
    <i>F</i>
    <i>G</i>
    <i>H</i>
    <i>I</i>
    <i>J</i>
    <i>K</i>
    <i>L</i>
    <i>M</i>
    <i>N</i>
    <i>O</i>
    <i>P</i>
    <i>Q</i>
    <i>R</i>
    <i>S</i>
    <i>T</i>
    <i>U</i>
    <i>V</i>
    <i>W</i>
    <i>X</i>
    <i>Y</i>
    <i>Z</i>
  </div>
</section>
```

```
#example-element {
  display: grid;
  grid-template-columns: repeat(7, 1fr);
  row-rule: solid thick orange;
  column-rule: solid thick lavender;
  gap: 15px;
}
#example-element i {
  padding: 5px;
}
```

Syntax

```
/* Keyword values */
row-rule-break: none;
row-rule-break: normal;
```

```
row-rule-break: intersection;

/* Global values */
row-rule-break: inherit;
row-rule-break: initial;
row-rule-break: revert;
row-rule-break: revert-layer;
row-rule-break: unset;
```

Values

This property is specified as a single keyword from the following list:

`none`

There are no breaks in row rules when they intersect column gaps; rather, a continuous row rule is painted the whole width of the container, from edge to edge.

`normal`

In grid, flex containers, and multi-col layout, behaves as `none`. This is the default value.

`intersection`

Row rules always break when they intersect column gaps, with row rule segments starting and ending at container and gap edges.

Description

The `row-rule-break` property specifies whether or not to break row rules into segments when they cross column gaps.

Row rules are painted within a row gap as one or more segments, with segments occurring between adjacent grid items in separate rows, between flex items or flex lines, depending on the `flex-direction` in flex layouts, or in gaps between adjacent rows of columns in multi-col layouts when `column-height` creates multiple rows of columns.

The `row-rule-break` property only determines if the break occurs. By default, the break, or space, between row rule segments is the width of the column gap, as each segments starts and ends at the edge of the gap (or edge of the container). If the gap is `0`, this break may not be visible. The end positions can be controlled with the `row-rule-inset` properties.

If `row-rule-break` is set to `none`, there are no breaks, the row rule line is continuous, and any `row-rule-inset` values only affect the row rule on the left and right edge of the container. When there are breaks, the `row-rule-inset` properties affect the start and end of every row rule segment.

The `row-rule-break` property, along with the `column-rule-break` property, can be set using the `rule-break` shorthand.

Whether a row rule is by default composed of a single continuous segment or segments that break when intersecting column gaps depends on the container type.

Grid containers

In grid containers, by default, row rule segments continue through visible "cross" intersections. Setting `row-rule-break: intersection` will force the segments to break at every column gap, where they would otherwise cross.

```
<h1>Default rule breaks in grid</h1>
<div class="grid">
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
</div>
<p>
  <label
    ><input type="checkbox" /> Set
    <code>row-rule-break: intersection</code></label
  >
</p>
```

```
body {
  font-family: sans-serif;
  text-align: center;
}
h1 {
  font-size: 1.25em;
}
h2 {
  font-size: 1em;
}

:has(:checked) .grid {
  row-rule-break: intersection;
}
.grid {
  display: grid;
  grid-template-columns: repeat(3, 1fr);
  gap: 20px;
  rule: 5px solid blue;
  column-rule-color: lightblue;
  width: 100%;
}

.grid > div {
  border: 1px solid green;
  background-color: lime;
  height: 30px;
}

@layer no-support {
  @supports not (row-rule-break: intersection) {
    body::before {
      content: "Your browser doesn't support the row-rule-break property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
```

```
  }
}
```

By default, there are no row rule breaks. Check the checkbox to set `ow-rule-break` to `intersection`, which makes the continuous rules break at every "cross" intersection. By default, the break between segments is the width of the `column-gap`.

Flex containers

In flexbox, when the `flex-direction` is `row` or `row-reverse` in horizontal writing modes, the row rule is continuous, with the column segments starting and ending at the at the edge of the row gaps. When the `flex-direction` is `column` or `column-reverse`, the column rule is continuous, with the row segments starting and ending at the at the edge of the column gaps.

```
<h1>Default rule breaks in flexbox</h1>
<article>
  <section>
    <h2>flex-direction: row</h2>
    <div class="flexbox">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
  <section>
    <h2>flex-direction: column</h2>
    <div class="flexbox column">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
</article>
<p>
  <label
    ><input type="checkbox" /> Set
    <code>row-rule-break: intersection</code></label
  >
</p>
```

```
body {
  font-family: sans-serif;
  text-align: center;
}
h1 {
  font-size: 1.25em;
}
h2 {
  font-size: 1em;
}

:has(:checked) .flexbox {
  row-rule-break: intersection;
}
article {
  display: flex;
  gap: 5vw;
  rule: 1px solid black;
  width: 100vw;
}
section {
  flex-basis: 45vw;
}
.flexbox {
  display: flex;
  flex-flow: balance;
  flex-line-count: 3;
  gap: 20px;
  rule: 5px solid blue;
  column-rule-color: lightblue;
  width: 100%;
}
.column {
  flex-flow: column balance;
  gap: 20px;
}

.flexbox > div {
  border: 1px solid green;
  background-color: lime;
  flex: 1 1 auto;
  height: 30px;
}

@layer no-support {
  @supports not (row-rule-break: intersection) {
    body::before {
      content: "Your browser doesn't support the row-rule-break property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

In horizontal writing modes, when set to `row` or `row-reverse`, the row rule is continuous by default, where as with `column` or `column-reverse`, the row rule breaks at every column gap. Setting the `row-rule-break` to `intersection` only impacts the row rules in the `row` and `row-reverse` scenarios.

Multi-col containers

In multi-col containers, the default `normal` behavior behaves the same as `none`.

```
<h1>Default rule breaks in multi-col</h1>
<ol>
  <li>One fish</li>
  <li>Two fish</li>
  <li>Red fish</li>
  <li>Blue fish</li>
  <li>Black fish</li>
  <li>Blue fish</li>
  <li>Old fish</li>
  <li>New fish.</li>
  <li>This one has a little star.</li>
  <li>This one has a little car.</li>
  <li>Say! What a lot</li>
  <li>Of fish there are.</li>
  <li>Yes. Some are blue.</li>
  <li>And some are blue.</li>
  <li>Some are old.</li>
  <li>And some are new.</li>
  <li>Some are sad.</li>
  <li>And some are glad.</li>
  <li>And some are very, very bad.</li>
  <li>Why are they</li>
  <li>Sad and glad and bad?</li>
  <li>I do not know.</li>
  <li>Go ask your dad.</li>
</ol>
<fieldset>
  <legend>Set <code>row-rule-break:</code></legend>
  <label
    ><input type="radio" name="break" value="none" /> <code>none</code></label
  >
  <label
    ><input type="radio" name="break" value="normal" checked />
    <code>normal</code></label
  >
  <label
    ><input type="radio" name="break" value="intersection" />
    <code>intersection</code></label
  >
</fieldset>
```

```
body {
  font-family: sans-serif;
  text-align: center;
}
h1 {
  font-size: 1.25em;
}
h2 {
  font-size: 1em;
}
ol {
  columns: 3 / 4em;
  gap: 20px;
  rule: 5px solid blue;
  column-rule-color: lightblue;
}
li {
  border: 1px solid green;
  background-color: lime;
  list-style-type: none;
  margin-bottom: 5px;
}
:has([value="normal"]:checked) ol {
  row-rule-break: normal;
}
:has([value="intersection"]:checked) ol {
  row-rule-break: intersection;
}
:has([value="none"]:checked) ol {
  row-rule-break: none;
}
label {
  margin-right: 20px;
}
@layer no-support {
  @supports not (row-rule-break: intersection) {
    body::before {
      content: "Your browser doesn't support the row-rule-break property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

If you select `intersection`, the row rule will break into segments whenever it reaches a column gap, with each segment starting and ending at the edge of the gap. The start and end positions can be changed with the `row-rule-inset` properties.

Formal definition

Value not found in DB!

Formal syntax

```
row-rule-break =
  none          |
  normal        |
  intersection
```

This syntax reflects the latest standard as per CSS Gap Decorations Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

In this example, we use the `row-rule-break` property to break each rule segment in a grid container so row rule segments are created between column gaps. Changing the `column-gap` property will change the size of the segments.

HTML

We create a list of 50 items and a slider to change the column gap width. Most of the HTML is hidden for brevity.

```
<ul>
  <li>1</li>
  <li>2</li>
  ...
  <li>49</li>
  <li>50</li>
</ul>
```

```
<p>
  <label
    >Change the width of the column gap.
    <input type="range" min="0" max="32" value="16" id="gap"
  /></label>
  <output id="o"></output>
</p>
<ul id="ul">
  <li>1</li>
  <li>2</li>
  <li>3</li>
  <li>5</li>
  <li>6</li>
  <li>7</li>
  <li>8</li>
  <li>9</li>
  <li>10</li>
  <li>11</li>
  <li>12</li>
  <li>13</li>
  <li>14</li>
  <li>15</li>
  <li>16</li>
  <li>17</li>
  <li>18</li>
  <li>19</li>
  <li>20</li>
  <li>21</li>
  <li>22</li>
  <li>23</li>
  <li>24</li>
  <li>25</li>
  <li>26</li>
  <li>27</li>
  <li>28</li>
  <li>29</li>
  <li>30</li>
  <li>31</li>
  <li>32</li>
  <li>33</li>
  <li>34</li>
  <li>35</li>
  <li>36</li>
  <li>37</li>
  <li>38</li>
  <li>39</li>
  <li>40</li>
  <li>41</li>
  <li>42</li>
  <li>43</li>
  <li>44</li>
  <li>45</li>
  <li>46</li>
  <li>47</li>
  <li>48</li>
  <li>49</li>
  <li>50</li>
</ul>
```

CSS

We define the unordered list as a 8-column container, creating columns and rows with the `grid-template-columns` property and setting `list-style-type` to `none` to remove the bullets. We include a `gap` of `20px` to provide enough room between the columns and rows to fit our `20px` solid column and row rules. Last, we set the row rules to break into segments at every intersection.

```
ul {
  display: grid;
  grid-template-columns: repeat(8, 1fr);
  list-style-type: none;
  gap: 20px;

  row-rule: 10px solid olive;
  column-rule: 10px solid palegoldenrod;
```

```
  row-rule-break: intersection;
}
```

The rest of the CSS is hidden for brevity.

```
ol {
  place-items: center;
  width: 95vw;
}
li {
  text-align: center;
  font-family: sans-serif;
  line-height: 50px;
}
@layer no-support {
  @supports not (row-rule-break: intersection) {
    body::before {
      content: "Your browser doesn't support the row-rule-break property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
const gap = document.getElementById("gap");
const ul = document.getElementById("ul");
const output = document.getElementById("o");

gap.addEventListener("input", () => {
  output.innerText = ul.style.columnGap = `${gap.value}px`;
});
```

Result

Make the column gaps wider and note how the breaks between row segments grow. Bring the column gap width down to `0px`, and notice how the row decoration appears continuous. It isn't! The `0px` gap between segments may not be visible, but the segments still start and end at the gap, so any offsets set with `row-rule-inset` properties will still be applied.

row-rule-color CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`row-rule-color`** CSS property defines the colors of the lines drawn between rows in multi-row grid, flex, and multi-col layouts.

Try it

```
row-rule-color: magenta;
```

```
row-rule-color: magenta, goldenrod;
```

```
row-rule-color: repeat(2, magenta), goldenrod;
```

```
row-rule-color: goldenrod, repeat(auto, magenta), goldenrod;
```

```
row-rule-color: currentColor;
```

```
<section id="default-example">
  <ul id="example-element">
    <li>One fish</li>
    <li>Two fish</li>
    <li>Red fish</li>
    <li>Blue fish</li>
  </ul>
</section>
```

```
#example-element {
  display: flex;
  flex-flow: column;
  row-rule-style: solid;
  row-rule-width: 5px;
  gap: 5px;
  text-align: left;
}
```

Syntax

```
/* Single value */
row-rule-color: red;
row-rule-color: rgb(192 56 78);
row-rule-color: transparent;
row-rule-color: hsl(0 100% 50% / 60%);
row-rule-color: var(--primaryColor);
```

```
/* Multiple values */
row-rule-color: red, transparent;
row-rule-color: repeat(3, red), repeat(3, transparent);
row-rule-color: repeat(3, red), repeat(3, yellow, blue);
row-rule-color: red, repeat(auto, transparent), red;
row-rule-color: red, repeat(auto, blue, yellow), red;
row-rule-color: repeat(3, red), repeat(auto, transparent), repeat(3, red);

/* Global values */
row-rule-color: inherit;
row-rule-color: initial;
row-rule-color: revert;
row-rule-color: revert-layer;
row-rule-color: unset;
```

Values

The `row-rule-color` property accepts a comma-separated list of values, including:

`<line-color>`

A `<color>` representing the color of the line.

`<repeat-line-color>`

A `repeat()` function, with an `<integer>` of `1` or more as the first argument and one or more `<color>` values as subsequent arguments. The `<integer>` specifies how many times the `<color>` values should be repeated.

`<auto-repeat-line-color>`

A `repeat()` function, with `auto` as the first argument and one or more `<color>` values as subsequent arguments. The provided `<color>` values are repeated as many times as needed to fill in values for any row-rules that are not explicitly specified by other components of the property value.

Description

The `row-rule-color` property defines the colors of any lines drawn in the gaps between rows in multi-column, flex, and grid containers with more than one row.

The value is a comma-separated list of components, which can include `<line-color>`, `<repeat-line-color>`, and `<auto-repeat-line-color>` types.

The `row-rule-color`, along with the `row-rule-width` and `row-rule-style` properties, can be set using the `row-rule` shorthand. The `row-rule-color`, along with the `column-rule-color` property, can also be set using the `rule-color` shorthand.

A `<line-color>` can be declared as any valid CSS `<color>` value. If the property value consists of only one `<color>`, all the rule lines will be that color. If we declare the following, the lines will all be blue:

```
row-rule-color: blue;
```

When more than one `<line-color>` is declared, they will be applied to row-rules in the order specified. If there are more row-rules than `<line-color>` values, the list of line colors is repeated until every row-rule has a color. If we declare the following, for example, every odd rule will be blue, and every even rule will be yellow.

```
row-rule-color: blue, yellow;
```

Repeated line colors

The `repeat()` function, with an integer of `1` or greater as the first argument, can be used to repeat a valid list of CSS `<color>` values passed as subsequent arguments the specified number of times. This allows the same color to be repeated a set number of times without repeating the same `<line-color>` multiple times. The following declarations are equivalent:

```
row-rule-color: blue, yellow, red, yellow, red;
row-rule-color: blue, repeat(2, yellow, red);
```

You can use any valid color value from any color space, including CSS color functions, custom properties, etc. Using `repeat()` can make values easier to write, especially as your color values become more complex. It enables a recurring pattern to be written using a single function, regardless of the number of rows.

If we set `--base: yellow` and `--mixin: blue`, the following will provide similar results to the previous declaration:

```
row-rule-color:
  color-mix(in lch decreasing hue, var(--base) 0%, var(--mixin)),
  repeat(
    2,
    color-mix(in lch decreasing hue, var(--base) 100%, var(--mixin)),
    color-mix(in lch decreasing hue, var(--base) 58%, var(--mixin))
  );
```

This creates a list of five colors. If the number of colors in the `row-rule-color` value's color list exceeds the number of gaps between rows, the excess color values are ignored. If the container has three rows, the rule in the first gutter will be blue and the second yellow.

If there are more gutters than colors, the list of colors is repeated until all row-rules receive a color. If the container has 6, 11, 16, or 21 rows, this sequence of colors will be repeated one, two, three, or four times, respectively, with the last one being red.

Auto-repeating line colors

The `repeat()` function also accepts `auto` as the first argument instead of a positive integer. With `auto` as the first argument, the `<color>` values passed in subsequent arguments will be repeated as many times as needed to fill in values for any row-rules that are not explicitly specified by other components of the property value, if any.

```
row-rule-color: blue, repeat(auto, yellow), red;
```

In this case, the first row-rule will be blue, the last will be red, and all others will be yellow. It doesn't matter if the container has 3, 6, 11, 16, or 21 rows; the first will always be blue and, as long as there are at least two row-rules, the last will always be red. All the other rules will be yellow, which means if there are only 2 or 3 rows, there will be no yellow lines.

The `auto` keyword within the `repeat()` function creates an auto-repeater that fills in values for the row-rule line colors that would not otherwise receive values from other parts of the list, preventing the list from being cycled. A `row-rule-color` value can include, at most, one `repeat(auto, <color>)`.

Formal definition

Value not found in DB!

Formal syntax

```
row-rule-color =
  <line-color-list>       |
  <auto-line-color-list>

<line-color-list> =
  <line-color-or-repeat>#

<auto-line-color-list> =
  <line-color-or-repeat>#? , <auto-repeat-line-color> , <line-color-or-repeat>#?

<line-color-or-repeat> =
  <color>               |
  <repeat-line-color>

<auto-repeat-line-color> =
  repeat( auto , [ <color> ]# )

<repeat-line-color> =
  repeat( [ <integer [1,∞]> ] , [ <color> ]# )

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

In this example, we define a single color for the lines drawn between flex items.

HTML

We include a list of dynamic sports duos:

```
<ul>
  <li>Simone Biles + Jonathan Owens</li>
  <li>Serena Williams + Venus Williams</li>
  <li>Aaron Judge + Giancarlo Stanton</li>
  <li>LeBron James + Dwyane Wade</li>
  <li>Xavi Hernandez + Andres Iniesta</li>
  <li>Kerri Walsh + Misty May Treanor</li>
</ul>
```

CSS

We define the list as a flex container, creating rows by setting `flex-direction` to `column` with the `flex-flow` shorthand. We include a `gap` of `5px` to provide enough room between the rows to fit our `3px` dashed rule:

```
ul {
  display: flex;
  flex-flow: column;
  gap: 5px;
  row-rule-style: dashed;
  row-rule-width: 3px;
  row-rule-color: blue;
}
```

Result

Repeating values

This example demonstrates how, when there are fewer values in the list of colors than gutters between rows, the values are repeated.

CSS

Using the same HTML and CSS as in the previous example, we include three comma-separated colors as the `row-rule-color` value:

```
ul {
  row-rule-color: blue, yellow, red;
}
```

Result

Using the <code>repeat()</code> function

This example demonstrates using the `repeat()` function within the `row-rule-color` property value and how this function can help prevent complex values from becoming unwieldy.

CSS

We use the same HTML and CSS as in the previous examples. To demonstrate how values can become complicated and the utility of the `repeat()` function, we declare two custom properties, which we use in three `color-mix()` color function declarations to create the same blue, red, and yellow colors as in the previous example. The second declaration is within a `repeat()` function, set to repeat 3 times.

```
ul {
  --base: yellow;
  --mixin: blue;
  row-rule-color:
    color-mix(in lch decreasing hue, var(--base) 0%, var(--mixin)),
    repeat(3, color-mix(in lch decreasing hue, var(--base) 100%, var(--mixin))),
    color-mix(in lch decreasing hue, var(--base) 58%, var(--mixin));
}
```

Result

The flex container has six rows, so five gutters. The `repeat()` function repeats our second color three times, creating a color list with five colors. Since there are as many row gutters as there are total colors, the colors are not repeated.

Using <code>auto</code> within <code>repeat()</code>

This example demonstrates using `auto`, instead of an integer, within the `repeat()` function.

CSS

Using `repeat(auto, <color>)`, we set all the lines to be almost transparent black (`#00000033`), except the first and last, which we set to a solid `black`.

```
ul {
  row-rule-color: black, repeat(auto, #00000033), black;
}
```

Result

```
@layer no-support {
  @supports not (row-rule-color: red, blue) {
    body::before {
      content: "Your browser doesn't support the row-rule-color property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

row-rule-inset-cap CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`row-rule-inset-cap`** shorthand CSS property can be used to offset the row rule segment cap endpoints at the container's left and right edges, and endpoints where the segments don't intersect other column or row segments.

Try it

```
row-rule-inset-cap: -20px;
```

```
row-rule-inset-cap: 0;
```

```
row-rule-inset-cap: 1em;
```

```
row-rule-inset-cap: 100%;
```

```
row-rule-inset-cap: overlap-join;
```

```
<section id="default-example">
  <div id="example-element">
    <i>A</i>
    <i>B</i>
    <i>C</i>
    <i>D</i>
    <i>E</i>
    <i>F</i>
    <i>G</i>
    <i>H</i>
    <i>I</i>
    <i>J</i>
    <i>K</i>
    <i>L</i>
    <i>M</i>
    <i>N</i>
    <i>O</i>
    <i>P</i>

    <i id="r">R</i>
    <i id="z">Z</i>
    <i id="bang">!</i>
  </div>
</section>
```

```
#example-element {
  display: grid;
  grid-template-columns: repeat(7, 1fr);
  rule: solid thick rebeccapurple;
  row-rule-color: magenta;
  gap: 0.5em;
  rule-overlap: row-over-column;
  rule-visibility-items: between;
  border: 1px solid rebeccapurple;
  overflow: visible;
  margin: 1em;
}
#example-element i {
  padding: 8px;
  border: 1px dashed;
}
#r {
```

```
  grid-column: 5 / 6;
  grid-row: 3 / 4;
}
#z {
  grid-column: 5 / 6;
  grid-row: 4 / 5;
}
#bang {
  grid-column: 5 / 6;
  grid-row: 5 / 6;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `row-rule-inset-cap-end`
- `row-rule-inset-cap-start`

Syntax

```
/* Keywords */
row-rule-inset-cap: overlap-join;

/* <length-percentage> values */
row-rule-inset-cap: 0;
row-rule-inset-cap: 1em;
row-rule-inset-cap: -5px;
row-rule-inset-cap: -25%;

/* Two values */
row-rule-inset-cap: overlap-join 1em;
row-rule-inset-cap: -5px -25%;

/* Global values */
row-rule-inset-cap: inherit;
row-rule-inset-cap: initial;
row-rule-inset-cap: revert;
row-rule-inset-cap: revert-layer;
row-rule-inset-cap: unset;
```

Values

This property is specified as a one or two values from the following list:

`overlap-join`

> Resolves to `0`.

`<length-percentage>`

> Specifies the size of the inset. Percentage values are relative to the crossing gap width, which is the width of the `column-gap` for segment endpoints at gap junctions and `0` for endpoints at the container's edge.

Description

The `row-rule-inset-cap` shorthand property can be used to set the `row-rule-inset-cap-start` and `row-rule-inset-cap-end` properties, insetting or outsetting both the left and right edges of cap segment endpoints in a single declaration.

If one value is specified, both properties are set to that value. If two values are specified, `-start` is set to the first value and `-end` is set to the second. The default value is `0`, which in the case of cap endpoints, is the same as `overlap-join`. Positive values reduce, or inset, the segment size, while negative values increase, or outset, it.

Row rules are painted within a row gap as one or more segments, with segments occurring between:

- Adjacent rows in CSS grid layouts.
- Adjacent flex items or flex lines in flex layouts, depending on the `flex-direction`.
- Adjacent rows in multi-col layouts, which may exist when `column-height` is set to a `<length>`.

Whether a row rule spans multiple columns or is broken into multiple segments is defined by the `row-rule-break` property, with interior breaks between row rule segments generally being the size of the `column-gap`.

Length `row-rule-inset-cap` values inset segments by the specified value. Negative length values create an outset, making the segment wider and causing cap segments on the left and right edges of the container to extend beyond the container's edge.

Percentage values are relative to the size of the `column-gap` for interior segments. Setting `-50%` will extend the segment to the middle of the gap, while `-100%` will extend the segment across the entire gap. For cap segments at the container's edge, percentage values are relative to `0`, so percentage values have no effect on cap segment endpoints at the container's edge.

The `row-rule-inset-cap` property is a constituent property of a few shorthand properties:

- To inset the left and right sides of all row segments, the `row-rule-inset-cap` property, along with the `row-rule-inset-junction` property, can be set using the `row-rule-inset` shorthand.
- To inset both row and column cap segment endpoints, the `row-rule-inset-cap` property, along with the `column-rule-inset-cap` property, can be set using the `rule-inset-cap` shorthand.

All segment endpoints, including this property's `-junction` and `column-` equivalents, can be set using the `rule-inset` shorthand.

Understanding cap endpoints

A *cap segment endpoint* is any segment endpoint that is not a junction segment endpoint. This includes endpoints at the container's content edges, as well as endpoints at a gap junction where no other column or row segments are present.

The `row-rule-inset-cap` property can outset or inset the start and end of row rules at the container edge, and the start and end of interior row segments where no other segments are present.

Cap segments are impacted by the `rule-visibility-items` properties, which define whether row- and column-rule segments are painted in gaps adjacent to empty areas. Changing the value from `auto` to `between` or `around` can create additional interior cap segments.

In the following demonstration, the rows end in cap endpoints at the container's left and right edges. With `row-rule-inset-cap: -32px` set, these endpoints are outset by `32px`. Change the inset `<length>` value to better visualize which segments start or end with cap segment endpoints.

```
<ul id="ul">
  <li>1</li>
```

```
  <li>2</li>
  <li>3</li>
  <li>4</li>
  <li>5</li>
  <li>6</li>
  <li>7</li>
  <li>8</li>
  <li>9</li>
  <li>10</li>
  <li>11</li>
  <li>12</li>
  <li>13</li>
  <li>14</li>
  <li>15</li>
  <li>16</li>
  <li>17</li>
</ul>

<p>
  <label>
    <code>rule-visibility-items</code> value
    <select id="visibility">
      <option>all</option>
      <option>between</option>
      <option>around</option>
      <option selected>normal</option>
    </select>
  </label>
</p>
```

```
<p>
  <label

}
li:nth-of-type(n + 13) {
  grid-row: 4 / 5;
}
li:nth-of-type(12),
li:nth-of-type(16) {
  grid-column: 5/6;
}
li:nth-of-type(17) {
  grid-column: 6/7;
}
@layer no-support {
  @supports not (row-rule-inset-cap: 16px) {
    body::before {
      content: "Your browser doesn't support the row-rule-inset-cap property";
```

```
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
ul {
  row-rule-inset-cap: 100%;
}
```

```
const inset = document.getElementById("inset");
const visibility = document.getElementById("visibility");
const ul = document.getElementById("ul");
const output = document.getElementById("o");

inset.addEventListener("input", () => {
  o.innerText =
    ul.style.rowRuleInsetCap = `${inset.value}${inset.dataset["unit"]}`;
});
```

```
visibility.addEventListener("change", () => {
  ul.style.ruleVisibilityItems = `${visibility.value}`;
  if (visibility.value === "between") {
    ul.style.rowRuleStyle = "repeat(2, solid), double";
  } else if (visibility.value === "around") {
    ul.style.rowRuleStyle = "repeat(3, solid), repeat(2, double)";
  } else {
    ul.style.rowRuleStyle = "solid";
  }
});
```

```
visibility.addEventListener("change", () => {
  ul.style.ruleVisibilityItems = `${visibility.value}`;
  if (visibility.value === "between") {
    ul.style.rowRuleStyle = "repeat(2, inset), double, repeat(2, solid)";
  } else if (visibility.value === "around") {
    ul.style.rowRuleStyle = "repeat(3, inset), repeat(2, double)";
  } else {
    ul.style.rowRuleStyle = "solid";
  }
});
```

Setting `0px` aligns the row rule ends with the left and right container edges. This is the default.

Select `between` as the `rule-visibility-items` value. This value paints rules in gap segments only if the two adjacent areas are occupied by items. Again, we have row rule cap endpoints at the start edge of the container, but now we have none at the end edge. The third row rule, denoted with a double-line style, has two additional cap endpoints: the end-side of the segment between `11` and `15` and the start-side of the segment between `12` and `16`. These do not meet any other rule segments; therefore, they are affected by the `row-rule-inset-cap-start` property.

In this case, the `around` value of the `rule-visibility-items` property, which paints rules in a gap segment as long as one adjacent area is occupied by an item, did not create additional cap segment endpoints. All the interior segment endpoints end in junctions where there are column segments, thus creating junction, not cap, segment endpoints. Junction endpoints can be inset using the `row-rule-inset-junction` shorthand property.

Understanding percentage values

The length a percentage value is relative to depends on the endpoint location. Interior endpoint percentage values are relative to the width of the gap at the cap endpoint, so relative to the `column-gap` if abutting a rule gap, plus any additional spacing added due to `justify-content` settings, and `0` at the edge of the container. For example, `row-rule-inset-cap: 50%` resolves to half the gap junction size at an interior cap (half the size of the `column-gap` value), and `0` at the container edges.

This example is not broken. When `rule-visibility-items` is set to `normal`, every row cap endpoint abuts the left or right edge of the container, so any percentage value set will be relative to `0`.

Select `around` as the `rule-visibility-items` value. The first three rows start and the first and last row end at the container edge. Any percentage values for these row cap segment endpoints will resolve to `0`. All the other segments end at interior gaps where column rule segments are present, so these row segments are not cap segment endpoints.

Select `between` as the `rule-visibility-items` value. As in the previous demonstration, this value creates two interior cap segment endpoints: the right side of the segment between items `11` and `15` and the left side of segment between items `12` and `16` again do not meet any other rule segments. For these two cap endpoints, the percentage offset is relative to the size of the `column-gap` width, which in this case is `20px`.

Formal definition

Value not found in DB!

Formal syntax

```
row-rule-inset-cap =
  <inset-value> <inset-value>?

<inset-value> =
  <length-percentage>  |
  overlap-join

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates setting `row-rule-inset-cap` to inset the row rule cap segment endpoints on flex containers.

HTML

The markup includes two `<div>` elements, each containing seven children. The only difference between the two containers is that the second one has an added `column` class.

```
<h1>Insetting cap row rule endpoints</h1>
<article>
```

```
  <section>
    <h2>flex-direction: row</h2>
    <div class="flexbox">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
  <section>
    <h2>flex-direction: column</h2>
    <div class="flexbox column">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
</article>
```

```
<p>
  <label
    >Change the size of the inset.
    <input type="range" min="-40" max="16" value="16" id="inset"
  /></label>
  <output id="o">16px</output>
</p>
```

CSS

We use the `display` property to turn the `.flexbox` elements into flex containers. We balance the items into three flex lines using `flex-wrap` and `flex-line-count`. We define a `lightblue` `rule` to paint both column and row gaps, then overwrite the `row-rule-color`, setting darker `blue` row gap decorations. Finally, we set the `row-rule-inset-cap` to `16px`.

```
.flexbox {
  display: flex;
  flex-wrap: balance;
  flex-line-count: 3;
  gap: 20px;
  rule: 5px solid lightblue;
  row-rule-color: blue;

  row-rule-inset-cap: 16px;
}
```

We also set the `flex-direction` on the `.column` container, to change the main axis of the flex container, and make the items flow in columns rather than rows.

```
.column {
  flex-direction: column;
}
```

The rest of the CSS is hidden for brevity.

```
body {
  font-family: sans-serif;
  text-align: center;
}
h1 {
  font-size: 1.25em;
}
h2 {
  font-size: 1em;
}
article {
  display: flex;
  gap: 5vw;
  rule: 1px solid black;
  width: 100vw;
}
section {
  flex-basis: 45vw;
}
.flexbox > div {
  border: 1px solid green;
  background-color: lime;
  flex: 1 1 auto;
  height: 30px;
}
output {
  display: inline-block;
  width: 2em;
}
p {
  margin-top: 2.5em;
}
@layer no-support {
  @supports not (row-rule-inset-cap: 16px) {
    body::before {
      content: "Your browser doesn't support the row-rule-inset-cap property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
```

```
  }
}
```

```
const inset = document.getElementById("inset");
const containers = document.querySelectorAll(".flexbox");
const output = document.getElementById("o");

inset.addEventListener("input", () => {
  const val = `${inset.value}px`;
  containers[0].style.rowRuleInsetCap = val;
  containers[1].style.rowRuleInsetCap = val;
  output.innerText = val;
});
```

Result

Change the size of the inset. Note how the row segments grow and shrink only at segment cap ends, either their left side, their right side, or both directions — the ends that don't intersect other row or column segments.

row-rule-inset-cap-end: unset;
```

Values

This property is specified as a single value from the following list:

`overlap-join`

Resolves to `0`.

`<length-percentage>`

Specifies the size of the inset. Percentage values are relative to the cap endpoint, which is either the height of the `column-gap` width or `0`.

Description

The `row-rule-inset-cap-end` property can be used to inset the end edge of row rule cap segment endpoints at the container's end edge and cap endpoints where no rule segments intersect. The default value is `0`, which is the same as `overlap-join`. Positive values reduce the row rule segment size, while negative values increase it.

Row rules are painted within a row gap as one or more segments, with segments occurring between:

- Adjacent rows in CSS grid layouts.
- Adjacent flex items or flex lines in flex layouts, depending on the `flex-direction`.
- Adjacent rows in multi-col layouts if the `column-height` is set to a `<length>`.

Whether a row rule spans multiple columns or is broken into multiple segments is defined by the `row-rule-break` property, with interior breaks between row rule segments being the size of the `column-gap`.

Length `row-rule-inset-cap-end` values are inset by the value specified for both interior and end edge cap segments. Negative length values create an outset, with end edge cap segments extending beyond the container's end edge.

Percentage values for interior cap segment endpoint insets are relative to the size of the `column-gap`. For end edge cap segments, percentage values are relative to `0`, so percentage values never inset or outset cap segment endpoints at the container's end edge.

The `row-rule-inset-cap-end` property is a constituent property of several shorthand properties:

- To inset both the start and ends of row rule caps, the `row-rule-inset-cap-end` property, along with the `row-rule-inset-cap-start` property, can be set using the `row-rule-inset-cap` shorthand.
- To inset the ends of all row segments, the `row-rule-inset-cap-end` property, along with the `row-rule-inset-junction-end` property, can be set using the `row-rule-inset-end` shorthand.

All segment endpoints, including this property's `-start`, `-junction`, and `column-` equivalents, can be set using the `rule-inset` shorthand.

Understanding cap end

A *cap segment endpoint* is any segment endpoint that is not a junction segment endpoint. This includes endpoints at the container's content edges, as well as endpoints at a gap junction where no other column or row segments are present.

The `row-rule-inset-cap-end` controls the inset of cap segment endpoints occurring at the end of a row rule segment. Depending on the writing mode, the property can inset the right or left edge of row rule segments at interior gaps with no other row or column rule segments, or at the container's end edge.

This property is affected by the `rule-visibility-items` properties, which define whether row- and column-rule segments are painted in gaps adjacent to empty areas. As row cap segment endpoints only exist at the end edge of the container and at interior gaps where no other row or column rule segments are present, whether segments are painted (or would otherwise be painted if the `rule` were set to a visible value) impacts which row segments are end cap segments.

In the following demonstration, the end segments of row rules with a solid line style end in a cap endpoint. With `row-rule-inset-cap-end: 16px` set, these endpoints are all inset by `16px`. Change the inset `<length>` value to better visualize which segments end in cap segment endpoints.

      padding: 1rem 0;
    }
  }
}
```

```
ul {
  row-rule-inset-cap-end: 100%;
  row-rule-style: inset;
}
```

```
const inset = document.getElementById("inset");
const visibility = document.getElementById("visibility");
const ul = document.getElementById("ul");
const output = document.getElementById("o");

inset.addEventListener("input", () => {
  output.innerText =
    ul.style.rowRuleInsetCapEnd = `${inset.value}${inset.dataset["unit"]}`;
});
```

```
visibility.addEventListener("change", () => {
  ul.style.ruleVisibilityItems = `${visibility.value}`;
  if (visibility.value === "between") {
    ul.style.rowRuleStyle = "repeat(2, solid), double";
  } else if (visibility.value === "around") {
    ul.style.rowRuleStyle = "repeat(3, solid), repeat(2, double)";
  } else {
    ul.style.rowRuleStyle = "solid";
  }
});
```

```
visibility.addEventListener("change", () => {
  ul.style.ruleVisibilityItems = `${visibility.value}`;
  if (visibility.value === "between") {
    ul.style.rowRuleStyle = "repeat(2, inset), double, repeat(2, solid)";
  } else if (visibility.value === "around") {
    ul.style.rowRuleStyle = "repeat(3, inset), repeat(2, double)";
  } else {
    ul.style.rowRuleStyle = "solid";
  }
});
```

Setting `-32px` outsets the end of all the row rules by `32px`: the lines are drawn `32px` past the right edge of the container. As row rules don't impact the box model, these lines have no impact on the layout of the container or the rest of the content. If `0px` is set, the end of the row rules will align with the edge of the container. This is the default.

The double line-style row rule segments, which appear when the `rule-visibility-items` property is set to `between`, add a cap endpoint. The `between` value only paints rules in gap segments between two adjacent areas occupied by an item. Because the row rule segment above item `24` ends at an intersection with no other row or column rule segments present, this is a cap endpoint, and therefore is affected by the `row-rule-inset-cap-end` property. The segment above item `22` ends at a gap junction where a rule segment is present, so it is not a cap endpoint. There are fewer segments abutting the right edge of the container, but the remaining segment, between `6` and `12`, remains a cap endpoint.

Rule segments abutting the end edge of the container are always row-rule cap end segments affected by the value of the `row-rule-inset-cap-end` property.

Understanding percentage values

The length a percentage value is relative to depends on the endpoint location. Interior endpoint percentage values are relative to the width of the gap at the cap endpoint, so relative to the `column-gap` if abutting a rule gap, and `0` at the top edge of the container.

This example isn't broken; all the cap segments end at the container's edge, so all the insets are `0` by default.

If you select `around` as the `rule-visibility-items` value, the only cap segment endpoints are at the edge of the container, so percentage value insets continue to resolve to `0`.

Select `between` as the `rule-visibility-items` value. We now have a row rule end cap affected by the inset — see the segment between grid items `18` and `24`! This segment ends at an interior gap where no other rule segments are present, so the percentage inset is relative to the size of the `column-gap` width, which in this case is `20px`. Setting `100%` insets the end by `20px`. Setting `-200%` will outset the segment by `40px`, with the lines drawn through the `20px` gap into the next column.

Formal definition

Value not found in DB!

Formal syntax

```
row-rule-inset-cap-end =
  <inset-value>

<inset-value> =
  <length-percentage>  |
  overlap-join

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates setting `row-rule-inset-cap-end` to inset the end edge of cap segments on flex containers.

HTML

The markup includes two `<div>` elements, each containing seven children. The only difference between the two containers is that the second one has an added `column` class.

```
<h1>Insetting cap row rule endpoints</h1>
<article>
  <section>
    <h2>flex-direction: row</h2>
    <div class="flexbox">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
```

```
      <div></div>
      <div></div>
    </div>
  </section>
  <section>
    <h2>flex-direction: column</h2>
    <div class="flexbox column">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
</article>
```

```
<p>
  <label
    >Change the size of the inset.
    <input type="range" min="-40" max="16" value="16" id="inset"
  /></label>
  <output id="o">16px</output>
</p>
```

CSS

We use the `display` property to turn the `.flexbox` elements into flex containers. We balance the items into three flex lines using with `flex-wrap` and `flex-line-count`. We define a light blue `rule` to be painted in both column and row gaps, then overwrite the `row-rule-color`, setting darker `blue` vertical gap decorations. Finally, we set the `row-rule-inset-cap-end` to `16px`.

```
.flexbox {
  display: flex;
  flex-wrap: balance;
  flex-line-count: 3;
  gap: 20px;
  rule: 5px solid lightblue;
  row-rule-color: blue;

  row-rule-inset-cap-end: 16px;
}
```

We also set the `flex-direction` on the `.column` container, to change the main axis of the flex container, and make the items flow in columns rather than rows. The rest of the CSS is hidden for brevity.

```
.column {
  flex-direction: column;
}
```

```
body {
  font-family: sans-serif;
  text-align: center;
}
h1 {
  font-size: 1.25em;
}
h2 {
  font-size: 1em;
}
article {
  display: flex;
  gap: 5vw;
  rule: 1px solid black;
  width: 100vw;
}
section {
  flex-basis: 45vw;
}
.flexbox > div {
  border: 1px solid green;
  background-color: lime;
  flex: 1 1 auto;
  height: 30px;
}
output {
  display: inline-block;
  width: 2em;
}
p {
  margin-top: 2.5em;
}
@layer no-support {
  @supports not (row-rule-inset-cap-end: 16px) {
    body::before {
      content: "Your browser doesn't support the row-rule-inset-cap-end property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
const inset = document.getElementById("inset");
const containers = document.querySelectorAll(".flexbox");
const output = document.getElementById("o");

inset.addEventListener("input", () => {
  const val = `${inset.value}px`;
  containers[0].style.rowRuleInsetCapEnd = val;
  containers[1].style.rowRuleInsetCapEnd = val;
```

```
  output.innerText = val;
});
```

Result

Change the size of the inset.

row-rule-inset-cap-start: overlap-join;
```

```
/* <length-percentage> values */
row-rule-inset-cap-start: 0;
row-rule-inset-cap-start: 1em;
row-rule-inset-cap-start: -5px;
row-rule-inset-cap-start: -25%;

/* Global values */
row-rule-inset-cap-start: inherit;
row-rule-inset-cap-start: initial;
row-rule-inset-cap-start: revert;
row-rule-inset-cap-start: revert-layer;
row-rule-inset-cap-start: unset;
```

Values

This property is specified as a single value from the following list:

`overlap-join`

Resolves to `0`.

`<length-percentage>`

Specifies the size of the inset. Percentage values are relative to the cap endpoint, which is either the `column-gap` or `0`.

Description

The `row-rule-inset-cap-start` property insets the start of cap segment endpoints at the container's start edge and at cap endpoints where no rule segments intersect. The default value is `0`, which is the same as `overlap-join`. Positive values reduce the segment size, while negative values increase it.

Row rules are painted within a row gap as one or more segments, with segments occurring between:

- Adjacent rows in CSS grid layouts.
- Adjacent flex items or flex lines in flex layouts, depending on the `flex-direction`.
- Adjacent rows in multi-col layouts, which may exist when `column-height` is set to a `<length>`.

Length `row-rule-inset-cap-start` values inset the start of both interior and start-edge cap segment endpoints by the specified value. Negative length values create an outset, with container-edge cap segments extending beyond the container's start edge.

Percentage value insets for interior cap segments are relative to the size of the `column-gap`. For cap segments at the container start edge, percentage values are relative to `0`, so they are always `0px`.

The `row-rule-inset-cap-start` property is a constituent property of several shorthand properties:

- To inset both the left and right ends of row cap segments, the `row-rule-inset-cap-start` property, along with the `row-rule-inset-cap-end` property, can be set using the `row-rule-inset-cap` shorthand.
- To inset the start edge of all row segments, the `row-rule-inset-cap-start` property, along with the `row-rule-inset-junction-start` property, can be set using the `row-rule-inset-start` shorthand.

All segment endpoints, including this property's `-end`, `-junction`, and `column-` equivalents, can be set using the `rule-inset` shorthand.

Understanding cap start

A *cap segment endpoint* is any segment endpoint that is not a junction segment endpoint. This includes endpoints at the container's content edges, as well as endpoints at a gap junction where no other rule segments are present.

The `row-rule-inset-cap-start` controls the start inset of row rules with cap endpoints. The property can shrink or extend the start of:

- Row rule segments abutting the container start edge.
- Row rule segments whose left side abuts an interior gap where no other row or column rule segments are present.

Row cap segments are impacted by the `rule-visibility-items` properties, which define whether row- and column-rule segments are painted in gaps adjacent to empty areas. Changing the value from `auto` to `between` or `around` can create additional interior cap segments.

In the following demonstration, the leftmost segments of the row rules abutting the container edge start in a cap endpoint. With `row-rule-inset-cap-start: -32px` set, these endpoints are all outset by `32px`. As row rules don't impact the box model, these protruding lines don't affect the content's layout. Change the inset `<length>` value to better visualize which segments start with cap segment endpoints.

```
<ul id="ul">
  <li>1</li>
  <li>2</li>
  <li>3</li>
  <li>4</li>
  <li>5</li>
  <li>6</li>
  <li>7</li>
  <li>8</li>
  <li>9</li>
  <li>10</li>
  <li>11</li>
  <li>12</li>

@layer no-support {
  @supports not (row-rule-inset-cap-start: 16px) {
    body::before {
      content: "Your browser doesn't support the row-rule-inset-cap-start property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
ul {
  row-rule-inset-cap-start: 100%;
}
```

```
const inset = document.getElementById("inset");
const visibility = document.getElementById("visibility");
const ul = document.getElementById("ul");
const output = document.getElementById("o");

inset.addEventListener("input", () => {
  output.innerText =
    ul.style.rowRuleInsetCapStart = `${inset.value}${inset.dataset["unit"]}`;
});
```

```
visibility.addEventListener("change", () => {
  ul.style.ruleVisibilityItems = `${visibility.value}`;
  if (visibility.value === "between") {
    ul.style.rowRuleStyle = "repeat(2, solid), double";
  } else {
    ul.style.rowRuleStyle = "solid";
  }
});
```

Change the inset. Setting `0px` aligns the start of the row rules with the start of the container. This is the default.

Select `between` as the `rule-visibility-items` value. This value paints rules in a gap segment only if the two adjacent areas are occupied by items. Again, we have row rule cap endpoints at the start edge of the container. The third row rule, denoted with a double line style, has an additional cap endpoint segment: the left side of the segment between items `12` and `16`. This does not meet any other rule segments and is therefore affected by the `row-rule-inset-cap-start` property.

In this case, the `around` value of the `rule-visibility-items` property, which paints rules in a gap segment as long as one adjacent area is occupied by an item, did not create additional cap segment endpoints. The rule start of the segment between `12` and `16` intersects with the column rule segments in the column-gap to the left of those items, creating junction, not cap, segment endpoints. Junction endpoints are inset using the `row-rule-inset-junction-start` property instead.

Understanding percentage values

The length a percentage value is relative to depends on the endpoint location. Interior endpoint percentage values are relative to the width of the gap at the cap endpoint, so relative to the `column-gap` if abutting a rule gap, and `0` at the edge of the container.

This example isn't broken; all the cap segments start at the container's edge, so all the insets are `0` by default.

The slider only has an effect when the `rule-visibility-items` value is set to `between`, and then only on the single inner cap endpoint segment that this value creates — the segment between `12` and `16`. For this segment only, the percentage offset is relative to the size of the `column-gap` width, which in this case is `20px`. Setting `100%` insets the start of the cap segment by `20px`. Setting `-200%` outsets the segment by `40px`, with the rule segment drawn through the `20px` gap and into the previous column.

Formal definition

Value not found in DB!

Formal syntax

```
row-rule-inset-cap-start =
  <inset-value>

<inset-value> =
  <length-percentage>  |
  overlap-join

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates setting `row-rule-inset-cap-start` to inset the start edge of cap segments on flex containers.

HTML

The markup includes two `<div>` elements, each containing seven children. The only difference between the two containers is that the second one has an added `column` class.

```
<h1>Insetting cap row rule endpoints</h1>
<article>
  <section>
    <h2>flex-direction: row</h2>
    <div class="flexbox">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
  <section>
    <h2>flex-direction: column</h2>
    <div class="flexbox column">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
</article>
```

```
<p>
  <label
    >Change the size of the inset.
    <input type="range" min="-40" max="16" value="16" id="inset"
  /></label>
  <output id="o">16px</output>
</p>
```

CSS

We use the `display` property to turn the `.flexbox` elements into flex containers. We balance the items into three flex lines using with `flex-wrap` and `flex-line-count`. We define a light blue `rule` to be painted in both column and row gaps, then overwrite the `row-rule-color`, setting darker `blue` row gap decorations. Finally, we set the `row-rule-inset-cap-start` to `16px`.

```
.flexbox {
  display: flex;
  flex-wrap: balance;
  flex-line-count: 3;
  gap: 20px;
  rule: 5px solid lightblue;
  row-rule-color: blue;
```

```
  row-rule-inset-cap-start: 16px;
}
```

We also set the `flex-direction` on the `.column` container, to change the main axis of the flex container, and make the items flow in columns rather than rows.

```
.column {
  flex-direction: column;
}
```

The rest of the CSS is hidden for brevity.

```
body {
  font-family: sans-serif;
  text-align: center;
}
h1 {
  font-size: 1.25em;
}
h2 {
  font-size: 1em;
}
article {
  display: flex;
  gap: 42px;
  rule: 1px solid black;
  width: 100vw;
  padding: 0 50px;
  box-sizing: border-box;
}
section {
  flex-basis: 45vw;
}
.flexbox > div {
  border: 1px solid green;
  background-color: lime;
  flex: 1 1 auto;
  height: 30px;
}
output {
  display: inline-block;
  width: 2em;
}
p {
  margin-top: 2.5em;
}
@layer no-support {
  @supports not (row-rule-inset-cap-start: 16px) {
    body::before {
      content: "Your browser doesn't support the row-rule-inset-cap-start property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
const inset = document.getElementById("inset");
const containers = document.querySelectorAll(".flexbox");
const output = document.getElementById("o");

inset.addEventListener("input", () => {
  const val = `${inset.value}px`;
  containers[0].style.rowRuleInsetCapStart = val;
  containers[1].style.rowRuleInsetCapStart = val;
  output.innerText = val;
});
```

Result

Change the size of the inset.

row-rule-inset-junction CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`row-rule-inset-junction`** CSS shorthand property can be used to offset both the left and right endpoints of row rule segments that are junction endpoints; that is, endpoints at gap junctions where rule segments intersect.

Try it

```
row-rule-inset-junction: 0;
```

```
row-rule-inset-junction: 10px;
```

```
row-rule-inset-junction: 0.5em -0.5em;
```

```
row-rule-inset-junction: overlap-join;
```

```
row-rule-inset-junction: overlap-join 10px;
```

```
<section id="default-example">
  <div id="example-element">
    <i>A</i>
    <i>B</i>
    <i>C</i>
    <i>D</i>
    <i>E</i>
    <i>F</i>
    <i>G</i>
    <i>H</i>
    <i>I</i>
    <i>J</i>
    <i>K</i>
    <i>L</i>
  </div>
</section>
```

```
#example-element {
  display: grid;
  grid-template-columns: repeat(5, 1fr);
  rule: solid thick lightpink;
  row-rule-color: magenta;
  row-rule-break: intersection;
  gap: 1.5em;
  rule-overlap: row-over-column;
  border: 1px solid rebeccapurple;
  margin: auto;
  rule-visibility-items: around;
}
#example-element i {
  background-color: #efefef;
  padding: 1em;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `row-rule-inset-junction-end`
- `row-rule-inset-junction-start`

Syntax

```
/* Keywords */
row-rule-inset-junction: overlap-join;

/* <length-percentage> values */
row-rule-inset-junction: 0;
row-rule-inset-junction: 1em;
row-rule-inset-junction: -5px;
row-rule-inset-junction: -25%;

/* Two values */
row-rule-inset-junction: 0 1em;
row-rule-inset-junction: -5px -25%;
row-rule-inset-junction: overlap-join 10px;

/* Global values */
row-rule-inset-junction: inherit;
row-rule-inset-junction: initial;
row-rule-inset-junction: revert;
row-rule-inset-junction: revert-layer;
row-rule-inset-junction: unset;
```

Values

This property is specified as one or two values from the following list:

`overlap-join`

Specifies that the junction segment should extend across the column-rule, resolving to half the `column-gap` value plus half the used `column-rule-width` value.

`<length-percentage>`

Specifies the size of the inset. Percentage values are relative to the junction endpoint, which is the `column-gap` value.

Description

The `row-rule-inset-junction` shorthand property can be used to set the `row-rule-inset-junction-start` and `row-rule-inset-junction-end` properties, insetting or outsetting both the start and end edges of junction segment endpoints occurring at the left and right (or right and left is right to left languages) of row rule segments.

If one value is specified, both properties are set to that value. If two values are specified, `-start` is set to the first value and `-end` is set to the second. Positive values reduce (or inset) the segment size, while negative values and the `overlap-join` keyword increase (or outset) it. The default value is `0`.

The `row-rule-inset-junction` property is a constituent property of a few shorthand properties:

- To inset both row and column segment junction endpoints, the `row-rule-inset-junction` shorthand property, along with the `column-rule-inset-junction` shorthand property, can be set using the `rule-inset-junction` shorthand.
- To inset both row cap and junction segment endpoints, the `row-rule-inset-junction` shorthand property, along with the `row-rule-inset-cap` shorthand property, can be set using the `row-rule-inset` shorthand.

All segment endpoints, including this property's `-cap` and `-column` equivalents, can be set using the `rule-inset` shorthand.

Formal definition

Value not found in DB!

Formal syntax

```
row-rule-inset-junction =
  <inset-value> <inset-value>?

<inset-value> =
  <length-percentage>  |
  overlap-join

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates setting `row-rule-inset-junction` to inset the edges of junction segments on flex containers.

HTML

The markup includes two `<div>` elements, each containing seven children. The only difference between the two containers is that the second one has an added `column` class.

```
<h1>Insetting junction row rule endpoints</h1>
<article>
  <section>
    <h2>flex-direction: row</h2>
    <div class="flexbox">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
  <section>
    <h2>flex-direction: column</h2>
    <div class="flexbox column">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
</article>
```

```
<p>
  <label
    >Change the size of the inset.
    <input type="range" min="-40" max="16" value="16" id="inset"
  /></label>
  <output id="o">16px</output>
</p>
```

CSS

We use the `display` property to turn the `.flexbox` elements into flex containers. We balance the items into three flex lines using `flex-wrap` and `flex-line-count`. We define a light blue `rule` to paint both column and row gaps, then overwrite the `row-rule-color`, setting darker `blue` row gap decorations. We also set the `rule-overlap` property to `row-over-column` to ensure the row segments are drawn on top of the column segments when the segments overlap. Finally, we set the `row-rule-inset-junction` to `16px`, setting the start and end to the same value.

```
.flexbox {
  display: flex;
  flex-wrap: balance;
  flex-line-count: 3;
  gap: 20px;
  rule: 5px solid lightblue;
  row-rule-color: blue;
  rule-overlap: row-over-column;

  row-rule-inset-junction: 16px;
}
```

We also set the `flex-direction` on the `.column` container to `column`, changing the main axis of the flex container to run up and down the page and making the items flow in columns rather than rows.

```
.column {
  flex-direction: column;
}
```

The rest of the CSS is hidden for brevity.

```
h1,
article {
  font-family: sans-serif;
  text-align: center;
}
h1 {
  font-size: 1.25em;
}
h2 {
  font-size: 1em;
}
article {
  display: flex;
  gap: 5vw;
  rule: 1px solid black;
  width: 100vw;
}
section {
  flex-basis: 45vw;
}
.flexbox > div {
  border: 1px solid green;
  background-color: lime;
  flex: 1 1 auto;
  height: 30px;
}
output {
  display: inline-block;
  width: 2em;
}
p {
  margin-top: 2.5em;
}
@layer no-support {
  @supports not (row-rule-inset-junction: 16px) {
    body::before {
      content: "Your browser doesn't support the row-rule-inset-junction property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
const inset = document.getElementById("inset");
const containers = document.querySelectorAll(".flexbox");
const output = document.getElementById("o");

inset.addEventListener("input", () => {
  const val = `${inset.value}px`;
  containers[0].style.rowRuleInsetJunction = val;
  containers[1].style.rowRuleInsetJunction = val;
  output.innerText = val;
});
```

Result

Change the size of the inset. Note that this property affects only row rules split into multiple segments. When a row rule is a single segment that spans the container, the segment has two cap endpoints and no junction endpoints, and remains unaffected by changes to the `row-rule-inset-junction` value.

With grid layout

This example demonstrates using the `row-rule-inset-junction` to inset the start and end row junction segment endpoints to two different values on a grid container.

HTML

We include the `<ul>` element as a container with several `<li>` children which will each be converted into a grid item.

```
<ul id="ul">
  <li>1</li>
  <li>2</li>
  <li>3</li>
  <li>4</li>
  <li>5</li>
  <li>6</li>
  <li>7</li>
  <li>8</li>
  <li>9</li>
  <li>10</li>
  <li>11</li>
  <li>12</li>
  <li>13</li>
  <li>15</li>
  <li>16</li>
  <li>17</li>
  <li>18</li>
  <li>19</li>
  <li>20</li>
  <li>21</li>
  <li>22</li>
  <li>23</li>
</ul>
```

```
<p>
  <label
    >Change the <code>-start</code> value.
    <input type="range" min="-40" max="40" value="16" id="start" data-unit="px"
  /></label>
  <output id="og">16px</output>
</p>
```

```
<p>
  <label
    >Change the <code>-end</code> value.
    <input type="range" min="-40" max="40" value="0" id="end" data-unit="px"
  /></label>
  <output id="ow">0px</output>
</p>
```

CSS

We turn the `<ul>` into a grid container by setting the `display` property to `grid`. The `grid-template-columns` property specifies that the grid has six columns. We remove the bullets with `list-style-type` and set the row and column gaps to `20px` with the `gap` shorthand. We set the color, size, and line style of all the rules using the `rule` shorthand, then change just the column rule color with the `column-rule-color` property.

We break the row rules at every intersection using the `row-rule-break` property. If the row rules didn't break, there would be no row junction segments to style!

Finally, we set the start of each row junction to be inset by `16px` and the end to not be inset using the `row-rule-inset-junction` property.

We also set the 6th grid item to span three columns.

```
ul {
  display: grid;
  grid-template-columns: repeat(6, auto);
  list-style-type: "";
  gap: 20px;
  rule: 10px solid olive;
  column-rule-color: palegoldenrod;
  row-rule-break: intersection;

  row-rule-inset-junction: 16px 0;
}

li:nth-of-type(8) {
  grid-column-end: span 3;
}
```

The rest of the CSS is hidden for brevity.

```
ul {
  border: 1px solid;
  place-items: center;
  width: 95vw;
  padding: 0;
}
li {
  text-align: center;
  font-family: sans-serif;
  background-color: #ededed;
  padding: 2em 1em;
  width: 100%;
  box-sizing: border-box;
}

li code {
  display: block;
  margin: 0 auto;
  text-align: left;
  width: 30vw;
}
output {
  font-family: monospace;
}
input {
  accent-color: olive;
}
@layer no-support {
  @supports not (row-rule-inset-junction: 16px) {
    body::before {
      content: "Your browser doesn't support the row-rule-inset-junction property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
const ul = document.querySelector("ul");
const startSize = document.getElementById("start");
const og = document.getElementById("og");
const endSize = document.getElementById("end");
const ow = document.getElementById("ow");
const cell = document.querySelector("li:nth-of-type(8)");
let text = "";
function update() {
  ul.style.rowRuleInsetJunction =
    text = `${startSize.value}px ${endSize.value}px`;
  cell.innerHTML = `<code>rule-inset-cap: ${text};</code>`;
}

update();

startSize.addEventListener("input", () => {
  og.innerText = `${startSize.value}px`;
  update();
});

endSize.addEventListener("input", () => {
  ow.innerText = `${endSize.value}px`;
  update();
});
```

row-rule-style CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`row-rule-style`** CSS property defines the line style of the lines drawn between rows in multi-row grid, flex, and multi-col layouts.

Try it

```
row-rule-style: solid;
```

```
row-rule-style: inset, outset;
```

```
row-rule-style: repeat(2, dashed, dotted), solid;
```

```
row-rule-style: solid, repeat(auto, dashed, dotted), solid;
```

```
row-rule-style: hidden;
```

```
<section id="default-example">
  <ul id="example-element">
    <li>One fish</li>
    <li>Two fish</li>
    <li>Red fish</li>
    <li>Blue fish</li>
  </ul>
</section>
```

```
#example-element {
  display: flex;
  flex-flow: column;
  row-rule-width: thick;
  row-rule-color: magenta;
  gap: 7px;
  text-align: left;
}
```

Syntax

```
/* One value */
row-rule-style: none;
row-rule-style: hidden;
row-rule-style: dotted;

/* Multiple values */
row-rule-style: groove, dashed, solid;
row-rule-style: double, repeat(5, ridge), double;
row-rule-style: solid, repeat(auto, inset, outset), solid;

/* Global values */
row-rule-style: inherit;
row-rule-style: initial;
row-rule-style: revert;
row-rule-style: revert-layer;
row-rule-style: unset;
```

Values

The `row-rule-style` property accepts a comma-separated list of values, including:

`<line-style>`

> A `<line-style>`: one of `none`, `hidden`, `dotted`, `dashed`, `solid`, `double`, `groove`, `ridge`, `inset`, or `outset`. The default value is `none`.

`<repeat-line-style>`

> A `repeat()` function, with the first argument being an `<integer>` of `1` or more, and subsequent arguments being `<line-style>` values. The integer specifies how many times the `<line-style>` values should be repeated.

`<auto-repeat-line-style>`

> A `repeat()` function, with `auto` as the first argument and one or more `<line-style>` values as subsequent arguments. The provided `<line-style>` values are repeated as many times as needed to fill in values for any row-rules that are not explicitly specified by other components of the property value.

Description

The `row-rule-style` property defines the line style of any row rule lines drawn in the gaps between rows in multi-column, flex, and grid containers with more than one row.

The value is a comma-separated list of components, which can include `<line-style>`, `<repeat-line-style>`, and `<auto-repeat-line-style>` types.

The `row-rule-style`, along with the `row-rule-color` and `row-rule-width` properties, can be set using the `row-rule` shorthand. The `row-rule-style`, along with the `column-rule-style` property, can also be set using the `rule-style` shorthand.

If the property value has only one `<line-style>`, all the row rules will be that style. If we declare the following, all row rules will be `dashed`:

```
row-rule-style: dashed;
```

When more than one `<line-style>` is declared, they will be applied to row-rules in the order specified. If there are more row-rules than `<line-style>` values, the list of line styles is repeated until every row rule has a style. If we declare the following, for example, every odd rule will be `dashed`, and every even rule will be `dotted`.

```
row-rule-style: dashed, dotted;
```

Repeated line styles

The `repeat()` function, with an integer of `1` or greater as the first argument, can be used to repeat a valid list of CSS `<line-style>` values passed as subsequent arguments the specified number of times. This allows the same style to be repeated a set number of times without repeating the same value. You can include `<line-style>` keyword values or custom properties that resolve to a valid `<line-style>`. Using `repeat()` can make values easier to write, enabling recurring patterns to be written using a single function, regardless of the number of rows. The following declarations are equivalent:

```
row-rule-style: solid, outset, inset, outset, inset;
row-rule-style: solid, repeat(2, outset, inset);
```

This creates a list of five styles. If the number of styles in the `row-rule-style` value's style list exceeds the number of gaps between rows, the excess style values are ignored. If the container has three rows, the rule in the first gutter will be `solid` and the second `outset`.

If there are more gutters than styles, the list of styles is repeated. If the container has 6, 11, 16, or 21 rows, this sequence of styles will be repeated one, two, three, or four times, respectively, with the last rule being `inset`.

Auto-repeating line styles

The `repeat()` function also accepts `auto` as the first argument instead of a positive integer. With `auto` as the first argument, the `<line-style>` values passed as subsequent parameters will be repeated as many times as needed to fill in values for any row-rules that are not explicitly specified by other components of the property value.

```
row-rule-style: solid, repeat(auto, dotted), solid;
```

In this case, it doesn't matter if the container has 3, 6, 11, 16, or 21 rows; the first and last row rules will always be `solid`, and all the other row rules will be `dotted`. If there are only 2 or 3 rows, there will be no dotted row rules.

The `auto` keyword within the `repeat()` function creates an auto repeater that fills in values for row rules that would not otherwise receive values from other parts of the list, preventing the list from being cycled. Only one `repeat(auto, <line-style>)` is allowed within a `row-rule-style` value.

Formal definition

Value not found in DB!

Formal syntax

```
row-rule-style =
  <line-style-list>       |
  <auto-line-style-list>

<line-style-list> =
  <line-style-or-repeat>#

<auto-line-style-list> =
  <line-style-or-repeat>#? , <auto-repeat-line-style> , <line-style-or-repeat>#?

<line-style-or-repeat> =
  <line-style>          |
  <repeat-line-style>

<auto-repeat-line-style> =
  repeat( auto , [ <line-style> ]# )

<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset

<repeat-line-style> =
  repeat( [ <integer [1,∞]> ] , [ <line-style> ]# )

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

In this example, we define a single style for the lines drawn between flex items.

HTML

We include a list of dynamic sports duos:

```
<ul>
  <li>Simone Biles + Jonathan Owens</li>
  <li>Serena Williams + Venus Williams</li>
  <li>Aaron Judge + Giancarlo Stanton</li>
  <li>LeBron James + Dwyane Wade</li>
  <li>Xavi Hernandez + Andres Iniesta</li>
```

```
  <li>Kerri Walsh + Misty May Treanor</li>
</ul>
```

CSS

We define the list to be a flex container, creating rows by setting the `flex-direction` to `column` using the `flex-flow` shorthand. We include a `gap` of `5px` to provide enough room between the rows to fit our `3px` dashed red rule:

```
ul {
  display: flex;
  flex-flow: column;
  gap: 5px;
  row-rule-width: 3px;
  row-rule-color: red;

  row-rule-style: dashed;
}
```

Result

Repeating values

This example demonstrates how, when there are fewer values in the list of styles than row rules, the values are repeated.

CSS

Using the same HTML and CSS as in the previous example, we include three comma-separated styles as the `row-rule-style` value:

```
ul {
  row-rule-style: solid, dotted, dashed;
}
```

Result

Using the <code>repeat()</code> function

This example demonstrates using the `repeat()` function within the `row-rule-style` property value.

CSS

We use the same HTML and CSS as in the previous examples. We include a `repeat()` function, setting the list of two `<line-style>` values to be repeated 3 times.

```
ul {
  row-rule-style: double, repeat(3, inset, dashed), double;
}
```

Result

The flex container has six rows, so five gutters. The `repeat()` function repeats two style values three times, creating a list of eight style values, so the last three values in the list are discarded.

Using <code>auto</code> within <code>repeat()</code>

This example demonstrates using `auto` instead of an integer within the `repeat()` function.

CSS

Using `repeat(auto, <line-style>)` we set all row rules to `dotted`, except the first and last, which we set to `solid`.

```
ul {
  row-rule-style: solid, repeat(auto, dotted), solid;
}
```

Result

```
@layer no-support {
  @supports not (row-rule-style: solid, dotted) {
    body::before {
      content: "Your browser doesn't support the row-rule-style property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

row-rule-visibility-items CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`row-rule-visibility-items`** CSS property defines whether a row-rule segment is painted in gaps adjacent to empty areas.

Try it

```
row-rule-visibility-items: all;
```

```
row-rule-visibility-items: around;
```

```
row-rule-visibility-items: between;
```

```
row-rule-visibility-items: normal;
```

```
<section id="default-example">
  <section id="example-element">
    <p>One fish</p>
    <p>Two fish</p>
    <p>Red fish</p>
    <p>Blue fish</p>
    <cite>-- Dr. Seuss</cite>
  </section>
</section>
```

```
#example-element {
  display: grid;
  row-rule: solid 5px red;
  gap: 10px;
  grid-template-columns: repeat(3, 1fr);
  grid-template-rows: repeat(3, 1fr);
}
cite {
  grid-column: 3;
  grid-row: 3;
}
```

Syntax

```
/* Keyword values */
row-rule-visibility-items: all;
row-rule-visibility-items: around;
row-rule-visibility-items: between;
row-rule-visibility-items: normal;

/* Global values */
row-rule-visibility-items: inherit;
row-rule-visibility-items: initial;
row-rule-visibility-items: revert;
row-rule-visibility-items: revert-layer;
row-rule-visibility-items: unset;
```

Values

This property is specified as one of the following keyword values:

`all`

The row rule should be painted in all gap segments, regardless of whether adjacent areas contain an item.

`around`

The row rule should be painted in a gap segment if at least one of the two adjacent areas is occupied by an item.

`between`

The row rule should be painted in a gap segment if both adjacent areas are occupied by items.

`normal`

Behaves the same as `all`. This is the default.

Description

The `row-rule-visibility-items` property defines whether, in multi-column and grid containers with more than one row, row rule segments are painted in the gaps between two adjacent areas if one or both of the areas are empty.

The `row-rule-visibility-items` and `column-rule-visibility-items` properties can both be set to the same values using the `rule-visibility-items` shorthand.

Formal definition

Value not found in DB!

Formal syntax

```
row-rule-visibility-items =
  all     |
  around  |
  between |
  normal
```

This syntax reflects the latest standard as per CSS Gap Decorations Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

In this example, we define a row rules to be drawn between two grid areas if at least one adjacent grid area contains grid items.

HTML

We include a list of dynamic sports duos:

```
<ol>
  <li>Simone Biles + Jonathan Owens</li>
  <li>Serena Williams + Venus Williams</li>
```

```
  <li>Aaron Judge + Giancarlo Stanton</li>
  <li>LeBron James + Dwyane Wade</li>
  <li>Xavi Hernandez + Andres Iniesta</li>
  <li>Kerri Walsh + Misty May Treanor</li>
</ol>
```

CSS

We define the ordered list (`<ol>`) to be a grid container, creating 4 rows and 4 columns by setting both the `grid-template-rows` and `grid-template-columns` properties to `repeat(4, 1fr)`, and move the last item to the bottom-right grid area using `grid-row` and `grid-column`. We include a `gap` of `20px` to provide enough room between the rows to fit our `5px` dashed rule.

Finally, we set `row-rule-visibility-items` to `around`, so that a row rule segment is only painted in a row gap if one or both adjacent grid areas contain a grid item.

```
ol {
  display: grid;
  grid-template-columns: repeat(4, 1fr);
  grid-template-rows: repeat(4, 1fr);
  gap: 10px;

  row-rule: dashed 5px blue;
  row-rule-visibility-items: around;
}
li:last-child {
  grid-column: 4;
  grid-row: 4;
}
```

```
li {
  margin-left: 1em;
}
@layer no-support {
  @supports not (row-rule-visibility-items: around) {
    body::before {
      content: "Your browser doesn't support the row-rule-visibility-items property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

Result

row-rule-width CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`row-rule-width`** CSS property defines the widths of the lines drawn between rows in multi-row grid, flex, and multi-col layouts.

Try it

```
row-rule-width: thin;
```

```
row-rule-width: thin, thick;
```

```
row-rule-width: repeat(2, thin, thick), 10px;
```

```
row-rule-width: thick, repeat(auto, 1px, 2px), thick;
```

```
row-rule-width: medium;
```

```
<section id="default-example">
  <ul id="example-element">
    <li>One fish</li>
    <li>Two fish</li>
    <li>Red fish</li>
    <li>Blue fish</li>
  </ul>
</section>
```

```
#example-element {
  display: flex;
  flex-flow: column;
  row-rule-style: solid;
  row-rule-color: magenta;
  gap: 5px;
  text-align: left;
}
```

Syntax

```
/* Keyword values */
row-rule-width: thin;
row-rule-width: medium;
row-rule-width: thick;
```

```
row-rule-width: thin, medium, thick;
row-rule-width: thick, repeat(5, thin), thick;
row-rule-width: thick, repeat(auto, thin, medium), thick;

/* Length values */
row-rule-width: 1px;
row-rule-width: 5px;
row-rule-width: 1px, 3px, 5px;
row-rule-width: 5px, repeat(auto, 1px), 10px, 15px;
row-rule-width: 5px, repeat(5, 1px, 3px), 5px;

/* Global values */
row-rule-width: inherit;
row-rule-width: initial;
row-rule-width: revert;
row-rule-width: revert-layer;
row-rule-width: unset;
```

Values

The `row-rule-width` property accepts a comma-separated list of values, including:

`<line-width>`

A `<line-width>`: This can be one of the keywords `thin`, `medium`, or `thick`, or a positive `<length>` value, representing the width of the line. The default value is `medium`.

`<repeat-line-width>`

A `repeat()` function, with the first argument being an `<integer>` of `1` or more, and one or more `<line-width>` values as subsequent arguments. The integer defines the number of times the `<line-width>` values should be repeated.

`<auto-repeat-line-width>`

A `repeat()` function, with `auto` as the first argument and one or more `<line-width>` values as subsequent arguments. The provided `<line-width>` values are repeated as many times as needed to fill in values for any row-rules that are not explicitly specified by other components of the property value.

Description

The `row-rule-width` property defines the widths of any row rule lines drawn in the gaps between rows in multi-column, flex, and grid containers with more than one row.

The value is a comma-separated list of components, which can include `<line-width>`, `<repeat-line-width>`, and `<auto-repeat-line-width>` types.

The `row-rule-width`, along with the `row-rule-color` and `row-rule-style` properties, can be set using the `row-rule` shorthand. The `row-rule-width`, along with the `column-rule-width` property, can also be set using the `rule-width` shorthand.

If the property value consists of only one `<line-width>`, all the row rules will be that width. If we declare the following, all row rules will be `3px`:

```
row-rule-width: 3px;
```

When more than one `<line-width>` is declared, they will be applied to row-rules in the order specified. If there are more row-rules than `<line-width>` values, the list of line widths is repeated until every rule has a width. If we declare the following, for example, every odd rule will be `thin`, and every even rule will be `1em`.

```
row-rule-width: thin, 1em;
```

Repeated line widths

The `repeat()` function, with an integer of `1` or greater as the first argument, can be used to repeat a valid list of CSS `<line-width>` values passed as subsequent arguments the specified number of times. This allows the same widths to be repeated a set number of times without repeating the same values multiple times. The following declarations are equivalent:

```
row-rule-width: 1rem, thick, thin, thick, thin;
row-rule-width: 1rem, repeat(2, thick, thin);
```

You can use any `<line-width>` values, including custom properties that resolve to a `<line-width>`. Using `repeat()` can make values easier to write, especially when using complex length calculations. It enables a recurring pattern to be written using a single function, regardless of the number of rows.

If we set `--base: 1vh` and `--secondary: 1vw`, the following will provide similar results to the previous declaration:

```
row-rule-width:
  1rem,
  repeat(
    2,
    min(calc(var(--base) - 3px), 10px),
    abs(calc(var(--secondary) - 30px))
  ),
  thin;
```

This creates a list of six widths. If the number of widths in the `row-rule-width` value's width list exceeds the number of gaps between rows, the excess width values are ignored. If the container has three rows, the rule in the first gutter will be `1rem` wide, and the second is determined by the `min()` function.

If there are more gutters than widths, the list of widths is repeated. If the container has 7, 13, 19, or 25 rows, this sequence of widths will be repeated one, two, three, or four times, respectively, with the last rule being `thin`.

Auto-repeating line widths

The `repeat()` function also accepts `auto` as the first argument instead of a positive integer. With `auto` as the first argument, the list of `<line-width>` values passed as subsequent arguments will be repeated as many times as needed to fill in values for any row-rules that are not explicitly specified by other components of the property value.

```
row-rule-width: thin, repeat(auto, medium), thin;
```

In this case, it doesn't matter if the container has 3, 6, 11, 16, or 21 rows; the first and last rows will always be `thin`, and all other row rules will be `medium`. If there are only 2 or 3 rows, there will be no medium-sized row rules.

The `auto` keyword within the `repeat()` function creates an auto repeater that fills in values for row rules that would not otherwise receive values from other parts of the list, preventing the list from being cycled. At most, only one `repeat(auto, <width>)` can be present in a `row-rule-width` value.

Formal definition

Value not found in DB!

Formal syntax

```
row-rule-width =
  <line-width-list>       |
  <auto-line-width-list>

<line-width-list> =
  <line-width-or-repeat>#

<auto-line-width-list> =
  <line-width-or-repeat>#? , <auto-repeat-line-width> , <line-width-or-repeat>#?

<line-width-or-repeat> =
  <line-width>          |
  <repeat-line-width>

<auto-repeat-line-width> =
  repeat( auto , [ <line-width> ]# )

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick

<repeat-line-width> =
  repeat( [ <integer [1,∞]> ] , [ <line-width> ]# )

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

In this example, we define a single width for the lines drawn between flex items.

HTML

We include a list of dynamic sports duos:

```
<ul>
  <li>Simone Biles + Jonathan Owens</li>
  <li>Serena Williams + Venus Williams</li>
  <li>Aaron Judge + Giancarlo Stanton</li>
  <li>LeBron James + Dwyane Wade</li>
  <li>Xavi Hernandez + Andres Iniesta</li>
  <li>Kerri Walsh + Misty May Treanor</li>
</ul>
```

CSS

We define the list to be a flex container, creating rows by setting the `flex-direction` to `column` using the `flex-flow` shorthand. We include a `gap` of `5px` to provide enough room between the rows to fit our `3px` dashed red rule:

```
ul {
  display: flex;
  flex-flow: column;
  gap: 5px;
  row-rule-style: dashed;
  row-rule-color: red;
  row-rule-width: 3px;
}
```

Result

Repeating values

This example demonstrates how, when there are fewer values in the list of widths than row rules, the values are repeated.

CSS

Using the same HTML and CSS as in the previous example, we include three comma-separated widths as the `row-rule-width` value:

```
ul {
  row-rule-width: 1px, 3px, 5px;
}
```

Result

Using the <code>repeat()</code> function

This example demonstrates using the `repeat()` function within the `row-rule-width` property value and how this function can help reduce the verbosity of value declarations.

CSS

We use the same HTML and CSS as in the previous examples. To demonstrate how values can become verbose and the utility of the `repeat()` function, we declare two custom properties, which we use in `repeat()` function declarations. The `repeat()` function sets a list of two `<line-width>` values to repeat 3 times.

```
ul {
  --base: 0.5vw;
  --secondary: 1vw;
  row-rule-width:
    15px,
    repeat(
      3,
      min(calc(var(--base) + 3px), 10px),
      abs(calc(var(--secondary) - 2px))
```

```
    ),
    15px;
}
```

Result

The flex container has six rows, so five gutters. The `repeat()` function repeats two width values three times, creating a list of eight width values. As there are fewer row gutters than total widths, the last three values in the list are discarded.

Using <code>auto</code> within <code>repeat()</code>

This example demonstrates using `auto` instead of an integer within the `repeat()` function.

CSS

Using `repeat(auto, <line-width>)` we set all row rules to `1px`, except the first and last, which we set to `5px`.

```
ul {
  row-rule-width: 5px, repeat(auto, 1px), 5px;
}
```

Result

```
@layer no-support {
  @supports not (row-rule-width: thin, thick) {
    body::before {
      content: "Your browser doesn't support the row-rule-width property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

ruby-align CSS property

The **`ruby-align`** CSS property defines the distribution of the different ruby elements over the base.

Syntax

```
/* Keyword values */
ruby-align: start;
ruby-align: center;
ruby-align: space-between;
ruby-align: space-around;

/* Global values */
ruby-align: inherit;
ruby-align: initial;
ruby-align: revert;
ruby-align: revert-layer;
ruby-align: unset;
```

Values

This property is specified as one of the following keyword values:

`start`

Is a keyword indicating that the ruby will be aligned with the start of the base text.

`center`

Is a keyword indicating that the ruby will be aligned at the middle of the base text.

`space-between`

Is a keyword indicating that the extra space will be distributed between the elements of the ruby.

`space-around`

Is a keyword indicating that the extra space will be distributed between the elements of the ruby, and around it.

Formal definition

Initial value	`space-around`
Applies to	ruby bases, ruby annotations, ruby base containers, ruby annotation containers
Inherited	yes
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
ruby-align =
  start          |
```

```
  center         |
  space-between  |
  space-around
```

This syntax reflects the latest standard as per CSS Ruby Annotation Layout Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Ruby aligned at the start of the base text

HTML

```
<ruby>
  <rb>This is a long text to check</rb>
  <rp> (</rp><rt>short ruby</rt><rp>) </rp>
</ruby>
```

CSS

```
ruby {
  ruby-align: start;
}
```

Result

Ruby aligned at the center of the base text

HTML

```
<ruby>
  <rb>This is a long text to check</rb>
  <rp> (</rp><rt>short ruby</rt><rp>) </rp>
</ruby>
```

CSS

```
ruby {
  ruby-align: center;
}
```

Result

Extra space distributed between ruby elements

HTML

```
<ruby>
  <rb>This is a long text to check</rb>
  <rp> (</rp><rt>short ruby</rt><rp>) </rp>
</ruby>
```

CSS

```
ruby {
  ruby-align: space-between;
}
```

Result

Extra space distributed between and around ruby elements

HTML

```
<ruby>
  <rb>This is a long text to check</rb>
  <rp> (</rp><rt>short ruby</rt><rp>) </rp>
</ruby>
```

CSS

```
ruby {
  ruby-align: space-around;
}
```

Result

See also

- `ruby-position`
- CSS ruby layout module
- HTML Ruby elements: `<ruby>`, `<rt>`, `<rp>`, and `<rtc>`

ruby-overhang CSS property

The **`ruby-overhang`** CSS property specifies whether or not a `<ruby>` annotation overhangs any surrounding text.

Try it

```
ruby-overhang: auto;
```

```
ruby-overhang: none;
```

```
<section id="default-example">
  <p id="example-element">
    あの<ruby>表<rp>(</rp><rt>ひょう</rt><rp>)</rp></ruby
    ><ruby>現<rp>(</rp><rt>げん</rt><rp>)</rp></ruby>は面白い。
  </p>
</section>
```

```
#default-example {
  font-size: 2em;
}
```

Syntax

```
/* Keyword values */
ruby-overhang: auto;
ruby-overhang: none;

/* Global values */
ruby-overhang: inherit;
ruby-overhang: initial;
ruby-overhang: revert;
ruby-overhang: revert-layer;
ruby-overhang: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

> When a ruby annotation container is longer than its corresponding base container, the annotation may partially overlap adjacent text. Whether, and how much to overhang are determined by the user agent.

`none`

> A keyword indicating that the ruby is never allowed to extend past adjacent containers.

Description

The `ruby-overhang` property controls whether the ruby annotation text box (`<rt>`) may overlap adjacent text outside the `<ruby>` container box.

When ruby annotation text is not allowed to overhang — when `ruby-overhang: none` is set on the `<ruby>` element — that element behaves like an inline box, as if its `display` property were set to `inline` with only its own contents rendered within its boundaries and adjacent elements not crossing the boundary box.

By default, the content of an `<rt>` element is allowed to overhang, so content may overlap the `<ruby>` container box, partially rendering over or under surrounding inline-level content. With `auto`, the default, content may overhang, but it will not overhang if doing so would overlap adjacent `<rt>` elements or elements with a `display` value resolving to `ruby-base` or `ruby-text`.

Formal definition

Initial value	`auto`
Applies to	ruby annotation containers
Inherited	yes
Computed value	the specified keyword
Animation type	by computed value type

Formal syntax

```
ruby-overhang =
  auto    |
  spaces
```

This syntax reflects the latest standard as per CSS Ruby Annotation Layout Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Ruby overhanging base text

This examples demonstrates both values of the `ruby-overhang` property.

HTML

We include two paragraphs with identical `<ruby>` content and structures, other than their class names.

```
<p class="auto">
  あの<ruby>表<rp>(</rp><rt>ひょう</rt><rp>)</rp></ruby
  ><ruby>現<rp>(</rp><rt>げん</rt><rp>)</rp></ruby>は面白い。
</p>

<p class="none">
  あの<ruby>表<rp>(</rp><rt>ひょう</rt><rp>)</rp></ruby
  ><ruby>現<rp>(</rp><rt>げん</rt><rp>)</rp></ruby>は面白い。
</p>
```

CSS

A red `outline` of `1px` helps highlight the text annotation of `<rt>` elements. The first paragraph has `ruby-overhang: auto` and the second has `ruby-overhang: none`.

```
p {
  font-size: 40px;
  display: block;
  margin: 0.5rem;
}
rt {
  font-size: 28px;
  outline: 1px solid red;
}
.auto {
  ruby-overhang: auto;
}
.none {
  ruby-overhang: none;
}
```

Results

When `ruby-overhang` is set to `none`, the annotation text is not allowed to overlap the adjacent boxes of base ruby text. If you look closely, you may notice that in the first paragraph, the red box encasing the ruby text slightly overlaps parts of non-associated `<ruby>` content, whereas in the `none` example in supporting browsers, there is no overlap between ruby content and not-associated ruby text.

- `<rt>`
- `<rp>`

ruby-position CSS property

The **`ruby-position`** CSS property defines the position of a ruby element relative to its base element. It can be positioned over the element (`over`), under it (`under`), or to the right (`inter-character`).

Try it

```
ruby-position: over;
```

```
ruby-position: under;
```

```
<section id="default-example">
  <ruby id="example-element"> 明日 <rp>(</rp><rt>Ashita</rt><rp>)</rp> </ruby>
</section>
```

```
#example-element {
  font-size: 2em;
}
```

Syntax

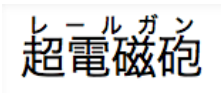
```
/* Keyword values */
ruby-position: over;
ruby-position: under;
ruby-position: alternate;
ruby-position: alternate over;
ruby-position: alternate under;
ruby-position: inter-character;

/* Global values */
ruby-position: inherit;
ruby-position: initial;
ruby-position: revert;
ruby-position: revert-layer;
ruby-position: unset;
```

Values

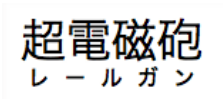
This property is specified as one of the following keyword values:

`over`



Is a keyword indicating that the ruby has to be placed over the main text for horizontal scripts and right to it for vertical scripts.

`under`



Is a keyword indicating that the ruby has to be placed under the main text for horizontal scripts and left to it for vertical scripts.

`alternate`

Is a keyword indicating that the ruby alternates between over and under, when there are multiple levels of annotation.

`inter-character`

Is a keyword indicating that the ruby annotation is placed to the right of the base text characters. This value is intended for bopomofo (zhuyin fuhao) ruby.

Formal definition

Initial value	`alternate`
Applies to	ruby annotation containers
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
ruby-position =
  [ alternate || [ over | under ] ]  |
  inter-character
```

This syntax reflects the latest standard as per CSS Ruby Annotation Layout Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Ruby positioned over the text

HTML

```
<ruby>
  <rb>超電磁砲</rb>
  <rp> (</rp><rt>レールガン</rt><rp>) </rp>
</ruby>
```

CSS

```
ruby {
  ruby-position: over;
}
```

Result

Ruby positioned under the text

HTML

```
<ruby>
  <rb>超電磁砲</rb>
  <rp> (</rp><rt>レールガン</rt><rp>) </rp>
</ruby>
```

CSS

```
ruby {
  ruby-position: under;
}
```

Result

Ruby alternate

HTML

```
<ruby>
  <rb>A</rb><rb>B</rb><rb>C</rb>
  <rtc>Above</rtc>
  <rtc>Below</rtc>
</ruby>
```

CSS

```
ruby {
  ruby-position: alternate; /* this is also the initial value */
}
```

Result

rule CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`rule`** CSS shorthand property sets the width, style, and color of the line drawn between rows and columns in multi-row grid, flex, and multi-col layouts, setting both the column and row rules to the same values.

Try it

```
rule: solid;
```

```
rule: dotted medium blue;
```

```
rule:
  dotted medium blue,
  repeat(3, dotted red 2px, double orange 5px);
```

```
rule:
  dashed medium magenta,
  repeat(auto, dotted blue 2px, dotted blue 5px),
  dashed medium magenta;
```

```
rule:
  dashed medium magenta,
  repeat(auto, dotted blue 2px),
  outset goldenrod 5px;
```

```
<section id="default-example">
  <div id="example-element">
    <i>A</i>
    <i>B</i>
    <i>C</i>
    <i>D</i>
    <i>E</i>
    <i>F</i>
```

```
    <i>G</i>
    <i>H</i>
    <i>I</i>
    <i>J</i>
    <i>K</i>
    <i>L</i>
    <i>M</i>
    <i>N</i>
    <i>O</i>
    <i>P</i>
    <i>Q</i>
    <i>R</i>
    <i>S</i>
    <i>T</i>
    <i>U</i>
    <i>V</i>
    <i>W</i>
    <i>X</i>
    <i>Y</i>
    <i>Z</i>
  </div>
</section>
```

```
#example-element {
  display: grid;
  grid-template-columns: repeat(7, 1fr);
  rule: solid thick;
}
#example-element i {
  padding: 5px;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `rule-color`
- `rule-style`
- `rule-width`

Syntax

```
/* One value */
rule: dotted;
rule: solid 8px;
rule: solid blue;
rule: thick inset blue;

/* Multiple values */
rule: groove, dashed, solid;
rule:
  dotted medium blue,
  dashed magenta 1px,
  outset green 5px;
rule:
  solid #0ff,
  repeat(3, dashed magenta 1px, outset green 5px);
rule:
  inset 3px yellow,
  repeat(auto, dashed magenta 1px, groove green 5px),
  inset 3px yellow;

/* Global values */
rule: inherit;
rule: initial;
rule: revert;
rule: revert-layer;
rule: unset;
```

Values

The `rule` property accepts a comma-separated list of values, including:

`<gap-rule>`

Specified as one, two, or three of the values listed below, in any order.

`<'line-width'>`

A `<line-width>`: a positive `<length>` or one of the three keywords, `thin`, `medium`, or `thick`. The default value is `medium`. See `rule-width`.

`<'line-style'>`

A `<line-style>`: one of `none`, `hidden`, `dotted`, `dashed`, `solid`, `double`, `groove`, `ridge`, `inset`, or `outset`. The default value is `none`. See `rule-style`.

`<'color'>`

A `<color>` value representing the color of the line. The default value is `currentcolor`. See `rule-color`.

`<gap-repeat-rule>`

A `repeat()` function, with an `<integer>` of `1` or more as the first argument and one or more `<gap-rule>` values as subsequent arguments. The `<integer>` specifies how many times the list of `<gap-rule>` values should be repeated.

`<gap-auto-repeat-rule>`

A `repeat()` function, with `auto` as the first argument and one or more `<gap-rule>` values as subsequent arguments. The provided list of `<gap-rule>` values is repeated as many times as needed to fill in values for any rules that are not explicitly specified by other components of the property value.

Description

The `rule` property defines the line style of any rule lines drawn in the gaps between rows and columns in multi-column, flex, and grid containers with more than one row or column.

The `rule` is shorthand for `rule-color`, `rule-style`, and `rule-width`. It sets the `row-rule` and `column-rule` shorthand properties to the same value.

The property value is a comma-separated list of components, which can include `<gap-rule>`, `<gap-repeat-rule>`, and `<gap-auto-repeat-rule>` types. Each `<gap-rule>` defines the width, color, and style of one or more rule lines.

If the property value consists of only one `<gap-rule>`, all the row and column rules will be that style, color, and size. If we declare the following, all row and column rules will be `dashed red 3px`:

```
rule: dashed red 3px;
```

When more than one `<gap-rule>` is declared, they will be applied to rules in the order specified. If there are more gutters between rows and columns than `<gap-rule>` values, the list of values is repeated until every row and column rule has a gap line. If we declare the following, for example, every odd rule will be `dashed red 3px`, and every even rule will be `dotted blue 5px`, in both directions.

```
rule:
  dashed red 3px,
  dotted blue 5px;
```

Repeated line styles

The `repeat()` function, with an integer of `1` or greater as the first argument, can be used to repeat a valid list of CSS `<gap-rule>` values passed as subsequent arguments the specified number of times. This allows the same `<gap-rule>` to be repeated a set number of times without repeating the same CSS multiple times. The following declarations are equivalent:

```
rule:
  solid red 5px,
  outset blue 10px,
  inset green 1px,
  outset blue 10px,
  inset green 1px,
  outset blue 10px,
  inset green 1px;
rule:
  solid red 5px,
  repeat(3, outset blue 10px, inset green 1px);
```

This creates a list of seven rules. If the number of styles in the `rule` value's style list exceeds the number of gaps between rows and columns, the excess style values are ignored. If the container on which this is applied has three rows and columns, the rule in the first gutter will be `solid red 5px` and the second `outset blue 10px`, in both directions.

If there are more gutters than styles, the list of styles is repeated. If the container has 8, 15, 22, or 29 rows or columns, this sequence of styles will be repeated in that direction one, two, three, or four times, respectively, with the last rule being `inset green 1px`.

Auto-repeating line styles

The `repeat()` function also accepts `auto` as the first argument instead of a positive integer. With `auto` as the first argument, the `<gap-rule>` values passed as subsequent arguments will be repeated as many times as needed to fill in values for any row and column rules that are not explicitly specified by other components of the property value.

```
rule:
  solid red 5px,
  repeat(auto, dotted green 1px, dashed blue 1px),
  solid red 5px;
```

In this case, the first and last row and column rules will be `solid red 5px`, and all others will alternate between `dotted green 1px` and `dashed blue 1px`. It doesn't matter if the container has 3, 6, 11, 16, or 21 rows and columns; the first and last gutters will always have a thick solid red line painted between them (unless `rule-visibility-items` leads to no line being drawn), and all the other row and column rules will be thin, dotted green or dashed blue lines. If there are only 2 or 3 rows and columns, there will be no dotted or dashed lines.

The `auto` keyword within the `repeat()` function creates an auto-repeater that fills in values for row and column rules that would not otherwise receive values from other parts of the list, preventing the list from being cycled. At most, only one `repeat(auto, <gap-rule>)` can be present in a `rule` value.

Formal definition

Value not found in DB!

Formal syntax

```
rule =
  <'column-rule'>

<column-rule> =
  <gap-rule-list>      |
  <gap-auto-rule-list>

<gap-rule-list> =
  <gap-rule-or-repeat>#

<gap-auto-rule-list> =
  <gap-rule-or-repeat>#? , <gap-auto-repeat-rule> , <gap-rule-or-repeat>#?

<gap-rule-or-repeat> =
  <gap-rule>         |
  <gap-repeat-rule>

<gap-auto-repeat-rule> =
  repeat( auto , <gap-rule># )

<gap-rule> =
  <line-width>  ||
  <line-style>  ||
  <color>

<gap-repeat-rule> =
  repeat( <integer [1,∞]> , <gap-rule># )

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick

<line-style> =
  none    |
  hidden  |
  dotted  |
```

```
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

In this example, we define a single rule for the lines drawn in the gutters between grid items.

HTML

We create a list of 75 items. Most of the HTML is hidden for brevity.

```
<ul>
  <li>1</li>
  <li>2</li>
  ...
  <li>74</li>
  <li>75</li>
</ul>
```

```
<ul>
  <li>1</li>
  <li>2</li>
  <li>3</li>
  <li>5</li>
  <li>6</li>
  <li>7</li>
  <li>8</li>
  <li>9</li>
  <li>10</li>
  <li>11</li>
  <li>12</li>
  <li>13</li>
  <li>14</li>
  <li>15</li>
  <li>16</li>
  <li>17</li>
  <li>18</li>
  <li>19</li>
  <li>20</li>
  <li>21</li>
  <li>22</li>
  <li>23</li>
  <li>24</li>
  <li>25</li>
  <li>26</li>
  <li>27</li>
  <li>28</li>
  <li>29</li>
  <li>30</li>
  <li>31</li>
  <li>32</li>
  <li>33</li>
  <li>34</li>
  <li>35</li>
  <li>36</li>
  <li>37</li>
  <li>38</li>
  <li>39</li>
  <li>40</li>
  <li>41</li>
  <li>42</li>
  <li>43</li>
  <li>44</li>
  <li>45</li>
  <li>46</li>
  <li>47</li>
  <li>48</li>
  <li>49</li>
  <li>50</li>
  <li>51</li>
  <li>52</li>
  <li>53</li>
  <li>54</li>
  <li>55</li>
  <li>56</li>
  <li>57</li>
  <li>58</li>
  <li>59</li>
  <li>60</li>
  <li>61</li>
  <li>62</li>
  <li>63</li>
  <li>64</li>
  <li>65</li>
  <li>66</li>
  <li>67</li>
  <li>68</li>
  <li>69</li>
  <li>70</li>
  <li>71</li>
```

```
  <li>72</li>
  <li>73</li>
  <li>74</li>
  <li>75</li>
</ul>
```

CSS

We define the unordered list as a 10-column container, creating columns and rows with the `grid-template-columns` property and setting `list-style-type` to `none` to remove the bullets. We include a `gap` of `5px` to provide enough room between the columns and rows to fit our `dashed 3px magenta` rule.

```
ul {
  display: grid;
  grid-template-columns: repeat(10, 1fr);
  list-style-type: none;
  gap: 5px;

  rule: dashed 3px magenta;
}
li {
  text-align: center;
  aspect-ratio: 1;
}
```

Result

Multiple gap-rules and default values

This example demonstrates using multiple, comma-separated values. It also demonstrates the default values for the width, color, and style of `medium`, `currentcolor` and `none`, respectively.

CSS

Using the same HTML and CSS as in the previous example, we include four comma-separated `<gap-rule>` values as the `rule` value, omitting the `<line-width>` in the first `<gap-rule>`, the `<color>` in the second, and the `<line-style>` from the third, with the fourth including all three components:

```
ul {
  rule:
    red dashed,
    1px dotted,
    5px blue,
    10px magenta solid;
}
```

Result

The red line is `3px` wide, the dotted line is the same color as the text, and there is no `5px`-wide blue line, as the style of the third `<gap-rule>` defaults to `none`, so no line is painted. As there are fewer rule styles than gutters, the list of rules is repeated until all rule lines are styled.

Using the <code>repeat()</code> function

This example demonstrates using the `repeat()` function within the `rule` property value.

CSS

We use the same HTML and CSS as in the previous examples, overriding the `rule` value with a comma-separated list of three components: two `<gap-rule>` values and a `<gap-repeat-rule>` that sets a list of two `<gap-rule>` values to repeat 3 times.

```
ul {
  rule:
    3px red dashed,
    repeat(3, dotted green 1px, dashed blue 1px),
    3px red dashed;
}
```

Result

The grid has ten columns and eight rows, so nine column gutters and seven row gutters. The `repeat()` function repeats two style values three times, creating a list of eight style values. As there are fewer row gutters than values, the last value is not used in the row direction. As there are more column gutters than values, the list repeats in the column direction.

Using <code>auto</code> within <code>repeat()</code>

This example demonstrates using the `auto` argument instead of an integer in the `repeat()` function.

CSS

Using `repeat(auto, <gap-rule>)`, we set all row and column rules to `1px dotted` (with the color defaulting to the current color), except the first and last rules, which we set to `3px solid red`.

```
ul {
  rule:
    3px red solid,
    repeat(auto, 1px dotted),
    3px red solid;
}
```

Result

```
@layer no-support {
  @supports not (rule: thin, thick) {
    body::before {
      content: "Your browser doesn't support the rule property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

rule-break CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`rule-break`** CSS shorthand property sets the behavior for breaking column and row rules into segments where rows and column gaps intersect, setting `column-rule-break` and `row-rule-break` to the same value.

Try it

```
rule-break: none;
```

```
rule-break: normal;
```

```
rule-break: intersection;
```

```
<section id="default-example">
  <div id="example-element">
    <i>A</i>
    <i>B</i>
    <i>C</i>
    <i>D</i>
    <i>E</i>
    <i>F</i>
    <i>G</i>
    <i>H</i>
    <i>I</i>
    <i>J</i>
    <i>K</i>
    <i>L</i>
    <i>M</i>
    <i>N</i>
    <i>O</i>
    <i>P</i>
    <i>Q</i>
    <i>R</i>
    <i>S</i>
    <i>T</i>
    <i>U</i>
    <i>V</i>
    <i>W</i>
    <i>X</i>
    <i>Y</i>
    <i>Z</i>
  </div>
</section>
```

```
#example-element {
  display: grid;
  grid-template-columns: repeat(7, 1fr);
  row-rule: solid thick orange;
  column-rule: solid thick purple;
  gap: 10px;
}
#example-element i {
  padding: 5px;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `column-rule-break`
- `row-rule-break`

Syntax

```
/* Keyword values */
rule-break: none;
rule-break: normal;
rule-break: intersection;

/* Global values */
rule-break: inherit;
rule-break: initial;
rule-break: revert;
rule-break: revert-layer;
rule-break: unset;
```

Values

This property is specified as a single keyword from the following list:

`none`

There are no breaks where row and column rules intersect; rather, a single continuous decoration is painted from one end of each gap to the other.

`normal`

In flex and grid containers, behaves as `none`. In multi-col, `column-rule-break` behaves as `intersection` and `row-rule-break` behaves as `none`. This is the default value.

`intersection`

Rules always break when they intersect a gap, with rule segments starting and ending at container and gap edges.

Description

The `rule-break` property is used to set the behavior for breaking rules into segments when they cross gaps.

Gap decorations are painted within a gap as one or more gap decoration segments, with segments occurring between any two adjacent items. Depending on the container type, by default, these segments may either end at the edge of a gap, or the column and row rule may extend the entire height and width of the container.

When there is a break in a rule, by default, the segments start and end at the edge of the gaps. If the gap size is `0`, the break may not be visible. The `rule-break` property determines if the break occurs. You can control the size of the break at the end of each segment with the `rule-inset` properties. When there are no breaks, and the line is continuous, `rule-inset` properties only affect the rule at the start and end edges of the container. When there are breaks, the `rule-inset` properties affect the start and end of every rule segment.

Whether a rule is by default composed of a single continuous segment or segments that break when intersecting gaps depends on the container type.

Grid containers

In grid containers, by default, rule segments continue through visible "cross" intersections. Setting `rule-break: intersection` will force the segments to break where they would otherwise cross.

```
<h1>Default rule breaks in grid</h1>
<div class="grid">
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
</div>
<p>
  <label
    ><input type="checkbox" /> Set <code>rule-break: intersection</code></label
  >
</p>
```

```
body {
  font-family: sans-serif;
  text-align: center;
}
h1 {
  font-size: 1.25em;
}
h2 {
  font-size: 1em;
}

:has(:checked) .grid {
  rule-break: intersection;
}
.grid {
  display: grid;
  grid-template-columns: repeat(3, 1fr);
  gap: 20px;
  rule: 5px solid red;
  width: 100%;
}

.grid > div {
  border: 1px solid green;
  background-color: lime;
  height: 30px;
}

@layer no-support {
  @supports not (rule-break: intersection) {
    body::before {
      content: "Your browser doesn't support the rule-break property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

Check the checkbox to set the `rule-break` to `intersection`, which makes the continuous rules break at every "cross" intersection.

Flex containers

In flexbox, when the `flex-direction` is `row` or `row-reverse`, the row rule is continuous, with the column segments starting and ending at the edge of the row gaps. When the `flex-direction` is `column` or `column-reverse`, the column rule is continuous, with the row segments starting and ending at the edge of the column gaps.

```
<h1>Default rule breaks in flexbox</h1>
<article>
  <section>
    <h2>flex-direction: row</h2>
    <div class="flexbox">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
  <section>
```

```
    <h2>flex-direction: column</h2>
    <div class="flexbox column">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
</article>
<p>
  <label
    ><input type="checkbox" /> Set <code>rule-break: intersection</code></label
  >
</p>
```

```
body {
  font-family: sans-serif;
  text-align: center;
}
h1 {
  font-size: 1.25em;
}
h2 {
  font-size: 1em;
}

:has(:checked) .flexbox {
  rule-break: intersection;
}
article {
  display: flex;
  gap: 5vw;
  rule: 1px solid black;
  width: 100vw;
}
section {
  flex-basis: 45vw;
}
.flexbox {
  display: flex;
  flex-flow: balance;
  flex-line-count: 3;
  gap: 20px;
  rule: 5px solid red;
  width: 100%;
}
.column {
  flex-flow: column balance;
  gap: 20px;
}

.flexbox > div {
  border: 1px solid green;
  background-color: lime;
  flex: 1 1 auto;
  height: 30px;
}
@layer no-support {
  @supports not (rule-break: intersection) {
    body::before {
      content: "Your browser doesn't support the rule-break property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

Note how, depending on the `flex-direction`, the column or row rules are continuous by default. If you set the `rule-break` to `intersection`, those continuous rules break at every intersection.

Multi-col containers

In multi-col containers, the default `normal` behavior differs between row rules and column rules. Column rule segments start and end when they intersect a row gap, behaving as `column-rule-break: intersection`, while row rules don't break when they intersect a column gap, behaving as `row-rule-break: none`.

```
<h1>Default rule breaks in multi-col</h1>
<ol>
  <li>One fish</li>
  <li>Two fish</li>
  <li>Red fish</li>
  <li>Blue fish</li>
  <li>Black fish</li>
  <li>Blue fish</li>
  <li>Old fish</li>
  <li>New fish.</li>
  <li>This one has a little star.</li>
  <li>This one has a little car.</li>
  <li>Say! What a lot</li>
  <li>Of fish there are.</li>
  <li>Yes. Some are red.</li>
  <li>And some are blue.</li>
  <li>Some are old.</li>
  <li>And some are new.</li>
  <li>Some are sad.</li>
  <li>And some are glad.</li>
  <li>And some are very, very bad.</li>
  <li>Why are they</li>
  <li>Sad and glad and bad?</li>
```

```
  <li>I do not know.</li>
  <li>Go ask your dad.</li>
</ol>
<fieldset>
  <legend>Set <code>rule-break:</code></legend>
  <label
    ><input type="radio" name="break" value="none" /> <code>none</code></label
  >
  <label

}
@layer no-support {
  @supports not (rule-break: intersection) {
    body::before {
      content: "Your browser doesn't support the rule-break property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

Check the radio buttons for each value to see the value's effect.

Formal definition

Value not found in DB!

Formal syntax

```
rule-break =
  <'column-rule-break'>

<column-rule-break> =
  none          |
  normal        |
  intersection
```

This syntax reflects the latest standard as per CSS Gap Decorations Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

In this example, we use the `rule-break` property to break each rule segment in a grid container so no rules intersect.

HTML

We create a list of 50 items. Most of the HTML is hidden for brevity.

```
<ul>
  <li>1</li>
  <li>2</li>
  ...
  <li>49</li>
  <li>50</li>
</ul>
```

```
<ul>
  <li>1</li>
  <li>2</li>
  <li>3</li>
```

```
  <li>5</li>
  <li>6</li>
  <li>7</li>
  <li>8</li>
  <li>9</li>
  <li>10</li>
  <li>11</li>
  <li>12</li>
  <li>13</li>
  <li>14</li>
  <li>15</li>
  <li>16</li>
  <li>17</li>
  <li>18</li>
  <li>19</li>
  <li>20</li>
  <li>21</li>
  <li>22</li>
  <li>23</li>
  <li>24</li>
  <li>25</li>
  <li>26</li>
  <li>27</li>
  <li>28</li>
  <li>29</li>
  <li>30</li>
  <li>31</li>
  <li>32</li>
  <li>33</li>
  <li>34</li>
  <li>35</li>
  <li>36</li>
  <li>37</li>
  <li>38</li>
  <li>39</li>
  <li>40</li>
  <li>41</li>
  <li>42</li>
  <li>43</li>
  <li>44</li>
  <li>45</li>
  <li>46</li>
  <li>47</li>
  <li>48</li>
  <li>49</li>
  <li>50</li>
</ul>
```

CSS

We define the unordered list as a 8-column container, creating columns and rows with the `grid-template-columns` property and setting `list-style-type` to `none` to remove the bullets. We include a `gap` of `20px` to provide enough room between the columns and rows to fit our `20px` solid column and row rules. Last, we set the rule segments to break instead of intersect.

```
ul {
  display: grid;
  grid-template-columns: repeat(8, 1fr);
  list-style-type: none;
  gap: 20px;

  row-rule: 20px solid palegoldenrod;
  column-rule: 20px solid olive;

  rule-break: intersection;
}
```

The rest of the CSS is hidden for brevity.

```
ol {
  place-items: center;
}
li {
  text-align: center;
  aspect-ratio: 1;
  font-family: sans-serif;
  line-height: 50px;
}
@layer no-support {
  @supports not (rule-break: intersection) {
    body::before {
      content: "Your browser doesn't support the rule-break property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

rule-color CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`rule-color`** CSS shorthand property defines the colors of the lines drawn between columns and rows in multi-column grid, flex, and multi-col layouts, setting the colors of the column and row rules to the same value.

Try it

```
rule-color: purple;
```

```
rule-color: rgb(48 125 222), rgb(222 48 125);
```

```
rule-color: rgb(48 125 222), repeat(3, rgb(222 48 125));
```

```
rule-color: purple, repeat(auto, red, yellow);
```

```
<section id="default-example">
  <div id="example-element">
    <i>A</i>
    <i>B</i>
    <i>C</i>
    <i>D</i>
    <i>E</i>
    <i>F</i>
    <i>G</i>
    <i>H</i>
    <i>I</i>
    <i>J</i>
    <i>K</i>
    <i>L</i>
    <i>M</i>
    <i>N</i>
    <i>O</i>
    <i>P</i>
    <i>Q</i>
    <i>R</i>
    <i>S</i>
    <i>T</i>
    <i>U</i>
    <i>V</i>
    <i>W</i>
    <i>X</i>
    <i>Y</i>
    <i>Z</i>
  </div>
</section>
```

```
#example-element {
  display: grid;
  grid-template-columns: repeat(7, 1fr);
  rule: solid thick;
}
#example-element i {
  padding: 5px;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `column-rule-color`
- `row-rule-color`

Syntax

```
/* Single <color> value */
rule-color: purple;
rule-color: rgb(192 56 78);
rule-color: transparent;
rule-color: hsl(0 100% 50% / 60%);

/* Multiple values */
rule-color: purple, magenta;
rule-color: repeat(3, purple), repeat(3, transparent);
rule-color: repeat(3, purple), repeat(3, yellow, blue);
rule-color: purple, repeat(auto, transparent), purple;
rule-color: purple, repeat(auto, blue, yellow), purple;
rule-color: repeat(3, purple), repeat(auto, transparent), repeat(3, purple);

/* Global values */
rule-color: inherit;
rule-color: initial;
rule-color: revert;
rule-color: revert-layer;
rule-color: unset;
```

Values

The `rule-color` property accepts a comma-separated list of values, including:

`<line-color>`

A `<color>` representing the color of the line.

`<repeat-line-color>`

A `repeat()` function, with an `<integer>` of `1` or more as the first argument and one or more `<color>` values as subsequent arguments. The `<integer>` specifies how many times the `<color>` values should be repeated.

`<auto-repeat-line-color>`

A `repeat()` function, with `auto` as the first argument and one or more `<color>` values as subsequent arguments. The provided `<color>` values are repeated as many times as needed to fill in values for any rules that are not explicitly specified by other components of the property value.

Description

The `rule-color` property defines the colors of any lines drawn in the gaps between columns and rows in multi-column, flex, and grid containers with more than one column or row. It is a shorthand property that sets both the `row-rule-color` and `column-rule-color` properties to the same value.

The value is a comma-separated list of components, which can include `<line-color>`, `<repeat-line-color>`, and `<auto-repeat-line-color>` types. The `rule-color` property, along with the `rule-width` and `rule-style` properties, can be set using the `rule` shorthand.

Line colors

A `<line-color>` can be declared as any valid CSS `<color>` value. If the property value consists of only one `<color>`, all the rule lines will be that color. For example, if we declare the following, the lines in the gutters between columns and rows will all be blue:

```
rule-color: blue;
```

When multiple `<line-color>` values are declared, they will be applied to lines painted in the column and row gutters in the order specified. If there are more rules than `<line-color>` values, the list of colors is repeated until every column-rule has a color. If we declare the following, for example, every odd rule will be red, and every even rule will be yellow.

```
rule-color: red, yellow;
```

Repeated line colors

The `repeat()` function, with an integer of `1` or greater as the first argument, can be used to repeat a valid list of CSS `<color>` values passed as subsequent arguments the specified number of times. This allows the color values to be repeated as many times as you need without having to list them individually. The following declarations are equivalent:

```
rule-color: blue, yellow, red, yellow, red, yellow, red;
rule-color: blue, repeat(3, yellow, red);
```

This creates a list of seven colors. If the number of colors in the `rule-color` value's color list exceeds the number of gaps between columns and rows, the excess color values are ignored. If there are fewer colors than gutters, the list of values is repeated until every rule has an associated color. For example, if the container has three columns and 18 rows, the rule in the first column gutter will be blue and the second yellow. For the row rules, the sequence repeats, with the first, eighth, and fifteenth row rules being blue.

Auto-repeating line colors

The `repeat()` function also accepts `auto` as the first argument instead of a positive integer. With `auto` as the first argument, the `<color>` values passed as subsequent arguments will be repeated as many times as needed to fill in values for any column and row rules that are not explicitly specified by other components of the property value.

```
rule-color: blue, repeat(auto, yellow), red;
```

In this case, the first column and row rules will be blue, the last will be red, and all others will be yellow. As long as there are at least two rules in either direction, the first rule will always be blue and the last will always be red. All the other rules will be yellow, which means if there are only 2 or 3 columns and rows, there will be no yellow lines.

The `auto` keyword within the `repeat()` function creates an auto-repeater that fills in values for the rule line colors that would not otherwise receive values from other parts of the list, preventing the list from being cycled. A `rule-color` value can include, at most, one `repeat(auto, <color>)`.

Formal definition

Value not found in DB!

Formal syntax

```
rule-color =
  <'column-rule-color'>

<column-rule-color> =
  <line-color-list>      |
  <auto-line-color-list>

<line-color-list> =
  <line-color-or-repeat>#

<auto-line-color-list> =
  <line-color-or-repeat>#? , <auto-repeat-line-color> , <line-color-or-repeat>#?

<line-color-or-repeat> =
  <color>              |
  <repeat-line-color>

<auto-repeat-line-color> =
  repeat( auto , [ <color> ]# )

<repeat-line-color> =
  repeat( [ <integer [1,∞]> ] , [ <color> ]# )

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

In this example, we define a single `<color>` for the lines drawn between the columns and rows of items in a grid container.

HTML

We create a list of 75 items. Most of the HTML is hidden for brevity.

```
<ul>
  <li>1</li>
```

```
  <li>2</li>
  ...
  <li>74</li>
  <li>75</li>
</ul>
```

```
<ul>
  <li>1</li>
  <li>2</li>
  <li>3</li>
  <li>4</li>
  <li>5</li>
  <li>6</li>
  <li>7</li>
  <li>8</li>
  <li>9</li>
  <li>10</li>
  <li>11</li>
  <li>12</li>
  <li>13</li>
  <li>14</li>
  <li>15</li>
  <li>16</li>
  <li>17</li>
  <li>18</li>
  <li>19</li>
  <li>20</li>
  <li>21</li>
  <li>22</li>
  <li>23</li>
  <li>24</li>
  <li>25</li>
  <li>26</li>
  <li>27</li>
  <li>28</li>
  <li>29</li>
  <li>30</li>
  <li>31</li>
  <li>32</li>
  <li>33</li>
  <li>34</li>
  <li>35</li>
  <li>36</li>
  <li>37</li>
  <li>38</li>
  <li>39</li>
  <li>40</li>
  <li>41</li>
  <li>42</li>
  <li>43</li>
  <li>44</li>
  <li>45</li>
  <li>46</li>
  <li>47</li>
  <li>48</li>
  <li>49</li>
  <li>50</li>
  <li>51</li>
  <li>52</li>
  <li>53</li>
  <li>54</li>
  <li>55</li>
  <li>56</li>
  <li>57</li>
  <li>58</li>
  <li>59</li>
  <li>60</li>
  <li>61</li>
  <li>62</li>
  <li>63</li>
  <li>64</li>
  <li>65</li>
  <li>66</li>
  <li>67</li>
  <li>68</li>
  <li>69</li>
  <li>70</li>
  <li>71</li>
  <li>72</li>
  <li>73</li>
  <li>74</li>
  <li>75</li>
</ul>
```

CSS

We define the unordered list as a 10-column container, creating columns and rows with the `grid-template-columns` property. We include a `gap` of `5px` to provide enough room between the columns and rows to fit our `3px` dashed rule, and set `list-style-type` to `none` to remove the bullets.

We include a `gap` of `5px` to provide enough room between the items to fit our medium dashed rule. We set the `rule-color` to `#22BB22`, a green `<hex-color>` value:

```
ul {
  display: grid;
  grid-template-columns: repeat(10, 1fr);
  list-style-type: none;
  gap: 5px;
  rule-style: dashed;
  rule-width: medium;

  rule-color: #22bb22;
}
li {
```

```
  text-align: center;
  aspect-ratio: 1;
}
```

```
@layer no-support {
  @supports not (rule-color: red) {
    body::before {
      content: "Your browser doesn't support the rule-color property";
      background-color: wheat;
      text-align: center;
      padding: 1rem 0;

      position: fixed;
      top: 0;
      left: 0;
      width: 100%;
    }
  }
}
```

Result

Multiple color values

This example demonstrates declaring more than one color, and how the values are repeated when there are fewer values in the list of colors than gutters between columns and rows.

Using the same HTML and CSS as in the previous example, we include three comma-separated colors as the `rule-color` value:

```
@layer no-support {
  @supports not (rule-color: red, blue) {
    body::before {
      content: "Your browser doesn't support multiple values for the rule-color property";
      background-color: wheat;
      text-align: center;
      padding: 1rem 0;

      position: fixed;
      top: 0;
      left: 0;
      width: 100%;
    }
  }
}
```

```
ul {
  rule-color: blue, yellow, red;
}
```

Result

There are nine column gutters and six row gutters, but only three colors in our color list, so the list gets repeated, with the first, fourth, and seventh lines being blue.

Using the <code>repeat()</code> function

This example demonstrates using the `repeat()` function within the `rule-color` property value and how this function can help prevent complex values from becoming unwieldy.

CSS

To demonstrate how values can become complicated and the utility of the `repeat()` function, we declare two custom properties, which we use in four `color-mix()` color function declarations to create blue, redish, tealish, and yellow colors. The redish and tealish `color-mix()` colors are within a `repeat()` function, set to repeat 3 times.

We also added a border around each grid item so you can see how the line is rule in the middle of the gutter between the columns and rows.

```
ul {
  --base: yellow;
  --mixin: blue;

  rule-color:
    color-mix(in lch decreasing hue, var(--base) 0%, var(--mixin)),
    repeat(
      3,
      color-mix(in lch decreasing hue, var(--base) 58%, var(--mixin)),
      color-mix(in lch increasing hue, var(--base) 58%, var(--mixin))
    ),
    color-mix(in lch decreasing hue, var(--base) 100%, var(--mixin));
}
```

Result

The grid has 10 columns and 7 rows, creating 9 column and 6 row gutters. The `repeat()` function repeats the two contained mixed colors three times, creating a color list with eight colors in all. While there is a lot of CSS to create the four colors, at least we didn't have to write out all eight `color-mix()` functions. Since there are more column gutters than list colors, the colors are repeated for the column gutters. As there are fewer row gutters than colors, the last two colors in the list are not used for the row gutters.

Using <code>auto</code> within <code>repeat()</code>

This example demonstrates using `auto`, instead of an integer, within the `repeat()` function.

We use the same HTML and CSS as in the previous examples, but override the `rule-color` value. Here, we use `repeat(auto, <color>)` to set all the lines to be almost transparent black (`#00000033`), except the first and last, which we set to a solid `black`.

```
ul {
  rule-color: black, repeat(auto, #00000033), black;
}
```

Result

Even though there are more column rule lines than row rule lines, the `<auto-repeat-line-color>` value enables the creation of this symmetric effect.

```
@layer no-support {
  @supports not (rule-color: repeat(3, red)) {
    body::before {
      content: "Your browser doesn't support `repeat()` functions within a rule-color property value";
      background-color: wheat;
      text-align: center;
      padding: 1rem 0;

      position: fixed;
      top: 0;
      left: 0;
      width: 100%;
    }
  }
}
```

rule-inset-cap CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`rule-inset-cap`** CSS shorthand property can be used to offset the column and row rule segment cap endpoints to the same value.

Try it

```
rule-inset-cap: -20px;
```

```
rule-inset-cap: 0;
```

```
rule-inset-cap: 1em;
```

```
rule-inset-cap: 100%;
```

```
rule-inset-cap: overlap-join;
```

```
<section id="default-example">
  <div id="example-element">
    <i>A</i>
    <i>B</i>
    <i>C</i>
    <i>D</i>
    <i>E</i>

    <i>G</i>
    <i>H</i>
    <i>I</i>
    <i>J</i>
    <i>K</i>
    <i>L</i>
    <i>M</i>
    <i>N</i>
    <i>O</i>
    <i>P</i>
    <i>Q</i>

    <i id="y">Y</i>
    <i id="z">Z</i>
    <i id="bang">!</i>
  </div>
</section>
```

```
#example-element {
  display: grid;
  grid-template-columns: repeat(7, 1fr);
  rule: solid thick magenta;
  column-rule-color: rebeccapurple;
  gap: 1em;
  rule-overlap: column-over-row;
  rule-visibility-items: between;
  border: 1px solid rebeccapurple;
  overflow: visible;
  margin: 1em;
}
#example-element i {
  padding: 8px;
  border: 1px dashed;
}
#y {
  grid-column: 4 / 5;
  grid-row: 4 / 5;
}
#z {
  grid-column: 5 / 6;
  grid-row: 4 / 5;
}
```

```
#bang {
  grid-column: 6 / 7;
  grid-row: 4 / 5;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `column-rule-inset-cap`
- `row-rule-inset-cap`

Syntax

```
/* Keywords */
rule-inset-cap: overlap-join;

/* A <length-percentage> value */
rule-inset-cap: 0;
rule-inset-cap: 1em;
rule-inset-cap: -5px;
rule-inset-cap: -25%;

/* Two values */
rule-inset-cap: 0 20px;
rule-inset-cap: 1em -5px;
rule-inset-cap: overlap-join -25%;

/* Global values */
rule-inset-cap: inherit;
rule-inset-cap: initial;
rule-inset-cap: revert;
rule-inset-cap: revert-layer;
rule-inset-cap: unset;
```

Values

This property is specified as one or two values from the following list:

`overlap-join`

> Resolves to `0`.

`<length-percentage>`

> Specifies the size of the inset. Percentage values resolve to `0` for caps at the container's edge. For interior gaps, percentages are relative to the height of the adjacent `row-gap` for column segment caps, or the width of the adjacent `column-gap` for row segment caps.

Description

The `rule-inset-cap` shorthand property can be used to set the `row-rule-inset-cap` and `column-rule-inset-cap` properties to the same value in a single declaration, insetting row and column cap segment endpoints by the specified values.

If you specify one value, both the start and end cap segment endpoints are set to that value. If you specify two values, the row and column cap start segment endpoints are set to the first value, and the row and column cap end segment endpoints are set to the second value.

The default value is `0`, which, in the case of cap endpoints, is the same as `overlap-join`. Positive values reduce the segment size, while negative values increase it.

The `rule-inset-cap` property, along with the `rule-inset-junction` property, can be set using the `rule-inset` shorthand.

Formal definition

Value not found in DB!

Formal syntax

```
rule-inset-cap =
  <'column-rule-inset-cap'>

<column-rule-inset-cap> =
  <inset-value> <inset-value>?

<inset-value> =
  <length-percentage>  |
  overlap-join

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example shows how to set `rule-inset-cap` to inset the endpoints of cap segments on flex containers.

HTML

The markup includes two `<div>` elements, each containing seven children. The only difference between the two containers is that the second one has an added `column` class.

```
<h1>Insetting cap endpoints</h1>
<article>
  <section>
    <h2>flex-direction: row</h2>
    <div class="flexbox">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
```

```
      <div></div>
      <div></div>
    </div>
  </section>
  <section>
    <h2>flex-direction: column</h2>
    <div class="flexbox column">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
</article>
```

```
<p>
  <label
    >Change the size of the inset.
    <input type="range" min="-40" max="16" value="16" id="inset"
  /></label>
  <output id="o">16px</output>
</p>
```

CSS

We use the `display` property to turn the `.flexbox` elements into flex containers. We balance the items into three flex lines using `flex-wrap` and `flex-line-count`. We define a light blue `rule` to paint in both row and column gaps, then override the `column-rule-color`, setting darker `blue` vertical gap decorations. Finally, we set the `rule-inset-cap` to `16px`.

```
.flexbox {
  display: flex;
  flex-wrap: balance;
  flex-line-count: 3;
  gap: 20px;
  rule: 5px solid lightblue;
  column-rule-color: blue;

  rule-inset-cap: 16px;
}
```

We also set the `flex-direction` on the `.column` container to make its items flow in columns rather than rows. We've hidden the other CSS styles, and the code that make the form interactive, for brevity.

```
.column {
  flex-direction: column;
}
```

```
h1,
article {
  font-family: sans-serif;
  text-align: center;
}
h1 {
  font-size: 1.25em;
}
h2 {
  font-size: 1em;
}
article {
  display: flex;
  gap: 5vw;
  rule: 1px solid black;
  width: 90vw;
  margin: auto;
}
section {
  flex-basis: 45vw;
}
.flexbox > div {
  border: 1px solid green;
  background-color: lime;
  flex: 1 1 auto;
  height: 30px;
}
output {
  display: inline-block;
  width: 2em;
}
p {
  margin-top: 2.5em;
}
@layer no-support {
  @supports not (rule-inset-cap: 16px) {
    body::before {
      content: "Your browser doesn't support the rule-inset-cap property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
const inset = document.getElementById("inset");
const containers = document.querySelectorAll(".flexbox");
const output = document.getElementById("o");

inset.addEventListener("input", () => {
  const val = `${inset.value}px`;
```

```
  containers[0].style.ruleInsetCap = val;
  containers[1].style.ruleInsetCap = val;
  output.innerText = val;
});
```

Result

Change the size of the inset.

Setting two values

HTML

```
<p>
  <label
    >Change the <code>row-rule-inset-cap</code> value.
    <input type="range" min="-40" max="40" value="40" id="row" data-unit="px"
  /></label>
  <output id="og">40px</output>
</p>
<p>
  <label
    >Change the <code>column-rule-inset-cap</code> value.
    <input type="range" min="-40" max="40" value="-40" id="col" data-unit="px"
  /></label>
  <output id="ow">-40px</output>
</p>
```

Our HTML includes an unordered list (`<ul>`) with nine list items (`<li>`):

```
<ul>
  <li>1</li>
  <li>2</li>
  <li>3</li>
  <li>4</li>
  <li>5</li>
  <li>6</li>
  <li>7</li>
  <li>8</li>
  <li>9</li>
</ul>
```

The user interface for selecting different values and the JavaScript that enables the interactivity have been hidden for brevity.

CSS

We create a grid container by setting the `display` to grid, creating 4 columns with `grid-template-columns`, and adding a `30px` `gap`. We use the `row-rule` and `column-rule` properties to define our rules. We then use the `rule-inset-cap` property to inset the start cap segment endpoints by `40px` and outset the end cap segment endpoints by `-40px`.

We also set the 6th grid item to span two columns.

```
ul {
  display: grid;
  grid-template-columns: repeat(4, auto);
  gap: 30px;
  row-rule: 16px solid olive;
  column-rule: 10px solid palegoldenrod;

  rule-inset-cap: 40px -40px;
}
li:nth-of-type(6) {
  grid-column-end: span 2;
}
```

```
ul {
  width: calc(95vw - 80px);
  border: 1px solid;
  list-style-type: none;
  margin: auto;
  padding: 0;
  place-items: center;
}
li {
  place-content: center;
  text-align: center;
  font-family: sans-serif;
  background-color: #ededed;
  padding: 5vw;
  width: 100%;
  box-sizing: border-box;
}
li:nth-of-type(6) {
  padding: 2em 0;
}
li code {
  display: block;
  margin: 0 auto;
  text-align: left;
  background-color: #fcfcfc;
  width: calc(47.5vw - 40px);
}
output {
  font-family: monospace;
}
input {
  accent-color: olive;
}
@layer no-support {
  @supports not (rule-inset-cap: 16px) {
    body::before {
      content: "Your browser doesn't support the rule-inset-cap property";
```

```
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
const ul = document.querySelector("ul");
const rowSize = document.getElementById("row");
const og = document.getElementById("og");
const colSize = document.getElementById("col");
const ow = document.getElementById("ow");
const cell = document.querySelector("li:nth-of-type(6)");
let text = "";
function update() {
  ul.style.ruleInsetCap = text = `${rowSize.value}px ${colSize.value}px`;
  cell.innerHTML = `<code>rule-inset-cap: ${text};</code>`;
}

update();

rowSize.addEventListener("input", () => {
  og.innerText = `${rowSize.value}px`;
  update();
});

colSize.addEventListener("input", () => {
  ow.innerText = `${colSize.value}px`;
  update();
});
```

Result

Change the inset values for the starts and ends of the cap segment endpoints.

Inner cap segments

This example shows how to set `rule-inset-cap` to inset the endpoints of cap segments on a grid container, and how the `rule-visibility-items` property can turn inner endpoints into cap segment endpoints.

HTML

We include an unordered list (`<ul>`) as our container for several list items (`<li>`).

We also include a `<select>` element with an `<option>` for each `rule-visibility-items` keyword, and an `<input>` of type range.

```
<ul id="ul">
  <li>1</li>
  <li>2</li>
  <li>3</li>
  <li>4</li>
  <li>5</li>
  <li>6</li>
  <li>7</li>
  <li>8</li>
  <li>9</li>
  <li>10</li>
  <li>11</li>
  <li>12</li>
  <li>13</li>
  <li>14</li>
  <li>15</li>
  <li>16</li>
  <li>17</li>
</ul>

<p>
  <label>
    <code>rule-visibility-items</code> value
    <select id="visibility">
      <option>all</option>
      <option>between</option>
      <option>around</option>
      <option selected>normal</option>
    </select>
  </label>
</p>

<p>
  <label
    >Change the inset size.
    <input type="range" min="-40" max="16" value="0" id="inset" data-unit="px"
  /></label>
  <output id="o"></output>
</p>
```

CSS

We create a grid container by setting the `display` to grid, creating 6 columns with `grid-template-columns`, and adding a `20px` `gap`. We use the `rule` property to define our rules, overriding the row rule color with the `row-rule-color` property. We set the `rule-break` property to break the rules at each intersection, making each rule segment distinct. We explicitly set `rule-visibility-items` to the default value of `normal`. We then use the `rule-inset-cap` property to inset all the cap segment endpoints by `16px`.

We also set the seventh list item to span two columns using the `grid-column-end` property.

```
ul {
  display: grid;
  grid-template-columns: repeat(6, auto);
  gap: 20px;
  rule: 10px solid olive;
  row-rule-color: palegoldenrod;
  rule-break: intersection;
```

```
  rule-visibility-items: normal;

  rule-inset-cap: 16px;
}

li:nth-of-type(7) {
  grid-column-end: span 2;
}
```

We've hidden the other CSS styles, and the code that make the form interactive, for brevity.

```
ul {
  place-items: center;
  padding: 0;
  list-style-type: none;
  border: 1px solid;
  margin: 40px;
}
li {
  text-align: center;
  font-family: sans-serif;
  background-color: #ededed;
  padding: 1em;
  width: 100%;
  box-sizing: border-box;
}
li:nth-of-type(n + 9) {
  grid-row: 3 / 4;
}
li:nth-of-type(n + 12) {
  grid-row: 4 / 5;
}
li:nth-of-type(10) {
  grid-column: 5/6;
}
li:nth-of-type(11) {
  grid-column: 6/7;
}

li:nth-of-type(15) {
  grid-area: 4 / 5 / 5 / 6;
}
li:nth-of-type(16) {
  grid-area: 4 / 6 / 5 / 7;
}
li:nth-of-type(17) {
  display: none;
  grid-area: 5 / 6 / 6 / 7;
}
@layer no-support {
  @supports not (rule-inset-cap: 16px) {
    body::before {
      content: "Your browser doesn't support the rule-inset-cap property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
const inset = document.getElementById("inset");
const visibility = document.getElementById("visibility");
const ul = document.getElementById("ul");
const output = document.getElementById("o");

inset.addEventListener("input", () => {
  output.innerText =
    ul.style.ruleInsetCap = `${inset.value}${inset.dataset["unit"]}`;
});

visibility.addEventListener("change", () => {
  ul.style.ruleVisibilityItems = `${visibility.value}`;
});
```

Result

Select `between` from the dropdown to paint only rule segments when both adjacent grid areas contain a grid item, thereby creating interior cap segments. Now change the inset value to visualize which segment endpoints are cap segment endpoints.

rule-inset-junction CSS property

> **Experimental: This is an experimental technology**

> Check the Browser compatibility table carefully before using this in production.

The **`rule-inset-junction`** CSS shorthand property can be used to offset the column and row rule segment junction endpoints to the same value.

Try it

```
rule-inset-junction: 0;
```

```
rule-inset-junction: 10px;
```

```
rule-inset-junction: 0.5em -0.5em;
```

```
rule-inset-junction: overlap-join;
```

```
rule-inset-junction: overlap-join 10px;
```

```
<section id="default-example">
  <div id="example-element">
    <i>A</i>
    <i>B</i>
    <i>C</i>
    <i>D</i>
    <i>E</i>
    <i>F</i>
    <i>G</i>
    <i>H</i>
    <i>I</i>
    <i>J</i>
    <i>K</i>
    <i>L</i>
  </div>
</section>
```

```
#example-element {
  display: grid;
  grid-template-columns: repeat(5, 1fr);
  rule: solid thick lightpink;
  column-rule-color: magenta;
  rule-break: intersection;
  gap: 1.5em;
  rule-overlap: column-over-row;
  border: 1px solid rebeccapurple;
  margin: auto;
  rule-visibility-items: around;
}
#example-element i {
  background-color: #efefef;
  padding: 1em;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `column-rule-inset-junction`
- `row-rule-inset-junction`

Syntax

```
/* Keywords */
rule-inset-junction: overlap-join;

/* <length-percentage> values */
rule-inset-junction: 0;
rule-inset-junction: 1em;
rule-inset-junction: -5px;
rule-inset-junction: -25%;

/* Two values */
rule-inset-junction: 0 1em;
rule-inset-junction: -5px -25%;
rule-inset-junction: overlap-join 10px;

/* Global values */
rule-inset-junction: inherit;
rule-inset-junction: initial;
rule-inset-junction: revert;
rule-inset-junction: revert-layer;
rule-inset-junction: unset;
```

Values

This property is specified as one or two values from the following list:

`overlap-join`

Specifies that the junction segment should extend across the row-rule, resolving to half the `row-gap` value plus half the used `row-rule-width` value.

`<length-percentage>`

Specifies the size of the inset. Percentage values are relative to the junction endpoint, which is the `row-gap` value for column segments and the `column-gap` value for row segments.

Description

The `rule-inset-junction` shorthand property can be used to set the `row-rule-inset-junction` and `column-rule-inset-junction` properties to the same value in a single declaration, insetting row and column junction segment endpoints by the specified values.

If one value is specified, both properties are set to that value. If two values are specified, `-start` is set to the first value and `-end` is set to the second. Positive values reduce (or inset) the segment size, while negative values and the `overlap-join` keyword increase (or outset) it. The default value is `0`.

To inset both cap and junction segment endpoints, the `rule-inset-junction` shorthand property, along with the `rule-inset-cap` shorthand property, can be set using the `rule-inset` shorthand.

Formal definition

Value not found in DB!

Formal syntax

```
rule-inset-junction =
  <'column-rule-inset-junction'>

<column-rule-inset-junction> =
  <inset-value> <inset-value>?

<inset-value> =
  <length-percentage>  |
  overlap-join

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates setting `rule-inset-junction` to inset the edges of junction segments on flex containers.

HTML

The markup includes two `<div>` elements, each containing seven children. The only difference between the two containers is that the second one has an added `column` class.

```
<h1>Insetting junction column rule endpoints</h1>
<article>
  <section>
    <h2>flex-direction: row</h2>
    <div class="flexbox">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
  <section>
    <h2>flex-direction: column</h2>
    <div class="flexbox column">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
</article>
```

```
<p>
  <label
    >Change the size of the inset.
    <input type="range" min="-40" max="16" value="16" id="inset"
  /></label>
  <output id="o">16px</output>
</p>
```

CSS

We use the `display` property to turn the `.flexbox` elements into flex containers. We balance the items into three flex lines using `flex-wrap` and `flex-line-count`. We define a `rule` and set the `rule-inset-junction` to `16px`.

```
.flexbox {
  display: flex;
  flex-wrap: balance;
  flex-line-count: 3;
  gap: 20px;
  rule: 5px solid blue;

  rule-inset-junction: 16px;
}
```

We also set the `flex-direction` on the `.column` container to `column`, changing the main axis of the flex container to run up and down the page and making the items flow in columns rather than rows.

```
.column {
  flex-direction: column;
}
```

The rest of the CSS is hidden for brevity.

```
h1,
article {
  font-family: sans-serif;
  text-align: center;
```

```
}
h1 {
  font-size: 1.25em;
}
h2 {
  font-size: 1em;
}
article {
  display: flex;
  gap: 5vw;
  rule: 1px solid black;
  width: 100vw;
}
section {
  flex-basis: 45vw;
}
.flexbox > div {
  border: 1px solid green;
  background-color: lime;
  flex: 1 1 auto;
  height: 30px;
}
output {
  display: inline-block;
  width: 2em;
}
p {
  margin-top: 2.5em;
}
@layer no-support {
  @supports not (rule-inset-junction: 16px) {
    body::before {
      content: "Your browser doesn't support the rule-inset-junction property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
const inset = document.getElementById("inset");
const containers = document.querySelectorAll(".flexbox");
const output = document.getElementById("o");

inset.addEventListener("input", () => {
  const val = `${inset.value}px`;
  containers[0].style.ruleInsetJunction = val;
  containers[1].style.ruleInsetJunction = val;
  output.innerText = val;
});
```

Result

Change the size of the inset. Note that where the rule is a single segment that goes from one edge of the container to the opposite edge, the segment has two cap endpoints and no junction endpoints. Therefore, changing the `rule-inset-junction` value does not affect these segments.

With grid layout

This example demonstrates using the `rule-inset-junction` property to inset junction segment endpoints to two different values on a grid container.

HTML

We include the `<ul>` element as a container with several `<li>` children which will each be converted into a grid item.

```
<ul id="ul">
  <li>1</li>
  <li>2</li>
  <li>3</li>
  <li>4</li>
  <li>5</li>
  <li>6</li>
  <li>7</li>
  <li>8</li>
  <li>9</li>
  <li>10</li>
  <li>11</li>
  <li>12</li>
  <li>13</li>
  <li>15</li>
  <li>16</li>
  <li>17</li>
  <li>18</li>
  <li>19</li>
</ul>
```

```
<p>
  <label
    >Change the <code>-start</code> value.
    <input type="range" min="-40" max="40" value="16" id="start" data-unit="px"
  /></label>
  <output id="og">16px</output>
</p>
<p>
  <label
    >Change the <code>-end</code> value.
    <input type="range" min="-40" max="40" value="0" id="end" data-unit="px"
  /></label>
  <output id="ow">0px</output>
</p>
```

CSS

We turn the `<ul>` into a grid container by setting the `display` property to `grid`. The `grid-template-columns` property specifies that the grid has five columns. We remove the bullets with the `list-style-type` property and set the row and column gaps to `20px` with the `gap` shorthand. We set the color, size, and line style of all the rules using the `rule` shorthand, then change just the row rule color with the `row-rule-color` property.

We break the rules at every intersection using the `rule-break` property. If the rules didn't break, there would be no junction segments to style!

Finally, we set the start of each column junction to be inset by `16px` and the end to not be inset using the `rule-inset-junction` property.

We also set the 6th grid item to span three columns.

```
ul {
  display: grid;
  grid-template-columns: repeat(5, auto);
  list-style-type: "";
  gap: 20px;
  rule: 10px solid olive;
  row-rule-color: palegoldenrod;
  rule-break: intersection;

  rule-inset-junction: 16px 0;
}

li:nth-of-type(7) {
  grid-column-end: span 3;
}
```

The rest of the CSS is hidden for brevity.

```
ul {
  border: 1px solid;
  place-items: center;
  width: 95vw;
  padding: 0;
}
li {
  text-align: center;
  font-family: sans-serif;
  background-color: #ededed;
  padding: 2em 1em;
  width: 100%;
  box-sizing: border-box;
}
li code {
  display: block;
  margin: 0 auto;
  text-align: left;
  width: 30vw;
}
output {
  font-family: monospace;
}
input {
  accent-color: olive;
}
@layer no-support {
  @supports not (rule-inset-junction: 16px) {
    body::before {
      content: "Your browser doesn't support the rule-inset-junction property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
const ul = document.querySelector("ul");
const startSize = document.getElementById("start");
const og = document.getElementById("og");
const endSize = document.getElementById("end");
const ow = document.getElementById("ow");
const cell = document.querySelector("li:nth-of-type(7)");
let text = "";
function update() {
  ul.style.ruleInsetJunction = text = `${startSize.value}px ${endSize.value}px`;
  cell.innerHTML = `<code>rule-inset-cap: ${text};</code>`;
}

update();

startSize.addEventListener("input", () => {
  og.innerText = `${startSize.value}px`;
  update();
});

endSize.addEventListener("input", () => {
  ow.innerText = `${endSize.value}px`;
  update();
});
```

rule-overlap CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`rule-overlap`** CSS property specifies which rule is painted on top when column rules and row rules intersect.

Try it

```
rule-overlap: row-over-column;
```

```
rule-overlap: column-over-row;
```

```
<section id="default-example">
  <div id="example-element">
    <i>A</i>
    <i>B</i>
    <i>C</i>
    <i>D</i>
    <i>E</i>
    <i>F</i>
    <i>G</i>
    <i>H</i>
    <i>I</i>
    <i>J</i>
    <i>K</i>
    <i>L</i>
    <i>M</i>
    <i>N</i>
    <i>O</i>
    <i>P</i>
    <i>Q</i>
    <i>R</i>
    <i>S</i>
    <i>T</i>
    <i>U</i>
    <i>V</i>
    <i>W</i>
    <i>X</i>
    <i>Y</i>
    <i>Z</i>
  </div>
</section>
```

```
#example-element {
  display: grid;
  grid-template-columns: repeat(7, 1fr);
  row-rule: solid thick orange;
  column-rule: solid thick purple;
}
#example-element i {
  padding: 5px;
}
```

Syntax

```
/* Keywords */
rule-overlap: row-over-column;
rule-overlap: column-over-row;

/* Global values */
rule-overlap: inherit;
rule-overlap: initial;
rule-overlap: revert;
rule-overlap: revert-layer;
rule-overlap: unset;
```

Values

This property is specified as a single keyword from the following list:

`row-over-column`

Specifies that row rules are painted over column rules. This is the default value.

`column-over-row`

Specifies that column rules are painted over row rules.

Formal definition

Value not found in DB!

Formal syntax

```
rule-overlap =
  row-over-column  |
  column-over-row
```

This syntax reflects the latest standard as per CSS Gap Decorations Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

In this example, we use the `rule-overlap` property to paint column rules on top of row rules.

HTML

We create a list of 75 items. Most of the HTML is hidden for brevity.

```
<ul>
  <li>1</li>
  <li>2</li>
  ...
  <li>74</li>
  <li>75</li>
</ul>
```

```
<ul>
  <li>1</li>
  <li>2</li>
  <li>3</li>
  <li>4</li>
  <li>5</li>
  <li>6</li>
  <li>7</li>
  <li>8</li>
  <li>9</li>
  <li>10</li>
  <li>11</li>
  <li>12</li>
  <li>13</li>
  <li>14</li>
  <li>15</li>
  <li>16</li>
  <li>17</li>
  <li>18</li>
  <li>19</li>
  <li>20</li>
  <li>21</li>
  <li>22</li>
  <li>23</li>
  <li>24</li>
  <li>25</li>
  <li>26</li>
  <li>27</li>
  <li>28</li>
  <li>29</li>
  <li>30</li>
  <li>31</li>
  <li>32</li>
  <li>33</li>
  <li>34</li>
  <li>35</li>
  <li>36</li>
  <li>37</li>
  <li>38</li>
  <li>39</li>
  <li>40</li>
  <li>41</li>
  <li>42</li>
  <li>43</li>
  <li>44</li>
  <li>45</li>
  <li>46</li>
  <li>47</li>
  <li>48</li>
  <li>49</li>
  <li>50</li>
  <li>51</li>
  <li>52</li>
  <li>53</li>
  <li>54</li>
  <li>55</li>
  <li>56</li>
  <li>57</li>
  <li>58</li>
  <li>59</li>
  <li>60</li>
  <li>61</li>
  <li>62</li>
  <li>63</li>
  <li>64</li>
  <li>65</li>
  <li>66</li>
  <li>67</li>
  <li>68</li>
  <li>69</li>
  <li>70</li>
  <li>71</li>
  <li>72</li>
  <li>73</li>
  <li>74</li>
  <li>75</li>
</ul>
<p>
  <label
    ><input type="checkbox" /> set to
    <code>rule-overlap: row-over-column;</code></label
  >
</p>
```

CSS

We define the unordered list as a 10-column grid container using the `grid-template-columns` property. We set `list-style-type` to an empty string to remove the bullets. We include a `gap` of `20px` to provide enough room between the columns and rows to fit our `20px` solid column and row rules. Finally, we use the `rule-overlap` property to draw the column rules on top of the row rules.

```
ul {
  display: grid;
  grid-template-columns: repeat(10, 1fr);
  list-style-type: "";
  gap: 20px;

  row-rule: 20px solid palegoldenrod;
  column-rule: 20px solid olive;

  rule-overlap: column-over-row;
}
```

The rest of the CSS has been hidden for brevity.

```
:has(:checked) ul {
  rule-overlap: row-over-column;
}
li {
  text-align: center;
  aspect-ratio: 1;
  line-height: 1.5em;
}
@layer no-support {
  @supports not (rule-overlap: row-over-column) {
    body::before {
      content: "Your browser doesn't support the rule-overlap property.";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

Result

Select the checkbox to toggle the value of the `rule-overlap` property.

rule-style CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`rule-style`** CSS shorthand property defines the line style of the lines drawn between columns and rows in multi-column grid, flex, and multi-col layouts, setting the styles of the column and row rules to the same value.

Try it

```
rule-style: solid;
```

```
rule-style: dashed, dotted;
```

```
rule-style: repeat(2, inset, dashed, double);
```

```
rule-style: solid, repeat(auto, double), solid;
```

```
rule-style: hidden;
```

```
<section id="default-example">
  <div id="example-element">
    <i>A</i>
    <i>B</i>
    <i>C</i>
    <i>D</i>
    <i>E</i>
    <i>F</i>
    <i>G</i>
    <i>H</i>
    <i>I</i>
    <i>J</i>
    <i>K</i>
    <i>L</i>
    <i>M</i>
    <i>N</i>
    <i>O</i>
    <i>P</i>
    <i>Q</i>
    <i>R</i>
    <i>S</i>
    <i>T</i>
```

```
    <i>U</i>
    <i>V</i>
    <i>W</i>
    <i>X</i>
    <i>Y</i>
    <i>Z</i>
  </div>
</section>
```

```
#example-element {
  display: grid;
  grid-template-columns: repeat(7, 1fr);
  rule: solid rebeccapurple 7px;
  gap: 7px;
}
#example-element i {
  padding: 5px;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `column-rule-style`
- `row-rule-style`

Syntax

```
/* One value */
rule-style: none;
rule-style: hidden;
rule-style: dotted;
rule-style: dashed;
rule-style: solid;
rule-style: double;
rule-style: groove;
rule-style: ridge;
rule-style: inset;
rule-style: outset;

/* Multiple values */
rule-style: groove, double, dashed;
rule-style: solid, repeat(5, ridge), solid;
rule-style: dotted, repeat(auto, inset, outset), dotted;

/* Global values */
rule-style: inherit;
rule-style: initial;
rule-style: revert;
rule-style: revert-layer;
rule-style: unset;
```

Values

The `rule-style` property accepts a comma-separated list of values, including:

`<line-style>`

> A `<line-style>`: one of `none`, `hidden`, `dotted`, `dashed`, `solid`, `double`, `groove`, `ridge`, `inset`, or `outset`. The default value is `none`.

`<repeat-line-style>`

> A `repeat()` function, with the first argument being an `<integer>` of `1` or more, and subsequent arguments being `<line-style>` values. The integer specifies how many times the `<line-style>` values should be repeated.

`<auto-repeat-line-style>`

> A `repeat()` function, with `auto` as the first argument and one or more `<line-style>` values as subsequent arguments. The provided `<line-style>` values are repeated as many times as needed to fill in values for any rules that are not explicitly specified by other components of the property value.

Description

The `rule-style` property defines the line style of any column and row rule lines drawn in the gaps between columns and rows in multi-column, flex, and grid containers with more than one column or row.

The `rule-style` sets both the `column-rule-style` and `row-rule-style` properties to the same value. The `rule-style` property, along with the `rule-color` and `rule-width` properties, can also be set using the `rule` shorthand.

The value is a comma-separated list of components, which can include `<line-style>`, `<repeat-line-style>`, and `<auto-repeat-line-style>` types.

If the property value has only one `<line-style>`, all the column and row rules will be that style. If we declare the following, all column and row rules will be `double`:

```
rule-style: double;
```

When multiple `<line-style>` values are declared, they will be applied to rules in the order specified. If there are more rules than `<line-style>` values, the list of line styles is repeated until every column and row rule has a style. For example, if we declare the following, every odd rule will be `double`, and every even rule will be `inset`.

```
rule-style: double, inset;
```

Repeated line styles

The `repeat()` function, with an integer of `1` or greater as the first argument, can be used to repeat a valid list of CSS `<line-style>` values passed as subsequent arguments the specified number of times. This allows the same style to be repeated a set number of times without repeating the same value. You can include `<line-style>` keyword values or custom properties that resolve to a valid `<line-style>`. Using `repeat()` can make values easier to write, enabling recurring patterns to be written using a single function, regardless of the number of columns or rows. The following declarations are equivalent:

```
rule-style: solid, outset, inset, outset, inset, outset, inset;
rule-style: solid, repeat(3, outset, inset);
```

This creates a list of seven styles. If the number of styles in the `rule-style` value's style list exceeds the number of gaps between columns or rows, the excess style values are ignored. If the container has three columns or rows, the rule in the first gutter will be `solid` and the second `outset`.

If there are more gutters than styles, the list of styles is repeated. If the container has 8, 15, 22, or 29 columns or rows, this sequence of styles will be repeated one, two, three, or four times, respectively, with the last rule being `inset`.

Auto-repeating line styles

The `repeat()` function also accepts `auto` as the first argument instead of a positive integer. With `auto` as the first argument, the `<line-style>` values passed as subsequent parameters will be repeated as many times as needed to fill in values for any rules that are not explicitly specified by other components of the property value.

The `auto` keyword within the `repeat()` function creates an auto repeater that fills in values for column and row rules that would not otherwise receive values from other parts of the list, preventing the list from being cycled. Only one `repeat(auto, <line-style>)` is allowed within a `rule-style` value.

```
rule-style: solid, repeat(auto, dotted), solid;
```

In this case, it doesn't matter if the container has 8, 15, 22, or 29 columns or rows; the first and last rules will always be `solid`, and all the other rules will be `dotted`. If there are only 2 or 3 columns and rows, there will be no dotted rules.

Formal definition

Value not found in DB!

Formal syntax

```
rule-style =
  <'column-rule-style'>

<column-rule-style> =
  <line-style-list>       |
  <auto-line-style-list>

<line-style-list> =
  <line-style-or-repeat>#

<auto-line-style-list> =
  <line-style-or-repeat>#? , <auto-repeat-line-style> , <line-style-or-repeat>#?

<line-style-or-repeat> =
  <line-style>         |
  <repeat-line-style>

<auto-repeat-line-style> =
  repeat( auto , [ <line-style> ]# )

<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset

<repeat-line-style> =
  repeat( [ <integer [1,∞]> ] , [ <line-style> ]# )

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

In this example, we define a single `<line-style>` for the lines drawn between the columns and rows of items in a grid container.

HTML

We create a list of 75 items. Most of the HTML is hidden for brevity.

```
<ul>
  <li>1</li>
  <li>2</li>
  ...
  <li>74</li>
  <li>75</li>
</ul>
```

```
<ul>
  <li>1</li>
  <li>2</li>
  <li>3</li>
  <li>4</li>
  <li>5</li>
  <li>6</li>
  <li>7</li>
  <li>8</li>
  <li>9</li>
  <li>10</li>
  <li>11</li>
  <li>12</li>
  <li>13</li>
  <li>14</li>
  <li>15</li>
  <li>16</li>
  <li>17</li>
  <li>18</li>
```

```
  <li>19</li>
  <li>20</li>
  <li>21</li>
  <li>22</li>
  <li>23</li>
  <li>24</li>
  <li>25</li>
  <li>26</li>
  <li>27</li>
  <li>28</li>
  <li>29</li>
  <li>30</li>
  <li>31</li>
  <li>32</li>
  <li>33</li>
  <li>34</li>
  <li>35</li>
  <li>36</li>
  <li>37</li>
  <li>38</li>
  <li>39</li>
  <li>40</li>
  <li>41</li>
  <li>42</li>
  <li>43</li>
  <li>44</li>
  <li>45</li>
  <li>46</li>
  <li>47</li>
  <li>48</li>
  <li>49</li>
  <li>50</li>
  <li>51</li>
  <li>52</li>
  <li>53</li>
  <li>54</li>
  <li>55</li>
  <li>56</li>
  <li>57</li>
  <li>58</li>
  <li>59</li>
  <li>60</li>
  <li>61</li>
  <li>62</li>
  <li>63</li>
  <li>64</li>
  <li>65</li>
  <li>66</li>
  <li>67</li>
  <li>68</li>
  <li>69</li>
  <li>70</li>
  <li>71</li>
  <li>72</li>
  <li>73</li>
  <li>74</li>
  <li>75</li>
</ul>
```

CSS

We define the unordered list as a 10-column container, creating columns and rows with the `grid-template-columns` property; we then set `list-style-type` to `none` to remove the bullets. We include a `gap` of `5px` to provide enough room between the columns and rows to fit our `thick dashed orange` rule.

```
ul {
  display: grid;
  grid-template-columns: repeat(10, 1fr);
  list-style-type: none;
  gap: 5px;
  rule-width: thick;
  rule-color: orange;

  rule-style: dashed;
}
li {
  text-align: center;
  aspect-ratio: 1;
}
```

```
@layer no-support {
  @supports not (rule-style: solid) {
    body::before {
      content: "Your browser doesn't support the rule-style property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

Result

Multiple values

This example demonstrates using multiple `<line-style>` values as a property value, and what happens when more `<line-style>` values are specified than there are gutters to style.

We set the `rule-style` property to be a comma-separated list of all the possible `<line-style>` values.

```
ul {
  rule-style:
```

```
    dotted, dashed, solid, double, groove, ridge, inset, outset, none, hidden;
}
```

Result

There are more values than gutters for both the rows and columns; the last values are not used in each case.

Repeating values

This example demonstrates how, when there are fewer values in the list of styles than column and row rules, the values are repeated.

CSS

Using the same HTML and CSS as in the previous example, we include three comma-separated styles as the `rule-style` value:

```
ul {
  rule-style: solid, groove, double;
}
```

Result

Using the <code>repeat()</code> function

This example demonstrates using the `repeat()` function within the `rule-style` property value.

CSS

We use the same HTML and CSS as in the previous examples. We include a `repeat()` function that sets a list of two `<line-style>` values to be repeated 3 times.

```
ul {
  rule-style: solid, repeat(3, inset, outset), solid;
}
```

Result

The `repeat()` function repeats two style values three times, creating a list of eight style values. The styles are repeated for the columns; however, the last values in the list are discarded for the rows.

Using <code>auto</code> within <code>repeat()</code>

This example demonstrates using `auto` instead of an integer within the `repeat()` function.

CSS

Using `repeat(auto, <line-style>)`, we set all column and row rules to `groove`, except the first and last, which we set to `solid`.

```
ul {
  rule-style: solid, repeat(auto, groove), solid;
}
```

Result

Even though there are more column rule lines than row rule lines, the `<auto-repeat-line-color>` enables the creation of this symmetric effect.

```
@layer no-support {
  @supports not (rule-style: solid, groove) {
    body::before {
      content: "Your browser doesn't support multiple values for the rule-style property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

rule-visibility-items CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`rule-visibility-items`** CSS shorthand property defines whether rule segments are painted in both row and column gaps adjacent to empty areas.

Constituent properties

This property is a shorthand for the following CSS properties:

- `column-rule-visibility-items`
- `row-rule-visibility-items`

Try it

```
rule-visibility-items: all;
```

```
rule-visibility-items: around;
```

```
rule-visibility-items: between;
```

```
rule-visibility-items: normal;
```

```
<section id="default-example">
  <section id="example-element">
    <p>One fish</p>
    <p>Two fish</p>
    <p>Red fish</p>
    <p>Blue fish</p>
    <cite>-- Dr. Seuss</cite>
  </section>
</section>
```

```
#example-element {
  display: grid;
  rule: solid 5px red;
  gap: 10px;
  grid-template-rows: repeat(3, 1fr);
  grid-template-columns: repeat(3, 1fr);
}
cite {
  grid-row: 3;
  grid-column: 3;
}
```

Syntax

```
/* Keyword values */
rule-visibility-items: all;
rule-visibility-items: around;
rule-visibility-items: between;
rule-visibility-items: normal;

/* Global values */
rule-visibility-items: inherit;
rule-visibility-items: initial;
rule-visibility-items: revert;
rule-visibility-items: revert-layer;
rule-visibility-items: unset;
```

Values

This property is specified as one of the following keyword values:

`all`

Rules should be painted in all gap segments, regardless of whether adjacent areas contain an item.

`around`

A rule should be painted in a gap segment if at least one of the two adjacent areas is occupied by an item.

`between`

A rule should be painted in a gap segment only if both adjacent areas are occupied by items.

`normal`

With grid containers, behaves the same as `all`. In multicol layout, behaves the same as `between`. This is the default.

Description

The `rule-visibility-items` property defines whether rule segments are painted in gaps adjacent to empty areas in the gaps between rows and columns in multi-row and grid containers with more than one row or column.

The value is a single keyword that sets the same value for both the `column-rule-visibility-items` and `row-rule-visibility-items` properties.

Formal definition

Value not found in DB!

Formal syntax

```
rule-visibility-items =
  <'column-rule-visibility-items'>

<column-rule-visibility-items> =
  all     |
  around  |
  between |
  normal
```

This syntax reflects the latest standard as per CSS Gap Decorations Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

In this example, we define a rule to be drawn between two grid areas if at least one adjacent grid area contains a grid item.

HTML

We include a list of dynamic sports duos:

```
<ol>
  <li>Simone Biles + Jonathan Owens</li>
  <li>Serena Williams + Venus Williams</li>
  <li>Aaron Judge + Giancarlo Stanton</li>
  <li>LeBron James + Dwyane Wade</li>
  <li>Xavi Hernandez + Andres Iniesta</li>
```

```
  <li>Kerri Walsh + Misty May Treanor</li>
</ol>
```

CSS

We define the ordered list (`<ol>`) to be a grid container, creating 4 columns and 4 rows by setting both the `grid-template-columns` and `grid-template-rows` properties to `repeat(4, 1fr)`, and move the last item to the bottom-right grid area using the `grid-column` and `grid-row` properties. We include a `gap` of `20px` to provide enough room between the columns to fit our `5px` rules. We set the column rules to `dashed` and the row rules to `solid`.

Finally, we set `rule-visibility-items` to `between`, so that row- and column-rules are painted only if both grid areas adjacent to them contain a grid item.

```
ol {
  display: grid;
  grid-template-rows: repeat(4, 1fr);
  grid-template-columns: repeat(4, 1fr);
  gap: 20px;

  column-rule: dashed 5px blue;
  row-rule: solid 5px red;

  rule-visibility-items: around;
}
li:last-child {
  grid-row: 4;
  grid-column: 4;
}
```

```
li {
  margin-left: 1em;
}
@layer no-support {
  @supports not (rule-visibility-items: around) {
    body::before {
      content: "Your browser doesn't support the rule-visibility-items shorthand";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

rule-width CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`rule-width`** CSS shorthand property defines the widths of any lines drawn in the gutters of multi-row grid, flex, and multi-col layouts, setting the widths of the column and row rules to the same value.

Try it

```
rule-width: thin;
```

```
rule-width: thin, thick;
```

```
rule-width: 1px, 10px;
```

```
rule-width: repeat(2, thin, thick), 10px;
```

```
rule-width: thick, repeat(auto, 1px, 2px), thick;
```

```
<section id="default-example">
  <div id="example-element">
    <i>A</i>
    <i>B</i>
    <i>C</i>
    <i>D</i>
    <i>E</i>
    <i>F</i>
    <i>G</i>
    <i>H</i>
    <i>I</i>
    <i>J</i>
    <i>K</i>
    <i>L</i>
    <i>M</i>
    <i>N</i>
    <i>O</i>
    <i>P</i>
    <i>Q</i>
    <i>R</i>
    <i>S</i>
    <i>T</i>
    <i>U</i>
    <i>V</i>
    <i>W</i>
    <i>X</i>
```

```
    <i>Y</i>
    <i>Z</i>
  </div>
</section>
```

```
#example-element {
  display: grid;
  grid-template-columns: repeat(7, 1fr);
  rule: solid magenta;
}
#example-element i {
  padding: 5px;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `column-rule-width`
- `row-rule-width`

Syntax

```
/* Keyword values */
rule-width: thin;
rule-width: medium;
rule-width: thick;
rule-width: thin, medium, thick;
rule-width: thick, repeat(5, thin), thick;
rule-width: thick, repeat(auto, thin, medium), thick;

/* Length values */
rule-width: 1px;
rule-width: 5px;
rule-width: 1px, 3px, 5px;
rule-width: 5px, repeat(auto, 1px), 10px, 15px;
rule-width: 5px, repeat(5, 1px, 3px), 5px;

/* Global values */
rule-width: inherit;
rule-width: initial;
rule-width: revert;
rule-width: revert-layer;
rule-width: unset;
```

Values

The `rule-width` property accepts a comma-separated list of values, including:

`<line-width>`

A `<line-width>`: This can be one of the keywords `thin`, `medium`, or `thick`, or a positive `<length>` value, representing the width of the line. The default value is `medium`.

`<repeat-line-width>`

A `repeat()` function, with the first argument being an `<integer>` of `1` or more, and one or more `<line-width>` values as subsequent arguments. The integer defines the number of times the `<line-width>` values should be repeated.

`<auto-repeat-line-width>`

A `repeat()` function, with `auto` as the first argument and one or more `<line-width>` values as subsequent arguments. The provided `<line-width>` values are repeated as many times as needed to fill in values for any rules that are not explicitly specified by other components of the property value.

Description

The `rule-width` shorthand property defines the widths of rule lines drawn in the gaps between columns and rows in multi-column, flex, and grid containers with more than one row or column.

The value is a comma-separated list of components, which can include `<line-width>`, `<repeat-line-width>`, and `<auto-repeat-line-width>` types.

The `rule-width` property, along with the `rule-color` and `rule-style` properties, can be set using the `rule` shorthand.

If the property value consists of only one `<line-width>`, all the row and column rules will be that width. If we declare the following, all rules will be `3px`:

```
rule-width: 3px;
```

When multiple `<line-width>` values are declared, they will be applied to rules in the order specified. If there are more rules than `<line-width>` values, the list of line widths is repeated until every rule has a width. If we declare the following, for example, every odd horizontal and vertical rule will be `thin`, and every even rule will be `1em`.

```
rule-width: thin, 1em;
```

Repeated line widths

The `repeat()` function, with an integer of `1` or greater as the first argument, can be used to repeat a valid list of CSS `<line-width>` values passed as subsequent arguments the specified number of times. This allows the same widths to be repeated a set number of times without repeating the values. The following declarations are equivalent:

```
rule-width: 1rem, thick, thin, thick, thin, thick, thin;
rule-width: 1rem, repeat(3, thick, thin);
```

You can use any `<line-width>` values, including custom properties that resolve to a `<line-width>`. Using `repeat()` can make values easier to write, especially when using complex length calculations. It enables a recurring pattern to be written using a single function, regardless of the number of columns or rows.

Auto-repeating line widths

The `repeat()` function also accepts `auto` as the first argument instead of a positive integer. With `auto` as the first argument, the list of `<line-width>` values passed as subsequent arguments will be repeated as many times as needed to fill in values for any rules that are not explicitly specified by other components of the property value.

```
rule-width: thin, repeat(auto, medium), thin;
```

In this case, the first and last column and row rules will always be `thin`, and all other rules will be `medium`. If there are only 2 or 3 columns and rows, there will be no medium-sized rules.

The `auto` keyword within the `repeat()` function creates an auto-repeater that fills in values for column and row rules that would not otherwise receive values from other parts of the list, preventing the list from being cycled. At most, only one `repeat(auto, <width>)` can be present in a `rule-width` value.

Formal definition

Value not found in DB!

Formal syntax

```
rule-width =
  <'column-rule-width'>

<column-rule-width> =
  <line-width-list>       |
  <auto-line-width-list>

<line-width-list> =
  <line-width-or-repeat>#

<auto-line-width-list> =
  <line-width-or-repeat>#? , <auto-repeat-line-width> , <line-width-or-repeat>#?

<line-width-or-repeat> =
  <line-width>          |
  <repeat-line-width>

<auto-repeat-line-width> =
  repeat( auto , [ <line-width> ]# )

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick

<repeat-line-width> =
  repeat( [ <integer [1,∞]> ] , [ <line-width> ]# )

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

In this example, we define a single width for the lines drawn between the columns and rows of items in a grid container.

HTML

We create a list of 75 items. Most of the HTML is hidden for brevity.

```
<ul>
  <li>1</li>
  <li>2</li>
  ...
  <li>74</li>
  <li>75</li>
</ul>
```

```
<ul>
  <li>1</li>
  <li>2</li>
  <li>3</li>
  <li>4</li>
  <li>5</li>
  <li>6</li>
  <li>7</li>
  <li>8</li>
  <li>9</li>
  <li>10</li>
  <li>11</li>
  <li>12</li>
  <li>13</li>
  <li>14</li>
  <li>15</li>
  <li>16</li>
  <li>17</li>
  <li>18</li>
  <li>19</li>
  <li>20</li>
  <li>21</li>
  <li>22</li>
  <li>23</li>
  <li>24</li>
  <li>25</li>
  <li>26</li>
  <li>27</li>
  <li>28</li>
  <li>29</li>
  <li>30</li>
  <li>31</li>
  <li>32</li>
  <li>33</li>
  <li>34</li>
  <li>35</li>
  <li>36</li>
  <li>37</li>
  <li>38</li>
```

```
  <li>39</li>
  <li>40</li>
  <li>41</li>
  <li>42</li>
  <li>43</li>
  <li>44</li>
  <li>45</li>
  <li>46</li>
  <li>47</li>
  <li>48</li>
  <li>49</li>
  <li>50</li>
  <li>51</li>
  <li>52</li>
  <li>53</li>
  <li>54</li>
  <li>55</li>
  <li>56</li>
  <li>57</li>
  <li>58</li>
  <li>59</li>
  <li>60</li>
  <li>61</li>
  <li>62</li>
  <li>63</li>
  <li>64</li>
  <li>65</li>
  <li>66</li>
  <li>67</li>
  <li>68</li>
  <li>69</li>
  <li>70</li>
  <li>71</li>
  <li>72</li>
  <li>73</li>
  <li>74</li>
  <li>75</li>
</ul>
```

CSS

We define the unordered list to be a 10-column grid container. We include a gap of `5px` to provide enough room between the items to fit our `3px` dashed red rule:

```
ul {
  display: grid;
  grid-template-columns: repeat(10, 1fr);
  list-style-type: none;
  gap: 5px;
  rule-style: dashed;
  rule-color: red;
  rule-width: 3px;
}
li {
  text-align: center;
  aspect-ratio: 1;
}
```

```
@layer no-support {
  @supports not (rule-width: medium) {
    body::before {
      content: "Your browser doesn't support the rule-width property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

Result

Repeating values

This example demonstrates how, when there are fewer values in the list of widths than column or row rules, the values are repeated.

CSS

Using the same HTML and CSS as in the previous example, we include three comma-separated widths as the `rule-width`.

```
ul {
  rule-width: thin, 6px, 12px;
}
```

Result

As the grid container has 8 rows and 10 columns, there are seven and nine gutters in each direction, respectively, so the sequence of three `<line-width>` values is repeated in both directions.

Using the <code>repeat()</code> function

This example demonstrates using the `repeat()` function within the `rule-width` property value and how this function can help reduce the verbosity of value declarations.

CSS

We use the same HTML and CSS as in the previous examples. In addition, we declare two custom properties, which we use in a `repeat()` function inside our `rule-width` value. The `repeat()` function sets a list of two `<line-width>` values to repeat 3 times.

```
ul {
  --base: 0.5vw;
  --secondary: 1vw;
  rule-width:
    15px,
```

```
    repeat(
      4,
      min(calc(var(--base) + 3px), 10px),
      abs(calc(var(--secondary) - 2px))
    ),
    15px;
}
```

Result

The `repeat()` function repeats two width values four times, creating a list of ten width values. As there are fewer column and row gutters than total widths, the last values in the list are discarded.

Using <code>auto</code> within <code>repeat()</code>

This example demonstrates using `auto` instead of an integer within the `repeat()` function.

CSS

Using `repeat(auto, <line-width>)`, we set all column and row rules to `1px`, except the first and last, which we set to `5px`.

```
ul {
  rule-width: 5px, repeat(auto, 1px), 5px;
}
```

Result

```
@layer no-support {
  @supports not (rule-width: thin, thick) {
    body::before {
      content: "Your browser doesn't support the rule-width property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

rx CSS property

The **`rx`** CSS property defines the x-axis, or horizontal, radius of an SVG `<ellipse>` and the horizontal curve of the corners of an SVG `<rect>` rectangle. If present, it overrides the shape's `rx` attribute.

> **Note:** The `rx` property only applies to `<ellipse>` and `<rect>` elements nested in an `<svg>`. It doesn't apply to other SVG elements or HTML elements or pseudo-elements.

Syntax

```
/* Initial value */
rx: auto;

/* Length and percentage values */
rx: 20px;
rx: 20%;

/* Global values */
rx: inherit;
rx: initial;
rx: revert;
rx: revert-layer;
rx: unset;
```

Values

The `<length>`, `<percentage>`, or `auto` keyword value denotes the horizontal radius of ellipses and the horizontal border-radius of rectangles.

`<length>`

Absolute or relative lengths can be expressed in any unit allowed by the CSS `<length>` data type. Negative values are invalid.

`<percentage>`

Percentages refer to the width of the current SVG viewport. The used value for a `<rect>` is never more than 50% of the width of the rectangle.

`auto`

When set or defaulting to `auto`, the `rx` value equals the absolute length value used for `ry`. If both `rx` and `ry` have a computed value of `auto`, the used value is `0`.

Formal definition

Initial value	`auto`
Applies to	`<ellipse>` and `<rect>` elements in `<svg>`
Inherited	no
Percentages	refer to the width of the current SVG viewport
Computed value	the percentage as specified or the absolute length
Animation type	by computed value type

Formal syntax

```
rx =
  <length-percentage>  |
  auto

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Specification, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Creating rounded corners

This example demonstrates creating rectangles with rounded corners by applying the `rx` property to SVG `<rect>` elements.

HTML

We include an SVG image with four `<rect>` elements; all the rectangles are the same except for their `x` attribute value, which positions them along the x-axis.

```
<svg xmlns="http://www.w3.org/2000/svg">
  <rect width="50" height="120" y="5" x="5" />
  <rect width="50" height="120" y="5" x="60" />
  <rect width="50" height="120" y="5" x="115" />
  <rect width="50" height="120" y="5" x="170" />
  <rect width="50" height="120" y="5" x="225" />
</svg>
```

CSS

With CSS, we set an `rx` value on four of the rectangles:

```
svg {
  border: 1px solid;
}

rect:nth-of-type(2) {
  rx: 10px;
  fill: red;
}

rect:nth-of-type(3) {
  rx: 2em;
  fill: blue;
}

rect:nth-of-type(4) {
  rx: 5%;
  fill: orange;
}

rect:nth-of-type(5) {
  rx: 80%;
  fill: green;
}
```

Results

The first rectangle defaults to `auto`; as all the `ry` values in this example also default to `auto`, the used value of `rx` is `0`. The red and blue rectangles have `10px` and `2em` rounded corners, respectively. As the SVG viewport defaults to 300px by 150px, the orange rectangle's `5%` value creates a `15px` radius. The green rectangle has `rx: 80%` set. However, as the value of `rx` is never more than `50%` of the width of the rectangle, the effect is as if `rx: 50%; ry: 50%` was set.

Defining the horizontal radius of an ellipse

This basic `<ellipse>` example demonstrates the CSS `rx` property taking precedence over an SVG `rx` attribute to define the shape's horizontal radius.

HTML

We include two identical `<ellipse>` elements in an SVG; each with the `rx` attribute set to `20`.

```
<svg xmlns="http://www.w3.org/2000/svg">
  <ellipse cx="80" cy="50" rx="20" ry="40" />
  <ellipse cx="80" cy="50" rx="20" ry="40" />
</svg>
```

CSS

We only style the first ellipse, letting its twin use default user agent styles (with `fill` defaulting to black). The geometric `rx` property overrides the value of the SVG `rx` attribute. We also set the `fill` and `stroke` properties to differentiate the styled shape from its twin.

```
svg {
  border: 1px solid;
}

ellipse:first-of-type {
  rx: 80px;
  fill: magenta;
  stroke: rebeccapurple;
}
```

Results

The styled ellipse's horizontal radius is `80px`, as defined in the CSS `rx` property value. The unstyled ellipse's horizontal radius is `20px`, which was defined by the `rx` attribute.

Ellipse horizontal radius percentage values

This example demonstrates using percentage values for `rx`.

HTML

We use the same markup as the previous example.

```
<svg xmlns="http://www.w3.org/2000/svg">
  <ellipse cx="80" cy="50" rx="20" ry="40" />
  <ellipse cx="80" cy="50" rx="20" ry="40" />
</svg>
```

CSS

The CSS is similar to the previous example, with the only difference being the `rx` property value; in this case, we use a percentage value.

```
svg {
  border: 1px solid;
}

ellipse:first-of-type {
  rx: 30%;
  fill: magenta;
  stroke: rebeccapurple;
}
```

Results

When using percentage values for `rx`, the values are relative to the width of the SVG viewport. Here, the size of the styled ellipse horizontal radius is `30%` of the width of the current SVG viewport. As the width defaulted to `300px`, the `rx` value is `90px`.

ry CSS property

The **`ry`** CSS property defines the y-axis, or vertical, radius of an SVG `<ellipse>` and the vertical curve of the corners of an SVG `<rect>` rectangle. If present, it overrides the shape's `ry` attribute.

> **Note:** The `ry` property only applies to `<ellipse>` and `<rect>` elements nested in an `<svg>`. It doesn't apply to other SVG elements or HTML elements or pseudo-elements.

Syntax

```
/* Initial value */
ry: auto;

/* Length and percentage values */
ry: 30px;
ry: 30%;

/* Global values */
ry: inherit;
ry: initial;
ry: revert;
ry: revert-layer;
ry: unset;
```

Values

The `<length>`, `<percentage>`, or `auto` keyword value denotes the vertical radius of ellipses and the vertical border-radius of rectangles.

`<length>`

Absolute or relative lengths can be expressed in any unit allowed by the CSS `<length>` data type. Negative values are invalid.

`<percentage>`

Percentages refer to the height of the current SVG viewport. The used value for a `<rect>` is never more than 50% of the height of the rectangle.

`auto`

When set or defaulting to `auto`, the `ry` value equals the absolute length value used for `rx`. If both `ry` and `rx` have a computed value of `auto`, the used value is `0`.

Formal definition

Initial value	`auto`
Applies to	`<ellipse>` and `<rect>` elements in `<svg>`
Inherited	no
Percentages	refer to the height of the current SVG viewport
Computed value	the percentage as specified or the absolute length
Animation type	by computed value type

Formal syntax

```
ry =
  <length-percentage>  |
  auto

<length-percentage> =
```

```
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Specification, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Creating rounded corners

This example demonstrates creating rectangles with rounded corners by applying the `ry` property to SVG `<rect>` elements.

HTML

We include an SVG image with four `<rect>` elements; all the rectangles are the same except for their `x` attribute value, which positions them along the x-axis.

```
<svg xmlns="http://www.w3.org/2000/svg">
  <rect width="50" height="120" y="5" x="5" />
  <rect width="50" height="120" y="5" x="60" />
  <rect width="50" height="120" y="5" x="115" />
  <rect width="50" height="120" y="5" x="170" />
  <rect width="50" height="120" y="5" x="225" />
</svg>
```

CSS

With CSS, we set an `ry` value on four of the rectangles:

```
svg {
  border: 1px solid;
}

rect:nth-of-type(2) {
  ry: 10px;
  fill: red;
}

rect:nth-of-type(3) {
  ry: 2em;
  fill: blue;
}

rect:nth-of-type(4) {
  ry: 5%;
  fill: orange;
}

rect:nth-of-type(5) {
  ry: 80%;
  fill: green;
}
```

Results

The first rectangle defaults to `auto`; as all the `rx` values in this example also default to `auto`, the used value of `ry` is `0`. The red and blue rectangles have `10px` and `2em` rounded corners, respectively. As the SVG viewport defaults to 300px by 150px, the orange rectangle's `5%` value creates a `7.5px` radius. The green rectangle has `ry: 80%` set. However, as the value of `ry` is never more than `50%` of the height of the rectangle, the effect is as if `ry: 50%; rx: 50%` was set.

Defining the vertical radius of an ellipse

This basic `<ellipse>` example demonstrates the CSS `ry` property taking precedence over an SVG `ry` attribute to define the shape's vertical radius.

HTML

We include two identical `<ellipse>` elements in an SVG; each with the `ry` attribute set to `20`.

```
<svg xmlns="http://www.w3.org/2000/svg">
  <ellipse cx="80" cy="50" rx="40" ry="20" />
  <ellipse cx="80" cy="50" rx="40" ry="20" />
</svg>
```

CSS

We only style the first ellipse, letting its twin use default user agent styles (with `fill` defaulting to black). The geometric `ry` property overrides the value of the SVG `ry` attribute. We also set the `fill` and `stroke` properties to differentiate the styled shape from its twin.

```
svg {
  border: 1px solid;
}

ellipse:first-of-type {
  ry: 80px;
  fill: magenta;
  stroke: rebeccapurple;
}
```

Results

The styled ellipse's vertical radius is `80px`, as defined in the CSS `ry` property value. The unstyled ellipse's vertical radius is `20px`, which was defined by the `ry` attribute.

Ellipse vertical radius percentage values

This example demonstrates using percentage values for `ry`.

HTML

We use the same markup as the previous example.

```
<svg xmlns="http://www.w3.org/2000/svg">
  <ellipse cx="80" cy="50" rx="40" ry="20" />
```

```
  <ellipse cx="80" cy="50" rx="40" ry="20" />
</svg>
```

CSS

The CSS is similar to the previous example, with the only difference being the `ry` property value; in this case, we use a percentage value.

```
svg {
  border: 1px solid;
}

ellipse:first-of-type {
  ry: 30%;
  fill: magenta;
  stroke: rebeccapurple;
}
```

Results

When using percentage values for `ry`, the values are relative to the height of the SVG viewport. Here, the size of the styled ellipse vertical radius is `30%` of the height of the current SVG viewport. As the height defaulted to `150px`, the `ry` value is `45px`, making the ellipse `90px` tall.

scale CSS property

The **`scale`** CSS property allows you to specify scale transforms individually and independently of the `transform` property. This maps better to typical user interface usage, and saves having to remember the exact order of transform functions to specify in the `transform` value.

Try it

```
scale: none;
```

```
scale: 1.5;
```

```
scale: 1.7 50%;
```

```
scale: 1 -1;
```

```
scale: 1.2 1.2 2;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    <div class="face front">1</div>
    <div class="face back">2</div>
    <div class="face right">3</div>
    <div class="face left">4</div>
    <div class="face top">5</div>
    <div class="face bottom">6</div>
  </div>
</section>
```

```
#default-example {
  background: linear-gradient(skyblue, khaki);
  perspective: 800px;
  perspective-origin: 150% 150%;
}

#example-element {
  width: 100px;
  height: 100px;
  perspective: 550px;
  transform-style: preserve-3d;
}

.face {
  display: flex;
  align-items: center;
  justify-content: center;
  width: 100%;
  height: 100%;
  position: absolute;
  backface-visibility: inherit;
  font-size: 60px;
  color: white;
}

.front {
  background: rgb(90 90 90 / 0.7);
  transform: translateZ(50px);
}

.back {
  background: rgb(0 210 0 / 0.7);
  transform: rotateY(180deg) translateZ(50px);
}

.right {
```

```
  background: rgb(210 0 0 / 0.7);
  transform: rotateY(90deg) translateZ(50px);
}

.left {
  background: rgb(0 0 210 / 0.7);
  transform: rotateY(-90deg) translateZ(50px);
}

.top {
  background: rgb(210 210 0 / 0.7);
  transform: rotateX(90deg) translateZ(50px);
}

.bottom {
  background: rgb(210 0 210 / 0.7);
  transform: rotateX(-90deg) translateZ(50px);
}
```

Syntax

```
/* Keyword value */
scale: none;

/* Single values */
/* values of more than 1 or 100% make the element grow */
scale: 2;
/* values of less than 1 or 100% make the element shrink */
scale: 50%;

/* Two values */
scale: 2 0.5;

/* Three values */
scale: 200% 50% 200%;

/* Global values */
scale: inherit;
scale: initial;
scale: revert;
scale: revert-layer;
scale: unset;
```

Values

Single value

A `<number>` or `<percentage>` specifying a scale factor to make the affected element scale by the same factor along both the X and Y axes. Equivalent to a `scale()` (2D scaling) function with a single value specified.

Two values

Two `<number>` or `<percentage>` values that specify the X and Y axis scaling values (respectively) of a 2D scale. Equivalent to a `scale()` (2D scaling) function with two values specified.

Three values

Three `<number>` or `<percentage>` values that specify the X, Y, and Z axis scaling values (respectively) of a 3D scale. Equivalent to a `scale3d()` (3D scaling) function.

`none`

Specifies that no scaling should be applied.

Formal definition

Initial value	none
Applies to	transformable elements
Inherited	no
Computed value	as specified
Animation type	a transform
Creates stacking context	yes

Formal syntax

```
scale =
  none                              |
  [ <number> | <percentage> ]{1,3}
```

This syntax reflects the latest standard as per CSS Transforms Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Scaling an element on hover

The following example shows how to scale an element on hover. Two boxes are shown, one with a single `scale` value which scales the element along both axes. The second box has two `scale` values which scales the element along the X and Y axes independently.

HTML

```
<div class="box" id="box1">single value</div>
<div class="box" id="box2">two values</div>
```

CSS

```
.box {
  float: left;
  margin: 1em;
  width: 7em;
  line-height: 7em;
```

```
  text-align: center;
  transition: 0.5s ease-in-out;
  border: 3px dotted;
}

#box1:hover {
  scale: 1.25;
}

#box2:hover {
  scale: 1.25 0.75;
}
```

Note: skew is not an independent transform value

scroll-behavior CSS property

The **`scroll-behavior`** CSS property sets the behavior for a scrolling box when scrolling is triggered by the navigation or CSSOM scrolling APIs.

Try it

```
scroll-behavior: auto;
```

```
scroll-behavior: smooth;
```

```
<section id="default-example">
  <div class="container">
    <p class="nav">
      Scroll to:
      <a href="#pageA">A</a>
      <a href="#pageB">B</a>
      <a href="#pageC">C</a>
    </p>
    <scroll-container id="example-element">
      <scroll-page id="pageA">A</scroll-page>
      <scroll-page id="pageB">B</scroll-page>
      <scroll-page id="pageC">C</scroll-page>
    </scroll-container>
  </div>
</section>
```

```
.container {
  flex-direction: column;
}

.nav a {
  color: #009e5f;
}

scroll-container {
  border: 1px solid black;
  display: block;
  height: 200px;
  overflow-y: scroll;
  width: 200px;
}

scroll-page {
  align-items: center;
  display: flex;
  font-size: 5em;
  height: 100%;
  justify-content: center;
}
```

Note that any other scrolls, such as those performed by the user, are not affected by this property. When this property is specified on the root element, it applies to the viewport instead. This property specified on the `body` element will *not* propagate to the viewport.

User agents are allowed to ignore this property.

Syntax

```
/* Keyword values */
scroll-behavior: auto;
scroll-behavior: smooth;

/* Global values */
scroll-behavior: inherit;
scroll-behavior: initial;
scroll-behavior: revert;
scroll-behavior: revert-layer;
scroll-behavior: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

The scrolling box scrolls instantly.

`smooth`

The scrolling box scrolls in a smooth fashion using a user-agent-defined easing function over a user-agent-defined period of time. User agents should follow platform conventions, if any.

Formal definition

Initial value	`auto`
Applies to	scrolling boxes
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
scroll-behavior =
  auto    |
  smooth
```

This syntax reflects the latest standard as per CSS Overflow Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting smooth scroll behavior

HTML

```
<nav>
  <a href="#page-1">1</a>
  <a href="#page-2">2</a>
  <a href="#page-3">3</a>
</nav>
<div class="scroll-container">
  <div class="scroll-page" id="page-1">1</div>
  <div class="scroll-page" id="page-2">2</div>
  <div class="scroll-page" id="page-3">3</div>
</div>
```

CSS

```
a {
  display: inline-block;
  width: 50px;
  text-decoration: none;
}
nav,
.scroll-container {
  display: block;
  margin: 0 auto;
  text-align: center;
}
nav {
  width: 339px;
  padding: 5px;
  border: 1px solid black;
}
.scroll-container {
  width: 350px;
  height: 200px;
  overflow-y: scroll;
  scroll-behavior: smooth;
}
.scroll-page {
  display: flex;
  align-items: center;
  justify-content: center;
  height: 100%;
  font-size: 5em;
}
```

Result

scroll-initial-target CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`scroll-initial-target`** CSS property enables the definition of elements that are potential snap targets when their ancestor scroll container is first rendered.

Syntax

```
/* Keyword values */
scroll-initial-target: none;
scroll-initial-target: nearest;

/* Global values */
scroll-initial-target: inherit;
scroll-initial-target: initial;
scroll-initial-target: revert;
scroll-initial-target: revert-layer;
scroll-initial-target: unset;
```

Values

This property is specified as one of the following keyword values:

`none`

The element is not an initial scroll target.

`nearest`

The element is potentially an initial scroll target for its nearest scroll container ancestor.

Description

The `scroll-initial-target` property enables defining elements that should be snapped when their parent scroll snap containers are first rendered. Setting the value to `nearest` defines the element as a potential target that should be snapped to when the nearest ancestor scroll container first shows up on the page.

If multiple elements or pseudo-elements in the scroll container are set to `nearest`, the first element in the tree order is the initial scroll-snapping target.

The initial value is `none`, meaning a scroll-snappable element is not by default an initial scroll target. The `none` value can also be set on an element to explicitly make it not be an initial scroll target.

If a scroll container's initial scroll position is potentially set by both the `place-content` content-distribution property and by `scroll-initial-target` on any descendants — the first descendant with `scroll-initial-target: nearest` wins.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	the specified keyword
Animation type	Not animatable

Formal syntax

```
scroll-initial-target =
  none     |
  nearest
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using <code>scroll-initial-target</code>

The example below demonstrates the two values of `scroll-initial-target`, and how the first element with `scroll-initial-target` gets snapped.

HTML

We include 5 containers, preceded by a paragraph explaining the expected effect.

```
<p><code>none</code> on #4 only</p>
<div class="none">
  <div>1</div>
  <div>2</div>
  <div>3</div>
  <div class="set">4</div>
  <div>5</div>
</div>

<p><code>nearest</code> on #4 only</p>
<div class="nearest">
  <div>1</div>
  <div>2</div>
  <div>3</div>
  <div class="set">4</div>
  <div>5</div>
</div>

<p><code>nearest</code> on even elements</p>
<div class="nearest">
  <div>1</div>
  <div class="set">2</div>
  <div>3</div>
  <div class="set">4</div>
  <div>5</div>
</div>

<p><code>nearest</code> on odd elements</p>
<div class="nearest">
  <div class="set">1</div>
  <div>2</div>
  <div class="set">3</div>
  <div>4</div>
  <div class="set">5</div>
</div>

<p><code>nearest</code> on odd elements, with <code>none</code> on #1</p>
<div class="nearest">
  <div class="set unset">1</div>
  <div>2</div>
  <div class="set">3</div>
  <div>4</div>
  <div class="set">5</div>
</div>
```

CSS

We set up the nearest and none elements as scroll-snap containers, centering the snapped elements.

```
/* mandatory scroll-snap on parent */
div.nearest,
div.none {
  scroll-snap-type: x mandatory;
}

/* scroll-snap alignment for children */
div > div {
```

```
  scroll-snap-align: center;
  scroll-snap-stop: always;
}
```

We then set `scroll-initial-target` of either `none` or `nearest` on all the elements with the `.set` class.

```
.none .set,
.nearest .set.unset {
  scroll-initial-target: none;
}
.nearest .set {
  scroll-initial-target: nearest;
}
```

```
/* setup */
body {
  height: 100%;
  display: flex;
  align-items: center;
  flex-flow: column nowrap;
  font-family: sans-serif;
  text-align: center;
}

div.nearest,
div.none {
  display: flex;
  overflow: auto;
  font-size: 3rem;
}

div div {
  width: 90%;
  min-width: 15rem;
  flex: none;
  outline: 1px solid #333333;
}

/* coloration */
div > div:nth-child(even) {
  background-color: #87ea87;
}

div > div:nth-child(odd) {
  background-color: #87ccea;
}

p {
  margin: 1em 0 0;
}

@supports not (scroll-initial-target: nearest) {
  :root::before {
    content: "Your browser doesn't support the scroll-initial-target property.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

Result

The property's effect is demonstrated when the scroll-snap container is drawn to the page.

Each row snaps to the first element with `nearest` set, if any, in tree order. In the last example, we've overridden the `nearest` value with `none` on the first element, so the first element with `nearest` applied is #3.

- CSS scroll snap

scroll-margin CSS property

The **`scroll-margin`** CSS shorthand property sets all of the scroll margins of an element at once, assigning values much like the `margin` property does for margins of an element.

Try it

```
scroll-margin: 0;
```

```
scroll-margin: 20px;
```

```
scroll-margin: 2em;
```

```
<section class="default-example" id="default-example">
  <div class="scroller">
    <div>1</div>
    <div id="example-element">2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example .info {
  inline-size: 100%;
  padding: 0.5em 0;
  font-size: 90%;
  writing-mode: vertical-rl;
}
```

```
.scroller {
  text-align: left;
  height: 250px;
  width: 270px;
  overflow-y: scroll;
  display: flex;
  flex-direction: column;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: y mandatory;
}

.scroller > div {
  flex: 0 0 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: start;
}

.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `scroll-margin-bottom`
- `scroll-margin-left`
- `scroll-margin-right`
- `scroll-margin-top`

Syntax

```
/* <length> values */
scroll-margin: 10px;
scroll-margin: 1em 0.5em 1em 1em;

/* Global values */
scroll-margin: inherit;
scroll-margin: initial;
scroll-margin: revert;
scroll-margin: revert-layer;
scroll-margin: unset;
```

Values

`<length>`

An outset from the corresponding edge of the scroll container.

Description

You can see the effect of `scroll-margin` by scrolling to a point partway between two of the "pages" of the example's content. The value specified for `scroll-margin` determines how much of the page that's primarily outside the snapport should remain visible.

Thus, the `scroll-margin` values represent outsets defining the scroll snap area that is used for snapping this box to the snapport. The scroll snap area is determined by taking the transformed border box, finding its rectangular bounding box (axis-aligned in the scroll container's coordinate space), then adding the specified outsets.

Formal definition

Initial value	as each of the properties of the shorthand: • `scroll-margin-bottom`: `0` • `scroll-margin-left`: `0` • `scroll-margin-right`: `0` • `scroll-margin-top`: `0`
Applies to	all elements
Inherited	no
Computed value	as each of the properties of the shorthand: • `scroll-margin-bottom`: as specified • `scroll-margin-left`: as specified • `scroll-margin-right`: as specified • `scroll-margin-top`: as specified
Animation type	by computed value type

Formal syntax

```
scroll-margin =
  <length>{1,4}
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic demonstration

This example implements something very similar to the interactive example above, except that here we'll explain to you how it's implemented.

The aim here is to create four horizontally-scrolling blocks, the second and third of which snap into place, near but not quite at the left of each block.

HTML

The HTML includes a scroller with four children:

```
<div class="scroller">
  <div>1</div>
  <div>2</div>
  <div>3</div>
  <div>4</div>
</div>
```

CSS

Let's walk through the CSS. The outer container is styled like this:

```
.scroller {
  text-align: left;
  width: 250px;
  height: 250px;
  overflow-x: scroll;
  display: flex;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: x mandatory;
}
```

The main parts relevant to the scroll snapping are `overflow-x: scroll`, which makes sure the contents will scroll and not be hidden, and `scroll-snap-type: x mandatory`, which dictates that scroll snapping must occur along the horizontal axis, and the scrolling will always come to rest on a snap point.

The child elements are styled as follows:

```
.scroller > div {
  flex: 0 0 250px;
  width: 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: start;
}

.scroller > div:nth-child(2n) {
  background-color: white;
  color: rebeccapurple;
}
```

The most relevant part here is `scroll-snap-align: start`, which specifies that the left-hand edges (the "starts" along the x axis, in our case) are the designated snap points.

Last of all we specify the scroll margin-values, a different one for the second and third child elements:

```
.scroller > div:nth-child(2) {
  scroll-margin: 1rem;
}

.scroller > div:nth-child(3) {
  scroll-margin: 2rem;
}
```

This means that when scrolling past the middle child elements, the scrolling will snap to `1rem` outside the left edge of the second `<div>`, and `2rems` outside the left edge of the third `<div>`.

> **Note:** Here we are setting `scroll-margin` on all sides at once, but only the start edge is really relevant. It would work just as well here to only set a scroll margin on that one edge, for example with `scroll-margin-inline-start: 1rem`, or `scroll-margin: 0 0 0 1rem`.

Result

Try it for yourself:

scroll-margin-block CSS property

The **`scroll-margin-block`** CSS shorthand property sets the scroll margins of an element in the block dimension.

Try it

```
scroll-margin-block: 0;
```

```
scroll-margin-block: 20px;
```

```
scroll-margin-block: 2em;
```

```
<section class="default-example" id="default-example">
  <div class="scroller">
    <div>1</div>
    <div id="example-element">2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example .info {
  inline-size: 100%;
  padding: 0.5em 0;
  font-size: 90%;
  writing-mode: vertical-rl;
}

.scroller {
  text-align: left;
  height: 250px;
  width: 270px;
  overflow-y: scroll;
  display: flex;
  flex-direction: column;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: y mandatory;
}

.scroller > div {
  flex: 0 0 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: start;
}

.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `scroll-margin-block-end`
- `scroll-margin-block-start`

Syntax

```
/* <length> values */
scroll-margin-block: 10px;
scroll-margin-block: 1em 0.5em;

/* Global values */
scroll-margin-block: inherit;
scroll-margin-block: initial;
scroll-margin-block: revert;
scroll-margin-block: revert-layer;
scroll-margin-block: unset;
```

Values

`<length>`

An outset from the corresponding edge of the scroll container.

Description

The scroll-margin values represent outsets defining the scroll snap area that is used for snapping this box to the snapport. The scroll snap area is determined by taking the transformed border box, finding its rectangular bounding box (axis-aligned in the scroll container's coordinate space), then adding the specified outsets.

Formal definition

Initial value	as each of the properties of the shorthand: • `scroll-margin-block-start`: `0` • `scroll-margin-block-end`: `0`
Applies to	all elements
Inherited	no
Computed value	as each of the properties of the shorthand: • `scroll-margin-block-start`: as specified • `scroll-margin-block-end`: as specified
Animation type	by computed value type

Formal syntax

```
scroll-margin-block =
  <length>{1,2}
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

See also

- CSS scroll snap module
- Well-controlled scrolling with CSS scroll snap on web.dev (2018)

scroll-margin-block-end CSS property

The `scroll-margin-block-end` property defines the margin of the scroll snap area at the end of the block dimension that is used for snapping this box to the snapport. The scroll snap area is determined by taking the transformed border box, finding its rectangular bounding box (axis-aligned in the scroll container's coordinate space), then adding the specified outsets.

Try it

```
scroll-margin-block-end: 0;
```

```
scroll-margin-block-end: 20px;
```

```
scroll-margin-block-end: 2em;
```

```
<section class="default-example" id="default-example">
  <div class="scroller">
    <div>1</div>
    <div id="example-element">2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example .info {
  inline-size: 100%;
  padding: 0.5em 0;
  font-size: 90%;
  writing-mode: vertical-rl;
}

.scroller {
  text-align: left;
  height: 250px;
  width: 270px;
  overflow-y: scroll;
  display: flex;
  flex-direction: column;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: y mandatory;
}

.scroller > div {
  flex: 0 0 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: end;
}

.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Syntax

```
/* <length> values */
scroll-margin-block-end: 10px;
scroll-margin-block-end: 1em;

/* Global values */
scroll-margin-block-end: inherit;
scroll-margin-block-end: initial;
scroll-margin-block-end: revert;
scroll-margin-block-end: revert-layer;
scroll-margin-block-end: unset;
```

Values

`<length>`

An outset from the block end edge of the scroll container.

Formal definition

Initial value	`0`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
scroll-margin-block-end =
  <length>
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

scroll-margin-block-start CSS property

The `scroll-margin-block-start` property defines the margin of the scroll snap area at the start of the block dimension that is used for snapping this box to the snapport. The scroll snap area is determined by taking the transformed border box, finding its rectangular bounding box (axis-aligned in the scroll container's coordinate space), then adding the specified outsets.

Try it

```
scroll-margin-block-start: 0;
```

```
scroll-margin-block-start: 20px;
```

```
scroll-margin-block-start: 2em;
```

```
<section class="default-example" id="default-example">
  <div class="scroller">
    <div>1</div>
    <div id="example-element">2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example .info {
  inline-size: 100%;
  padding: 0.5em 0;
  font-size: 90%;
  writing-mode: vertical-rl;
}

.scroller {
  text-align: left;
  height: 250px;
  width: 270px;
  overflow-y: scroll;
  display: flex;
  flex-direction: column;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: y mandatory;
}

.scroller > div {
  flex: 0 0 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: start;
}

.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Syntax

```
/* <length> values */
scroll-margin-block-start: 10px;
scroll-margin-block-start: 1em;

/* Global values */
scroll-margin-block-start: inherit;
scroll-margin-block-start: initial;
scroll-margin-block-start: revert;
scroll-margin-block-start: revert-layer;
scroll-margin-block-start: unset;
```

Values

`<length>`

An outset from the block start edge of the scroll container.

Formal definition

Initial value	`0`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
scroll-margin-block-start =
  <length>
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

scroll-margin-bottom CSS property

The `scroll-margin-bottom` property defines the bottom margin of the scroll snap area that is used for snapping this box to the snapport. The scroll snap area is determined by taking the transformed border box, finding its rectangular bounding box (axis-aligned in the scroll container's coordinate space), then adding the specified outsets.

Try it

```
scroll-margin-bottom: 0;
```

```
scroll-margin-bottom: 20px;
```

```
scroll-margin-bottom: 2em;
```

```
<section class="default-example" id="default-example">
  <div class="scroller">
    <div>1</div>
    <div id="example-element">2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example .info {
  inline-size: 100%;
  padding: 0.5em 0;
  font-size: 90%;
  writing-mode: vertical-rl;
}

.scroller {
  text-align: left;
  height: 250px;
  width: 270px;
  overflow-y: scroll;
  display: flex;
  flex-direction: column;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: y mandatory;
}

.scroller > div {
  flex: 0 0 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: end;
}

.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Syntax

```
/* <length> values */
scroll-margin-bottom: 10px;
scroll-margin-bottom: 1em;

/* Global values */
scroll-margin-bottom: inherit;
scroll-margin-bottom: initial;
scroll-margin-bottom: revert;
scroll-margin-bottom: revert-layer;
scroll-margin-bottom: unset;
```

Values

`<length>`

An outset from the bottom edge of the scroll container.

Formal definition

Initial value	`0`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
scroll-margin-bottom =
  <length>
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

scroll-margin-inline CSS property

The **`scroll-margin-inline`** CSS shorthand property sets the scroll margins of an element in the inline dimension.

Try it

```
scroll-margin-inline: 0;
```

```
scroll-margin-inline: 40px 20px;
```

```
scroll-margin-inline: 4em 0;
```

```
scroll-margin-inline: 0px 3em;
```

```
<section class="default-example" id="default-example">
  <div class="scroller">
    <div>1</div>
    <div id="example-element">2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example {
  flex-wrap: wrap;
}

.default-example .info {
  width: 100%;
  padding: 0.5em 0;
  font-size: 90%;
}

.scroller {
  text-align: left;
  width: 250px;
  height: 250px;
  overflow-x: scroll;
  display: flex;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: x mandatory;
}

.scroller > div {
  flex: 0 0 250px;
  width: 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: end;
}

.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `scroll-margin-inline-end`
- `scroll-margin-inline-start`

Syntax

```
/* <length> values */
scroll-margin-inline: 10px;
scroll-margin-inline: 1em 0.5em;

/* Global values */
scroll-margin-inline: inherit;
scroll-margin-inline: initial;
scroll-margin-inline: revert;
scroll-margin-inline: revert-layer;
scroll-margin-inline: unset;
```

Values

`<length>`

An outset from the corresponding edge of the scroll container.

Description

The scroll-margin values represent outsets defining the scroll snap area that is used for snapping this box to the snapport. The scroll snap area is determined by taking the transformed border box, finding its rectangular bounding box (axis-aligned in the scroll container's coordinate space), then adding the specified outsets.

Formal definition

Initial value	as each of the properties of the shorthand: • `scroll-margin-inline-start`: `0` • `scroll-margin-inline-end`: `0`
Applies to	all elements
Inherited	no

Computed value	as each of the properties of the shorthand: • `scroll-margin-inline-start`: as specified • `scroll-margin-inline-end`: as specified
Animation type	by computed value type

Formal syntax

```
scroll-margin-inline =
  <length>{1,2}
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic demonstration

This example implements something very similar to the interactive example above, except that here we'll explain to you how it's implemented.

The aim here is to create four horizontally-scrolling blocks, the second and third of which snap into place, near but not quite at the right of each block.

HTML

The HTML includes a scroller with four children:

```
<div class="scroller">
  <div>1</div>
  <div>2</div>
  <div>3</div>
  <div>4</div>
</div>
```

CSS

Let's walk through the CSS. The outer container is styled like this:

```
.scroller {
  text-align: left;
  width: 250px;
  height: 250px;
  overflow-x: scroll;
  display: flex;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: x mandatory;
}
```

The main parts relevant to the scroll snapping are `overflow-x: scroll`, which makes sure the contents will scroll and not be hidden, and `scroll-snap-type: x mandatory`, which dictates that scroll snapping must occur along the horizontal axis, and the scrolling will always come to rest on a snap point.

The child elements are styled as follows:

```
.scroller > div {
  flex: 0 0 250px;
  width: 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: end;
}

.scroller > div:nth-child(2n) {
  background-color: white;
  color: rebeccapurple;
}
```

The most relevant part here is `scroll-snap-align: end`, which specifies that the right-hand edges (the "ends" along the x axis, in our case) are the designated snap points.

Last of all we specify the scroll margin values, a different one for the second and third child elements:

```
.scroller > div:nth-child(2) {
  scroll-margin-inline: 1rem;
}

.scroller > div:nth-child(3) {
  scroll-margin-inline: 2rem;
}
```

This means that when scrolling past the middle child elements, the scrolling will snap to `1rem` outside the inline end edge of the second `<div>`, and `2rems` outside the inline end edge of the third `<div>`.

> **Note:** Here we are setting `scroll-margin` on the start *and* end of the inline axis (x in our case), but only the end edge is really relevant. It would work just as well here to only set a scroll margin on that one edge, for example with `scroll-margin-inline: 0 1rem`, or `scroll-margin-inline-end: 1rem`.

Result

Try it for yourself:

scroll-margin-inline-end CSS property

The `scroll-margin-inline-end` property defines the margin of the scroll snap area at the end of the inline dimension that is used for snapping this box to the snapport. The scroll snap area is determined by taking the transformed border box, finding its rectangular bounding box (axis-aligned in the scroll container's coordinate space), then adding the specified outsets.

Try it

```
scroll-margin-inline-end: 0;
```

```
scroll-margin-inline-end: 20px;
```

```
scroll-margin-inline-end: 2em;
```

```
<section class="default-example" id="default-example">
  <div class="scroller">
    <div>1</div>
    <div id="example-element">2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example {
  flex-wrap: wrap;
}

.default-example .info {
  width: 100%;
  padding: 0.5em 0;
  font-size: 90%;
}

.scroller {
  text-align: left;
  width: 250px;
  height: 250px;
  overflow-x: scroll;
  display: flex;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: x mandatory;
}

.scroller > div {
  flex: 0 0 250px;
  width: 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: end;
}

.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Syntax

```
/* <length> values */
scroll-margin-inline-end: 10px;
scroll-margin-inline-end: 1em;

/* Global values */
scroll-margin-inline-end: inherit;
scroll-margin-inline-end: initial;
scroll-margin-inline-end: revert;
scroll-margin-inline-end: revert-layer;
scroll-margin-inline-end: unset;
```

Values

`<length>`

An outset from the inline end edge of the scroll container.

Formal definition

Initial value	`0`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
scroll-margin-inline-end =
  <length>
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic demonstration

This example implements something very similar to the interactive example above, except that here we'll explain to you how it's implemented.

The aim here is to create four horizontally-scrolling blocks, the second and third of which snap into place, near but not quite at the right of each block.

HTML

The HTML includes a scroller with four children:

```
<div class="scroller">
  <div>1</div>
  <div>2</div>
  <div>3</div>
  <div>4</div>
</div>
```

CSS

Let's walk through the CSS. The outer container is styled like this:

```
.scroller {
  text-align: left;
  width: 250px;
  height: 250px;
  overflow-x: scroll;
  display: flex;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: x mandatory;
}
```

The main parts relevant to the scroll snapping are `overflow-x: scroll`, which makes sure the contents will scroll and not be hidden, and `scroll-snap-type: x mandatory`, which dictates that scroll snapping must occur along the horizontal axis, and the scrolling will always come to rest on a snap point.

The child elements are styled as follows:

```
.scroller > div {
  flex: 0 0 250px;
  width: 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: end;
}

.scroller > div:nth-child(2n) {
  background-color: white;
  color: rebeccapurple;
}
```

The most relevant part here is `scroll-snap-align: end`, which specifies that the right-hand edges (the "ends" along the x axis, in our case) are the designated snap points.

Last of all we specify the scroll margin values, a different one for the second and third child elements:

```
.scroller > div:nth-child(2) {
  scroll-margin-inline-end: 1rem;
}

.scroller > div:nth-child(3) {
  scroll-margin-inline-end: 2rem;
}
```

This means that when scrolling past the middle child elements, the scrolling will snap to `1rem` outside the inline end edge of the second `<div>`, and `2rem`s outside the inline end edge of the third `<div>`.

Result

Try it for yourself:

scroll-margin-inline-start CSS property

The `scroll-margin-inline-start` property defines the margin of the scroll snap area at the start of the inline dimension that is used for snapping this box to the snapport. The scroll snap area is determined by taking the transformed border box, finding its rectangular bounding box (axis-aligned in the scroll container's coordinate space), then adding the specified outsets.

Try it

```
scroll-margin-inline-start: 0;
```

```
scroll-margin-inline-start: 20px;
```

```
scroll-margin-inline-start: 2em;
```

```
<section class="default-example" id="default-example">
  <div class="scroller">
    <div>1</div>
    <div id="example-element">2</div>
    <div>3</div>
  </div>
```

```
  <div class="info">Scroll »</div>
</section>
```

```
.default-example {
  flex-wrap: wrap;
}

.default-example .info {
  width: 100%;
  padding: 0.5em 0;
  font-size: 90%;
}

.scroller {
  text-align: left;
  width: 250px;
  height: 250px;
  overflow-x: scroll;
  display: flex;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: x mandatory;
}

.scroller > div {
  flex: 0 0 250px;
  width: 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: start;
}

.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Syntax

```
/* <length> values */
scroll-margin-inline-start: 10px;
scroll-margin-inline-start: 1em;

/* Global values */
scroll-margin-inline-start: inherit;
scroll-margin-inline-start: initial;
scroll-margin-inline-start: revert;
scroll-margin-inline-start: revert-layer;
scroll-margin-inline-start: unset;
```

Values

`<length>`

An outset from the inline start edge of the scroll container.

Formal definition

Initial value	`0`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
scroll-margin-inline-start =
  <length>
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic demonstration

This example implements something very similar to the interactive example above, except that here we'll explain to you how it's implemented.

The aim here is to create four horizontally-scrolling blocks, the second and third of which snap into place, near but not quite at the left of each block.

HTML

The HTML includes a scroller with four children:

```
<div class="scroller">
  <div>1</div>
  <div>2</div>
  <div>3</div>
  <div>4</div>
</div>
```

CSS

Let's walk through the CSS. The outer container is styled like this:

```
.scroller {
  text-align: left;
  width: 250px;
  height: 250px;
  overflow-x: scroll;
  display: flex;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: x mandatory;
}
```

The main parts relevant to the scroll snapping are `overflow-x: scroll`, which makes sure the contents will scroll and not be hidden, and `scroll-snap-type: x mandatory`, which dictates that scroll snapping must occur along the horizontal axis, and the scrolling will always come to rest on a snap point.

The child elements are styled as follows:

```
.scroller > div {
  flex: 0 0 250px;
  width: 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: start;
}

.scroller > div:nth-child(2n) {
  background-color: white;
  color: rebeccapurple;
}
```

The most relevant part here is `scroll-snap-align: start`, which specifies that the left-hand edges (the "starts" along the x axis, in our case) are the designated snap points.

Last of all we specify the scroll margin-values, a different one for the second and third child elements:

```
.scroller > div:nth-child(2) {
  scroll-margin-inline-start: 1rem;
}

.scroller > div:nth-child(3) {
  scroll-margin-inline-start: 2rem;
}
```

This means that when scrolling past the middle child elements, the scrolling will snap to `1rem` outside the inline start edge of the second `<div>`, and `2rems` outside the inline start edge of the third `<div>`.

Result

Try it for yourself:

scroll-margin-left CSS property

The `scroll-margin-left` property defines the left margin of the scroll snap area that is used for snapping this box to the snapport. The scroll snap area is determined by taking the transformed border box, finding its rectangular bounding box (axis-aligned in the scroll container's coordinate space), then adding the specified outsets.

Try it

```
scroll-margin-left: 0;
```

```
scroll-margin-left: 20px;
```

```
scroll-margin-left: 2em;
```

```
<section class="default-example" id="default-example">
  <div class="scroller">
    <div>1</div>
    <div id="example-element">2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example {
  flex-wrap: wrap;
}

.default-example .info {
  width: 100%;
  padding: 0.5em 0;
  font-size: 90%;
}

.scroller {
  text-align: left;
  width: 250px;
  height: 250px;
  overflow-x: scroll;
  display: flex;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: x mandatory;
}
```

```
.scroller > div {
  flex: 0 0 250px;
  width: 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: start;
}

.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Syntax

```
/* <length> values */
scroll-margin-left: 10px;
scroll-margin-left: 1em;

/* Global values */
scroll-margin-left: inherit;
scroll-margin-left: initial;
scroll-margin-left: revert;
scroll-margin-left: revert-layer;
scroll-margin-left: unset;
```

Values

`<length>`

An outset from the left edge of the scroll container.

Formal definition

Initial value	`0`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
scroll-margin-left =
  <length>
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

scroll-margin-right CSS property

The `scroll-margin-right` property defines the right margin of the scroll snap area that is used for snapping this box to the snapport. The scroll snap area is determined by taking the transformed border box, finding its rectangular bounding box (axis-aligned in the scroll container's coordinate space), then adding the specified outsets.

Try it

```
scroll-margin-right: 0;
```

```
scroll-margin-right: 20px;
```

```
scroll-margin-right: 2em;
```

```
<section class="default-example" id="default-example">
  <div class="scroller">
    <div>1</div>
    <div id="example-element">2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example {
  flex-wrap: wrap;
}

.default-example .info {
  width: 100%;
  padding: 0.5em 0;
  font-size: 90%;
}

.scroller {
  text-align: left;
  width: 250px;
  height: 250px;
  overflow-x: scroll;
  display: flex;
  box-sizing: border-box;
```

```
  border: 1px solid black;
  scroll-snap-type: x mandatory;
}

.scroller > div {
  flex: 0 0 250px;
  width: 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: end;
}

.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Syntax

```
/* <length> values */
scroll-margin-right: 10px;
scroll-margin-right: 1em;

/* Global values */
scroll-margin-right: inherit;
scroll-margin-right: initial;
scroll-margin-right: revert;
scroll-margin-right: revert-layer;
scroll-margin-right: unset;
```

Values

`<length>`

An outset from the right edge of the scroll container.

Formal definition

Initial value	`0`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
scroll-margin-right =
  <length>
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

scroll-margin-top CSS property

The `scroll-margin-top` property defines the top margin of the scroll snap area that is used for snapping this box to the snapport. The scroll snap area is determined by taking the transformed border box, finding its rectangular bounding box (axis-aligned in the scroll container's coordinate space), then adding the specified outsets.

Try it

```
scroll-margin-top: 0;
```

```
scroll-margin-top: 20px;
```

```
scroll-margin-top: 2em;
```

```
<section class="default-example" id="default-example">
  <div class="scroller">
    <div>1</div>
    <div id="example-element">2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example .info {
  inline-size: 100%;
  padding: 0.5em 0;
  font-size: 90%;
  writing-mode: vertical-rl;
}

.scroller {
  text-align: left;
  height: 250px;
  width: 270px;
  overflow-y: scroll;
  display: flex;
  flex-direction: column;
```

```
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: y mandatory;
}

.scroller > div {
  flex: 0 0 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: start;
}

.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Syntax

```
/* <length> values */
scroll-margin-top: 10px;
scroll-margin-top: 1em;

/* Global values */
scroll-margin-top: inherit;
scroll-margin-top: initial;
scroll-margin-top: revert;
scroll-margin-top: revert-layer;
scroll-margin-top: unset;
```

Values

`<length>`

An outset from the top edge of the scroll container.

Formal definition

Initial value	`0`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
scroll-margin-top =
  <length>
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

scroll-marker-group CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`scroll-marker-group`** CSS property controls whether a scroll container element has a `::scroll-marker-group` pseudo-element generated. If present, the property also specifies whether the scroll marker group should be placed `before` *or* `after` the contents of the scroll group container in the default visual and tab order.

> **Note:** To create a scroll marker group container from an existing element that contains a set of `<a>` elements, use the `scroll-target-group` property. Read about the differences in behavior between the two.

Syntax

```
/* Single values */
scroll-marker-group: before;
scroll-marker-group: after;
scroll-marker-group: none;

/* Global values */
scroll-marker-group: inherit;
scroll-marker-group: initial;
scroll-marker-group: revert;
scroll-marker-group: revert-layer;
scroll-marker-group: unset;
```

Values

This property is specified as one of the following keyword values:

`after`

A `::scroll-marker-group` pseudo-element is generated as a sibling of the scroll container's child DOM elements, immediately preceding them, and any generated `::scroll-button()` pseudo-elements. It appears at the end of the container's tab order and layout box order (but not DOM structure).

`before`

A `::scroll-marker-group` pseudo-element is generated as a sibling of the scroll container's child DOM elements, immediately preceding them, and any generated `::scroll-button()` pseudo-elements. The scroll marker group appears at the start of the container's tab order and layout box order.

`none`

No `::scroll-marker-group` pseudo-element will be generated on the element. This is the default value.

> **Note:** As an accessibility best practice, match the visual rendering position of the scroll marker group container with the tab order. When positioning the marker group at the start of the content with styles applied to `::scroll-marker-group`, put it at the beginning of the tab order using `before`. When positioning the group at the end of the content, put it at the end of the tab order using `after`.

Formal definition

Initial value	none
Applies to	scroll containers
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
scroll-marker-group =
  none                                  |
  [ [ before | after ] || [ links | tabs ] ]
```

This syntax reflects the latest standard as per CSS Overflow Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

See Creating CSS carousels for full examples that use the `scroll-marker-group` property.

Placement of the scroll markers

In this example, we demonstrate the three values of the `scroll-marker-group` property.

HTML

We have a basic HTML `<ul>` list with several `<li>` list items.

```
<fieldset>
  <legend>Select <code>scroll-marker-group</code> value:</legend>
  <label><input type="radio" name="p" value="before" />before</label>
  <label><input type="radio" name="p" value="after" checked />after</label>
  <label><input type="radio" name="p" value="none" />none</label>
</fieldset>
```

```
<ul>
  <li>Item 1</li>
  <li>Item 2</li>
  <li>Item 3</li>
  <li>Item 4</li>
  <li>Item 5</li>
  <li>Item 6</li>
  <li>Item 7</li>
  <li>Item 8</li>
</ul>
```

CSS

We convert our `<ul>` into a carousel by setting the `display` to `flex`, creating a single, non-wrapping row of `<li>` elements. The `overflow-x` property is set to `auto`, meaning if the items overflow their container on the x-axis, the content will scroll horizontally. We then convert the `<ul>` into a scroll-snap container, ensuring that items always snap into place when the container is scrolled with a `scroll-snap-type` value of `mandatory`.

We create a scroll marker group container with the `scroll-marker-group` property, placing the group after all the content.

```
ul {
  display: flex;
  gap: 4vw;
  padding-left: 0;
  margin: 32px 0;
  overflow-x: auto;
  overscroll-behavior-x: contain;
  scroll-snap-type: x mandatory;

  scroll-marker-group: after;
}
```

Next, we style the `<li>` elements, using the `flex` property to make them `33%` of the width of the container. The `scroll-snap-align` value of `start` makes the left-hand side of the left-most visible item snap to the left edge of the container when the content is scrolled.

```
li {
  list-style-type: none;
  background-color: #eeeeee;
  flex: 0 0 33%;
  scroll-snap-align: start;
  text-align: center;
  line-height: 5;
}
```

We then use the `::scroll-marker` pseudo-element to create a square marker for each list item with a red border, and apply styles to the `::scroll-marker-group` pseudo-element to lay out the scroll markers in a row with a `0.2em` gap between each one.

```
li::scroll-marker {
  content: " ";
  border: 1px solid red;
```

```
  height: 1em;
  width: 1em;
}

::scroll-marker-group {
  display: flex;
  gap: 0.2em;
}
```

Finally, to ensure good user experience, we style the marker of the currently-scrolled element differently from the others, targeting the marker with the `:target-current` pseudoclass.

```
::scroll-marker:target-current {
  background: red;
}
```

```
fieldset {
  width: 20em;
}

label {
  font-family: monospace;
  display: block;
}

:has([value="before"]:checked) ul {
  scroll-marker-group: before;
}
:has([value="after"]:checked) ul {
  scroll-marker-group: after;
}

:has([value="none"]:checked) ul {
  scroll-marker-group: none;
}
```

Result

Note the placement of the scroll marker group container. Check out how the keyboard tabbing order is different for `before` versus `after`, and note how the group disappears when the value is set to `none`.

scroll-padding CSS property

The **`scroll-padding`** CSS shorthand property sets scroll padding on all sides of an element at once. It specifies offsets that define the optimal viewing region of a scrollport within a scroll container.

Try it

```
scroll-padding: 0;
```

```
scroll-padding: 20px;
```

```
scroll-padding: 20%;
```

```
<section class="default-example" id="default-example">
  <div class="scroller" id="example-element">
    <div>1</div>
    <div>2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example .info {
  inline-size: 100%;
  padding: 0.5em 0;
  font-size: 90%;
  writing-mode: vertical-rl;
}

.scroller {
  text-align: left;
  height: 250px;
  width: 270px;
  overflow-y: scroll;
  display: flex;
  flex-direction: column;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: y mandatory;
}

.scroller > div {
  flex: 0 0 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
```

```
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: start;
}

.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `scroll-padding-bottom`
- `scroll-padding-left`
- `scroll-padding-right`
- `scroll-padding-top`

Syntax

```
/* Keyword value */
scroll-padding: auto;

/* <length> values */
scroll-padding: 10px;
scroll-padding: 1em 0.5em 1em 1em;
scroll-padding: 10%;

/* Global values */
scroll-padding: inherit;
scroll-padding: initial;
scroll-padding: revert;
scroll-padding: revert-layer;
scroll-padding: unset;
```

Values

`<length-percentage>`

An inwards offset from the corresponding edge of the scrollport, as a valid `<length>` or a `<percentage>`.

`auto`

The offset is determined by the user agent. This will generally be `0px`, but the user agent is free to detect and do something else if a non-zero value is more appropriate.

Description

The `scroll-padding` property is a shorthand that sets `scroll-padding-top`, `scroll-padding-right`, `scroll-padding-bottom`, and `scroll-padding-left`, in that order, setting the top, right, bottom, and left scroll padding of a scroll container, respectively.

Useful when creating scroll-snap containers, the `scroll-padding` property enables defining offsets for the *optimal viewing region* of the scrollport: the region used as the target region for placing elements in view of the user. This allows you to create insets in the scrollport to make room for objects that might obscure the content, such as fixed-positioned toolbars or sidebars, or to put more breathing room between a targeted element and the edges of the scrollport.

While defined in the CSS scroll snap module, this property applies to all scroll containers, no matter the value of the `scroll-snap-type` property.

Formal definition

Initial value	as each of the properties of the shorthand: • `scroll-padding-bottom`: `auto` • `scroll-padding-left`: `auto` • `scroll-padding-right`: `auto` • `scroll-padding-top`: `auto`
Applies to	scroll containers
Inherited	no
Percentages	relative to the scroll container's scrollport
Computed value	as each of the properties of the shorthand: • `scroll-padding-bottom`: as specified • `scroll-padding-left`: as specified • `scroll-padding-right`: as specified • `scroll-padding-top`: as specified
Animation type	by computed value type

Formal syntax

```
scroll-padding =
  [ auto | <length-percentage [0,∞]> ]{1,4}

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Preventing content from being hidden by a fixed header

A common use case for `scroll-padding` is to prevent scrolling content from being hidden by a fixed-position header. This example demonstrates how to use `scroll-padding` for this purpose.

HTML

The header contains links to three sections on the page.

```
<header>
  <nav>
    <a href="#section-1">Section 1</a>
    <a href="#section-2">Section 2</a>
    <a href="#section-3">Section 3</a>
  </nav>
</header>
<main>
  <section id="section-1">
    <h2>Section 1</h2>
    <p>Use the links in the header to jump to another section.</p>
  </section>
  <section id="section-2">
    <h2>Section 2</h2>
    <p>This heading remains visible below the fixed header.</p>
  </section>
  <section id="section-3">
    <h2>Section 3</h2>
    <p>This heading also remains visible below the fixed header.</p>
  </section>
</main>
```

CSS

```
header {
  display: flex;
  align-items: center;
  justify-content: center;
  background-color: #eeeeee;
}

nav {
  display: flex;
  gap: 1rem;
}

section {
  box-sizing: border-box;
  padding: 1rem;
  min-height: 60vh;
}

h2 {
  margin-top: 0;
}
```

The header is fixed to the top of the viewport and is `60px` tall. We set `scroll-padding` on the root element to reserve `60px` at the top of the viewport when scrolling to a section, with no offset on the other sides.

```
html {
  --navbar-height: 60px;

  scroll-padding: var(--navbar-height) 0 0;
  scroll-behavior: smooth;
}

header {
  position: fixed;
  top: 0;
  height: var(--navbar-height);
  width: 100%;
}
```

We add padding to the main content so the first section starts below the header on initial load.

```
main {
  padding-top: var(--navbar-height);
}
```

Result

Click the links in the header to jump between sections. Each section appears below the header, keeping its heading visible. Open this example in the playground, remove the `scroll-padding` line, and click the links again to see the header obscure the headings.

scroll-padding-block CSS property

The **`scroll-padding-block`** CSS shorthand property sets the scroll padding of an element in the block dimension.

The scroll-padding properties define offsets for the *optimal viewing region* of the scrollport: the region used as the target region for placing things in view of the user. This allows the author to exclude regions of the scrollport that are obscured by other content (such as fixed-positioned toolbars or sidebars) or to put more breathing room between a targeted element and the edges of the scrollport.

Try it

```
scroll-padding-block: 0;
```

```
scroll-padding-block: 20px;
```

```
scroll-padding-block: 2em;
```

```
<section class="default-example" id="default-example">
  <div class="scroller" id="example-element">
    <div>1</div>
    <div>2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example .info {
  inline-size: 100%;
  padding: 0.5em 0;
  font-size: 90%;
  writing-mode: vertical-rl;
}

.scroller {
  text-align: left;
  height: 250px;
  width: 270px;
  overflow-y: scroll;
  display: flex;
  flex-direction: column;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: y mandatory;
}

.scroller > div {
  flex: 0 0 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: start;
}

.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `scroll-padding-block-end`
- `scroll-padding-block-start`

Syntax

```
/* Keyword value */
scroll-padding-block: auto;

/* <length> values */
scroll-padding-block: 10px;
scroll-padding-block: 1em 0.5em;
scroll-padding-block: 10%;

/* Global values */
scroll-padding-block: inherit;
scroll-padding-block: initial;
scroll-padding-block: revert;
scroll-padding-block: revert-layer;
scroll-padding-block: unset;
```

Values

`<length-percentage>`

An inwards offset from the corresponding edge of the scrollport, as a valid length or a percentage.

`auto`

The offset is determined by the user agent. This will generally be 0px, but a user agent is able to detect and do something else if a non-zero value is more appropriate.

Formal definition

Initial value	as each of the properties of the shorthand: • `scroll-padding-block-start`: `auto` • `scroll-padding-block-end`: `auto`
Applies to	scroll containers
Inherited	no
Percentages	relative to the scroll container's scrollport
Computed value	as each of the properties of the shorthand: • `scroll-padding-block-start`: as specified • `scroll-padding-block-end`: as specified
Animation type	by computed value type

Formal syntax

```
scroll-padding-block =
  [ auto | <length-percentage [0,∞]> ]{1,2}

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

scroll-padding-block-end CSS property

The `scroll-padding-block-end` property defines offsets for the end edge in the block dimension of the *optimal viewing region* of the scrollport: the region used as the target region for placing things in view of the user. This allows the author to exclude regions of the scrollport that are obscured by other content (such as fixed-positioned toolbars or sidebars) or to put more breathing room between a targeted element and the edges of the scrollport.

Try it

```
scroll-padding-block-end: 0;
```

```
scroll-padding-block-end: 20px;
```

```
scroll-padding-block-end: 2em;
```

```
<section class="default-example" id="default-example">
  <div class="scroller" id="example-element">
    <div>1</div>
    <div>2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example .info {
  inline-size: 100%;
  padding: 0.5em 0;
  font-size: 90%;
  writing-mode: vertical-rl;
}

.scroller {
  text-align: left;
  height: 250px;
  width: 270px;
  overflow-y: scroll;
  display: flex;
  flex-direction: column;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: y mandatory;
}

.scroller > div {
  flex: 0 0 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: end;
}

.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Syntax

```
/* Keyword value */
scroll-padding-block-end: auto;

/* <length> values */
scroll-padding-block-end: 10px;
scroll-padding-block-end: 1em;
scroll-padding-block-end: 10%;

/* Global values */
scroll-padding-block-end: inherit;
scroll-padding-block-end: initial;
scroll-padding-block-end: revert;
scroll-padding-block-end: revert-layer;
scroll-padding-block-end: unset;
```

Values

`<length-percentage>`

An inwards offset from the block end edge of the scrollport, as a valid length or a percentage.

`auto`

The offset is determined by the user agent. This will generally be 0px, but a user agent is able to detect and do something else if a non-zero value is more appropriate.

Formal definition

Initial value	`auto`
Applies to	scroll containers
Inherited	no
Percentages	relative to the scroll container's scrollport
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
scroll-padding-block-end =
  auto                      |
  <length-percentage [0,∞]>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

scroll-padding-block-start CSS property

The `scroll-padding-block-start` property defines offsets for the start edge in the block dimension of the *optimal viewing region* of the scrollport: the region used as the target region for placing things in view of the user. This allows the author to exclude regions of the scrollport that are obscured by other content (such as fixed-positioned toolbars or sidebars) or to put more breathing room between a targeted element and the edges of the scrollport.

Try it

```
scroll-padding-block-start: 0;
```

```
scroll-padding-block-start: 20px;
```

```
scroll-padding-block-start: 2em;
```

```
<section class="default-example" id="default-example">
  <div class="scroller" id="example-element">
    <div>1</div>
    <div>2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example .info {
  inline-size: 100%;
  padding: 0.5em 0;
  font-size: 90%;
  writing-mode: vertical-rl;
}

.scroller {
  text-align: left;
  height: 250px;
  width: 270px;
  overflow-y: scroll;
  display: flex;
  flex-direction: column;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: y mandatory;
}

.scroller > div {
  flex: 0 0 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: start;
}

.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Syntax

```
/* Keyword value */
scroll-padding-block-start: auto;

/* <length> values */
scroll-padding-block-start: 10px;
scroll-padding-block-start: 1em;
scroll-padding-block-start: 10%;
```

```
/* Global values */
scroll-padding-block-start: inherit;
scroll-padding-block-start: initial;
scroll-padding-block-start: revert;
scroll-padding-block-start: revert-layer;
scroll-padding-block-start: unset;
```

Values

`<length-percentage>`

An inwards offset from the block start edge of the scrollport, as a valid length or a percentage.

`auto`

The offset is determined by the user agent. This will generally be 0px, but a user agent is able to detect and do something else if a non-zero value is more appropriate.

Formal definition

Initial value	`auto`
Applies to	scroll containers
Inherited	no
Percentages	relative to the scroll container's scrollport
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
scroll-padding-block-start =
  auto                     |
  <length-percentage [0,∞]>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

scroll-padding-bottom CSS property

The `scroll-padding-bottom` property defines offsets for the bottom of the *optimal viewing region* of the scrollport: the region used as the target region for placing things in view of the user. This allows the author to exclude regions of the scrollport that are obscured by other content (such as fixed-positioned toolbars or sidebars) or to put more breathing room between a targeted element and the edges of the scrollport.

Try it

```
scroll-padding-bottom: 0;
```

```
scroll-padding-bottom: 20px;
```

```
scroll-padding-bottom: 2em;
```

```
<section class="default-example" id="default-example">
  <div class="scroller" id="example-element">
    <div>1</div>
    <div>2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example .info {
  inline-size: 100%;
  padding: 0.5em 0;
  font-size: 90%;
  writing-mode: vertical-rl;
}

.scroller {
  text-align: left;
  height: 250px;
  width: 270px;
  overflow-y: scroll;
  display: flex;
  flex-direction: column;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: y mandatory;
}

.scroller > div {
  flex: 0 0 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: end;
}
```

```
.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Syntax

```
/* Keyword value */
scroll-padding-bottom: auto;

/* <length> values */
scroll-padding-bottom: 10px;
scroll-padding-bottom: 1em;
scroll-padding-bottom: 10%;

/* Global values */
scroll-padding-bottom: inherit;
scroll-padding-bottom: initial;
scroll-padding-bottom: revert;
scroll-padding-bottom: revert-layer;
scroll-padding-bottom: unset;
```

Values

`<length-percentage>`

An inwards offset from the bottom edge of the scrollport, as a valid length or a percentage.

`auto`

The offset is determined by the user agent. This will generally be 0px, but a user agent is able to detect and do something else if a non-zero value is more appropriate.

Formal definition

Initial value	`auto`
Applies to	scroll containers
Inherited	no
Percentages	relative to the scroll container's scrollport
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
scroll-padding-bottom =
  auto                     |
  <length-percentage [0,∞]>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

scroll-padding-inline CSS property

The **`scroll-padding-inline`** CSS shorthand property sets the scroll padding of an element in the inline dimension.

The scroll-padding properties define offsets for the *optimal viewing region* of the scrollport: the region used as the target region for placing things in view of the user. This allows the author to exclude regions of the scrollport that are obscured by other content (such as fixed-positioned toolbars or sidebars) or to put more breathing room between a targeted element and the edges of the scrollport.

Try it

```
scroll-padding-inline: 0;
```

```
scroll-padding-inline: 20px;
```

```
scroll-padding-inline: 2em;
```

```
<section class="default-example" id="default-example">
  <div class="scroller" id="example-element">
    <div>1</div>
    <div>2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example {
  flex-wrap: wrap;
}

.default-example .info {
  width: 100%;
  padding: 0.5em 0;
  font-size: 90%;
}

.scroller {
  text-align: left;
```

```
  width: 250px;
  height: 250px;
  overflow-x: scroll;
  display: flex;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: x mandatory;
}

.scroller > div {
  flex: 0 0 250px;
  width: 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: start;
}

.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `scroll-padding-inline-end`
- `scroll-padding-inline-start`

Syntax

```
/* Keyword value */
scroll-padding-inline: auto;

/* <length> values */
scroll-padding-inline: 10px;
scroll-padding-inline: 1em 0.5em;
scroll-padding-inline: 10%;

/* Global values */
scroll-padding-inline: inherit;
scroll-padding-inline: initial;
scroll-padding-inline: revert;
scroll-padding-inline: revert-layer;
scroll-padding-inline: unset;
```

Values

`<length-percentage>`

An inwards offset from the corresponding edge of the scrollport, as a valid length or a percentage.

`auto`

The offset is determined by the user agent. This will generally be 0px, but a user agent is able to detect and do something else if a non-zero value is more appropriate.

Formal definition

Initial value	as each of the properties of the shorthand: • `scroll-padding-inline-start`: `auto` • `scroll-padding-inline-end`: `auto`
Applies to	scroll containers
Inherited	no
Percentages	relative to the scroll container's scrollport
Computed value	as each of the properties of the shorthand: • `scroll-padding-inline-start`: as specified • `scroll-padding-inline-end`: as specified
Animation type	by computed value type

Formal syntax

```
scroll-padding-inline =
  [ auto | <length-percentage [0,∞]> ]{1,2}

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

scroll-padding-inline-end CSS property

The `scroll-padding-inline-end` property defines offsets for the end edge in the inline dimension of the *optimal viewing region* of the scrollport: the region used as the target region for placing things in view of the user. This allows the author to exclude regions of the scrollport that are obscured by other content (such as fixed-positioned toolbars or sidebars) or to put more breathing room between a targeted element

and the edges of the scrollport.

Try it

```
scroll-padding-inline-end: 0;
```

```
scroll-padding-inline-end: 20px;
```

```
scroll-padding-inline-end: 2em;
```

```
<section class="default-example" id="default-example">
  <div class="scroller" id="example-element">
    <div>1</div>
    <div>2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example {
  flex-wrap: wrap;
}

.default-example .info {
  width: 100%;
  padding: 0.5em 0;
  font-size: 90%;
}

.scroller {
  text-align: left;
  width: 250px;
  height: 250px;
  overflow-x: scroll;
  display: flex;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: x mandatory;
}

.scroller > div {
  flex: 0 0 250px;
  width: 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: end;
}

.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Syntax

```
/* Keyword value */
scroll-padding-inline-end: auto;

/* <length> values */
scroll-padding-inline-end: 10px;
scroll-padding-inline-end: 1em;
scroll-padding-inline-end: 10%;

/* Global values */
scroll-padding-inline-end: inherit;
scroll-padding-inline-end: initial;
scroll-padding-inline-end: revert;
scroll-padding-inline-end: revert-layer;
scroll-padding-inline-end: unset;
```

Values

`<length-percentage>`

An inwards offset from the inline end edge of the scrollport, as a valid length or a percentage.

`auto`

The offset is determined by the user agent. This will generally be 0px, but a user agent is able to detect and do something else if a non-zero value is more appropriate.

Formal definition

Initial value	`auto`
Applies to	scroll containers
Inherited	no
Percentages	relative to the scroll container's scrollport
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
scroll-padding-inline-end =
  auto                      |
```

```
  <length-percentage [0,∞]>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

scroll-padding-inline-start CSS property

The `scroll-padding-inline-start` property defines offsets for the start edge in the inline dimension of the *optimal viewing region* of the scrollport: the region used as the target region for placing things in view of the user. This allows the author to exclude regions of the scrollport that are obscured by other content (such as fixed-positioned toolbars or sidebars) or to put more breathing room between a targeted element and the edges of the scrollport.

Try it

```
scroll-padding-inline-start: 0;
```

```
scroll-padding-inline-start: 20px;
```

```
scroll-padding-inline-start: 2em;
```

```
<section class="default-example" id="default-example">
  <div class="scroller" id="example-element">
    <div>1</div>
    <div>2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example {
  flex-wrap: wrap;
}

.default-example .info {
  width: 100%;
  padding: 0.5em 0;
  font-size: 90%;
}

.scroller {
  text-align: left;
  width: 250px;
  height: 250px;
  overflow-x: scroll;
  display: flex;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: x mandatory;
}

.scroller > div {
  flex: 0 0 250px;
  width: 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: start;
}

.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Syntax

```
/* Keyword value */
scroll-padding-inline-start: auto;

/* <length> values */
scroll-padding-inline-start: 10px;
scroll-padding-inline-start: 1em;
scroll-padding-inline-start: 10%;

/* Global values */
scroll-padding-inline-start: inherit;
scroll-padding-inline-start: initial;
scroll-padding-inline-start: revert;
scroll-padding-inline-start: revert-layer;
scroll-padding-inline-start: unset;
```

Values

`<length-percentage>`

An inwards offset from the inline start edge of the scrollport, as a valid length or a percentage.

`auto`

The offset is determined by the user agent. This will generally be 0px, but a user agent is able to detect and do something else if a non-zero value is more appropriate.

Formal definition

Initial value	`auto`
Applies to	scroll containers
Inherited	no
Percentages	relative to the scroll container's scrollport
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
scroll-padding-inline-start =
  auto                      |
  <length-percentage [0,∞]>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

scroll-padding-left CSS property

The `scroll-padding-left` property defines offsets for the left of the *optimal viewing region* of the scrollport: the region used as the target region for placing things in view of the user. This allows the author to exclude regions of the scrollport that are obscured by other content (such as fixed-positioned toolbars or sidebars) or to put more breathing room between a targeted element and the edges of the scrollport.

Try it

```
scroll-padding-left: 0;
```

```
scroll-padding-left: 20px;
```

```
scroll-padding-left: 2em;
```

```
<section class="default-example" id="default-example">
  <div class="scroller" id="example-element">
    <div>1</div>
    <div>2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example {
  flex-wrap: wrap;
}

.default-example .info {
  width: 100%;
  padding: 0.5em 0;
  font-size: 90%;
}

.scroller {
  text-align: left;
  width: 250px;
  height: 250px;
  overflow-x: scroll;
  display: flex;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: x mandatory;
}

.scroller > div {
  flex: 0 0 250px;
  width: 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: start;
}

.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Syntax

```
/* Keyword value */
scroll-padding-left: auto;

/* <length> values */
scroll-padding-left: 10px;
```

```
scroll-padding-left: 1em;
scroll-padding-left: 10%;

/* Global values */
scroll-padding-left: inherit;
scroll-padding-left: initial;
scroll-padding-left: revert;
scroll-padding-left: revert-layer;
scroll-padding-left: unset;
```

Values

`<length-percentage>`

An inwards offset from the left edge of the scrollport, as a valid length or a percentage.

`auto`

The offset is determined by the user agent. This will generally be 0px, but a user agent is able to detect and do something else if a non-zero value is more appropriate.

Formal definition

Initial value	`auto`
Applies to	scroll containers
Inherited	no
Percentages	relative to the scroll container's scrollport
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
scroll-padding-left =
  auto                          |
  <length-percentage [0,∞]>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

scroll-padding-right CSS property

The `scroll-padding-right` property defines offsets for the right of the *optimal viewing region* of the scrollport: the region used as the target region for placing things in view of the user. This allows the author to exclude regions of the scrollport that are obscured by other content (such as fixed-positioned toolbars or sidebars) or to put more breathing room between a targeted element and the edges of the scrollport.

Try it

```
scroll-padding-right: 0;
```

```
scroll-padding-right: 20px;
```

```
scroll-padding-right: 2em;
```

```
<section class="default-example" id="default-example">
  <div class="scroller" id="example-element">
    <div>1</div>
    <div>2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example {
  flex-wrap: wrap;
}

.default-example .info {
  width: 100%;
  padding: 0.5em 0;
  font-size: 90%;
}

.scroller {
  text-align: left;
  width: 250px;
  height: 250px;
  overflow-x: scroll;
  display: flex;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: x mandatory;
}

.scroller > div {
  flex: 0 0 250px;
  width: 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
```

```
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: end;
}

.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Syntax

```
/* Keyword value */
scroll-padding-right: auto;

/* <length> values */
scroll-padding-right: 10px;
scroll-padding-right: 1em;
scroll-padding-right: 10%;

/* Global values */
scroll-padding-right: inherit;
scroll-padding-right: initial;
scroll-padding-right: revert;
scroll-padding-right: revert-layer;
scroll-padding-right: unset;
```

Values

`<length-percentage>`

An inwards offset from the right edge of the scrollport, as a valid length or a percentage.

`auto`

The offset is determined by the user agent. This will generally be 0px, but a user agent is able to detect and do something else if a non-zero value is more appropriate.

Formal definition

Initial value	`auto`
Applies to	scroll containers
Inherited	no
Percentages	relative to the scroll container's scrollport
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
scroll-padding-right =
  auto                          |
  <length-percentage [0,∞]>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

scroll-padding-top CSS property

The **`scroll-padding-top`** property defines offsets for the top of the *optimal viewing region* of the scrollport: the region used as the target region for placing things in view of the user. This allows the author to exclude regions of the scrollport that are obscured by other content (such as fixed-positioned toolbars or sidebars) or to put more breathing room between a targeted element and the edges of the scrollport.

Try it

```
scroll-padding-top: 0;
```

```
scroll-padding-top: 20px;
```

```
scroll-padding-top: 2em;
```

```
<section class="default-example" id="default-example">
  <div class="scroller" id="example-element">
    <div>1</div>
    <div>2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example .info {
  inline-size: 100%;
  padding: 0.5em 0;
  font-size: 90%;
  writing-mode: vertical-rl;
}

.scroller {
  text-align: left;
```

```
  height: 250px;
  width: 270px;
  overflow-y: scroll;
  display: flex;
  flex-direction: column;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: y mandatory;
}

.scroller > div {
  flex: 0 0 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: start;
}

.scroller > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Syntax

```
/* Keyword value */
scroll-padding-top: auto;

/* <length> values */
scroll-padding-top: 10px;
scroll-padding-top: 1em;
scroll-padding-top: 10%;

/* Global values */
scroll-padding-top: inherit;
scroll-padding-top: initial;
scroll-padding-top: revert;
scroll-padding-top: revert-layer;
scroll-padding-top: unset;
```

Values

`<length-percentage>`

An inwards offset from the top edge of the scrollport, as a valid length or a percentage.

`auto`

The offset is determined by the user agent. This will generally be 0px, but a user agent is able to detect and do something else if a non-zero value is more appropriate.

Formal definition

Initial value	`auto`
Applies to	scroll containers
Inherited	no
Percentages	relative to the scroll container's scrollport
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
scroll-padding-top =
  auto                  |
  <length-percentage [0,∞]>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

scroll-snap-align CSS property

The **`scroll-snap-align`** CSS property specifies the box's snap position as an alignment of its snap area.

Try it

```
scroll-snap-align: start;
```

```
scroll-snap-align: end;
```

```
scroll-snap-align: center;
```

```
<section class="default-example" id="default-example">
  <div id="example-parent">
    <div>1</div>
    <div id="example-element">2</div>
    <div>3</div>
```

```
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example {
  flex-wrap: wrap;
}

.default-example .info {
  width: 100%;
  padding: 0.5em 0;
  font-size: 90%;
}

#example-parent {
  text-align: left;
  width: 250px;
  height: 250px;
  overflow-x: scroll;
  display: flex;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: x mandatory;
}

#example-parent > div {
  flex: 0 0 66%;
  width: 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
}

#example-parent > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Syntax

```
/* Single keyword value */
scroll-snap-align: none;
scroll-snap-align: center;
scroll-snap-align: start;
scroll-snap-align: end;

/* Two keyword values */
scroll-snap-align: start end;
scroll-snap-align: end center;
scroll-snap-align: center start;

/* Global values */
scroll-snap-align: inherit;
scroll-snap-align: initial;
scroll-snap-align: revert;
scroll-snap-align: revert-layer;
scroll-snap-align: unset;
```

Values

This property is specified as one or two of the following keyword values, space-separated:

`none`

The box does not define a snap position in that axis.

`start`

The start alignment of this box's scroll snap area, within the scroll container's snapport is a snap position in this axis.

`end`

The end alignment of this box's scroll snap area, within the scroll container's snapport is a snap position in this axis.

`center`

The center alignment of this box's scroll snap area, within the scroll container's snapport is a snap position in this axis.

Description

The `scroll-snap-align` property specifies the box's snap position as an alignment of its snap area (as the alignment subject) within its snap container's snap port (as the alignment container).

One or two values can be specified for the `scroll-snap-align` property. If one value is set, it is applied to both the block and inline axes. If two values are set, the first value controls the block axis and the second value controls the inline axis.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
scroll-snap-align =
  [ none | start | end | center ]{1,2}
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

- Well-controlled scrolling with CSS scroll snap on web.dev (2018)

scroll-snap-stop CSS property

The **`scroll-snap-stop`** CSS property defines whether or not the scroll container is allowed to "pass over" possible snap positions.

Try it

```
scroll-snap-stop: normal;
```

```
scroll-snap-stop: always;
```

```
<section class="default-example" id="default-example">
  <p class="explanation">
    The effect of this property can be noticed on devices with a touchpad. Try
    to scroll through all items with a single swing. Value
    <b class="keyword">'normal'</b> should pass through all pages, while
    <b class="keyword">'always'</b> will stop at the second page.
  </p>
  <div class="snap-container">
    <div>1</div>
    <div id="example-element">2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example {
  flex-direction: column;
}

.explanation {
  margin-top: 0;
}

.keyword {
  color: darkorange;
}

.default-example .info {
  width: 100%;
  padding: 0.5em 0;
  font-size: 90%;
}

.snap-container {
  text-align: left;
  width: 250px;
  height: 250px;
  overflow-x: scroll;
  display: flex;
  box-sizing: border-box;
  border: 1px solid black;
  scroll-snap-type: x mandatory;
}

.snap-container > div {
  flex: 0 0 250px;
  width: 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: start;
}

.snap-container > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

Syntax

```
/* Keyword values */
scroll-snap-stop: normal;
scroll-snap-stop: always;

/* Global values */
scroll-snap-stop: inherit;
scroll-snap-stop: initial;
scroll-snap-stop: revert;
scroll-snap-stop: revert-layer;
scroll-snap-stop: unset;
```

Values

This property is specified as one of the following keyword values:

`normal`

When the visual viewport of this element's scroll container is scrolled, it may "pass over" possible snap positions.

`always`

The scroll container must not "pass over" a possible snap position; and must snap to the first of this elements' snap positions.

Formal definition

Initial value	`normal`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
scroll-snap-stop =
  normal  |
  always
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting different snap stops

The example below demonstrates the contrast between the `always` and `normal` values of `scroll-snap-stop`. The difference in the two `scroll-snap-stop` values is more noticeable when the `scroll-snap-type` property is set to `mandatory`, which is what is used in this example.

HTML

```
<p>scroll-snap-stop: always (X Mandatory)</p>
<div class="x mandatory-scroll-snapping always-stop">
  <div>1</div>
  <div>2</div>
  <div>3</div>
  <div>4</div>
  <div>5</div>
</div>

<p>scroll-snap-stop: always (X Mandatory) on odd child elements</p>
<div class="x mandatory-scroll-snapping always-stop-odd">
  <div>1</div>
  <div>2</div>
  <div>3</div>
  <div>4</div>
  <div>5</div>
</div>

<p>scroll-snap-stop: always (X Mandatory) on even child elements</p>
<div class="x mandatory-scroll-snapping always-stop-even">
  <div>1</div>
  <div>2</div>
  <div>3</div>
  <div>4</div>
  <div>5</div>
</div>

<p>scroll-snap-stop: normal (X Mandatory)</p>
<div class="x mandatory-scroll-snapping normal-stop">
  <div>1</div>
  <div>2</div>
  <div>3</div>
  <div>4</div>
  <div>5</div>
</div>

<p>scroll-snap-stop: always (Y Mandatory)</p>
<div class="y mandatory-scroll-snapping always-stop">
  <div>1</div>
  <div>2</div>
  <div>3</div>
  <div>4</div>
  <div>5</div>
</div>

<p>scroll-snap-stop: normal (Y Mandatory)</p>
<div class="y mandatory-scroll-snapping normal-stop">
  <div>1</div>
  <div>2</div>
  <div>3</div>
  <div>4</div>
  <div>5</div>
</div>
```

CSS

```
/* setup */
body {
  height: 100%;
  display: flex;
  align-items: center;
  justify-content: space-between;
  flex-flow: column nowrap;
```

```
  font-family: monospace;
  text-align: center;
}

div[class] {
  font-size: 3rem;
  display: flex;
  overflow: auto;
  flex: none;
}

.x {
  width: 50%;
  min-width: 15rem;
  height: 6rem;
  flex-flow: row nowrap;
}

.y {
  width: 30%;
  min-width: 12rem;
  height: 12rem;
  flex-flow: column nowrap;
}

div > div {
  flex: none;
  outline: 1px solid #333333;
}

.x > div {
  width: 90%;
  height: 100%;
}

.y > div {
  width: 100%;
  height: 80%;
}

/* coloration */
div > div:nth-child(even) {
  background-color: #87ea87;
}

div > div:nth-child(odd) {
  background-color: #87ccea;
}
```

```
/* setting up mandatory scroll-snap on parent */
.x.mandatory-scroll-snapping {
  scroll-snap-type: x mandatory;
}

.y.mandatory-scroll-snapping {
  scroll-snap-type: y mandatory;
}

/* defining scroll-snap alignment on children */
div > div {
  scroll-snap-align: center;
}

/* defining scroll-snap stop on children */
.always-stop > div {
  scroll-snap-stop: always;
}

.always-stop-odd > div:nth-of-type(odd) {
  scroll-snap-stop: always;
}

.always-stop-even > div:nth-of-type(even) {
  scroll-snap-stop: always;
}

.normal-stop > div {
  scroll-snap-stop: normal;
}
```

Result

Scroll from left to right and from top to bottom in the X and Y boxes below, respectively. In the X and Y boxes where the `scroll-snap-stop` property is set to `always`, the scrolling is forced to stop at the snap point even when you scroll fast. However, in the boxes where the `scroll-snap-stop` property is set to `normal`, the snap points are skipped when you scroll fast.

If required, you can be selective about the items that are `always` stopped at inside the scroll container. This is demonstrated in the example below by targeting odd and even items; you can choose a different strategy based on your requirement. In the example below, scrolling does not "pass over" odd and even items in the second and third boxes, respectively.

scroll-snap-type CSS property

The **`scroll-snap-type`** CSS property is set on a scroll container, opting it into scroll snapping by setting the direction and strictness of snap point enforcement within the snap port.

Try it

```
scroll-snap-type: none;
```

```
scroll-snap-type: x mandatory;
```

```
scroll-snap-type: x proximity;
```

```
<section class="default-example" id="default-example">
  <div id="example-element">
    <div>1</div>
    <div>2</div>
    <div>3</div>
  </div>
  <div class="info">Scroll »</div>
</section>
```

```
.default-example {
  flex-wrap: wrap;
}

.default-example .info {
  width: 100%;
  padding: 0.5em 0;
  font-size: 90%;
}

#example-element {
  text-align: left;
  width: 250px;
  height: 250px;
  overflow-x: scroll;
  display: flex;
  box-sizing: border-box;
  border: 1px solid black;
}

#example-element > div {
  flex: 0 0 250px;
  width: 250px;
  background-color: rebeccapurple;
  color: white;
  font-size: 30px;
  display: flex;
  align-items: center;
  justify-content: center;
  scroll-snap-align: start;
}

#example-element > div:nth-child(even) {
  background-color: white;
  color: rebeccapurple;
}
```

If the content in the scroll port changes — for example, if content is added, moved, deleted, or resized — the scroll container will re-snap to the previously snapped content if that content is still present.

If the value of a scroll snap-related property, such as `scroll-snap-type` or `scroll-margin`, is changed, the scroll container will re-snap based on the current value of `scroll-snap-type`.

Specifying any precise animations or physics used to enforce those snap points is not covered by this property but instead left up to the user agent.

Syntax

```
/* No snapping */
scroll-snap-type: none;

/* Keyword values for snap axes */
scroll-snap-type: x;
scroll-snap-type: y;
scroll-snap-type: block;
scroll-snap-type: inline;
scroll-snap-type: both;

/* Optional keyword values for snap strictness */
/* mandatory | proximity */
scroll-snap-type: x mandatory;
scroll-snap-type: y proximity;
scroll-snap-type: both mandatory;

/* Global values */
scroll-snap-type: inherit;
scroll-snap-type: initial;
scroll-snap-type: revert;
scroll-snap-type: revert-layer;
scroll-snap-type: unset;
```

Values

This property is specified as one or two of the following keyword values:

`none`

When the visual viewport of this scroll container is scrolled, it must ignore snap points.

`x`

The scroll container snaps to snap positions in its horizontal axis only.

`y`

The scroll container snaps to snap positions in its vertical axis only.

`block`

The scroll container snaps to snap positions in its block axis only.

`inline`

The scroll container snaps to snap positions in its inline axis only.

`both`

The scroll container snaps to snap positions in both of its axes independently (potentially snapping to different elements in each axis).

`mandatory`

The visual viewport of this scroll container must snap to a snap position if it isn't currently scrolled.

`proximity`

The visual viewport of this scroll container may snap to a snap position if it isn't currently scrolled. The user agent decides if it snaps or not based on scroll parameters. This is the default snap strictness if any snap axis is specified.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
scroll-snap-type =
  none                                          |
  [ x | y | block | inline | both | pair ] [ mandatory | proximity ]?
```

This syntax reflects the latest standard as per CSS Scroll Snap Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Snapping in different axes

HTML

```
<main>
  <section class="x mandatory-scroll-snapping" dir="ltr">
    <div>X Mand. LTR</div>
    <div>2</div>
    <div>3</div>
    <div>4</div>
    <div>5</div>
  </section>
  <section class="x proximity-scroll-snapping" dir="ltr">
    <div>X Prox. LTR</div>
    <div>2</div>
    <div>3</div>
    <div>4</div>
    <div>5</div>
  </section>

scroll-target-group CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`scroll-target-group`** CSS property specifies whether an element is a scroll marker group container.

Syntax

```
/* Keyword values */
scroll-target-group: none;
scroll-target-group: auto;

/* Global values */
scroll-target-group: inherit;
scroll-target-group: initial;
scroll-target-group: revert;
scroll-target-group: revert-layer;
scroll-target-group: unset;
```

The `scroll-target-group` property is specified as one of the following keyword values:

Values

`none`

The element is not a scroll marker group container.

`auto`

The element is a scroll marker group container.

Description

Setting `scroll-target-group: auto` on an element denotes it as a **scroll marker group container**. This groups together a set of navigation items that allow users to navigate between elements on a page (such as carousel items or article sections) and highlight which element is currently in view.

Any `<a>` elements with fragment identifiers inside the container are automatically set as scroll markers. The anchor element whose scroll target is currently in view can be styled via the `:target-current` pseudo-class.

Differences between <code>scroll-target-group</code> and <code>scroll-marker-group</code>

Scroll marker group containers created using `scroll-target-group` behave in a very similar way to those created using the `scroll-marker-group` property, with some differences:

- With `scroll-target-group`, you have to create your own markup to represent the scroll marker group container and scroll markers, whereas `scroll-marker-group` automatically creates a set of pseudo-elements to represent the container (`::scroll-marker-group`) and the markers (one or more instances of `::scroll-marker`). These automatically have the expected navigation associations with the scroll container they are generated on. Using `scroll-marker-group` provides a quicker setup because you don't need to use your own markup. However, creating your own markup and setting it as a scroll marker group container via `scroll-target-group` provides more control and flexibility.
- Links denoted as scroll markers via `scroll-target-group` have no special navigation behavior, whereas markers generated via `scroll-marker-group` automatically have `tablist`/`tab` semantics applied to them, meaning they behave like a single item in the tab order, and users can move between scroll markers with the arrow keys. Again, `scroll-marker-group` provides useful default behavior, but you have the flexibility of providing alternative semantics and behavior for markers specified using `scroll-target-group`.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
scroll-target-group =
  none  |
  auto
```

This syntax reflects the latest standard as per CSS Overflow Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic <code>scroll-target-group</code> usage

This example shows a page with a table of contents linking to different sections.

HTML

Our markup has a series of `<section>` elements containing content, and a table of contents created using an ordered list (`<ol>`/`<li>`) and `<a>` elements.

```
<nav id="toc">
  <ol>
    <li><a href="#intro">Introduction</a></li>
    <li><a href="#ch1">Chapter 1</a></li>
    <li><a href="#ch2">Chapter 2</a></li>
    <li><a href="#ch3">Chapter 3</a></li>
    <li><a href="#ch4">Chapter 4</a></li>
  </ol>
</nav>
<section id="intro" class="chapter">
  <h1>Prose of the century</h1>
  <p>
    Lorem ipsum dolor sit amet, consectetur adipiscing elit. Nulla luctus
    aliquam dolor, eu lacinia lorem placerat vulputate. Duis felis orci,
    pulvinar id metus ut, rutrum luctus orci. Cras porttitor imperdiet nunc, at
    ultricies tellus laoreet sit amet.
  </p>
</section>
<section id="ch1" class="chapter">
  <h2>Chapter 1</h2>

  <!-- ... -->
</section>
<section id="ch2" class="chapter">
  <h2>Chapter 2</h2>

  <!-- ... -->
```

```
</section>

<!-- ... -->
```

```
<nav id="toc">
  <ol>
    <li><a href="#intro">Introduction</a></li>
    <li><a href="#ch1">Chapter 1</a></li>
    <li><a href="#ch2">Chapter 2</a></li>
    <li><a href="#ch3">Chapter 3</a></li>
    <li><a href="#ch4">Chapter 4</a></li>
  </ol>
</nav>
<section id="intro" class="chapter">
  <h1>My story</h1>
  <p>
    Lorem ipsum dolor sit amet, consectetur adipiscing elit. Nulla luctus
    aliquam dolor, eu lacinia lorem placerat vulputate. Duis felis orci,
    pulvinar id metus ut, rutrum luctus orci. Cras porttitor imperdiet nunc, at
    ultricies tellus laoreet sit amet.
  </p>
</section>
<section id="ch1" class="chapter">
  <h2>Chapter 1</h2>
  <p>
    Lorem ipsum dolor sit amet, consectetur adipiscing elit. Nulla luctus
    aliquam dolor, eu lacinia lorem placerat vulputate. Duis felis orci,
    pulvinar id metus ut, rutrum luctus orci. Cras porttitor imperdiet nunc, at
    ultricies tellus laoreet sit amet.

    varius commodo et a urna. Ut id ornare felis, eget fermentum sapien.
  </p>
</section>
```

CSS

We've hidden most of the styling for brevity. Most pertinent to this example, we've set `scroll-target-group: auto` on the `<ol>` to turn it into a scroll marker group container and trigger the browser's algorithm for calculating which `<a>` element is the `:target-current` at any given time (that is, which link's target is currently in view). We then style the `:target-current` pseudo-class with a `red` `color` so that it stands out clearly.

```
body {
  font: 1.2em / 1.5 system-ui;
  width: 50%;
  max-width: 700px;
  margin: 0 auto;
}

nav {
  position: fixed;
  top: 0;
  left: 0;
  right: 0;
  display: flex;
  justify-content: center;
}

section {
  padding-top: 60px;
}

a {
  color: black;
  text-decoration: none;
}

a:hover,
a:focus {
  text-decoration: underline;
}

ol {
  display: flex;
  width: 100%;
  justify-content: space-around;
  list-style-type: none;
  padding: 20px 0;
  margin: 0;
  background: white;
}
```

```
ol {
  scroll-target-group: auto;
}

:target-current {
  color: red;
}
```

Result

Try navigating by activating the links and by scrolling. You'll see that in each case, the red highlight moves between the links to match the section currently being shown.

CSS carousel with <code>scroll-target-group</code> scroll markers

This example shows how to create CSS carousel scroll markers using `scroll-target-group`. The code for this example is similar to our Carousel with single pages example; we'll just explain the differences below.

HTML

The markup has IDs set on the list items that define each page, and an ordered list added that we'll turn into a scroll marker group container using CSS.

```
<h1>CSS carousel single item per page</h1>
<ul>
  <li id="page1">
    <h2>Page 1</h2>
  </li>
  <li id="page2">
    <h2>Page 2</h2>
  </li>
  <li id="page3">
    <h2>Page 3</h2>
  </li>
  <li id="page4">
    <h2>Page 4</h2>
  </li>
</ul>
<ol>
  <li><a href="#page1">1</a></li>
  <li><a href="#page2">2</a></li>
  <li><a href="#page3">3</a></li>
  <li><a href="#page4">4</a></li>
</ol>
```

CSS

We create the scroll marker group container and scroll markers by setting `scroll-target-group` on the `<ol>` element. The rest of the code for styling these is very similar, except that we are targeting elements of our own choosing (`<ol>` and `<a>`) rather than the `::scroll-marker-group` and `::scroll-marker` pseudo-elements.

We complete the code by setting some styles on the `:target-current`, `a:hover`, and `a:focus` states to indicate which page is currently being shown and which links are being hovered/focused.

```
/* General styles */

* {
  box-sizing: border-box;
}
```

```css
body {
  margin: 0;
  font-family: "Helvetica", "Arial", sans-serif;
}

h1 {
  text-align: center;
}

button {
  background-color: white;
}

/* General styling of list as scrolling carousel */

ul {
  width: 100%;
  height: 400px;
  padding: 20px;
  gap: 4%;
  display: grid;
  grid-auto-flow: column;
  grid-auto-columns: 100%;
  overflow-x: scroll;
  scroll-snap-type: x mandatory;
}

ul li {
  list-style-type: none;
  background-color: #eeeeee;
  border: 1px solid #dddddd;
  padding: 20px;

  scroll-snap-align: center;
}

/* CSS scroll buttons */

/* Style the scroll buttons */

ul::scroll-button(*) {
  border: 0;
  font-size: 2rem;
  background: none;
  color: rgb(0 0 0 / 0.7);
  cursor: pointer;
}

ul::scroll-button(*):hover,
ul::scroll-button(*):focus {
  color: black;
}

ul::scroll-button(*):active {
  translate: 1px 1px;
}

ul::scroll-button(*):disabled {
  color: rgb(0 0 0 / 0.2);
}

ul::scroll-button(left) {
  content: "◄";
}

ul::scroll-button(right) {
  content: "►";
}

/* Position the scroll buttons */

ul {
  anchor-name: --my-carousel;
}

ul::scroll-button(*) {
  position: absolute;
  position-anchor: --my-carousel;
}

ul::scroll-button(left) {
  right: calc(anchor(left) - 70px);
  top: calc(anchor(bottom) - 80px);
}

ul::scroll-button(right) {
  left: calc(anchor(right) - 70px);
  top: calc(anchor(bottom) - 80px);
}
```

```css
ol {
  position: absolute;
  position-anchor: --my-carousel;
  top: calc(anchor(bottom) - 90px);
  justify-self: anchor-center;
  display: flex;
  justify-content: center;
  gap: 20px;

  list-style-type: none;
  padding: 0;
  scroll-target-group: auto;
}
```

```
ol a {
  width: 28px;
  height: 28px;
  display: inline-block;
  text-align: center;
  text-decoration: none;
  padding-top: 4px;
  color: black;
  background-color: transparent;
  border: 2px solid black;
  border-radius: 50%;
}

ol a:hover,
ol a:focus,
:target-current {
  background-color: black;
  color: white;
}
```

Result

Try navigating in each of these three ways: by activating the scroll marker links, by horizontal scrolling, or by pressing the scroll buttons on either side. You'll see that in each case, the highlight moves between the links to match the section currently being shown.

scroll-timeline CSS property

The **`scroll-timeline`** CSS shorthand property is used to define a named scroll progress timeline, which is progressed through by scrolling a scrollable element (*scroller*) between top and bottom (or left and right).

Constituent properties

This property is a shorthand for the following CSS properties, in order:

- `scroll-timeline-name`
- `scroll-timeline-axis`

Syntax

```
/* One value */
scroll-timeline: none;
scroll-timeline: --custom_name_for_timeline;

/* Two values */
scroll-timeline: --custom_name_for_timeline block;
scroll-timeline: --custom_name_for_timeline x;
scroll-timeline: none inline;
scroll-timeline: none y;

/* Global values */
scroll-timeline: inherit;
scroll-timeline: initial;
scroll-timeline: revert;
scroll-timeline: revert-layer;
scroll-timeline: unset;
```

Values

`<scroll-timeline-name>`

A `<dashed-ident>` or the keyword `none`.

`<scroll-timeline-axis>`

An `<axis>` keyword. The default value is `block`.

Description

The `scroll-timeline` shorthand property can be applied to a container element to set both the `scroll-timeline-name` and `scroll-timeline-axis` properties. It is set on the scroller that will provide the timeline. If the container has no overflow to scroll or if the overflow is hidden or clipped, no timeline will be created.

The value for the `scroll-timeline-name`, if not set to `none`, must be a `<dashed-ident>`, which means it must start with `--`. This helps avoid name clashes with standard CSS keywords. The name can then be used as the value of an element's `animation-timeline` property to define the scrolling container element that will define its animation timeline, driving the animation progress as it scrolls.

The optional scroll `<axis>` value defines the `scroll-timeline-axis`, which defaults to `block` if omitted. If both a name and axis are specified, the order must be the `<scroll-timeline-name>` value followed by the `<axis>` value. If the `<axis>` is listed first, the declaration is invalid and will be ignored.

Formal definition

Initial value	as each of the properties of the shorthand: • `scroll-timeline-name`: `none` • `scroll-timeline-axis`: `block`
Applies to	scroll containers
Inherited	no

Computed value	as each of the properties of the shorthand: • `scroll-timeline-name`: `none` or an ordered list of identifiers • `scroll-timeline-axis`: as specified
Animation type	as each of the properties of the shorthand: • `scroll-timeline-name`: Not animatable • `scroll-timeline-axis`: Not animatable

Formal syntax

```
scroll-timeline =
  [ <'scroll-timeline-name'> <'scroll-timeline-axis'>? ]#

<scroll-timeline-name> =
  [ none | <dashed-ident> ]#

<scroll-timeline-axis> =
  [ block | inline | x | y ]#
```

This syntax reflects the latest standard as per Scroll-driven Animations. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Creating a named scroll progress timeline animation

In this example, a scroll timeline named `--square-timeline` is defined using the `scroll-timeline-name` property on the `#container` element. The timeline name is then applied to the animation on the `#square` element using `animation-timeline: --square-timeline`.

HTML

We include a container with two child `<div>` elements.

```
<div id="container">
  <div id="square"></div>
  <div id="stretcher"></div>
</div>
```

CSS

We set the container to `300px` tall to make it scroll vertically.

Using the `scroll-timeline` property, we define the container as the source of a scroll timeline named `--square-timeline`, explicitly setting the default vertical scrollbar as the timeline controller.

```
#container {
  height: 300px;
  overflow-y: scroll;

  scroll-timeline: --square-timeline y;
  /* Firefox supports the non-standard vertical/horizontal syntax */
  scroll-timeline: --square-timeline vertical;

  position: relative;
}
```

We provide basic styles for the square. We apply the `rotateAnimation` using the `animation-name` property. By default, this would use the time-based document timeline. By setting the `animation-timeline` property to the `--square-timeline` timeline named above, we set the square to rotate according to the scroll-based timeline, which progresses as the container scrolls.

```
#square {
  background-color: deeppink;
  width: 100px;
  height: 100px;
  position: absolute;
  bottom: 0;

  animation: rotateAnimation 1ms linear;
  animation-timeline: --square-timeline;
}
```

We ensure the container overflows by defining a stretcher that is wider than its parent. Without content that overflows the container, there would be no scrollbar, and hence no scroll timeline. We also define a CSS keyframe animation that rotates the elements on which it is applied by one full rotation.

```
#stretcher {
  height: 600px;
  background: #dedede;
}

@keyframes rotateAnimation {
  from {
    transform: rotate(0deg);
  }

  to {
    transform: rotate(360deg);
  }
}
```

```
@layer no-support {
  @supports not (scroll-timeline: --square-timeline) {
    body::before {
      content: "Your browser doesn't support the `scroll-timeline` property.";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
```

```
  }
}
```

Result

Scroll the vertical bar to see the square animate as you scroll.

The square animates as you scroll. When using `scroll-timeline`, the duration of the animation depends on how fast you scroll, not the value of the `animation-duration` property.

scroll-timeline-axis CSS property

The **`scroll-timeline-axis`** CSS property is used to specify the scrollbar direction that will be used to provide the timeline for a scroll driven animation, which is progressed through by scrolling a scrollable element (*scroller*).

Syntax

```
/* Logical property values */
scroll-timeline-axis: block;
scroll-timeline-axis: inline;

/* Physical property values */
scroll-timeline-axis: y;
scroll-timeline-axis: x;

/* Global values */
scroll-timeline-axis: inherit;
scroll-timeline-axis: initial;
scroll-timeline-axis: revert;
scroll-timeline-axis: revert-layer;
scroll-timeline-axis: unset;
```

Values

`<axis>`

> An `<axis>` keyword value describing the direction, or axis, of the scrollport that controls the scroll-driven animation. The default value is `block`.

Description

The `scroll-timeline-axis` property specifies which scrollbar will be used to provide the timeline for a scroll progress timeline animation. The value is the `<axis>` of the scrollbar. The `scroll-timeline` property is set on the scroller that will provide the timeline.

If the scroller element does not overflow its container in the axis dimension or if the overflow is hidden or clipped, no scroll progress timeline will be created.

The `scroll-timeline-axis` and `scroll-timeline-name` properties can also be set using the `scroll-timeline` shorthand property.

Formal definition

Initial value	`block`
Applies to	scroll containers
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
scroll-timeline-axis =
  [ block | inline | x | y ]#
```

This syntax reflects the latest standard as per Scroll-driven Animations. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Defining the axis of the scroll progress timeline

In this example, a scroll progress timeline named `--my-scroller` is defined using the `scroll-timeline-name` property on the `:root` element (`<html>`). This timeline is then applied to the animation on the element with the `animation` class using `animation-timeline: --my-scroller`.

To demonstrate the effect of `scroll-timeline-axis`, a horizontal (non-default) scrollbar is used in this example to drive the animation.

HTML

The HTML for the example is shown below.

```
<body>
  <div class="content"></div>
  <div class="box animation"></div>
</body>
```

CSS

The CSS for the container sets the `:root` as the source of a scroll progress timeline named `--my-scroller` using the `scroll-timeline-name` property. The scroll axis is set using `scroll-timeline-axis: x;` which causes the *horizontal scrollbar* position to determine the animation timeline. We also include `scroll-timeline-axis: horizontal;` for browsers that support the non-standard legacy `horizontal` and `vertical` values and not `x` and `y`.

The width of the `.content` element is set to a large value to make it overflow the `:root` element.

The `.animation` element has the animation applied to it using the `animation` shorthand, and the scroll timeline set using the `animation-timeline`.

```
:root {
  scroll-timeline-name: --my-scroller;

  scroll-timeline-axis: x;
  scroll-timeline-axis: horizontal;
}

body {
  margin: 0;
  overflow-y: hidden;
}

.content {
  height: 100vh;
  width: 2000px;
}

.box {
  width: 100px;
  height: 100px;
  border-radius: 10px;
  background-color: rebeccapurple;
  position: fixed;
  top: 25px;
  left: 25px;
}

.animation {
  animation: rotate-appear 1ms linear;
  animation-timeline: --my-scroller;
}

@keyframes rotate-appear {
  from {
    rotate: 0deg;
    top: 0%;
  }

  to {
    rotate: 720deg;
    top: 100%;
  }
}
```

```
@layer no-support {
  @supports not (scroll-timeline-axis: block) {
    body::before {
      content: "Your browser doesn't support the `scroll-timeline-axis` property.";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

Result

Scroll the horizontal bar at the bottom to see the square animate as you scroll.

- `scroll-timeline-name`
- Scroll-driven animation timelines
- CSS scroll-driven animations module

scroll-timeline-name CSS property

The **`scroll-timeline-name`** CSS property is used to define the name of a named scroll progress timeline.

Syntax

```
/* Keyword value */
scroll-timeline-name: none;

/* Named timeline */
scroll-timeline-name: --custom_name_for_timeline;

/* Global values */
scroll-timeline-name: inherit;
scroll-timeline-name: initial;
scroll-timeline-name: revert;
scroll-timeline-name: revert-layer;
scroll-timeline-name: unset;
```

Values

This property is specified as one of the following values:

`none`

The timeline has no name.

`<dashed-ident>`

An arbitrary custom identifier defining a name for a scroll progress timeline, which can then be referenced in an `animation-timeline` property.

Description

The `scroll-timeline-name` property is used to define the name of a *named scroll progress timeline*, which is progressed through by scrolling a scrollable element (*scroller*) between top and bottom (or left and right).

Set the `scroll-timeline-name` property on the scroller that provides the timeline. The name is then referenced in an `animation-timeline` declaration to indicate the container's element that is used to drive the progress of the animation through the scrolling action.

If the element does not overflow its container in the axis dimension or if the overflow is hidden or clipped, no timeline will be created.

The `scroll-timeline-name`, along with the `scroll-timeline-axis` property, can also be set using the `scroll-timeline` shorthand.

Formal definition

Initial value	none
Applies to	scroll containers
Inherited	no
Computed value	`none` or an ordered list of identifiers
Animation type	Not animatable

Formal syntax

```
scroll-timeline-name =
  [ none | <dashed-ident> ]#
```

This syntax reflects the latest standard as per Scroll-driven Animations. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Creating a named scroll progress timeline animation

In this example, a scroll timeline named `--square-timeline` is defined using the `scroll-timeline-name` property on the element with the ID `container`. This is then applied to the animation on the `#square` element using `animation-timeline: --square-timeline`.

HTML

The HTML for the example is shown below.

```
<div id="container">
  <div id="square"></div>
  <div id="stretcher"></div>
</div>
```

CSS

The CSS for the container sets it as the source of a scroll timeline named `--square-timeline` using the `scroll-timeline-name` property. No scrollbar axis is defined here because the vertical axis will be used by default.

The height of the container is set to `300px`, and the container is also set to create a vertical scrollbar if it overflows (the CSS `height` rule on the `stretcher` element below does make the content overflow its container).

```
#container {
  height: 300px;
  overflow-y: scroll;
  scroll-timeline-name: --square-timeline;
  position: relative;
}
```

The CSS below defines a square that rotates according to the timeline provided by the `animation-timeline` property, which is set to the `--square-timeline` timeline named above.

```
#square {
  background-color: deeppink;
  width: 100px;
  height: 100px;
  margin-top: 100px;
  animation-name: rotateAnimation;
  animation-duration: 1ms; /* Firefox requires this to apply the animation */
  animation-timeline: --square-timeline;
  position: absolute;
  bottom: 0;
}

#stretcher {
  height: 600px;
  background: #dedede;
}

@keyframes rotateAnimation {
  from {
    transform: rotate(0deg);
  }

  to {
    transform: rotate(360deg);
  }
}
```

The `stretcher` CSS rule sets the block height to `600px`, which creates content that overflows the container element, thereby creating scroll bars. Without this element, the content would not overflow the container, there would be no scrollbar, and hence no scroll timeline to associate with the animation timeline.

Result

Scroll the vertical bar to see the square animate as you scroll.

- `timeline-scope`
- Scroll-driven animation timelines
- CSS scroll-driven animations

scrollbar-color CSS property

The **`scrollbar-color`** CSS property sets the color of the scrollbar track and thumb.

The **track** refers to the background of the scrollbar, which is generally fixed regardless of the scrolling position.

The **thumb** refers to the moving part of the scrollbar, which usually floats on top of the track.

When `scrollbar-color` value is set on the document's root element, the values are applied to the viewport scrollbars.

> **Note:** Browsers ignore the non-standard `::-webkit-scrollbar` family of pseudo-elements on any element whose *computed* `scrollbar-color` value is anything other than `auto`. Because `scrollbar-color` is inherited, this includes elements that don't set it themselves but inherit a non-`auto` value from an ancestor. Setting `scrollbar-color: auto` on such an element restores its `::-webkit-scrollbar-*` styling if it was previously removed by a `scrollbar-color` setting on an ancestor. See Adding a fallback for scrollbar styles.

Syntax

```
/* Keyword value */
scrollbar-color: auto;

/* <color> values */
scrollbar-color: rebeccapurple green; /* Two valid colors.
The first applies to the thumb of the scrollbar, the second to the track. */

/* Global values */
scrollbar-color: inherit;
scrollbar-color: initial;
scrollbar-color: revert;
scrollbar-color: revert-layer;
scrollbar-color: unset;
```

Values

`<scrollbar-color>`

Defines the color of the scrollbar.

`auto`	Default platform rendering for the track portion of the scrollbar, in the absence of any other related scrollbar color properties.
`<color> <color>`	Applies the first color to the scrollbar thumb, the second to the scrollbar track.

> **Note:** `@media (forced-colors: active)` sets `scrollbar-color` to `auto`.

Accessibility

When using `scrollbar-color` property with specific color values, authors should ensure the specified colors have enough contrast between them. For keyword values, UAs should ensure the colors they use have enough contrast. See Techniques for WCAG 2.0: G183: Using a contrast ratio of 3:1.

Formal definition

Initial value	`auto`
Applies to	scrolling boxes
Inherited	yes
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
scrollbar-color =
  auto        |
  <color>{2}
```

This syntax reflects the latest standard as per CSS Scrollbars Styling Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Coloring overflow scrollbars

CSS

```
.scroller {
  width: 300px;
  height: 100px;
  overflow-y: scroll;
  scrollbar-color: #000077 #bada55;
}
```

HTML

```
<div class="scroller">
  Veggies es bonus vobis, proinde vos postulo essum magis kohlrabi welsh onion
  daikon amaranth tatsoi tomatillo melon azuki bean garlic. Gumbo beet greens
  corn soko endive gumbo gourd. Parsley shallot courgette tatsoi pea sprouts
  fava bean collard greens dandelion okra wakame tomato. Dandelion cucumber
  earthnut pea peanut soko zucchini.
</div>
```

- `scrollbar-width`

scrollbar-gutter CSS property

The **`scrollbar-gutter`** CSS property allows authors to reserve space for the scrollbar, preventing unwanted layout changes as the content grows while also avoiding unnecessary visuals when scrolling isn't needed.

An element's *scrollbar gutter* is the space between the inner border edge and the outer padding edge, where the browser may display a scrollbar. If no scrollbar is present, the gutter will be painted as an extension of the padding.

The browser determines whether *classic* scrollbars or *overlay* scrollbars are used:

- Classic scrollbars are always placed in a gutter, consuming space when present.
- Overlay scrollbars are placed over the content, not in a gutter, and are usually partially transparent.

Syntax

```
/* Initial value */
scrollbar-gutter: auto;

/* "stable" keyword, with optional modifier */
scrollbar-gutter: stable;
scrollbar-gutter: stable both-edges;

/* Global values */
scrollbar-gutter: inherit;
scrollbar-gutter: initial;
scrollbar-gutter: revert;
scrollbar-gutter: revert-layer;
scrollbar-gutter: unset;
```

Values

`auto`

The initial value. Classic scrollbars create a gutter when `overflow` is `scroll`, or when `overflow` is `auto` and the box is overflowing. Overlay scrollbars do not consume space.

`stable`

When using classic scrollbars, the gutter will be present if `overflow` is `auto`, `scroll`, or `hidden` even if the box is not overflowing. When using overlay scrollbars, the gutter will not be present.

`both-edges`

If a gutter would be present on one of the inline start/end edges of the box, another will be present on the opposite edge as well.

Formal definition

Initial value	`auto`
Applies to	scrolling boxes
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
scrollbar-gutter =
  auto                  |
  stable && both-edges?
```

This syntax reflects the latest standard as per CSS Overflow Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

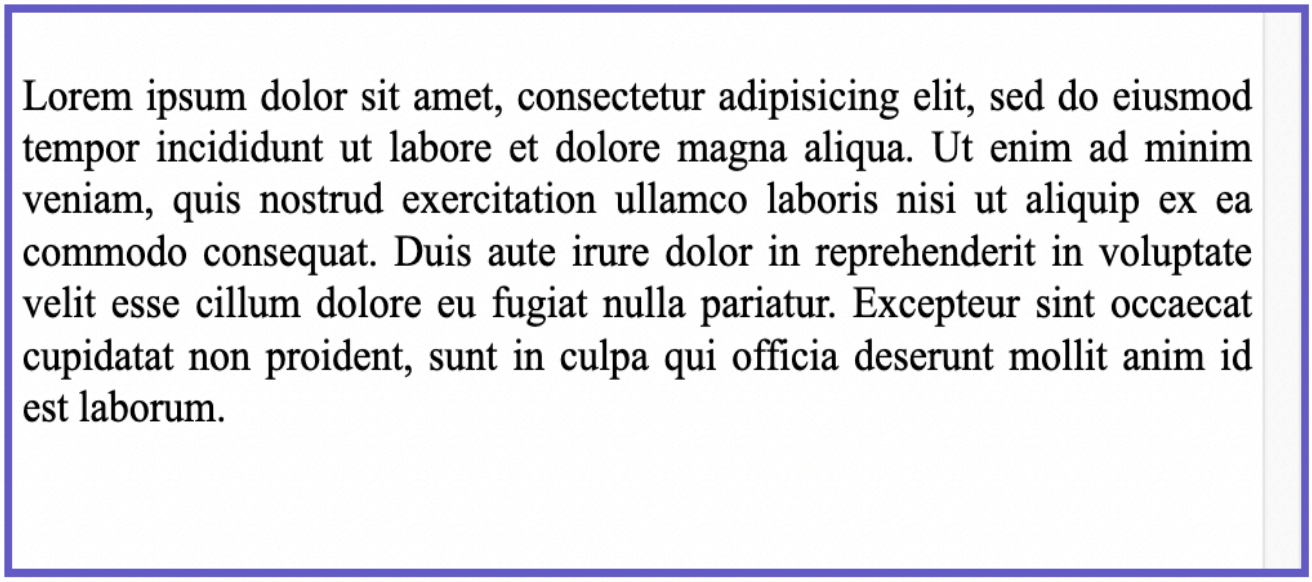
The examples below show how the different values for the `scrollbar-gutter` property would affect a scrollable `div` element (`.container`) with one or more paragraphs contained within.

> **Note:** In the images for the examples, the user's system settings are set to classic scrollbars (always shown).

Example 1

Prevent unneeded layout changes as the content growing or shrinking causes the scrollbar to appear/disappear, a space is reserved for it.

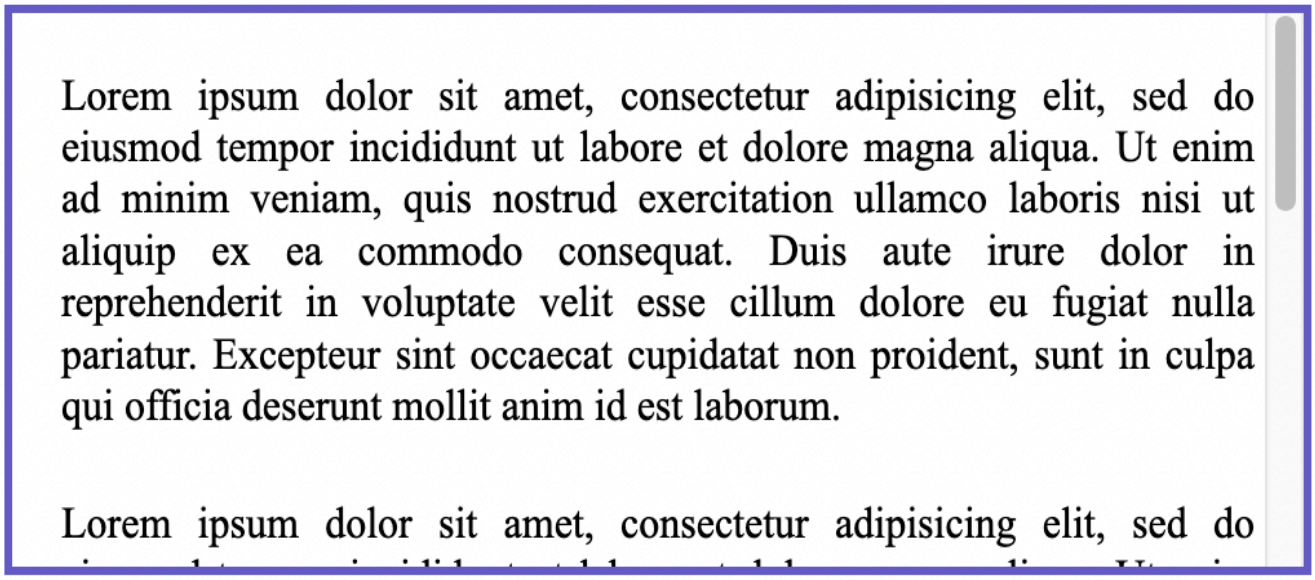
```
.container {
  scrollbar-gutter: stable;
}
```



Example 2

Add symmetric spacing to both sides of the box so the content is centered:

```
.container {
  scrollbar-gutter: stable both-edges;
}
```

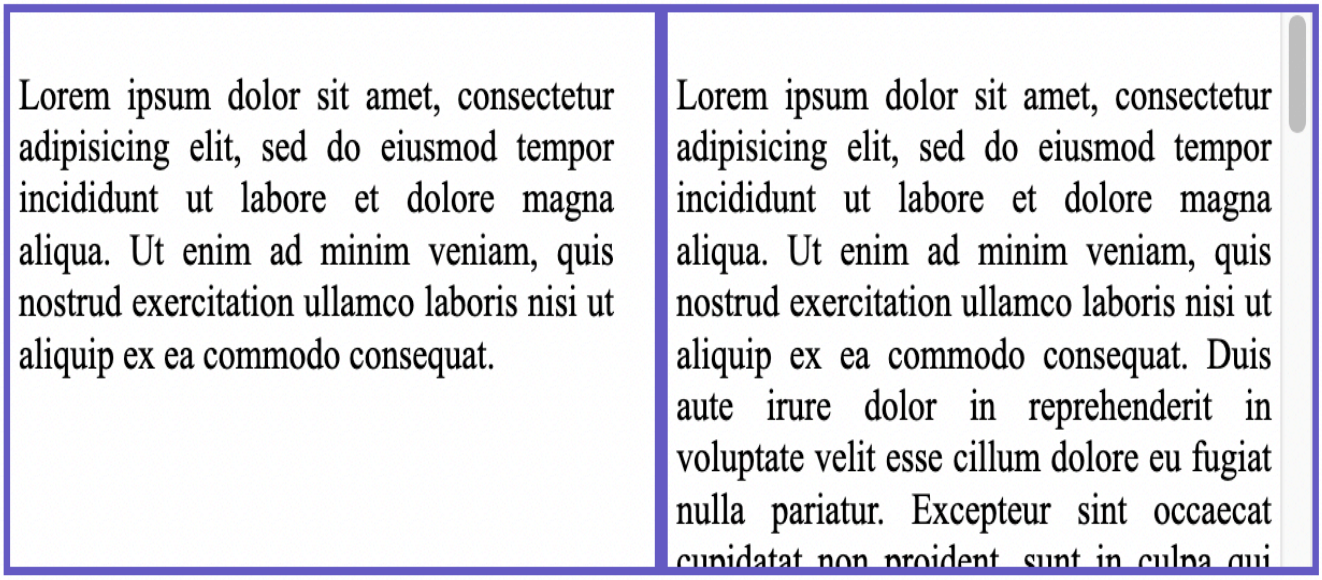


Example 3

Align the contents of a non-scrolling element and a scrolling one adjacent to it: This example shows two divs side by side. The one on the left has no scroll, but the one on the right does. Both have `scrollbar-gutter` applied, which also reserves space for the div on the left which doesn't have scrollable content. This is a good technique to use to keep the width of content consistent.

```
.container1 {
  overflow: hidden;
  scrollbar-gutter: stable;
}

.container2 {
  scrollbar-gutter: stable;
}
```



Overlay scrollbars

For reference, this image shows the same div as above, but with the user's system settings set to overlay scrollbars. Note here the scrollbar will only show when the user is scrolling and on top of the content, so no space is reserved for it and the `scrollbar-gutter` property has no effect.

- CSS overflow module
- CSS scrollbars styling module
- `overflow`
- `scrollbar-width`
- `scrollbar-color`

scrollbar-width CSS property

The **`scrollbar-width`** property allows the author to set the desired thickness of an element's scrollbars when they are shown.

The purpose of the `scrollbar-width` is to optimize the space occupied by the scrollbar on a page or element; the purpose is not related to scrollbar aesthetics. The `scrollbar-width` predefined keyword values indicate to the user agent whether a normal or smaller scrollbar should be rendered. Avoid using `none`, as hiding a scrollbar negatively impacts accessibility.

> **Note:** For elements that are scrollable only via programmatic means and not by direct user interaction, use the `overflow` property with a value of `hidden` rather than `scrollbar-width: none`.

> **Note:** Browsers ignore the non-standard `::-webkit-scrollbar` family of pseudo-elements on any element whose *computed* `scrollbar-width` value is anything other than `auto`. Unlike `scrollbar-color`, `scrollbar-width` is not inherited, so an ancestor's value doesn't affect its descendants. Setting `scrollbar-width: auto` on an element restores its `::-webkit-scrollbar-*` styling. See Adding a fallback for scrollbar styles.

Syntax

```
/* Keyword values */
scrollbar-width: auto;
scrollbar-width: thin;
scrollbar-width: none;

/* Global values */
scrollbar-width: inherit;
scrollbar-width: initial;
scrollbar-width: revert;
scrollbar-width: revert-layer;
scrollbar-width: unset;
```

Values

`auto`

The default scrollbar width for the platform.

`thin`

A thin scrollbar width variant on platforms that provide that option, or a thinner scrollbar than the default platform scrollbar width.

`none`

No scrollbar shown, however the element will still be scrollable.

> **Note:** User Agents must apply any `scrollbar-width` value set on the root element to the viewport.

Accessibility

Use this property with caution — setting `scrollbar-width` to `thin` or `none` can make content hard or impossible to scroll if the author does not provide an alternative scrolling mechanism. While swiping gestures or mouse wheels can enable scrolling on such content, some devices have no scroll alternative.

WCAG criterion 2.1.1 (Keyboard) has been in place for a long time to advise on basic keyboard accessibility, and this should include scrolling of content areas. And introduced in WCAG 2.1, criterion 2.5.5 (Target Size) advises that touch targets should be at least 44px in width and height (although the problem is compounded on high-resolution screens; thorough testing is advised).

- MDN Understanding WCAG, Guideline 2.5 explanations
- Understanding Success Criterion 2.1.1 | W3C Understanding WCAG 2.1
- Understanding Success Criterion 2.5.5 | W3C Understanding WCAG 2.1

Formal definition

Initial value	`auto`
Applies to	scrolling boxes
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
scrollbar-width =
  auto  |
  thin  |
  none
```

This syntax reflects the latest standard as per CSS Scrollbars Styling Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Sizing overflow scrollbars

CSS

```
.scroller {
  width: 300px;
  height: 100px;
  overflow-y: scroll;
  scrollbar-width: thin;
}
```

HTML

```
<div class="scroller">
  Veggies es bonus vobis, proinde vos postulo essum magis kohlrabi welsh onion
  daikon amaranth tatsoi tomatillo melon azuki bean garlic. Gumbo beet greens
  corn soko endive gumbo gourd. Parsley shallot courgette tatsoi pea sprouts
  fava bean collard greens dandelion okra wakame tomato. Dandelion cucumber
  earthnut pea peanut soko zucchini.
</div>
```

shape-image-threshold CSS property

The **`shape-image-threshold`** CSS property sets the alpha channel threshold used to extract the shape using an image as the value for `shape-outside`.

Any pixels whose alpha component's value is greater than the threshold are considered to be part of the shape for the purposes of determining its boundaries. For example, a value of `0.5` means that the shape will enclose all the pixels that are more than 50% opaque.

Try it

```
shape-outside: linear-gradient(
  50deg,
  rgb(77 26 103),
  transparent 80%,
  transparent
);
shape-image-threshold: 0.2;
```

```
shape-outside: linear-gradient(
  50deg,
  rgb(77 26 103),
  transparent 80%,
  transparent
);
shape-image-threshold: 0.4;
```

```
shape-outside: linear-gradient(
  50deg,
  rgb(77 26 103),
  transparent 80%,
  transparent
);
shape-image-threshold: 0.6;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element"></div>
    We had agreed, my companion and I, that I should call for him at his house,
    after dinner, not later than eleven o'clock. This athletic young Frenchman
    belongs to a small set of Parisian sportsmen, who have taken up "ballooning"
    as a pastime. After having exhausted all the sensations that are to be found
    in ordinary sports, even those of "automobiling" at a breakneck speed, the
    members of the "Aéro Club" now seek in the air, where they indulge in all
    kinds of daring feats, the nerve-racking excitement that they have ceased to
    find on earth.
  </div>
</section>
```

```
.example-container {
  text-align: left;
  padding: 20px;
}

#example-element {
  float: left;
  width: 150px;
  height: 150px;
  margin: 20px;
  background-image: linear-gradient(
    50deg,
    rgb(77 26 103),
    transparent 80%,
    transparent
  );
}
```

Syntax

```
/* <number> value */
shape-image-threshold: 0.7;

/* Global values */
shape-image-threshold: inherit;
shape-image-threshold: initial;
shape-image-threshold: revert;
shape-image-threshold: revert-layer;
shape-image-threshold: unset;
```

Values

`<alpha-value>`

> Sets the threshold used for extracting a shape from an image. The shape is defined by the pixels whose alpha value is greater than the threshold. Values outside the range 0.0 (fully transparent) to 1.0 (fully opaque) are clamped to this range.

Formal definition

Initial value	`0.0`
Applies to	floats
Inherited	no
Computed value	The same as the specified value after clipping the `<number>` to the range [0.0, 1.0].
Animation type	a number

Formal syntax

```
shape-image-threshold =
  <opacity-value>
```

```
<opacity-value> =
  <number>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Shapes Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Aligning text to a gradient

This example creates a `<div>` block with a gradient background image. The gradient is established as a CSS shape using `shape-outside`, so that pixels within the gradient which are at least 20% opaque (that is, those pixels with an alpha component greater than 0.2) are considered part of the shape.

HTML

```
<div id="gradient-shape"></div>

<p>
  Lorem ipsum dolor sit amet, consectetur adipisicing elit. Vel at commodi
  voluptates enim, distinctio officia. Saepe optio accusamus doloribus sint
  facilis itaque ab nulla, dolor molestiae assumenda cum sit placeat adipisci,
  libero quae nihil porro debitis laboriosam inventore animi impedit nostrum
  nesciunt quisquam expedita! Dolores consectetur iure atque a mollitia dicta
  repudiandae illum exercitationem aliquam repellendus ipsum porro modi, id nemo
  eligendi, architecto ratione quibusdam iusto nisi soluta? Totam inventore ea
  eum sed velit et eligendi suscipit accusamus iusto dolore, at provident eius
  alias maxime pariatur non deleniti ipsum sequi rem eveniet laboriosam magni
  expedita?
</p>
```

CSS

```
#gradient-shape {
  width: 150px;
  height: 150px;
  float: left;
  background-image: linear-gradient(30deg, black, transparent 80%, transparent);
  shape-outside: linear-gradient(30deg, black, transparent 80%, transparent);
  shape-image-threshold: 0.2;
}
```

The shape is established here using `background-image` with a linear gradient rather than an image file. The same gradient is also used as the image from which the shape is derived for establishing the float area, using the `shape-outside` property.

The 20% opacity threshold for treating gradient pixels as part of the shape is then established using `shape-image-threshold` with a value of `0.2`.

shape-margin CSS property

The **`shape-margin`** CSS property sets a margin for a CSS shape created using `shape-outside`.

The margin lets you adjust the distance between the edges of the shape (the **float element**) and the surrounding content.

Try it

```
shape-margin: 0;
```

```
shape-margin: 20px;
```

```
shape-margin: 1em;
```

```
shape-margin: 5%;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element"></div>
    We had agreed, my companion and I, that I should call for him at his house,
    after dinner, not later than eleven o'clock. This athletic young Frenchman
    belongs to a small set of Parisian sportsmen, who have taken up "ballooning"
    as a pastime. After having exhausted all the sensations that are to be found
    in ordinary sports, even those of "automobiling" at a breakneck speed, the
    members of the "Aéro Club" now seek in the air, where they indulge in all
    kinds of daring feats, the nerve-racking excitement that they have ceased to
    find on earth.
  </div>
</section>
```

```
.example-container {
  text-align: left;
  padding: 20px;
}

#example-element {
  float: left;
  margin: 20px;
  width: 180px;
  height: 180px;
  border-radius: 50%;
  background-color: rebeccapurple;
```

```
  shape-outside: circle(50%);
}
```

Syntax

```
/* <length> values */
shape-margin: 10px;
shape-margin: 20mm;

/* <percentage> value */
shape-margin: 60%;

/* Global values */
shape-margin: inherit;
shape-margin: initial;
shape-margin: revert;
shape-margin: revert-layer;
shape-margin: unset;
```

Values

`<length-percentage>`

Sets the margin of the shape to a `<length>` value or to a `<percentage>` of the width of the element's containing block.

Formal definition

Initial value	`0`
Applies to	floats
Inherited	no
Percentages	refer to the width of the containing block
Computed value	as specified, but with relative lengths converted into absolute lengths
Animation type	a length, percentage or calc();

Formal syntax

```
shape-margin =
  <length-percentage [0,∞]>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Shapes Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Adding a margin to a polygon

HTML

```
<section>
  <div class="shape"></div>
  We are not quite sure of any one thing in biology; our knowledge of geology is
  relatively very slight, and the economic laws of society are uncertain to
  every one except some individual who attempts to set them forth; but before
  the world was fashioned the square on the hypotenuse was equal to the sum of
  the squares on the other two sides of a right triangle, and it will be so
  after this world is dead; and the inhabitant of Mars, if one exists, probably
  knows its truth as we know it.
</section>
```

CSS

```
section {
  max-width: 400px;
}

.shape {
  float: left;
  width: 150px;
  height: 150px;
  background-color: maroon;
  clip-path: polygon(0 0, 150px 150px, 0 150px);
  shape-outside: polygon(0 0, 150px 150px, 0 150px);
  shape-margin: 20px;
}
```

shape-outside CSS property

The **`shape-outside`** CSS property defines a shape—which may be non-rectangular—around which adjacent inline content should wrap. By default, inline content wraps around its margin box; `shape-outside` provides a way to customize this wrapping, making it possible to wrap text around complex objects rather than rectangular boxes.

Try it

```
shape-outside: circle(50%);
```

```
shape-outside: ellipse(130px 140px at 20% 20%);
```

```
shape-outside: url("/shared-assets/images/examples/round-balloon.png");
```

```
shape-outside: polygon(50% 0, 100% 50%, 50% 100%, 0 50%);
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <img
      class="transition-all"
      id="example-element"
      src="/shared-assets/images/examples/round-balloon.png"
      width="150" />
    We had agreed, my companion and I, that I should call for him at his house,
    after dinner, not later than eleven o'clock. This athletic young Frenchman
    belongs to a small set of Parisian sportsmen, who have taken up "ballooning"
    as a pastime. After having exhausted all the sensations that are to be found
    in ordinary sports, even those of "automobiling" at a breakneck speed, the
    members of the "Aéro Club" now seek in the air, where they indulge in all
    kinds of daring feats, the nerve-racking excitement that they have ceased to
    find on earth.
  </div>
</section>
```

```
.example-container {
  text-align: left;
  padding: 20px;
}

#example-element {
  float: left;
  width: 150px;
  margin: 20px;
}
```

Syntax

```
/* Keyword values */
shape-outside: none;
shape-outside: margin-box;
shape-outside: content-box;
shape-outside: border-box;
shape-outside: padding-box;

/* Function values */
shape-outside: circle();
shape-outside: ellipse();
shape-outside: inset(10px 10px 10px 10px);
shape-outside: polygon(10px 10px, 20px 20px, 30px 30px);

/* Shape box with basic shape */
shape-outside: circle() border-box;
shape-outside: margin-box ellipse();

/* <url> value */
shape-outside: url("image.png");

/* <gradient> value */
shape-outside: linear-gradient(45deg, white 150px, red 150px);

/* Global values */
shape-outside: inherit;
shape-outside: initial;
shape-outside: revert;
shape-outside: revert-layer;
shape-outside: unset;
```

The `shape-outside` property is specified using the values from the list below, which define the *float area* for *float elements*. The float area determines the shape around which inline content (float elements) wrap.

Values

`none`

The float area is unaffected. Inline content wraps around the element's margin box, like usual.

`<shape-box>`

The float area is computed according to the shape of a float element's edges (as defined by the CSS box model). This can be `margin-box`, `border-box`, `padding-box`, or `content-box`. The shape includes any curvature created by the `border-radius` property (behavior which is similar to `background-clip`).

`margin-box`

Defines the shape enclosed by the outside margin edge. The corner radii of this shape are determined by the corresponding `border-radius` and `margin` values. If the `border-radius / margin` ratio is `1` or more, then the margin box corner radius is `border-radius + margin`. If the ratio is less than `1`, then the margin box corner radius is `border-radius + (margin * (1 + (ratio - 1) ^ 3))`.

`border-box`

Defines the shape enclosed by the outside border edge. The shape follows the normal border radius shaping rules for the outside of the border.

`padding-box`

Defines the shape enclosed by the outside padding edge. The shape follows the normal border radius shaping rules for the inside of the border.

`content-box`

Defines the shape enclosed by the outside content edge. Each corner radius of this box is the larger of `0` or `border-radius - border-width - padding`.

`<basic-shape>`

The float area is computed based on the shape created by an `inset()`, `circle()`, `ellipse()`, or `polygon()` function; other `<basic-shape>` functions are invalid. If a `<shape-box>` is also supplied, it defines the reference box for the `<basic-shape>` function. Otherwise, the reference box defaults to `margin-box`.

`<image>`

The float area is extracted and computed based on the alpha channel of the specified `<image>` as defined by `shape-image-threshold`.

> **Note:** If the image is invalid, the effect is as if the keyword `none` had been specified. Additionally, the image must be served with CORS headers allowing its use.

Formal definition

Initial value	none
Applies to	floats
Inherited	no
Computed value	as defined for `<basic-shape>` (with `shape-box` following, if supplied), the `<image>` with its URI made absolute, otherwise as specified.
Animation type	yes, as specified for `<basic-shape>`, otherwise no

Formal syntax

```
shape-outside =
  none                              |
  [ <basic-shape> || <shape-box> ]  |
  <image>

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Box Model Module Level 4, CSS Fill and Stroke Module Level 3, CSS Images Module Level 3, CSS Images Module Level 4, CSS Images Module Level 5, CSS Masking Module Level 1, CSS Shapes Module Level 1, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Funneling text

HTML

```
<div class="main">
  <div class="left"></div>
  <div class="right"></div>
  <p>
    Sometimes a web page's text content appears to be funneling your attention
    towards a spot on the page to drive you to follow a particular link.
    Sometimes you don't notice.
  </p>
</div>
```

CSS

```
.main {
  width: 530px;
}

.left,
.right {
  background-color: lightgray;
  height: 12ex;
  width: 40%;
}

.left {
  clip-path: polygon(0 0, 100% 100%, 0 100%);
  float: left;
  shape-outside: polygon(0 0, 100% 100%, 0 100%);
}

.right {
  clip-path: polygon(100% 0, 100% 100%, 0 100%);
  float: right;
  shape-outside: polygon(100% 0, 100% 100%, 0 100%);
}

p {
  text-align: center;
}
```

shape-rendering CSS property

The **`shape-rendering`** CSS property provides hints to the renderer about what tradeoffs to make when rendering shapes like paths, circles, or rectangles. It only has an effect on the `<circle>`, `<ellipse>`, `<line>`, `<path>`, `<polygon>`, `<polyline>`, and `<rect>` elements. If explicitly declared, the value of the CSS property overrides the any values of the element's `shape-rendering` attribute.

Syntax

```
shape-rendering: auto;
shape-rendering: crispEdges;
shape-rendering: geometricPrecision;
shape-rendering: optimizeSpeed;

/* Global values */
shape-rendering: inherit;
shape-rendering: initial;
shape-rendering: revert;
shape-rendering: revert-layer;
shape-rendering: unset;
```

Values

The `<length>` and `<percentage>` values denote the horizontal center of the circle or ellipse.

`auto`

> This value directs the user agents to make tradeoffs in order to balance speed, edge crispness, and geometric precision, with geometric precision given more importance than speed and edge crispness.

`crispEdges`

> This value directs the user agent to emphasize edge contrast over geometric precision or rendering speed. The final rendering is likely to skip techniques such as anti-aliasing. It may also adjust line positions and line widths in order to align edges with device pixels.

`geometricPrecision`

> This value directs the user agent to emphasize geometric precision over speed or crisp edges. The final rendering may involve techniques such as anti-aliasing.

`optimizeSpeed`

This value directs the user agent to emphasize rendering speed over geometric precision or edge crispness. The final rendering is likely to skip techniques such as anti-aliasing.

Formal definition

Initial value	`auto`
Applies to	`<circle>`, `<ellipse>`, `<line>`, `<path>`, `<polygon>`, `<polyline>`, and `<rect>` elements in an `svg`
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
shape-rendering =
  auto               |
  optimizeSpeed      |
  crispEdges         |
  geometricPrecision
```

This syntax reflects the latest standard as per CSS Specification. Not all browsers may have implemented every part. See Browser compatibility for support information.

Example

To show the different renderings, we create a set of four ellipses of equal size and shape.

```
<svg xmlns="http://www.w3.org/2000/svg" viewBox="0 0 400 120">
  <ellipse cx="50" cy="60" rx="40" ry="60" />
  <ellipse cx="150" cy="60" rx="40" ry="60" />
  <ellipse cx="250" cy="60" rx="40" ry="60" />
  <ellipse cx="350" cy="60" rx="40" ry="60" />
</svg>
```

We then apply the four values of `shape-rendering`, one per ellipse.

```
ellipse:nth-of-type(1) {
  shape-rendering: crispEdges;
}
ellipse:nth-of-type(2) {
  shape-rendering: geometricPrecision;
}
ellipse:nth-of-type(3) {
  shape-rendering: optimizeSpeed;
}
ellipse:nth-of-type(4) {
  shape-rendering: auto;
}
```

The resulting SVG is shown here. The first and third ellipses (counting from left to right) are more likely to show jagged edges, whereas the second should have a smoother appearance. The fourth and last ellipse's appearance will be dictated by the specific tradeoffs made by the user agent you use to view the example.

- SVG `shape-rendering` attribute

speak-as CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`speak-as`** CSS property is used to define how HTML content is spoken. The one to three enumerated key terms determine the manner by which elements and text get rendered by aural technologies, such as screen readers and digital assistants.

This property applies to all content, including pseudo-elements, with the exception `::marker` pseudo-elements constructed via a `@counter-style` with a defined `speak-as` descriptor, which takes precedence over any inherited `speak-as` property value.

Syntax

```
/* single value syntax */
speak-as: normal;
speak-as: spell-out;
speak-as: literal-punctuation;
speak-as: digits;
speak-as: no-punctuation;

/* multiple value syntax */
speak-as: spell-out literal-punctuation;
speak-as: spell-out no-punctuation;
speak-as: digits literal-punctuation;
speak-as: digits no-punctuation;
speak-as: spell-out digits literal-punctuation;
speak-as: spell-out digits no-punctuation;
```

Values

`normal`

Normal pronunciation rules with punctuation replaced by pauses. For example, "Hello, world!" would be pronounced as "Hello (pause) world (pause)". This is the default value.

`spell-out`

Content is spelled out letter by letter. For example, "role" would be pronounced as "r" "o" "l" "e".

`literal-punctuation`

Punctuation marks are spelled out literally. For example, "Hello, world!" would be pronounced as "Hello comma world exclamation mark."

`digits`

Numbers are pronounced as individual digits. For example, "31" would be pronounced as "three one".

`no-punctuation`

Content is pronounced normally without any punctuation. For example, "Hello, world!" would be pronounced as "Hello" "world".

> **Note:** Support of the `speak-as` property is limited and inconsistently implemented across different assistive technologies, such as screen readers or speech synthesizers. To ensure any pronunciation-dependent critical information remains user-friendly and accessible to a wide audience, do not rely solely on this CSS property to define how this information content is presented aurally.

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	yes
Computed value	specified value
Animation type	discrete

Formal syntax

```
speak-as =
  normal                                          |
  spell-out || digits || [ literal-punctuation | no-punctuation ]
```

This syntax reflects the latest standard as per CSS Speech Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<p class="normal">Hello, world! I'm 25.</p>
<p class="spell-out">Hello, world! I'm 25.</p>
<p class="literal-punctuation">Hello, world! I'm 25.</p>
<p class="no-punctuation">Hello, world! I'm 25.</p>
<p class="digits">Hello, world! I'm 25.</p>
<p class="multi">Hello, world! I'm 25.</p>
```

CSS

```
.normal {
  speak-as: normal;
}

.spell-out {
  speak-as: spell-out;
}

.literal-punctuation {
  speak-as: literal-punctuation;
}

.no-punctuation {
  speak-as: no-punctuation;
}

.digits {
  speak-as: digits;
}
.multi {
  speak-as: literal-punctuation digits;
}
```

stop-color CSS property

The **`stop-color`** CSS property defines the color to use for an SVG `<stop>` element within a gradient. If present, it overrides the element's `stop-color` attribute.

> **Note:** The `stop-color` property only applies to `<stop>` elements nested in an `<svg>`. It doesn't apply to other SVG, HTML, or pseudo-elements.

Syntax

```
/* <color> values */
stop-color: red;
stop-color: hsl(120deg 75% 25% / 60%);
stop-color: currentColor;

/* Global values */
stop-color: inherit;
stop-color: initial;
stop-color: revert;
stop-color: revert-layer;
stop-color: unset;
```

Values

`<color>`

The color of the fill. This can be any valid CSS `<color>` value.

Formal definition

Initial value	`black`
Applies to	`<stop>` elements in `<svg>`
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
stop-color =
  <color>
```

Examples

Defining the color stops of SVG gradients

This example demonstrates the basic use case of `stop-color`, and how the CSS `stop-color` property takes precedence over the `stop-color` attribute.

HTML

We have an SVG with three `<rect>` squares and three `<linearGradient>` elements. Each gradient has four `<stop>` elements creating gradients that go from black to white and then white to gray; the only difference between them is the `id` value.

```
<svg viewBox="0 0 264 100" xmlns="http://www.w3.org/2000/svg">
  <defs>
    <linearGradient id="myGradient1">
      <stop offset="25%" stop-color="black" />
      <stop offset="40%" stop-color="white" />
      <stop offset="60%" stop-color="white" />
      <stop offset="75%" stop-color="#333333" />
    </linearGradient>
    <linearGradient id="myGradient2">
      <stop offset="25%" stop-color="black" />
      <stop offset="40%" stop-color="white" />
      <stop offset="60%" stop-color="white" />
      <stop offset="75%" stop-color="#333333" />
    </linearGradient>
    <linearGradient id="myGradient3">
      <stop offset="25%" stop-color="black" />
      <stop offset="40%" stop-color="white" />
      <stop offset="60%" stop-color="white" />
      <stop offset="75%" stop-color="#333333" />
    </linearGradient>
  </defs>
  <rect x="2" y="10" width="80" height="80" fill="url('#myGradient1')" />
  <rect x="92" y="10" width="80" height="80" fill="url('#myGradient2')" />
  <rect x="182" y="10" width="80" height="80" fill="url('#myGradient3')" />
</svg>
```

CSS

We include a `stroke` and `stroke-width` outlining the rectangle. We define the colors of the first and last stops in each gradient, overriding their `stop-color` attribute values, using the `stop-color` property. Various CSS `<color>` syntaxes are shown.

```
svg {
  border: 1px solid;
  height: calc(100vh - 20px);
  margin-bottom: 10px;
}
```

```
rect {
  stroke: #333333;
  stroke-width: 1px;
}

#myGradient1 {
  stop:first-of-type {
    stop-color: #66ccff;
  }
  stop:last-of-type {
    stop-color: #f4aab9;
  }
}
#myGradient2 {
  stop:first-of-type {
    stop-color: yellow;
  }
  stop:last-of-type {
    stop-color: purple;
  }
}
#myGradient3 {
  stop:first-of-type {
    stop-color: hsl(0deg 90% 50%);
  }
  stop:last-of-type {
    stop-color: hsl(20deg 60% 50%);
  }
}
```

stop-opacity CSS property

The **`stop-opacity`** CSS property defines the opacity of a given color gradient stop in the SVG `<stop>` element within an SVG gradient. If present, it overrides the element's `stop-opacity` attribute.

The property value impacts the `stop-color`'s alpha channel; it can increase the transparency of a `<stop>`'s color but cannot make the color defined by the `stop-color` property more opaque.

> **Note:** The `stop-opacity` property only applies to `<stop>` elements nested in an `<svg>`. It doesn't apply to other SVG, HTML, or pseudo-elements.

Syntax

```
/* numeric and percentage values */
stop-opacity: 0.2;
stop-opacity: 20%;

/* Global values */
stop-opacity: inherit;
stop-opacity: initial;
stop-opacity: revert;
stop-opacity: revert-layer;
stop-opacity: unset;
```

Values

The `<opacity-value>` is a `<number>` or `<percentage>` denoting the opacity of the SVG gradient `<stop>` element.

`<number>`

A numeric value between `0` and `1`, inclusive.

`<percentage>`

A percentage value between `0%` and `100%`, inclusive.

With `0` or `0%` set, the stop is fully transparent. With `1` or `100%` set, the element is the full opacity of the `stop-color` value, which may or may not be partially opaque.

Formal definition

Initial value	`black`
Applies to	`<stop>` elements in `<svg>`
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
stop-opacity =
  <number>     |
  <percentage>
```

Examples

Defining the opacity of an SVG gradient color stop

This example demonstrates the basic use case of `stop-opacity`, and how the CSS `stop-opacity` property takes precedence over the `stop-opacity` attribute.

HTML

We have an SVG with a few `<polygon>` stars and three `<linearGradient>` elements: each has three `<stop>` elements defining three color-stops that create a gradient going from blue to white to pink; the only difference between them is the `id` value.

```
<svg viewBox="0 0 250 120" xmlns="http://www.w3.org/2000/svg">
  <defs>
    <linearGradient id="myGradient1">
      <stop offset="5%" stop-color="#66ccff" stop-opacity="1" />
      <stop offset="50%" stop-color="#fefefe" stop-opacity="1" />
      <stop offset="95%" stop-color="#f4aab9" stop-opacity="1" />
    </linearGradient>
    <linearGradient id="myGradient2">
      <stop offset="5%" stop-color="#66ccff" stop-opacity="1" />
      <stop offset="50%" stop-color="#fefefe" stop-opacity="1" />
      <stop offset="95%" stop-color="#f4aab9" stop-opacity="1" />
    </linearGradient>
    <linearGradient id="myGradient3">
      <stop offset="5%" stop-color="#66ccff" stop-opacity="1" />
      <stop offset="50%" stop-color="#fefefe" stop-opacity="1" />
      <stop offset="95%" stop-color="#f4aab9" stop-opacity="1" />
    </linearGradient>
  </defs>
  <polygon points="40,10 10,100 80,40 0,40 70,100" />
  <polygon points="125,10 95,100 165,40 85,40 155,100" />
  <polygon points="210,10 180,100 250,40 170,40 240,100" />
</svg>
```

CSS

We include a `stroke` and `stroke-width` making the polygon path line visible.

Each `polygon` has a gradient background set using the `fill` property; the gradient's `id` is the `url()` parameter. We set `magenta` as the fallback color.

We define the opacity of the stops of each gradient using the `stop-opacity` property.

The SVG has a striped background to make the transparency settings more apparent.

```
svg {
  border: 1px solid;
  height: calc(100vh - 20px);
  margin-bottom: 10px;
  background: repeating-linear-gradient(
    to top left,
    white 0 9px,
    black 9px 10px
  );
}
```

```
polygon {
  stroke: #333333;
  stroke-width: 1px;
}
polygon:nth-of-type(1) {
  fill: url("#myGradient1") magenta;
}
polygon:nth-of-type(2) {
  fill: url("#myGradient2") magenta;
}
polygon:nth-of-type(3) {
  fill: url("#myGradient3") magenta;
}

#myGradient1 stop {
  stop-opacity: 1;
}
#myGradient2 stop {
  stop-opacity: 0.8;
}
#myGradient3 stop {
  stop-opacity: 25%;
}
```

Results

The first star is fully opaque. The fill of the second star is 80% opaque because the color stops are slightly translucent; the `stop-opacity: 0.8;` overrode the `stop-opacity="1"` element attribute value. The fill of the last star is barely noticeable with color stops that are 25% opaque. Note the stroke is the same opaque dark gray in all cases.

> **Note:** Because we used the same `stop-opacity` value for all the sibling `<stop>` elements in the linear gradient, we could have instead used a single `<linearGradient>` with fully opaque stops, and set a value for each `<polygon>`s `fill-opacity` property instead.

stroke CSS property

The **`stroke`** CSS property defines the color or SVG paint server used to draw an element's stroke. As such, `stroke` only has an effect on elements that can be given a stroke (for example, `<rect>` or `<ellipse>`); see the page on the SVG `stroke` attribute for a complete list. When declared, the CSS value overrides any value of the element's `stroke` SVG attribute.

> **Note:** According to the 4 April 2017 draft of the CSS Fill and Stroke Module Level 3 specification, the `stroke` property is a shorthand for a number of other stroke properties. In practice, as of August 2024, browsers do not support the setting of other stroke-related values such as width or dash patterns via the `stroke` property, treating it instead as a direct analogue of the SVG `stroke` attribute.

Syntax

```
/* assorted color values */
stroke: rgb(153 51 102 / 1);
stroke: color-mix(in lch, var(--primaryColor) 35%, gray 15%);
stroke: dodgerblue;
stroke: currentColor;
stroke: transparent;
stroke: context-stroke;

/* Global values */
stroke: inherit;
stroke: initial;
stroke: revert;
stroke: revert-layer;
stroke: unset;
```

Values

`<color>`

Sets the painting of the stroke with any valid CSS color value.

`<image>`

Sets the painting of the stroke with what SVG calls a *paint server*, which in this context is an SVG gradient or pattern. CSS gradients cannot be used with the `stroke` property.

`context-stroke`

Causes an element to "inherit" its stroke definition from its *context element*. If there is no valid context element, then this value will result in no paint being used for the stroke.

Formal definition

Initial value	as each of the properties of the shorthand: • `stroke-dasharray`: `none` • `stroke-dashoffset`: `0` • `stroke-linecap`: `butt` • `stroke-linejoin`: `miter` • `stroke-miterlimit`: `4` • `stroke-opacity`: `1` • `stroke-width`: `1px`
Applies to	as each of the properties of the shorthand:
Inherited	yes
Computed value	as each of the properties of the shorthand:
Animation type	as each of the properties of the shorthand: • `stroke-dasharray`: a repeatable list • `stroke-dashoffset`: by computed value type • `stroke-linecap`: discrete • `stroke-linejoin`: discrete • `stroke-miterlimit`: by computed value type • `stroke-opacity`: by computed value type • `stroke-width`: by computed value type

Formal syntax

```
stroke =
  <paint>

<paint> =
  none         |
  <image>      |
  <svg-paint>

<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
  <gradient>

<svg-paint> =
  child              |
  child( <integer> )

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-set()> =
  image-set( <image-set-option># )

<cross-fade()> =
  cross-fade( <cf-image># )

<element()> =
  element( <id-selector> )

<integer> =
  <number-token>

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Fill and Stroke Module Level 3, CSS Images Module Level 4, CSS Images Module Level 5, CSS Specification, CSS Values and Units Module Level 4, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic color stroking

In this example, we create two different shapes, a circle and a rectangle, which are part of a `<g>` (group) that has a gray stroke color as a default for the two shapes.

```
<svg>
  <g fill="none" stroke="gray" stroke-width="10">
    <circle cx="100" cy="100" r="40" />
    <rect x="20" y="20" width="80" height="80" />
```

```
  </g>
</svg>
```

Via CSS, we then apply a dusky purple color to the rectangle and a red to the circle.

```
rect {
  stroke: rebeccapurple;
}
circle {
  stroke: red;
}
```

Pattern stroking

This example uses the same group and shapes (with the circle moved over a bit) as seen in the previous example, but also has an SVG pattern defined.

```
<svg>
  <g fill="none" stroke="gray" stroke-width="23">
    <circle cx="150" cy="90" r="40" />
    <rect x="20" y="20" width="80" height="80" />
  </g>
  <defs>
    <pattern id="star" viewBox="0,0,10,10" width="10%" height="10%">
      <polygon points="0,0 2,5 0,10 5,8 10,10 8,5 10,0 5,2" />
    </pattern>
  </defs>
</svg>
```

The pattern is then referenced in the CSS with a URL value pointing to the ID of the pattern. This pattern is applied to both shapes as a stroking paint, with the result shown.

```
rect,
circle {
  stroke: url("#star");
}
```

The pattern is drawn relative to the shapes' bounding boxes, which can lead to visual interference where they overlap, because parts of the pattern are transparent.

SVG versus CSS gradients

Here, we once again use the same group-and-shapes markup as the first example, but also add a definition for an SVG gradient.

```
<svg>
  <g fill="none" stroke="gray" stroke-width="10">
    <circle cx="100" cy="100" r="40" />
    <rect x="20" y="20" width="80" height="80" />
  </g>
  <defs>
    <linearGradient id="greenwhite">
      <stop offset="0%" stop-color="green" />
      <stop offset="100%" stop-color="white" />
    </linearGradient>
  </defs>
</svg>
```

In the CSS, we apply that SVG gradient to the rectangle using a URL value pointing to the ID of the linear gradient. To the circle, we apply a CSS linear gradient that is equivalent in intent to the SVG gradient.

```
rect {
  stroke: url("#greenwhite");
}
circle {
  stroke: linear-gradient(90deg, green, white);
}
```

Only the rectangle receives a gradient stroke, whereas the circle falls back to the gray stroke set by the group element. This happens because CSS gradients are not valid values for the `stroke` property, whereas URL references to SVG gradients are permitted.

Contextual stroking

In this case, we again start with a group element, inside of which two rectangle-shaped paths are defined. After that, a linear gradient and an SVG marker are defined.

```
<svg>
  <g fill="none" stroke="gray" stroke-width="4">
    <path d="M 20,20 l 180,0 0,100 -180,0 z" />
    <path d="M 100,40 l 180,0 0,100 -180,0 z" />
  </g>
  <defs>
    <linearGradient id="orangered">
      <stop offset="0%" stop-color="orange" />
      <stop offset="100%" stop-color="red" />
    </linearGradient>
    <marker
      id="circle"
      markerWidth="20"
      markerHeight="20"
      refX="10"
      refY="10"
      markerUnits="userSpaceOnUse">
      <circle
        cx="10"
        cy="10"
        r="8"
        stroke-width="4"
        stroke="none"
        fill="none" />
    </marker>
  </defs>
</svg>
```

We then write CSS to add a marker to both paths, and also to have a dusky purple stroke color. This is overridden for the second path, which is given a URL value to apply the orange-to-red gradient as its stroke. Finally, we set the circle element in the marker element to have a stroke value of `context-stroke`.

```
path {
  stroke: rebeccapurple;
  marker: url("#circle");
}
path:nth-of-type(2) {
  stroke: url("#orangered");
}
marker circle {
  stroke: context-stroke;
}
```

Because `stroke-context` is being applied to an element that descends from a `<marker>` element, the context element for every circle is the element that called the `<marker>` element; that is, the `<path>` elements. The result is that the markers on the first path use the color of the calling path, and are purple. The markers on the second path, by contrast, use the same orange-to-red SVG gradient the path uses. This latter case illustrates how SVG gradients are applied as a single gradient to the entire shape, rather than being applied independently to each individual part of the shape.

- `stroke-linejoin`
- `stroke-miterlimit`
- `stroke-opacity`
- `stroke-width`
- `paint-order`
- SVG `stroke` attribute

stroke-dasharray CSS property

The **`stroke-dasharray`** CSS property defines a pattern of dashes and gaps used in the painting of the SVG shape's stroke. If present, it overrides the element's `stroke-dasharray` attribute.

This property applies to any SVG shape or text-content element (see `stroke-dasharray` for a full list), but as an inherited property, it may be applied to elements such as `<g>` and still have the intended effect on descendant elements' strokes.

Syntax

```
/* Keyword value */
stroke-dasharray: none;

/* Numeric, length, and percentage values */
stroke-dasharray: 2px, 5px;
stroke-dasharray: 20%, 50%;
stroke-dasharray: 2, 5;

/* The following two rules are equivalent */
stroke-dasharray: 2, 5, 3;
stroke-dasharray: 2, 5, 3, 2, 5, 3;

/* Global values */
stroke-dasharray: inherit;
stroke-dasharray: initial;
stroke-dasharray: revert;
stroke-dasharray: revert-layer;
stroke-dasharray: unset;
```

Values

The value is a list of comma and/or white space separated `<number>`, `<length>`, and / or `<percentage>` values that specify the lengths of alternating dashes and gaps, or the keyword `none`. If an odd number of values are given, the entire value will be repeated in order to set an even number of values.

`none`

The stroke will be drawn without any dashes. The default value.

`<number>`

A number of SVG units, the size of which are defined by the current unit space. Negative values are invalid.

`<length>`

Pixel units are handled the same as SVG units (see `<number>`, above) and font-based lengths such as `em` are calculated with respect to the element's SVG value for the text size; the effects of other length units may depend on the browser. Negative values are invalid.

`<percentage>`

Percentages refer to the normalized diagonal of the current SVG viewport, which is calculated as $\frac{\sqrt{\text{<width>}^2 + \text{<height>}^2}}{\sqrt{2}}$. Negative values are invalid.

Formal definition

Initial value	none
Applies to	`<circle>`, `<ellipse>`, `<line>`, `<path>`, `<polygon>`, `<polyline>`, and `<rect>` elements in an `svg`
Inherited	yes
Percentages	refer to the normalized diagonal measure of the current SVG viewport's applied `viewBox`, or of the viewport itself if no `viewBox` is specified
Computed value	A comma separated list of absolute lengths or percentages, numbers converted to absolute lengths first, or keyword specified
Animation type	a repeatable list

Formal syntax

```
stroke-dasharray =
  none                                |
  [ <length-percentage> | <number> ]+#
```

```
<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Fill and Stroke Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic dash array

This example demonstrates basic usage of the `stroke-dasharray` property using space-separated `<number>` values.

HTML

First, we set up a basic SVG rectangle shape. To this rectangle, a red stroke with a width of 2 is applied.

```
<svg viewBox="0 0 100 50" width="500" height="250">
  <rect
    x="10"
    y="10"
    width="80"
    height="30"
    fill="none"
    stroke="red"
    stroke-width="2" />
</svg>
```

CSS

We define a dash pattern for the stroke: ten units of dash, followed by five units of space. This means the gaps between dashes will be half the length as the dashes themselves.

```
rect {
  stroke-dasharray: 10 5;
}
```

Results

Where the stroke turns a corner, the pattern is carried along, as it were. At the top left corner, where the start and end of the stroke meet, the ten-unit-long starting dash appears to join with the part of the dash pattern seen at the end of the path, creating what looks like a longer-than-ten-units line bending around the corner.

Dash array repetition

This example includes an odd-number of comma-separated `<number>` values to demonstrates how the value is repeated if an odd number of values is given in order to set an even number of values.

HTML

In this case, we define two rectangles.

```
<svg viewBox="0 0 100 100" width="500" height="500">
  <rect
    x="10"
    y="10"
    width="80"
    height="30"
    fill="none"
    stroke="red"
    stroke-width="2" />
  <rect
    x="10"
    y="60"
    width="80"
    height="30"
    fill="none"
    stroke="red"
    stroke-width="2" />
</svg>
```

CSS

To the first rectangle, we define a dasharray of `5, 5, 1`, which calls for five units of dash, five of gap, and one unit of dash. However, because this is an odd number of numbers, the entire set of numbers is repeated, thus creating a value identical to that applied to the second rectangle.

```
rect:nth-of-type(1) {
  stroke-dasharray: 5, 5, 1;
}
rect:nth-of-type(2) {
  stroke-dasharray: 5, 5, 1, 5, 5, 1;
}
```

Result

The reason an even count of numbers is required is so that every dash array begins with a dash and ends with a gap. Thus, the pattern defined is a five-unit dash, a five-unit gap, a one-unit dash, a five-unit gap, a five-unit dash, and a one-unit gap. In the resulting stroke, every instance of a one-unit gap between two five-unit dashes indicates a place where the dash array starts over.

Percentage and pixel values

This example demonstrates the use of `<percentage>` and `<length>` values within the `stroke-dasharray` property value.

HTML

As in the previous example, we define two rectangles.

```
<svg viewBox="0 0 100 100" width="500" height="500">
  <rect
    x="10"
    y="10"
    width="80"
    height="30"
```

```
    fill="none"
    stroke="red"
    stroke-width="2" />
  <rect
    x="10"
    y="60"
    width="80"
    height="30"
    fill="none"
    stroke="red"
    stroke-width="2" />
</svg>
```

CSS

This time, rather than collections of bare numbers, we use pixel units and percentages.

```
rect:nth-of-type(1) {
  stroke-dasharray: 5px, 5px, 1px;
}
rect:nth-of-type(2) {
  stroke-dasharray: 5%, 5%, 1%;
}
```

Results

The results are essentially indistinguishable from the results in the previous example.

- `stroke-width`
- `stroke`
- SVG `stroke-dasharray` attribute

stroke-dashoffset CSS property

The **`stroke-dashoffset`** CSS property defines an offset for the starting point of the rendering of an SVG element's associated dash array. If present, it overrides the element's `stroke-dashoffset` attribute.

This property applies to any SVG shape or text-content element (see `stroke-dashoffset` for a full list), but as an inherited property, it may be applied to elements such as `<g>` and still have the intended effect on descendant elements' strokes.

Syntax

```
/* Keyword value */
stroke-dashoffset: none;

/* Length and percentage values */
stroke-dashoffset: 2;
stroke-dashoffset: 2px;
stroke-dashoffset: 2%;

/* Global values */
stroke-dashoffset: inherit;
stroke-dashoffset: initial;
stroke-dashoffset: revert;
stroke-dashoffset: revert-layer;
stroke-dashoffset: unset;
```

Values

`<number>`

> A number of SVG units, the size of which defined by the current unit space. The value given, if other than `0`, moves the starting point from the start of the dash array to another point within it. Thus, positive values will appear to shift the dash-gap pattern *backwards*, and negative values will appear to shift the pattern *forwards*.

`<length>`

> Pixel units are handled the same as SVG units (see `<number>`, above) and font-based lengths such as `em` are calculated with respect to the element's SVG value for the text size; the effects of other length units may depend on the browser. The shifting effect for any value is the same as for `<number>` values (see above).

`<percentage>`

> Percentages refer to the normalized diagonal of the current SVG viewport, which is calculated as $\frac{\sqrt{\text{<width>}^2 + \text{<height>}^2}}{\sqrt{2}}$, *not* to the overall length of the stroke path. Negative values are invalid.

Formal definition

Initial value	`0`
Applies to	`<circle>`, `<ellipse>`, `<line>`, `<path>`, `<polygon>`, `<polyline>`, and `<rect>` elements in an `svg`
Inherited	yes
Percentages	refer to the normalized diagonal measure of the current SVG viewport's applied `viewBox`, or of the viewport itself if no `viewBox` is specified
Computed value	an absolute `<length>` or `<percentage>`, numbers converted to absolute lengths first
Animation type	by computed value type

Formal syntax

```
stroke-dashoffset =
  <length-percentage>  |
  <number>
```

```
<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Fill and Stroke Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Dash offsetting

To show how dashes can be offset, we first set up five identical paths, all of which are given a dash array of a 20-unit dash followed by a 3-unit gap via the SVG attribute `stroke-dasharray`. (This could also have been done with the CSS property `stroke-dasharray`.) The paths are then given individual dash offsets via CSS.

```
<svg viewBox="0 0 100 50" width="500" height="250">
  <rect x="10" y="5" width="80" height="30" fill="#eeeeee" />
  <g stroke="dodgerblue" stroke-width="2" stroke-dasharray="20,3">
    <path d="M 10,10 h 80" />
    <path d="M 10,15 h 80" />
    <path d="M 10,20 h 80" />
    <path d="M 10,25 h 80" />
    <path d="M 10,30 h 80" />
  </g>
</svg>
```

```
path:nth-of-type(1) {
  stroke-dashoffset: 0;
}
path:nth-of-type(2) {
  stroke-dashoffset: -5;
}
path:nth-of-type(3) {
  stroke-dashoffset: 5;
}
path:nth-of-type(4) {
  stroke-dashoffset: 5px;
}
path:nth-of-type(5) {
  stroke-dashoffset: 5%;
}
```

In order:

1. The first of the five paths is given a zero offset, which is the default behavior.
2. The second path is given an offset of `-5`, which shifts the start point of the array to five units before the zero-point. The visual effect is that the dash pattern is pushed forward five units; thus, we see, at the start of the path, the last two units of a dash and then a three-unit gap.
3. The third path has an offset of `5`, which means the starting point of the dashes is five units into the dash pattern. The visual effect is to push the dash pattern backward by five units; thus, we see, at the start of the path, the last fifteen units of a dash followed by a three-unit gap.
4. The fourth path has an offset of `5px`, which has the same effect as a value of `5` (see previous).
5. The fifth and last path has an offset of `5%`, which is very similar to the previous two examples, but is not quite the same. Percentages are calculated against the diagonal measure of the SVG viewport, and so can very depending on that viewport's size and aspect ratio.

stroke-linecap CSS property

The **`stroke-linecap`** CSS property defines the shape to be used at the end of open subpaths of SVG elements' unclosed strokes. If present, it overrides the element's `stroke-linecap` attribute.

This property applies to any SVG shape that can have unclosed strokes and text-content element (see `stroke-linecap` for a full list), but as an inherited property, it may be applied to elements such as `<g>` and still have the intended effect on descendant elements' strokes.

Syntax

```
/* keyword values */
stroke-linecap: butt;
stroke-linecap: round;
stroke-linecap: square;

/* Global values */
stroke-linecap: inherit;
stroke-linecap: initial;
stroke-linecap: revert;
stroke-linecap: revert-layer;
stroke-linecap: unset;
```

Values

This property is specified as one of the following keyword values:

`butt`

> Indicates that the stroke for each subpath does not extend beyond its two endpoints. On a zero-length subpath, the path will not be rendered at all. This is the default value.

`round`

> Indicates that at the end of each subpath the stroke will be extended by a half circle with a diameter equal to the stroke width. On a zero-length subpath, the stroke consists of a full circle centered at the subpath's point.

`square`

> Indicates that at the end of each subpath the stroke will be extended by a rectangle with a width equal to half the width of the stroke and a height equal to the width of the stroke. On a zero-length subpath, the stroke consists of a square with its width equal to the stroke width, centered at the subpath's point.

Formal definition

Initial value	`butt`
Applies to	`<circle>`, `<ellipse>`, `<line>`, `<path>`, `<polygon>`, `<polyline>`, and `<rect>` elements in an `svg`
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
stroke-linecap =
  butt    |
  round   |
  square
```

This syntax reflects the latest standard as per CSS Fill and Stroke Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Linecaps

This example demonstrates the property's three keyword values.

HTML

We first set up a light-gray rectangle. Then, in a group, three paths are defined whose length is exactly the same as the width of the rectangle, and all of which start at the left edge of the rectangle. They are all set to have a `dodgerblue` stroke with a width of seven.

```
<svg viewBox="0 0 100 50" width="500" height="250">
  <rect x="10" y="5" width="80" height="30" fill="#dddddd" />
  <g stroke="dodgerblue" stroke-width="7">
    <path d="M 10,10 h 80" />
    <path d="M 10,20 h 80" />
    <path d="M 10,30 h 80" />
  </g>
</svg>
```

CSS

We then apply a different linecap style to each path via CSS.

```
path:nth-of-type(1) {
  stroke-linecap: butt;
}
path:nth-of-type(2) {
  stroke-linecap: square;
}
path:nth-of-type(3) {
  stroke-linecap: round;
}
```

Results

The first path has `butt` linecaps, which essentially means the stroke runs exactly to the end points (both the start and the end) of the path, and no further. The second path has `square` linecaps, so the visible path extends out past the end points of the path, making the overall length of the path appear to be 87, since the path length is 80 and each of the two square caps is 3.5 wide. The third path has `circle` caps, so while it also appears to be 87 units long, the two caps are semicircular instead of square.

- `stroke-linejoin`
- `stroke-miterlimit`
- `stroke-opacity`
- `stroke-width`
- `stroke`
- SVG `stroke-linecap` attribute

stroke-linejoin CSS property

The **`stroke-linejoin`** CSS property defines the shape to be used at the corners of an SVG element's stroked paths. If present, it overrides the element's `stroke-linejoin` attribute.

This property applies to any SVG corner-generating shape or text-content element (see `stroke-linejoin` for a full list), but as an inherited property, it may be applied to elements such as `<g>` and still have the intended effect on descendant elements'

Syntax

```
/* keyword values */
stroke-linejoin: bevel;
stroke-linejoin: miter;
stroke-linejoin: round;

/* Global values */
stroke-linejoin: inherit;
stroke-linejoin: initial;
stroke-linejoin: revert;
stroke-linejoin: revert-layer;
stroke-linejoin: unset;
```

Values

`bevel`

> Indicates that a beveled corner is to be used to join path segments. The bevel is formed by truncating the corner by a line perpendicular to a line that bisects the difference in the subpath angles where they meet the join point.

`miter`

Indicates that a sharp corner is to be used to join path segments. The corner is formed by extending the outer edges of the stroke at the tangents of the path segments until they intersect. This is the default value.

`round`

Indicates that a round corner is to be used to join path segments. This is accomplished by cropping the join as per `bevel`, and then appending a filled arc tangent in order to round the corner.

The following values are defined, but not supported in any browser:

`arcs`

(Unsupported.) Indicates that an *arcs corner* is to be used to join path segments. The arc's shape is formed by extending the outer edges of the stroke at the join point with arcs that have the same curvature as the outer edges at the join point.

`crop`

(Unsupported.) Indicates the corner should extend past the join point by the minimum amount necessary to form a convex corner. This is functionally equivalent to `miter` (see above) with a `stroke-miterlimit` value of `1`.

`fallback`

(Unsupported; at risk.) behaves identically to `crop bevel` when the `stroke-miterlimit` value is exceeded.

Formal definition

Initial value	`miter`
Applies to	`<circle>`, `<ellipse>`, `<line>`, `<path>`, `<polygon>`, `<polyline>`, and `<rect>` elements in an `svg`
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
stroke-linejoin =
  [ crop | arcs | miter ]      ||
  [ bevel | round | fallback ]
```

This syntax reflects the latest standard as per CSS Fill and Stroke Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Line-joining styles

This example demonstrates the three currently supported keyword values for `stroke-linejoin`.

HTML

We set up four identical paths, all of which have a black stroke with a width of one and no fill.

```
<svg viewBox="0 0 15 12" xmlns="http://www.w3.org/2000/svg">
  <g stroke="black" stroke-width="1" fill="none">
    <path d="M2,5  a2,2 0,0,0 2,-3 a3,3 0 0 1 2,3.5" />
    <path d="M8,5  a2,2 0,0,0 2,-3 a3,3 0 0 1 2,3.5" />
    <path d="M2,11 a2,2 0,0,0 2,-3 a3,3 0 0 1 2,3.5" />
    <path d="M8,11 a2,2 0,0,0 2,-3 a3,3 0 0 1 2,3.5" />
  </g>
</svg>
```

CSS

To each of the four paths, a supported line-joining value is applied. The first is beveled, the second rounded, the third mitered, and the fourth also mitered but with a `stroke-miterlimit` of `2`, which forces the corner to be beveled instead of mitered.

```
path:nth-child(1) {
  stroke-linejoin: bevel;
}
path:nth-child(2) {
  stroke-linejoin: round;
}
path:nth-child(3) {
  stroke-linejoin: miter;
}
path:nth-child(4) {
  stroke-linejoin: miter;
  stroke-miterlimit: 2;
}
```

- `stroke-width`
- `stroke`
- SVG `stroke-linejoin` attribute

stroke-miterlimit CSS property

The **`stroke-miterlimit`** CSS property defines a limit on the ratio of the miter length to the `stroke-width` when the shape to be used at the corners of an SVG element's stroked path is a mitered join. If the limit defined by this property is exceeded, the join is converted from `miter` to `bevel`, thus making the corner appear truncated.

This property applies to any SVG corner-generating shape or text-content element (see `stroke-miterlimit` for a full list), but as an inherited property, it may be applied to elements such as `<g>` and still have the intended effect on descendant elements' strokes. If present, it overrides the element's `stroke-miterlimit` attribute.

Description

When two line segments meet at a sharp angle and `miter` joins have been specified for `stroke-linejoin`, or if they default to that value, it is possible for the miter to extend far beyond the thickness of the line stroking the path. The `stroke-miterlimit` ratio is used to define a limit, past which the join is converted from a miter to a bevel.

The ratio of miter length (the distance between the outer tip and the inner corner of the miter) to `stroke-width` is directly related to the angle (theta) between the segments in user space by the formula:

$$\text{stroke-miterlimit} = \frac{\text{miterLength}}{\text{stroke-width}} = \frac{1}{\sin\left(\frac{\theta}{2}\right)}$$

For example, a miter limit of `1.414` converts miters to bevels for a theta value of less than 90 degrees, a limit of `4.0` converts them for a theta less than approximately 29 degrees, and a limit of `10.0` converts them for theta less than approximately 11.5 degrees.

Syntax

```
/* number values */
stroke-miterlimit: 1;
stroke-miterlimit: 3.1416;

/* Global values */
stroke-miterlimit: inherit;
stroke-miterlimit: initial;
stroke-miterlimit: revert;
stroke-miterlimit: revert-layer;
stroke-miterlimit: unset;
```

Values

`<number>`

Any real positive number equal to or greater than `1`; values below that are invalid. The initial value is `4`.

Formal definition

Initial value	`4`
Applies to	`<circle>`, `<ellipse>`, `<line>`, `<path>`, `<polygon>`, `<polyline>`, and `<rect>` elements in an `svg`
Inherited	yes
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
stroke-miterlimit =
  <number>
```

This syntax reflects the latest standard as per CSS Fill and Stroke Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Various miter limits

This example demonstrates the effect of different values for the `stroke-miterlimit` property.

HTML

We set up five multi-segment paths, all of which use a black stroke with a width of one, and no fill. Each path creates a series of mountain symbols, going from left (a shallow corner angle) to right (an extreme corner angle).

```
<svg viewBox="0 0 39 36" xmlns="http://www.w3.org/2000/svg">
  <g stroke="black" stroke-width="1" fill="none">
    <path
      d="M1,5 l7   ,-3 l7   ,3
         m2,0 l3.5 ,-3 l3.5 ,3
         m2,0 l2   ,-3 l2   ,3
         m2,0 l0.75,-3 l0.75,3
         m2,0 l0.5 ,-3 l0.5 ,3" />
    <path
      d="M1,12 l7,-3 l7,3 m2,0 l3.5,-3 l3.5,3 m2,0 l2,-3 l2,3 m2,0 l0.75,-3 l0.75,3 m2,0 l0.5,-3 l0.5,3" />
    <path
      d="M1,19 l7,-3 l7,3 m2,0 l3.5,-3 l3.5,3 m2,0 l2,-3 l2,3 m2,0 l0.75,-3 l0.75,3 m2,0 l0.5,-3 l0.5,3" />
    <path
      d="M1,26 l7,-3 l7,3 m2,0 l3.5,-3 l3.5,3 m2,0 l2,-3 l2,3 m2,0 l0.75,-3 l0.75,3 m2,0 l0.5,-3 l0.5,3" />
    <path
      d="M1,33 l7,-3 l7,3 m2,0 l3.5,-3 l3.5,3 m2,0 l2,-3 l2,3 m2,0 l0.75,-3 l0.75,3 m2,0 l0.5,-3 l0.5,3" />
  </g>
</svg>
```

CSS

We apply increasingly large values of `stroke-miterlimit` to the paths, such that for the first path, only the first (leftmost) subpath is mitered; for the second path, the first two subpaths are mitered; and so on until for the fifth path, all five subpaths are mitered.

```
path:nth-child(1) {
  stroke-miterlimit: 1.1;
}
path:nth-child(2) {
  stroke-miterlimit: 1.4;
}
path:nth-child(3) {
  stroke-miterlimit: 1.9;
}
path:nth-child(4) {
  stroke-miterlimit: 4.2;
}
```

```
path:nth-child(5) {
  stroke-miterlimit: 6.1;
}
```

- stroke-linejoin
- stroke-opacity
- stroke-width
- stroke
- SVG stroke-miterlimit attribute

stroke-opacity CSS property

The **stroke-opacity** CSS property defines the opacity of an SVG shape's stroke. The effect is identical to that of opacity, except it is applied only to the stroke, not to the entire element. If present, it overrides the element's stroke-opacity attribute.

This property applies to SVG shapes and text-content elements (see stroke-opacity for a full list), but as an inherited property, it may be applied to elements such as <g> and still have the intended effect on descendant elements' strokes.

Note that a shape's stroke partially covers the fill of that shape, so a stroke with an opacity less than 1 will show the fill blended with the stroke where they overlap. To avoid this effect, it is possible to apply a global opacity with the opacity property or to put the stroke behind the fill with the paint-order attribute.

Syntax

```
/* numeric and percentage values */
stroke-opacity: 1;
stroke-opacity: 0.3;
stroke-opacity: 50%;

/* Global values */
stroke-opacity: inherit;
stroke-opacity: initial;
stroke-opacity: revert;
stroke-opacity: revert-layer;
stroke-opacity: unset;
```

Values

<number>

Any real number from 0 to 1, inclusive. A value of 0 makes the stroke completely transparent, and a value of 1 makes it completely opaque. Values outside the range 0 – 1 are clipped to the nearest end of that range; thus, negative values are clipped to 0.

<percentage>

The same as <number> (see above), except the allowed range is 0% to 100% and clipping is done with regard to that range.

Formal definition

Initial value	1
Applies to	<circle>, <ellipse>, <line>, <path>, <polygon>, <polyline>, and <rect> elements in an svg
Inherited	yes
Computed value	the specified value, clipped in the range [0,1]
Animation type	by computed value type

Formal syntax

```
stroke-opacity =
  <'opacity'>

<opacity> =
  <opacity-value>

<opacity-value> =
  <number>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Fill and Stroke Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Various stroke opacities

This example demonstrates basic usage of the stroke-opacity property and how, as a shape's stroke partially covers its fill, a stroke with an opacity less than 1 blends with the fill where they overlap.

HTML

First, we set up five multi-segment paths, all of which use a black stroke with a width of one, and a dodgerblue fill for the subpaths. Each path creates a series of mountain symbols, going from left (a shallow corner angle) to right (an extreme corner angle).

```
<svg viewBox="0 0 39 36" xmlns="http://www.w3.org/2000/svg">
  <g stroke="black" stroke-width="1" fill="dodgerblue">
    <path
      d="M1,5 l7   ,-3 l7   ,3
         m2,0 l3.5 ,-3 l3.5 ,3
         m2,0 l2   ,-3 l2   ,3
         m2,0 l0.75,-3 l0.75,3
         m2,0 l0.5 ,-3 l0.5 ,3" />
    <path
      d="M1,12 l7,-3 l7,3 m2,0 l3.5,-3 l3.5,3 m2,0 l2,-3 l2,3 m2,0 l0.75,-3 l0.75,3 m2,0 l0.5,-3 l0.5,3" />
    <path
      d="M1,19 l7,-3 l7,3 m2,0 l3.5,-3 l3.5,3 m2,0 l2,-3 l2,3 m2,0 l0.75,-3 l0.75,3 m2,0 l0.5,-3 l0.5,3" />
```

```
    <path
      d="M1,26 l7,-3 l7,3 m2,0 l3.5,-3 l3.5,3 m2,0 l2,-3 l2,3 m2,0 l0.75,-3 l0.75,3 m2,0 l0.5,-3 l0.5,3" />
    <path
      d="M1,33 l7,-3 l7,3 m2,0 l3.5,-3 l3.5,3 m2,0 l2,-3 l2,3 m2,0 l0.75,-3 l0.75,3 m2,0 l0.5,-3 l0.5,3" />
  </g>
</svg>
```

CSS

To these paths, we apply a successively higher stroke opacity value. For the first four paths, the fill can be seen through the inner half of the stroke path, though it may be difficult to discern for the fourth path. For the fifth and last path, the stroke is fully opaque and so the fill cannot be seen through the stroke.

```
g path:nth-child(1) {
  stroke-opacity: 0.2;
} /* equiv. 20% */
g path:nth-child(2) {
  stroke-opacity: 0.4;
} /* equiv. 40% */
g path:nth-child(3) {
  stroke-opacity: 0.6;
} /* equiv. 60% */
g path:nth-child(4) {
  stroke-opacity: 0.8;
} /* equiv. 80% */
g path:nth-child(5) {
  stroke-opacity: 1;
} /* equiv. 100% */
```

stroke-width CSS property

The **stroke-width** CSS property defines the width of a stroke applied to the SVG shape. If present, it overrides the element's stroke-width attribute.

This property applies to any SVG shape or text-content element (see stroke-width for a full list), but as an inherited property, it may be applied to elements such as <g> and still have the intended effect on descendant elements' strokes. If the value evaluates to zero, the stroke is not drawn.

Syntax

```
/* Length and percentage values */
stroke-width: 0%;
stroke-width: 1.414px;

/* Global values */
stroke-width: inherit;
stroke-width: initial;
stroke-width: revert;
stroke-width: revert-layer;
stroke-width: unset;
```

Values

<length>

Pixel units are handled the same as SVG units (see <number>, above) and font-based lengths such as em are calculated with respect to the element's SVG value for the text size; the effects of other length units may depend on the browser.

<percentage>

Percentages refer to the normalized diagonal of the current SVG viewport, which is calculated as $\frac{\sqrt{\text{<width>}^2 + \text{<height>}^2}}{\sqrt{2}}$.

<number>

A number of SVG units, the size of which defined by the current unit space.

Formal definition

Initial value	1px
Applies to	<circle>, <ellipse>, <line>, <path>, <polygon>, <polyline>, and <rect> elements in an svg
Inherited	yes
Percentages	refer to the normalized diagonal measure of the current SVG viewport's applied viewBox, or of the viewport itself if no viewBox is specified
Computed value	an absolute <length> or <percentage>, numbers converted to absolute lengths first
Animation type	by computed value type

Formal syntax

```
stroke-width =
  [ <length-percentage> | <line-width> | <number> ]#

<length-percentage> =
```

```
  <length>      |
  <percentage>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Fill and Stroke Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Various stroke widths

This example demonstrates various value syntaxes for the `stroke-width` property.

HTML

First, we set up five multi-segment paths, all of which use a black stroke with a width of one, and no fill. Each path creates a series of mountain symbols, going from left (a shallow corner angle) to right (an extreme corner angle).

```
<svg viewBox="0 0 39 30" xmlns="http://www.w3.org/2000/svg">
  <g stroke="black" stroke-width="1" fill="none">
    <path
      d="M1,5 l7   ,-3 l7   ,3
         m2,0 l3.5 ,-3 l3.5 ,3
         m2,0 l2   ,-3 l2   ,3
         m2,0 l0.75,-3 l0.75,3
         m2,0 l0.5 ,-3 l0.5 ,3" />
    <path
      d="M1,8 l7,-3 l7,3 m2,0 l3.5,-3 l3.5,3 m2,0 l2,-3 l2,3 m2,0 l0.75,-3 l0.75,3 m2,0 l0.5,-3 l0.5,3" />
    <path
      d="M1,14 l7,-3 l7,3 m2,0 l3.5,-3 l3.5,3 m2,0 l2,-3 l2,3 m2,0 l0.75,-3 l0.75,3 m2,0 l0.5,-3 l0.5,3" />
    <path
      d="M1,18 l7,-3 l7,3 m2,0 l3.5,-3 l3.5,3 m2,0 l2,-3 l2,3 m2,0 l0.75,-3 l0.75,3 m2,0 l0.5,-3 l0.5,3" />
    <path
      d="M1,26 l7,-3 l7,3 m2,0 l3.5,-3 l3.5,3 m2,0 l2,-3 l2,3 m2,0 l0.75,-3 l0.75,3 m2,0 l0.5,-3 l0.5,3" />
  </g>
</svg>
```

CSS

To the first four paths, we apply stroke width values as pairs to show how bare number values and pixel values are functionally equivalent. For the first two paths, the values are `.25` and `.25px`. For the second two paths, the values are `1` and `1px`.

For the fifth and last path, a value of `5%` is applied, thus setting a stroke width that is five percent as wide as the SVG viewport's diagonal measure is long.

```
path:nth-child(1) {
  stroke-width: 0.25;
}
path:nth-child(2) {
  stroke-width: 0.25px;
}
path:nth-child(3) {
  stroke-width: 1;
}
path:nth-child(4) {
  stroke-width: 1px;
}
path:nth-child(5) {
  stroke-width: 5%;
}
```

tab-size CSS property

The **`tab-size`** CSS property is used to customize the width of tab characters (U+0009).

Try it

```
tab-size: 10px;
```

```
tab-size: 16px;
```

```
tab-size: 24px;
```

```
tab-size: 4;
```

```
<section id="default-example">
  <pre id="example-element">&#9;123</pre>
</section>
```

```
#example-element {
  border: 1px solid;
}
```

Syntax

```
/* <number> values */
tab-size: 4;
tab-size: 0;

/* <length> values */
tab-size: 10px;
tab-size: 2em;

/* Global values */
tab-size: inherit;
tab-size: initial;
tab-size: revert;
tab-size: revert-layer;
tab-size: unset;
```

Values

`<number>`

A multiple of the advance width of the space character (U+0020) to be used as the width of tabs. Must be non-negative. The advance width means the distance a cursor or a print head moves before printing the next character.

`<length>`

The width of tabs. Must be non-negative.

Formal definition

Initial value	`8`
Applies to	block containers
Inherited	yes
Computed value	the specified integer or an absolute length
Animation type	a length

Formal syntax

```
tab-size =
  <number [0,∞]>  |
  <length [0,∞]>
```

This syntax reflects the latest standard as per CSS Text Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Expanding by character count

```
pre {
  tab-size: 4; /* Set tab size to 4 characters wide */
}
```

Collapse tabs

```
pre {
  tab-size: 0; /* Remove indentation */
}
```

Default tab size vs custom sizes

This example compares a default tab size with a custom tab size. Note that `white-space` is set to `pre` to prevent the tabs from collapsing.

HTML

```
<p>no tab</p>
<p>&#0009;default tab size of 8 characters wide</p>
<p class="custom-number">&#0009;custom tab size of 3 characters wide</p>
<p>   3 spaces, equivalent to the custom tab size</p>
<p class="custom-length">&#0009;custom tab size of 50px wide</p>
```

CSS

```
body {
  border: 1px solid red;
  margin: 1rem;
}
```

```
p {
  white-space: pre;
}

.custom-number {
  tab-size: 3;
}

.custom-length {
  tab-size: 50px;
}
```

Result

table-layout CSS property

The **table-layout** CSS property sets the algorithm used to lay out <table> cells, rows, and columns.

Try it

```
table-layout: auto;
width: 150px;
```

```
table-layout: fixed;
width: 150px;
```

```
table-layout: auto;
width: 100%;
```

```
table-layout: fixed;
width: 100%;
```

```
<section class="default-example" id="default-example">
  <table class="transition-all" id="example-element">
    <tbody>
      <tr>
        <th>Name</th>
        <th>Location</th>
      </tr>
      <tr>
        <td>Lion</td>
        <td>Africa</td>
      </tr>
      <tr>
        <td>Norwegian Lemming</td>
        <td>Europe</td>
      </tr>
      <tr>
        <td>Seal</td>
        <td>Antarctica</td>
      </tr>
      <tr>
        <td>Tiger</td>
        <td>Asia</td>
      </tr>
    </tbody>
  </table>
</section>
```

```
table {
  border: 1px solid #113399;
}

th,
td {
  border: 2px solid #aa1199;
  padding: 0.25rem 0.5rem;
}
```

Syntax

```
/* Keyword values */
table-layout: auto;
table-layout: fixed;

/* Global values */
table-layout: inherit;
table-layout: initial;
table-layout: revert;
table-layout: revert-layer;
table-layout: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

The automatic table layout algorithm is used. The widths of the table and its cells are adjusted to fit the content. Most browsers use this algorithm by default.

`fixed`

The fixed table layout algorithm is used. When using this keyword, the table's width *needs to be specified explicitly* using the `width` property. If the value of the `width` property is set to `auto` or is not specified, the browser uses the automatic table layout algorithm, in which case the `fixed` value has no effect.
The fixed table layout algorithm is faster than the automatic layout algorithm because the horizontal layout of the table depends only on the table's width, the width of the columns, and borders or cell spacing. The horizontal layout doesn't depend on the contents of the cells because it depends only on explicitly set widths.

In the fixed table layout algorithm, the width of each column is determined as follows:

- A column element with explicit width sets the width for that column.
- Otherwise, a cell in the first row with explicit width determines the width for that column.
- Otherwise, the column gets the width from the shared remaining horizontal space.

With this algorithm the entire table can be rendered once the first table row has been downloaded and analyzed. This can speed up rendering time over the "automatic" layout method, but subsequent cell content might not fit in the column widths provided. Cells use the `overflow` property to determine whether to clip any overflowing content, but only if the table has a known width; otherwise, they won't overflow the cells.

Formal definition

Initial value	`auto`
Applies to	`table` and `inline-table` elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
table-layout =
  auto   |
  fixed
```

This syntax reflects the latest standard as per CSS Table Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Fixed-width tables with text-overflow

This example uses a fixed table layout, combined with the `width` property, to restrict the table's width. The `text-overflow` property is used to apply an ellipsis to words that are too long to fit. If the table layout were `auto`, the table would grow to accommodate its contents, despite the specified `width`.

HTML

```
<table>
  <tbody>
    <tr>
      <td>Ed</td>
      <td>Wood</td>
    </tr>
    <tr>
      <td>Albert</td>
      <td>Schweitzer</td>
    </tr>
    <tr>
      <td>Jane</td>
      <td>Fonda</td>
    </tr>
    <tr>
      <td>William</td>
      <td>Shakespeare</td>
    </tr>
  </tbody>
</table>
```

CSS

```
table {
  table-layout: fixed;
  width: 120px;
  border: 1px solid red;
}

td {
  border: 1px solid blue;
  overflow: hidden;
  white-space: nowrap;
  text-overflow: ellipsis;
}
```

Result

text-align CSS property

The **`text-align`** CSS property sets the horizontal alignment of the inline-level content inside a block element or table-cell box. This means it works like `vertical-align` but in the horizontal direction.

Try it

```
text-align: start;
```

```
text-align: end;
```

```
text-align: center;
```

```
text-align: justify;
```

```
<section id="default-example">
  <div id="example-element">
    <p>
      Lorem ipsum dolor sit amet, consectetur adipisicing elit, sed do eiusmod
      tempor incididunt ut labore et dolore magna aliqua. Ut enim ad minim
      veniam, quis nostrud exercitation ullamco laboris nisi ut aliquip ex ea
      commodo consequat. Duis aute irure dolor in reprehenderit in voluptate
      velit esse cillum dolore eu fugiat nulla pariatur. Excepteur sint occaecat
      cupidatat non proident, sunt in culpa qui officia deserunt mollit anim id
      est laborum.
    </p>
  </div>
</section>
```

```
section {
  font-size: 1.5em;
}

#default-example > div {
  width: 250px;
}
```

Syntax

```
/* Keyword values */
text-align: start;
text-align: end;
text-align: left;
text-align: right;
text-align: center;
text-align: justify;
text-align: match-parent;

/* Block alignment values (Non-standard syntax) */
text-align: -moz-center;
text-align: -webkit-center;

/* Global values */
text-align: inherit;
text-align: initial;
text-align: revert;
text-align: revert-layer;
text-align: unset;
```

Values

This property is specified as one of the following keyword values:

`start`

The same as `left` if direction is left-to-right and `right` if direction is right-to-left.

`end`

The same as `right` if direction is left-to-right and `left` if direction is right-to-left.

`left`

The inline contents are aligned to the left edge of the line box.

`right`

The inline contents are aligned to the right edge of the line box.

`center`

The inline contents are centered within the line box.

`justify`

The inline contents are justified. Spaces out the content to line up its left and right edges to the left and right edges of the line box, except for the last line.

`match-parent`

Similar to `inherit`, but the values `start` and `end` are calculated according to the parent's `direction` and are replaced by the appropriate `left` or `right` value.

Accessibility

The inconsistent spacing between words created by justified text can be problematic for people with cognitive concerns such as Dyslexia.

- MDN Understanding WCAG, Guideline 1.4 explanations
- Understanding Success Criterion 1.4.8 | Understanding WCAG 2.0

Formal definition

Initial value	`start`, or a nameless value that acts as `left` if `direction` is `ltr`, `right` if `direction` is `rtl` if `start` is not supported by the browser.
Applies to	block containers
Inherited	yes
Computed value	as specified, except for the `match-parent` value which is calculated against its parent's `direction` value and results in a computed value of either `left` or `right`
Animation type	discrete

Formal syntax

```
text-align =
  start         |
  end           |
  left          |
  right         |
  center        |
  <string>      |
  justify       |
  match-parent  |
  justify-all
```

This syntax reflects the latest standard as per CSS Text Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Start alignment

HTML

```
<p class="example">
  Integer elementum massa at nulla placerat varius. Suspendisse in libero risus,
```

```
  in interdum massa. Vestibulum ac leo vitae metus faucibus gravida ac in neque.
  Nullam est eros, suscipit sed dictum quis, accumsan a ligula.
</p>
```

CSS

```
.example {
  text-align: start;
  border: solid;
}
```

Result

Centered text

HTML

```
<p class="example">
  Integer elementum massa at nulla placerat varius. Suspendisse in libero risus,
  in interdum massa. Vestibulum ac leo vitae metus faucibus gravida ac in neque.
  Nullam est eros, suscipit sed dictum quis, accumsan a ligula.
</p>
```

CSS

```
.example {
  text-align: center;
  border: solid;
}
```

Result

Example using "justify"

HTML

```
<p class="example">
  Integer elementum massa at nulla placerat varius. Suspendisse in libero risus,
  in interdum massa. Vestibulum ac leo vitae metus faucibus gravida ac in neque.
  Nullam est eros, suscipit sed dictum quis, accumsan a ligula.
</p>
```

CSS

```
.example {
  text-align: justify;
  border: solid;
}
```

Result

Table alignment

This example demonstrates the use of `text-align` on `<table>` elements:

- The `<caption>` is set to right-aligned.
- The first two `<th>` elements inherit the left alignment from the `text-align: left` set on the `<thead>`, while the third is set to right-aligned.
- Inside the `<tbody>` element, the first row is set to right-aligned, the second is set to center-aligned, and the third uses the default (left) alignment.
- Within each row, some cells (c12, c31) are set to override the alignment of the row.

HTML

```
<table>
  <caption>
    Example table
  </caption>
  <thead>
    <tr>
      <th>Col 1</th>
      <th>Col 2</th>
      <th class="right">Col 3</th>
    </tr>
  </thead>
  <tbody>
    <tr class="right">
      <td>11</td>
      <td class="center">12</td>
      <td>13</td>
    </tr>
    <tr class="center">
      <td>21</td>
      <td>22</td>
      <td>23</td>
    </tr>
    <tr id="r3">
      <td class="right">31</td>
      <td>32</td>
      <td>33</td>
    </tr>
  </tbody>
</table>
```

CSS

```
table {
  border-collapse: collapse;
  border: solid black 1px;
  width: 250px;
  height: 150px;
}
```

```
thead {
  text-align: left;
}

td,
th {
  border: solid 1px black;
}

.center {
  text-align: center;
}

.right,
caption {
  text-align: right;
}
```

Result

See also

- `margin: auto`, `margin-left: auto`, `vertical-align`

text-align-last CSS property

The **`text-align-last`** CSS property sets how the last line of a block or a line, right before a forced line break, is aligned.

Try it

```
text-align-last: right;
```

```
text-align-last: center;
```

```
text-align-last: left;
```

```
<section id="default-example">
  <div>
    <p id="example-element">
      Ut enim ad minim veniam, quis nostrud exercitation ullamco laboris nisi ut
      aliquip ex ea commodo consequat.
    </p>
  </div>
</section>
```

```
section {
  font-size: 1.5em;
}

#default-example > div {
  width: 250px;
}

#example-element {
  text-align: justify;
}
```

Syntax

```
/* Keyword values */
text-align-last: auto;
text-align-last: start;
text-align-last: end;
text-align-last: left;
text-align-last: right;
text-align-last: center;
text-align-last: justify;

/* Global values */
text-align-last: inherit;
text-align-last: initial;
text-align-last: revert;
text-align-last: revert-layer;
text-align-last: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

The affected line is aligned per the value of `text-align`, unless `text-align` is `justify`, in which case the effect is the same as setting `text-align-last` to `start`.

`start`

The same as `left` if direction is left-to-right and `right` if direction is right-to-left.

`end`

The same as `right` if direction is left-to-right and `left` if direction is right-to-left.

`left`

The inline contents are aligned to the left edge of the line box.

`right`

The inline contents are aligned to the right edge of the line box.

`center`

The inline contents are centered within the line box.

`justify`

The text is justified. Text should line up their left and right edges to the left and right content edges of the paragraph.

Formal definition

Initial value	`auto`
Applies to	block containers
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
text-align-last =
  auto          |
  start         |
  end           |
  left          |
  right         |
  center        |
  justify       |
  match-parent
```

This syntax reflects the latest standard as per CSS Text Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Justifying the last line

```
<p>
  Integer elementum massa at nulla placerat varius. Suspendisse in libero risus,
  in interdum massa. Vestibulum ac leo vitae metus faucibus gravida ac in neque.
  Nullam est eros, suscipit sed dictum quis, accumsan a ligula.
</p>
```

CSS

```
p {
  font-size: 1.4em;
  text-align: justify;
  text-align-last: center;
}
```

Results

See also

- `text-align`

text-anchor CSS property

The **`text-anchor`** CSS property aligns a box containing a string of text where the wrapping area is determined from the `inline-size` property, and the text is then placed relative to the anchor point of the element, which is defined using the `x` and `y` (or `dx` and `dy`) attributes. If present, the value of the CSS property overrides any value of the element's `text-anchor` attribute.

Each individual text fragment within an element is aligned independently; thus, a multi-line `<text>` element will have each line of text aligned as per the value of `text-anchor`. `text-anchor` values only have an effect on the `<text>`, `<textPath>`, and `<tspan>` SVG elements. `text-anchor` does not apply to automatically wrapped text; for that, see `text-align`.

Syntax

```
text-anchor: start;
text-anchor: middle;
text-anchor: end;

/* Global values */
text-anchor: inherit;
text-anchor: initial;
text-anchor: revert;
text-anchor: revert-layer;
text-anchor: unset;
```

Values

This property is specified as one of the following keyword values:

`start`

Aligns the text such that the inline start of the text string is aligned with the anchor point. This alignment is relative to the writing direction of the text; thus, for example, in right-to-left top-to-bottom writing, the text will be placed to the left of the anchor point. If the text's inline direction is vertical, as with many Asian languages, the top edge of the text is aligned with the anchor point.

`middle`

Aligns the text such that the center (middle) of the text string's inline box is aligned with the anchor point.

`end`

Aligns the text such that the inline end of the text string is aligned with the anchor point. This alignment is relative to the writing direction of the text; thus, for example, in right-to-left top-to-bottom writing, the text will be placed to the right of the anchor point. If the text's inline direction is vertical, as with many Asian languages, the bottom edge of the text is aligned with the anchor point.

Formal definition

Initial value	`start`
Applies to	`<text>`, `<textPath>`, and `<tspan>` elements in `<svg>`
Inherited	yes

Computed value	as specified
Animation type	discrete

Formal syntax

```
text-anchor =
  start   |
  middle  |
  end
```

This syntax reflects the latest standard as per CSS Specification. Not all browsers may have implemented every part. See Browser compatibility for support information.

Example

Three `<text>` elements are given the same `x` position, but different values for `text-anchor`. A dashed red line is included to mark the `x`-axis position of all three anchor points.

```
<svg
  viewBox="0 0 200 150"
  height="150"
  width="200"
  xmlns="http://www.w3.org/2000/svg">
  <line
    x1="100"
    y1="0"
    x2="100"
    y2="150"
    stroke="red"
    stroke-dasharray="10,5" />
  <text x="100" y="40">Anchored</text>
  <text x="100" y="80">Anchored</text>
  <text x="100" y="120">Anchored</text>
</svg>
```

```
text {
  font-size: 24px;
}
```

```
text:nth-of-type(1) {
  text-anchor: start;
}
text:nth-of-type(2) {
  text-anchor: middle;
}
text:nth-of-type(3) {
  text-anchor: end;
}
```

- `dominant-baseline`
- SVG `<text>` element
- SVG `text-anchor` attribute

text-autospace CSS property

The **`text-autospace`** CSS property allows you to specify the space applied between Chinese/Japanese/Korean (CJK) and non-CJK characters.

Syntax

```
text-autospace: normal;
text-autospace: no-autospace;
text-autospace: ideograph-alpha;
text-autospace: ideograph-numeric;
text-autospace: punctuation;
text-autospace: insert;
text-autospace: replace;
text-autospace: ideograph-alpha ideograph-numeric punctuation;
text-autospace: ideograph-alpha ideograph-numeric;
text-autospace: ideograph-alpha ideograph-numeric insert;
text-autospace: auto;

/* Global values */
text-autospace: inherit;
text-autospace: initial;
text-autospace: revert;
text-autospace: revert-layer;
text-autospace: unset;
```

Values

`normal`

> Creates the default behavior to automatically apply spacing between CJK and non-CJK characters and around punctuation. This value has the same effect as applying both `ideograph-alpha` and `ideograph-numeric`.

`<autospace>`

> Provides more control over spacing behaviors. It accepts the keyword `no-autospace`, or a combination of one or more of `ideograph-alpha`, `ideograph-numeric`, and `punctuation`, optionally followed by `insert` or `replace`.
>
> `no-autospace`
>
> > Disables automatic spacing between CJK and non-CJK characters.
>
> `ideograph-alpha`
>
> > Adds spacing only between ideographic characters (such as Katakana and Han) and non-ideographic letters (such as Latin). It does not add spacing between ideographic characters and non-ideographic numbers.

`ideograph-numeric`

Adds spacing only between ideographic characters (such as Katakana and Han) and non-ideographic numbers (such as Latin). It does not add spacing between ideographic characters and non-ideographic letters.

`punctuation`

Adds non-breaking spacing around punctuation as required by language-specific typographic conventions.

`insert`

Adds the specified spacing only if there are no existing spaces between the ideographic and non-ideographic scripts.

`replace`

Replaces existing spacing (such as U+0020) between ideographic and non-ideographic characters with the specified spacing.

`auto`

Lets the browser choose typographically appropriate spacing. The spacing may vary across browsers and platforms.

> **Note:** If neither `insert` nor `replace` are specified, the behavior is the same as `insert`.

> **Note:** This property is additive with the `word-spacing` and `letter-spacing` properties. The amount of spacing contributed by the `letter-spacing` setting is added to the spacing created by `text-autospace`. The same applies to `word-spacing`.

Formal definition

Initial value	`normal`
Applies to	text elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
text-autospace =
  normal       |
  <autospace>  |
  auto

<autospace> =
  no-autospace                                    |
  [ ideograph-alpha || ideograph-numeric || punctuation ] || [ insert | replace ]
```

This syntax reflects the latest standard as per CSS Text Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

This example shows the difference between various values of `text-autospace`. Try selecting a value from the drop-down box to see how it affects the spacing in the text.

```
<form>
  <label for="autospace">Choose value for <code>text-autospace:</code></label>
  <select name="autospace" id="autospace">
    <option selected value="no-autospace">no-autospace</option>
    <option value="normal">normal</option>
    <option value="ideograph-alpha">ideograph-alpha</option>
    <option value="ideograph-numeric">ideograph-numeric</option>
  </select>
</form>
<div class="unsupported">
  <code>text-autospace</code> is not supported in your browser.
</div>
```

```
<main>
  <figure class="no-autospace">
    <figcaption>
      <code>
        text-autospace: <span id="autospace-value">no-autospace</span>;
      </code>
    </figcaption>
    <div>
      <p>HTML超文本标记语言</p>
      <p>42四十二</p>
    </div>
  </figure>
</main>
```

```
.no-autospace {
  text-autospace: no-autospace;
}
.auto {
  text-autospace: auto;
}
.normal {
  text-autospace: normal;
}
.ideograph-alpha {

text-box CSS property

The **`text-box`** CSS shorthand property corresponds to the `text-box-trim` and `text-box-edge` properties, which together specify the amount of space to trim from the block-start edge and block-end edge of a text element's block container.

Constituent properties

This property is a shorthand for the following CSS properties:

- `text-box-trim`
- `text-box-edge`

Syntax

```
/* Single keyword */
text-box: normal;

/* One text-box-edge keyword */
text-box: trim-start text;
text-box: trim-both text;

/* Two text-box-edge keywords */
text-box: trim-start cap alphabetic;
text-box: trim-both ex text;

/* Global values */
text-box: inherit;
text-box: initial;
text-box: revert;
text-box: revert-layer;
text-box: unset;
```

Values

The `text-box` value can be composed of a `text-box-trim` value and a `text-box-edge` value separated by a space. See those pages for value descriptions.

The `text-box` property can also take a keyword of `normal`, which is equivalent to `text-box: none auto;`

If `text-box-trim` is omitted, it is set to `trim-both`. If `text-box-edge` is omitted, it is set to `auto`.

Formal definition

Initial value	`normal`
Applies to	Block containers and inline boxes
Inherited	no
Computed value	the specified keyword
Animation type	discrete

Formal syntax

```
text-box =
  normal                                |
  <'text-box-trim'> || <'text-box-edge'>
```

```
<text-box-trim> =
  none        |
  trim-start  |
  trim-end    |
  trim-both

<text-box-edge> =
  auto        |
  <text-edge>

<text-edge> =
  [ text | ideographic | ideographic-ink ]            |
  [ text | ideographic | ideographic-ink | cap | ex ] [ text | ideographic | ideographic-ink | alphabetic ]
```

This syntax reflects the latest standard as per CSS Inline Layout Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Description

The height of text-only content is relative to the height of the font. In digital font files, the height contains all characters, including capital letters, ascenders, descenders, etc. Different fonts have different base line-heights, meaning that lines of text with the same `font-size` will produce line boxes of differing heights, affecting the appearance of spacing between lines.

The `text-box` properties enable trimming off extra spacing from the block-start edge and block-end edge of a text element's block container, which can include the leading at the text's block-start edge and block-end edges, and the spacing defined inside the font (as described above). This makes it much easier to control text spacing in the block direction.

Examples

Basic <code>text-box</code> usage

In the following example, we have two `<p>` elements with classes of `one` and `two`.

We apply a `text-box` value of `trim-end cap alphabetic` to the first paragraph. The `text-box-edge` value of `cap alphabetic` specifies trimming the over edge to the top of the capital letters and the under edge flush with the text baseline. Because the `text-box-trim` value is set to `trim-end`, only the under edge of the paragraph is trimmed.

We apply a `text-box` value of `trim-both ex alphabetic` to the second paragraph. The `text-box-edge` value of `ex alphabetic` specifies trimming the over edge to the font's x-height (the top edge of the short lower-case letters) and the under edge flush with the text baseline. Because the `text-box-trim` value is set to `trim-both`, both the over *and* under edge of the paragraph are trimmed.

```
<p class="one">This is .one</p>

<p class="two">This is .two</p>
```

```
html {
  font-family: sans-serif;
  height: 100%;
}

body {
  height: inherit;
  display: flex;
  flex-direction: column;
  justify-content: center;
  gap: 100px;
}

p {
  margin: 0;
  font-size: 6rem;
  font-weight: bold;
}
```

```
.one {
  text-box: trim-end cap alphabetic;
}

.two {
  text-box: trim-both ex alphabetic;
}

p {
  border-top: 5px solid magenta;
  border-bottom: 5px solid magenta;
}
```

Result

The output is as follows. Note how we've included a top and bottom border on each paragraph, so that you can see how the space has been trimmed in each case.

- CSS text-box-edge on developer.chrome.com (2025)

text-box-edge CSS property

The **`text-box-edge`** CSS property specifies an amount of space to trim from a text element's block container.

Syntax

```
/* Single keyword */
text-box-edge: auto;
text-box-edge: text;

/* Two <text-edge> values */
text-box-edge: text text;
text-box-edge: text alphabetic;
text-box-edge: cap alphabetic;
text-box-edge: ex text;

/* Global values */
text-box-edge: inherit;
```

```
text-box-edge: initial;
text-box-edge: revert;
text-box-edge: revert-layer;
text-box-edge: unset;
```

Value

The `text-box-edge` property value is specified as `auto` or a `<text-edge>` value:

`auto`

The default value. Equivalent to the `text-edge` value `text`.

`<text-edge>`

One or two separate keywords representing over and under edge positions to trim the text element's block container to.

- If two values are specified, the first value specifies the trimming behavior to apply to the block-start (over) edge of the text, and the second value specifies the trimming behavior to apply to the block-end (under) edge of the text.
  - Valid over edge trimming values: `text`, `cap`, and `ex`.
  - Valid under edge trimming values: `text` and `alphabetic`.
- If one value is specified, it specifies the over *and* under edge trimming behavior. At the time of writing, the only valid single value is `text`.

Description

The `text-box-edge` property specifies an amount of space to trim from a text element's block container.

Vertical spacing differs between fonts, making consistent typesetting historically challenging on the web. The `text-box-edge` property — along with its counterpart property `text-box-trim`, which specifies which edge(s) to trim space from — makes consistent typesetting easier to achieve. The `text-box-edge` property has no effect if `text-box-trim` is not set or is set to `none`.

The height of text-only content is relative to the height of the font. In digital font files, the height contains all characters, including capital letters, ascenders, descenders, etc. Different fonts have different base line-heights, meaning that lines of text with the same `font-size` will produce line boxes of differing heights, affecting the appearance of spacing between lines.

The `text-box-edge` property allows you to trim space from the start and/or end edge of the text's block container. This can include the leading at the text's block-start edge and block-end edges and the spacing defined inside the font (as described above). It does this by specifying a `<text-edge>` value that indicates the over edge and under edge to trim the space to.

Which edge(s) to trim space from is specified using the `text-box-trim` property. For example, you can choose to trim space from the over edge or the under edge of the text's block container, or both.

These properties make it much easier to control text spacing in the block direction.

The `text-box-edge` property, along with the `text-box-trim` property, can also be set by using the `text-box` shorthand.

Formal definition

Initial value	`auto`
Applies to	Block containers and inline boxes
Inherited	no
Computed value	the specified keyword
Animation type	discrete

Formal syntax

```
text-box-edge =
  auto         |
  <text-edge>

<text-edge> =
  [ text | ideographic | ideographic-ink ]            |
  [ text | ideographic | ideographic-ink | cap | ex ] [ text | ideographic | ideographic-ink | alphabetic ]
```

This syntax reflects the latest standard as per CSS Inline Layout Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic <code>text-box-edge</code> usage

The most common `text-box-edge` values you'll use for horizontal `writing-mode` languages such as English or Arabic are `cap alphabetic` and `ex alphabetic`. The `cap` value trims the over edge of the text element's block container to the top of the capital letters, whereas `ex` trims the over edge to the font's x-height (the top edge of the short lower-case letters). In each case, `alphabetic` trims the under-edge flush with the text baseline.

In this example, we demonstrate the effect of both of these common values, on two `<p>` elements. Additionally, a `text-box-trim` value of `trim-both` has been set on both of them, so that their start *and* end edges are trimmed.

```
<p class="one">This is .one</p>

<p class="two">This is .two</p>
```

```
html {
  font-family: sans-serif;
  height: 100%;
}

body {
  height: inherit;
  display: flex;
  flex-direction: column;
  justify-content: center;
  gap: 100px;
}

p {
  margin: 0;
  font-size: 6rem;
  font-weight: bold;
}
```

```
p {
  text-box-trim: trim-both;
  border-top: 5px solid magenta;
  border-bottom: 5px solid magenta;
}

.one {
  text-box-edge: cap alphabetic;
}

.two {
  text-box-edge: ex alphabetic;
}
```

Result

The output is as follows. Note how we've included a top and bottom border on each paragraph, so that you can see how the space has been trimmed in each case.

Interactive <code>text-box-edge</code> value comparison

For a complete interactive `text-box-edge` example, see the `text-box-trim` page.

text-box-trim CSS property

The **`text-box-trim`** CSS property specifies which of the over and under edges of text content to trim from a text element's block container.

Syntax

```
/* Keyword values */
text-box-trim: none;
text-box-trim: trim-both;
text-box-trim: trim-start;
text-box-trim: trim-end;

/* Global values */
text-box-trim: inherit;
text-box-trim: initial;
text-box-trim: revert;
text-box-trim: revert-layer;
text-box-trim: unset;
```

Value

The `text-box-trim` property value may be specified as one of the following keywords:

`none`

The default value. No space is trimmed from the text.

`trim-both`

The start (over) and end (under) edges are both trimmed.

`trim-start`

The start (over) edge is trimmed.

`trim-end`

The end (under) edge is trimmed.

Description

The `text-box-trim` property specifies which of the over and under edges of text content to trim from a text element's block container.

Vertical spacing differs between fonts, making consistent typesetting historically challenging on the web. The `text-box-trim` property — along with its counterpart property `text-box-edge`, which specifies how much space to trim — makes consistent vertical spacing of text easier to achieve.

The height of text-only content is relative to the height of the font. In digital font files, the height contains all characters, including capital letters, ascenders, descenders, etc. Different fonts have different base line-heights, meaning that lines of text with the same `font-size` will produce line boxes of differing heights, affecting the appearance of spacing between lines.

The `text-box-trim` property allows you to trim the over and under edge of the text's block container, making it easier to control text spacing in the block direction.

The actual amount of space trimmed is specified using the `text-box-edge` property. For example, you can choose to trim the over edge in line with a font's capital letters or lower-case letters, and the under edge flush with the font's baseline.

The `text-box-trim` property, along with the `text-box-edge` property, can also be set by using the `text-box` shorthand.

Formal definition

Initial value	none
Applies to	Block containers and inline boxes
Inherited	no
Computed value	the specified keyword
Animation type	discrete

Formal syntax

```
text-box-trim =
  none        |
  trim-start  |
```

```
  trim-end    |
  trim-both
```

This syntax reflects the latest standard as per CSS Inline Layout Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic <code>text-box-trim</code> usage

In the following example we set `text-box-edge: cap alphabetic` on two paragraphs, which trims the over edge of the text elements' block containers to the top of the capital letters and the under edge flush with the text baseline.

We then set `text-box-trim` values of `trim-end` on the first one, and `trim-both` on the second one. This results in the first paragraph only having its under edge trimmed, whereas the second one has both the over *and* under edge trimmed.

```
<p class="one">This is .one</p>

<p class="two">This is .two</p>
```

```
html {
  font-family: sans-serif;
  height: 100%;
}

body {
  height: inherit;
  display: flex;
  flex-direction: column;
  justify-content: center;
  gap: 100px;
}

p {
  margin: 0;
  font-size: 6rem;
  font-weight: bold;
}
```

```
p {
  text-box-edge: cap alphabetic;
  border-top: 5px solid magenta;
  border-bottom: 5px solid magenta;
}

.one {
  text-box-trim: trim-end;
}

.two {
  text-box-trim: trim-both;
}
```

Result

The output is as follows. Note how we've included a top and bottom border on each paragraph, so that you can see how the space has been trimmed in each case.

Interactive <code>text-box-trim</code> and <code>text-box-edge</code> value comparison

In this example we provide a user interface that allows you to choose the `text-box-trim` and `text-box-edge` values applied to a paragraph of text.

HTML

In our HTML, we include three main items:

- Three `<select>` elements allowing you to set which edges of the paragraph should be trimmed (the `text-box-trim` value) and how much space to trim from the block-start and block-end edges of the paragraph (the `text-box-edge` value).
- A `<p>` element containing text, which the `text-box-*` values are applied to. This paragraph has `contenteditable` set on it so you can edit the text.
- An `<output>` element that displays the `text-box-*` declarations applied to the paragraph. This is updated when a selection is made.

We also import a font from the Google Fonts service to apply to our demo's text.

We have hidden the exact HTML code for brevity.

```
<link rel="preconnect" href="https://fonts.googleapis.com" />
<link rel="preconnect" href="https://fonts.gstatic.com" crossorigin />
<link
  href="https://fonts.googleapis.com/css2?family=Roboto:ital,wght@0,100..900;1,100..900&display=swap"
  rel="stylesheet" />
<section>
  <div>
    <label for="box-trim">Select edge(s) to trim:</label>
    <select id="box-trim">
      <option>none</option>
      <option>trim-start</option>
      <option>trim-end</option>
      <option selected>trim-both</option>
    </select>
  </div>
  <div>
    <label for="trim-over">Select trim over (start) value:</label>
    <select id="trim-over">
      <option>text</option>
      <option selected>cap</option>
      <option>ex</option>
    </select>
  </div>
</section>
<p class="display" contenteditable>Holly Golightly</p>
<section>
  <div>
    <label for="trim-under">Select trim under (end) value:</label>
```

```
    <select id="trim-under">
      <option>text</option>
      <option selected>alphabetic</option>
    </select>
  </div>
</section>
<output></output>
```

CSS

In our CSS, we apply the imported font to the `<html>` element and lay out the UI using flexbox. We have hidden most of the CSS code for brevity, but below we show the rules styling the paragraph the `text-box-*` effects are applied to and the `<output>` that shows the `text-box-*` rules being applied:

```
html {
  font-family: "Roboto", sans-serif;
  height: 100%;
}

body {
  height: inherit;
  display: flex;
  flex-direction: column;
  justify-content: center;
  gap: 30px;
}

section {
  display: flex;
  justify-content: space-between;
}

section:nth-of-type(2) {
  justify-content: flex-end;
  padding-bottom: 30px;
}

select {
  width: 6rem;
}
```

```
p {
  margin: 0;
  font-size: 6rem;
  font-weight: bold;
  border-top: 5px solid magenta;
  border-bottom: 5px solid magenta;
}

output {
  border: 2px solid gray;
  border-radius: 10px;
  padding: 10px;
  margin: 0;
  width: fit-content;
}
```

Again, note how we've included a top and bottom border on the `.display` paragraph, so that you can see how the space being trimmed changes when different `text-box-*` values are selected.

JavaScript

In the JavaScript, we start by grabbing references to the three `<select>` elements and two `<p>` elements:

```
const boxTrimSelect = document.getElementById("box-trim");
const trimOverSelect = document.getElementById("trim-over");
const trimUnderSelect = document.getElementById("trim-under");

const displayElem = document.querySelector("p");
const codeElem = document.querySelector("output");
```

Next, we define a function called `setEdgeTrim()`. This applies a `text-box` value to the paragraph based on the values of the `<select>` elements, and also prints the applied declarations to the output (both the longhand and shorthand equivalents):

```
function setEdgeTrim() {
  const textBoxTrimValue = boxTrimSelect.value;
  const textBoxEdgeValue = `${trimOverSelect.value} ${trimUnderSelect.value}`;
  displayElem.style.textBox = `${textBoxTrimValue} ${textBoxEdgeValue}`;

  codeElem.innerHTML = `
    <span><code>text-box-trim: ${textBoxTrimValue}</code></span>
    <br>
    <span><code>text-box-edge: ${textBoxEdgeValue}</code></span>
    <br><br>
    <span>Shorthand equivalent:</span>
    <br><br>
    <span><code>text-box: ${textBoxTrimValue} ${textBoxEdgeValue}</code></span>
  `;
}
```

In the last part of the JavaScript we run the `setEdgeTrim()` function once to set an initial state for the UI. We then apply `change` event listeners to all of the `<select>` elements (via `addEventListener`) so that `setEdgeTrim()` is run whenever one of the `<select>` values changes to update the UI accordingly:

```
setEdgeTrim();

boxTrimSelect.addEventListener("change", setEdgeTrim);
trimOverSelect.addEventListener("change", setEdgeTrim);
trimUnderSelect.addEventListener("change", setEdgeTrim);
```

Result

The output is as follows:

`text-box-trim` is initially set to `trim-both`, meaning that the over *and* under edges of the paragraph are trimmed. `text-box-edge` is initially set to `cap alphabetic`, meaning that the text is trimmed flush with the top of capital letters at the start edge, and flush with the baseline at the end edge.

Try changing the `<select>` values to see the effect they have on the display text.

- CSS inline layout module
- CSS text-box-trim on developer.chrome.com (2025)

text-combine-upright CSS property

The **`text-combine-upright`** CSS property sets the combination of characters into the space of a single character. If the combined text is wider than 1em, the user agent must fit the contents within 1em. The resulting composition is treated as a single upright glyph for layout and decoration. This property only has an effect in vertical writing modes.

This is used to produce an effect that is known as tate-chū-yoko "縦中横" in Japanese, or as "横向文字" in Chinese.

Try it

```
text-combine-upright: none;
```

```
text-combine-upright: all;
```

```
<section class="default-example" id="default-example">
  <div>
    <p>
      <span class="transition-all" id="example-element"
        >2022<span>年</span>12<span>月</span>8</span
      >日から楽しい
    </p>
  </div>
</section>
```

```
p {
  writing-mode: vertical-rl;
}
```

Syntax

```
/* Keyword values */
text-combine-upright: none;
text-combine-upright: all;

/* Global values */
text-combine-upright: inherit;
text-combine-upright: initial;
text-combine-upright: revert;
text-combine-upright: revert-layer;
text-combine-upright: unset;
```

Values

This property is specified as one of the following keyword values:

`none`

There is no special processing.

`all`

Attempts to typeset all consecutive characters within the box horizontally, such that they take up the space of a single character within the vertical line of the box.

> **Note:** The CSS writing modes module defines a `digits <integer>` value for the `text-combine-upright` property to display two to four consecutive ASCII digits (U+0030–U+0039) such that it takes up the space of a single character within the vertical line box, however, this is not supported in any browsers.

Formal definition

Initial value	none
Applies to	non-replaced inline elements
Inherited	yes
Computed value	specified keyword, plus integer if 'digits'
Animation type	Not animatable

Formal syntax

```
text-combine-upright =
  none                          |
  all                           |
  [ digits <integer [2,4]>? ]

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4, CSS Writing Modes Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using 'all' with horizontal text

The all value requires markup around every piece of horizontal text, but it is currently supported by more browsers than the digits value.

HTML

```
<p lang="zh-Hant">
  民國<span class="num">105</span>年<span class="num">4</span>月<span
    class="num"
    >29</span
  >日
</p>
```

CSS

```
html {
  writing-mode: vertical-rl;
  font: 24px serif;
}
.num {
  text-combine-upright: all;
}
```

Results

text-decoration CSS property

The **`text-decoration`** CSS shorthand property sets the appearance of decorative lines on text. It is a shorthand for `text-decoration-line`, `text-decoration-color`, `text-decoration-style`, and the newer `text-decoration-thickness` property.

Text decorations are drawn across descendant text elements. This means that if an element specifies a text decoration, then a child element can't remove the decoration. For example, in the markup `<p>This text has <em>some emphasized words</em> in it.</p>`, the style rule `p { text-decoration: underline; }` would cause the entire paragraph to be underlined. The style rule `em { text-decoration: none; }` would not cause any change; the entire paragraph would still be underlined. However, the rule `em { text-decoration: overline; }` would cause a second decoration to appear on "some emphasized words".

Try it

```
text-decoration: underline;
```

```
text-decoration: underline dotted;
```

```
text-decoration: underline dotted red;
```

```
text-decoration: green wavy underline;
```

```
text-decoration: underline overline #ff3028;
```

```
<section id="default-example">
  <p>
    I'd far rather be
    <span class="transition-all" id="example-element">happy than right</span>
    any day.
  </p>
</section>
```

```
p {
  font: 1.5em sans-serif;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `text-decoration-color`
- `text-decoration-line`
- `text-decoration-style`
- `text-decoration-thickness`

Syntax

```
text-decoration: underline;
text-decoration: overline red;
text-decoration: none;

/* Global values */
text-decoration: inherit;
text-decoration: initial;
text-decoration: revert;
text-decoration: revert-layer;
text-decoration: unset;
```

The `text-decoration` property is specified as one or more space-separated values representing the various longhand text-decoration properties.

Values

`text-decoration-line`

Sets the kind of decoration used, such as `underline` or `line-through`.

`text-decoration-color`

Sets the color of the decoration.

`text-decoration-style`

Sets the style of the line used for the decoration, such as `solid`, `wavy`, or `dashed`.

`text-decoration-thickness`

Sets the thickness of the line used for the decoration.

Formal definition

Initial value	as each of the properties of the shorthand: • `text-decoration-color`: `currentcolor` • `text-decoration-style`: `solid` • `text-decoration-line`: `none`
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Computed value	as each of the properties of the shorthand: • `text-decoration-line`: as specified • `text-decoration-style`: as specified • `text-decoration-color`: computed color • `text-decoration-thickness`: as specified
Animation type	as each of the properties of the shorthand: • `text-decoration-color`: a color • `text-decoration-style`: discrete • `text-decoration-line`: discrete • `text-decoration-thickness`: by computed value type

Formal syntax

```
text-decoration =
  <'text-decoration-line'>      ||
  <'text-decoration-thickness'> ||
  <'text-decoration-style'>     ||
  <'text-decoration-color'>

<text-decoration-line> =
  none                                          |
  [ underline || overline || line-through || blink ]  |
  spelling-error                                |
  grammar-error

<text-decoration-thickness> =
  auto                  |
  from-font             |
  <length-percentage>   |
  <line-width>

<text-decoration-style> =
  solid    |
  double   |
  dotted   |
  dashed   |
  wavy

<text-decoration-color> =
  <color>

<length-percentage> =
  <length>      |
  <percentage>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Text Decoration Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Demonstration of text-decoration values

```
.under {
  text-decoration: underline red;
}

.over {
  text-decoration: wavy overline lime;
}

.line {
  text-decoration: line-through;
}

.plain {
  text-decoration: none;
}

.underover {
  text-decoration: dashed underline overline;
}
```

```
.thick {
  text-decoration: solid underline purple 4px;
}

.blink {
  text-decoration: blink;
}
```

```
<p class="under">This text has a line underneath it.</p>
<p class="over">This text has a line over it.</p>
<p class="line">This text has a line going through it.</p>
<p>
  This <a class="plain" href="#">link will not be underlined</a>, as links
  generally are by default. Be careful when removing the text decoration on
  anchors since users often depend on the underline to denote hyperlinks.
</p>
<p class="underover">This text has lines above <em>and</em> below it.</p>
<p class="thick">
  This text has a really thick purple underline in supporting browsers.
</p>
<p class="blink">
  This text might blink for you, depending on the browser you use.
</p>
```

- The `text-decoration-skip-ink`, `text-underline-offset`, and `text-underline-position` properties also affect text-decoration, but are not included in the shorthand.
- The `list-style` property controls the appearance of items in HTML `<ol>` and `<ul>` lists.
- SVG `text-decoration` attribute

text-decoration-color CSS property

The **`text-decoration-color`** CSS property sets the color of decorations added to text by `text-decoration-line`.

The color applies to decorations, such as underlines, overlines, strikethroughs, and wavy lines like those used to mark misspellings, in the scope of the property's value.

CSS does not provide a direct mechanism for specifying a unique color for each line type. This effect can nevertheless be achieved by nesting elements, applying a different line type to each element (with the `text-decoration-line` property), and specifying the line color (with `text-decoration-color`) on a per-element basis.

Try it

```
text-decoration-color: red;
```

```
text-decoration-color: #21ff21;
```

```
text-decoration-color: rgb(255 90 255);
```

```
text-decoration-color: hsl(70 100% 40%);
```

```
text-decoration-color: currentColor;
```

```
<section id="default-example">
  <p>
    I'd far rather be
    <span class="transition-all" id="example-element">happy than right</span>
    any day.
  </p>
</section>
```

```
p {
  font: 1.5em sans-serif;
}

#example-element {
  text-decoration-line: underline;
}
```

Syntax

```
/* <color> values */
text-decoration-color: currentColor;
text-decoration-color: red;
text-decoration-color: #00ff00;
text-decoration-color: rgb(255 128 128 / 50%);
text-decoration-color: transparent;

/* Global values */
text-decoration-color: inherit;
text-decoration-color: initial;
text-decoration-color: revert;
text-decoration-color: revert-layer;
text-decoration-color: unset;
```

Values

This property is specified as one `<color>` value:

`<color>`

The color of the line decoration.

Accessibility

It is important to ensure that the contrast ratio between the color of the text, the background the text is placed over, and the text decoration line is high enough that people experiencing low vision conditions will be able to read the content of the page. Color contrast ratio is determined by comparing the luminosity of the text and background color values.

Color alone should not be used to convey meaning. For example, change of text and text-decoration-color alone is not enough to indicate a link has focus.

- WebAIM: Color Contrast Checker
- MDN Understanding WCAG, Guideline 1.4 explanations
- Understanding Success Criterion 1.4.3 | W3C Understanding WCAG 2.0

Formal definition

Initial value	`currentcolor`
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Computed value	computed color
Animation type	a color

Formal syntax

```
text-decoration-color =
  <color>
```

This syntax reflects the latest standard as per CSS Text Decoration Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

```
<p>
  This paragraph has <s>some erroneous text</s> inside it that I want to call
  attention to.
</p>
```

```
p {
  text-decoration-line: underline;
  text-decoration-color: cyan;
}

s {
  text-decoration-line: line-through;
  text-decoration-color: red;
  text-decoration-style: wavy;
}
```

See also

- When setting multiple line-decoration properties at once, it may be more convenient to use the `text-decoration` shorthand property instead.
- The `<color>` data type
- Other color-related properties: `background-color`, `border-color`, `outline-color`, `text-emphasis-color`, `text-shadow`, `caret-color`, and `column-rule-color`

text-decoration-inset CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`text-decoration-inset`** CSS property enables adjusting the start and end points of an element's text decoration so it can be shortened, lengthened, or have its position shifted with respect to the rendered text.

Try it

```
text-decoration-inset: 20px;
```

```
text-decoration-inset: -0.5em;
```

```
text-decoration-inset: 20px 1em;
```

```
text-decoration-inset: -0.5rem -1.5rem;
```

```
text-decoration-inset: -2ex 10vw;
```

```
<section id="default-example">
  <p id="example-element">Karmadrome</p>
</section>
```

```
#example-element {
  font: 2.5em sans-serif;
  text-decoration: underline 0.3em limegreen;
}
```

Syntax

```
/* auto keyword */
text-decoration-inset: auto;

/* One <length> value */
text-decoration-inset: 20px;
text-decoration-inset: -2rem;
text-decoration-inset: 5%;

/* Two <length> values */
```

```
text-decoration-inset: 20px 1em;
text-decoration-inset: -0.5rem -1.5rem;
text-decoration-inset: -2ex 1vw;
text-decoration-inset: -5% -5%;

/* Global values */
text-decoration-inset: inherit;
text-decoration-inset: initial;
text-decoration-inset: revert;
text-decoration-inset: revert-layer;
text-decoration-inset: unset;
```

Values

This property is specified as one or two of the following value or the keyword `auto`:

`<length-percentage>`

> Specifies the amount to adjust the text decoration position by. Positive values inset the text decoration (make it shorter) while negative values outset the text decoration (make it longer). If one value is specified, it applies to both the text decoration start and end points. If two values are specified, the first one applies to the text decoration start point and the second one applies to the text decoration end point. Percentage values either refer to the total inline size of the decorating box if `box-decoration-break` is set to `slice`, or to the inline size of each individual box fragment, if it is set to `clone`.

`auto`

> The browser chooses a start and end inset amount to ensure that, if two decorated text boxes appear side-by-side, the appearance of a gap is created between their text decorations so they do not appear to have a single text decoration.

Description

By default, an element's text decoration, as set by the `text-decoration` shorthand and associated longhand properties, is the same size as the rendered text.

The `text-decoration-inset` property allows you to adjust the start and/or end points of a text container's text decoration. This is useful for creating effects where you want the text decoration to be inset or outset from the text itself, or shifted in position. See Basic use cases for an example of each.

A single `<length-percentage>` value will set the inset (if positive) or outset (if negative) on the start and end positions of the text decoration. To set the start and end positions separately, you can use two `<length-percentage>` values — the first one applies to the start position of the text decoration and the second one applies to the end.

> **Note:** A percentage value depends on the value of `box-decoration-break`, if it is set to `slice` (the initial value) it refers to the inline size of the decorating box or if it is set to `clone` it refers to each individual box fragment.

The `text-decoration-inset` property can also take the `auto` keyword. This causes the browser to inset the text decoration start and end points to ensure that, if two decorated text boxes appear side-by-side, they do not appear to have a single text decoration. The `auto` value is particularly important when rendering Chinese text, where underlining is used to punctuate proper nouns, and adjacent proper nouns should have separate underlines. See Effect of the `auto` value for an example.

The `auto` value does not have the same effect as the initial value `0`. Setting `text-decoration-inset` to `0` causes there to be no space between decorations.

The `text-decoration-inset` property is not inherited, and it is not a constituent property of the `text-decoration` shorthand.

Formal definition

Initial value	`0`
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Percentages	refer to the size of the box itself
Computed value	for percentage and length values, the absolute length, otherwise the keyword as specified
Animation type	by computed value

Formal syntax

```
text-decoration-inset =
  <length-percentage>{1,2}  |
  auto

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Text Decoration Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic use cases

In this example, we demonstrate the outset, inset, and "shifted" use cases.

HTML

We define an unordered list with three list items, each with a separate `id`.

```
<ul>
  <li id="one">Outset decoration</li>
  <li id="two">Inset decoration</li>
  <li id="three">Shifted decoration</li>
</ul>
```

CSS

We give each list item a different `text-decoration` and `text-decoration-inset`:

- The first one has a thick lime green underline, which is outset equally by `10px` on both sides.
- The second one has a medium thickness white strike-through, which is inset equally by `0.5em` on both sides.
- The third one has a thin wavy blue underline, which is moved to the right by `1em`.

```
li {
  font-family: sans-serif;
  font-size: 2em;
  margin-bottom: 20px;
}

@supports not (text-decoration-inset: auto) {
  body::before {
    content: "Your browser doesn't support the text-decoration-inset property.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

```
#one {
  text-decoration: underline 0.3em limegreen;
  text-decoration-inset: -10px;
}

#two {
  text-decoration: line-through 5px white;
  text-decoration-inset: 0.5em;
}

#three {
  text-decoration: underline wavy 2px blue;
  text-decoration-inset: 1em -1em;
}
```

Result

This renders like so:

Effect of the <code>auto</code> value

This example demonstrates the effect of the `text-decoration-inset: auto` value.

HTML

We define two groups of side-by-side `<u>` elements:

```
<p lang="zh" id="one"><u>石井</u><u>艾俐俐</u></p>

<p lang="zh" id="two"><u>石井</u><u>艾俐俐</u></p>
```

CSS

Each `<u>` element has a `red` color and `3px` thickness set on its underline. The first group of `<u>` elements has a `text-decoration-inset` value of `auto` set on them, while the second set has the initial `text-decoration-inset` value of `0` explicitly set on them, for comparison purposes:

```
u {
  font-family: sans-serif;
  font-size: 2em;
}

@supports not (text-decoration-inset: auto) {
  body::before {
    content: "Your browser doesn't support the text-decoration-inset property.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

```
u {
  text-decoration-color: red;
  text-decoration-thickness: 3px;
}

#one u {
  text-decoration-inset: auto;
}

#two u {
  text-decoration-inset: 0;
}
```

Result

This renders like so:

Note how the `auto` value insets the text decoration subtly on both sides, creating a gap in between the underlines of the two elements (no space is added between the two elements themselves). The `0` value results in no gap.

- `text-decoration`
- The CSS text decoration module

text-decoration-line CSS property

The **`text-decoration-line`** CSS property sets the kind of decoration that is used on text in an element, such as an underline or overline.

When setting multiple line-decoration properties at once, it may be more convenient to use the `text-decoration` shorthand property instead.

Try it

```
text-decoration-line: none;
```

```
text-decoration-line: underline;
```

```
text-decoration-line: overline;
```

```
text-decoration-line: line-through;
```

```
text-decoration-line: grammar-error;
```

```
text-decoration-line: spelling-error;
```

```
text-decoration-line: underline overline;
```

```
text-decoration-line: underline line-through;
```

```
<section id="default-example">
  <p>
    I'd far rather be
    <span class="transition-all" id="example-element">happy than right</span>
    any day.
  </p>
</section>
```

```
p {
  font: 1.5em sans-serif;
}
```

Syntax

```
/* Single keyword */
text-decoration-line: none;
text-decoration-line: underline;
text-decoration-line: overline;
text-decoration-line: line-through;
text-decoration-line: blink;
text-decoration-line: spelling-error;
text-decoration-line: grammar-error;

/* Multiple keywords */
text-decoration-line: underline overline; /* Two decoration lines */
text-decoration-line: overline underline line-through; /* Multiple decoration lines */

/* Global values */
text-decoration-line: inherit;
text-decoration-line: initial;
text-decoration-line: revert;
text-decoration-line: revert-layer;
text-decoration-line: unset;
```

Values

This property is specified either as `none` or a space-separated list of keyword values chosen from the list below:

`none`

Produces no text decoration.

`underline`

Each line of text has a decorative line beneath it.

`overline`

Each line of text has a decorative line above it.

`line-through`

Each line of text has a decorative line going through its middle.

`blink`

The text blinks (alternates between visible and invisible). Conforming user agents may not blink the text. This value is **deprecated** in favor of CSS animations.

`spelling-error`

Each line of text uses the user agents' method of highlighting spelling mistakes, which is a dotted red line in most browsers.

`grammar-error`

Each line of text uses the user agents' method of highlighting grammar mistakes, which is a dotted green line in most browsers.

> **Note:** When using `spelling-error` and `grammar-error` values, the browser disregards the other properties in the `text-decoration` shorthand (such as `text-underline-position`, `color`, or `stroke`).

Formal definition

Initial value	none
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
text-decoration-line =
  none                                          |
  [ underline || overline || line-through || blink ]  |
  spelling-error                                |
  grammar-error
```

This syntax reflects the latest standard as per CSS Text Decoration Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

```
<p class="wavy">Here's some text with wavy red underline!</p>
<p class="both">This text has lines both above and below it.</p>
```

```
.wavy {
  text-decoration-line: underline;
  text-decoration-style: wavy;
  text-decoration-color: red;
}

.both {
  text-decoration-line: underline overline;
}
```

Errors example

In this example, the first paragraph contains a spelling mistake and uses the browser's styling for spelling errors on the misspelled word. The second paragraph uses the browser's styling for grammar errors. There is no styling change in browsers that do not support these `text-decoration-line` values.

```
<p>This text contains a <span class="spelling">speling</span> mistake.</p>
<p class="grammar">This text contain grammatical errors.</p>
```

```
.spelling {
  text-decoration-line: spelling-error;
}

.grammar {
  text-decoration-line: grammar-error;
}
```

See also

- When setting multiple line-decoration properties at once, it may be more convenient to use the `text-decoration` shorthand property instead, which also includes:
  - `text-decoration-style`
  - `text-decoration-color`
  - `text-decoration-thickness`
- `text-underline-offset`
- `::spelling-error`
- `::grammar-error`

text-decoration-skip CSS property

The **`text-decoration-skip`** CSS property sets what parts of an element's content any text decoration affecting the element must skip over. It controls all text decoration lines drawn by the element and also any text decoration lines drawn by its ancestors.

> **Note:** Most other browsers are converging on supporting the simpler `text-decoration-skip-ink` property.

Syntax

```
/* Keyword values */
text-decoration-skip: none;
text-decoration-skip: objects;
text-decoration-skip: spaces;
text-decoration-skip: edges;
text-decoration-skip: box-decoration;

/* Multiple keywords */
text-decoration-skip: objects spaces;
text-decoration-skip: leading-spaces trailing-spaces;
text-decoration-skip: objects edges box-decoration;

/* Global values */
text-decoration-skip: inherit;
text-decoration-skip: initial;
text-decoration-skip: revert;
text-decoration-skip: revert-layer;
text-decoration-skip: unset;
```

Values

`none`

Nothing is skipped. Thus, text decoration is drawn for all text content and across atomic inline-level boxes.

`objects`

The entire margin box of the element is skipped if it is an atomic inline such as an image or inline-block.

`spaces`

All spacing is skipped: all Unicode white space characters and all word separators, plus any adjacent `letter-spacing` or `word-spacing`.

`leading-spaces`

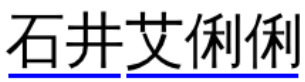
The same as `spaces`, except that only leading spaces are skipped.

`trailing-spaces`

The same as `spaces`, except that only trailing spaces are skipped.

`edges`

The start and end of the text decoration is inset slightly (e.g., by half of the line thickness) from the content edge of the decorating box. Thus, adjacent elements receive separate underlines. (This is important in Chinese, where underlining is a form of punctuation.)



`box-decoration`

The text decoration is skipped over the box's margin, border, and padding areas. This only has an effect on decorations imposed by an ancestor; a *decorating box* never draws over its own box decoration.

Formal definition

Initial value	`objects`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
text-decoration-skip =
  none  |
  auto
```

This syntax reflects the latest standard as per CSS Text Decoration Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Skipping edges

HTML

```
<p>Hey, grab a cup of <em>coffee!</em></p>
```

CSS

```
p {
  margin: 0;
  font-size: 3em;
  text-decoration: underline;
  text-decoration-skip: edges;
}
```

Result

See also

- `text-decoration-skip-ink`

text-decoration-skip-ink CSS property

The **`text-decoration-skip-ink`** CSS property specifies how overlines and underlines are drawn when they pass over glyph ascenders and descenders.

`text-decoration-skip-ink` is not part of the `text-decoration` shorthand.

Try it

```
text-decoration-skip-ink: auto;
```

```
text-decoration-skip-ink: none;
```

```
<section id="default-example">
  <p>
    <span class="transition-all" id="example-element">parapsychologists</span>
  </p>
</section>
```

```
p {
  font:
    1.9em "Georgia",
    serif;
  text-decoration: underline;
}
```

Syntax

```
/* Single keyword */
text-decoration-skip-ink: none;
text-decoration-skip-ink: auto;
text-decoration-skip-ink: all;

/* Global keywords */
text-decoration-skip-ink: inherit;
text-decoration-skip-ink: initial;
text-decoration-skip-ink: revert;
```

```
text-decoration-skip-ink: revert-layer;
text-decoration-skip-ink: unset;
```

Values

This property is specified as one of the following keyword values:

`none`

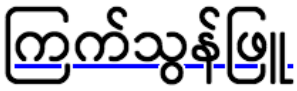
Underlines and overlines are drawn across the full length of the text content, including parts that cross over glyph descenders and ascenders.

`auto`

The default — the browser *may* interrupt underlines and overlines so that they do not touch or closely approach a glyph. That is, they are interrupted where they would otherwise cross over a glyph.

`all`

The browser *must* interrupt underlines and overlines so that they do not touch or closely approach a glyph. This can be helpful with certain Chinese, Japanese, or Korean (CJK) fonts, where the `auto` behavior might not create interruptions.



Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
text-decoration-skip-ink =
  auto  |
  none  |
  all
```

This syntax reflects the latest standard as per CSS Text Decoration Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<p>You should go on a quest for a cup of coffee.</p>
<p class="no-skip-ink">Or maybe you'd prefer some tea?</p>
<p>この文は、 text-decoration-skip-ink: auto の使用例を示しています。</p>
<p class="skip-ink-all">
  この文は、 text-decoration-skip-ink: all の使用例を示しています。
</p>
```

CSS

```
p {
  font-size: 1.5em;
  text-decoration: underline blue;
  text-decoration-skip-ink: auto; /* this is the default anyway */
}

.no-skip-ink {
  text-decoration-skip-ink: none;
}

.skip-ink-all {
  text-decoration-skip-ink: all;
}
```

Result

See also

- `text-decoration`
- `text-decoration-skip`

text-decoration-style CSS property

The **`text-decoration-style`** CSS property sets the style of the lines specified by `text-decoration-line`. The style applies to all lines that are set with `text-decoration-line`.

Try it

```
text-decoration-style: solid;
```

```
text-decoration-style: double;
```

```
text-decoration-style: dotted;
```

```
text-decoration-style: dashed;
```

```
text-decoration-style: wavy;
```

```
<section id="default-example">
  <p>
```

```
    I'd far rather be
    <span class="transition-all" id="example-element">happy than right</span>
    any day.
  </p>
</section>
```

```
p {
  font: 1.5em sans-serif;
}

#example-element {
  text-decoration-line: underline;
}
```

If the specified decoration has a specific semantic meaning, like a line-through line meaning that some text has been deleted, authors are encouraged to denote this meaning using an HTML tag, like `<del>` or `<s>`. As browsers can disable styling in some cases, the semantic meaning won't disappear in such a situation.

When setting multiple line-decoration properties at once, it may be more convenient to use the `text-decoration` shorthand property instead.

Syntax

```
/* Keyword values */
text-decoration-style: solid;
text-decoration-style: double;
text-decoration-style: dotted;
text-decoration-style: dashed;
text-decoration-style: wavy;

/* Global values */
text-decoration-style: inherit;
text-decoration-style: initial;
text-decoration-style: revert;
text-decoration-style: revert-layer;
text-decoration-style: unset;
```

Values

solid

Draws a single line.

double

Draws a double line.

dotted

Draws a dotted line.

dashed

Draws a dashed line.

wavy

Draws a wavy line.

-moz-none

Draws no line. Use `text-decoration-line: none` instead.

Formal definition

Initial value	`solid`
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
text-decoration-style =
  solid   |
  double  |
  dotted  |
  dashed  |
  wavy
```

This syntax reflects the latest standard as per CSS Text Decoration Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting a wavy underline

The following creates a red wavy underline:

CSS

```
.wavy {
  text-decoration-line: underline;
  text-decoration-style: wavy;
  text-decoration-color: red;
}
```

HTML

```
<p class="wavy">This text has a wavy red line beneath it.</p>
```

Results

- When setting multiple line-decoration properties at once, it may be more convenient to use the `text-decoration` shorthand property instead.
- `text-decoration-line`
- `text-decoration-color`
- `text-decoration-thickness`
- `text-underline-offset`

text-decoration-thickness CSS property

The **`text-decoration-thickness`** CSS property sets the stroke thickness of the decoration line that is used on text in an element, such as a line-through, underline, or overline.

Try it

```
text-decoration-line: underline;
text-decoration-thickness: 3px;
```

```
text-decoration-line: line-through;
text-decoration-thickness: 0.4rem;
```

```
text-decoration-line: underline overline;
text-decoration-thickness: from-font;
font-size: 2rem;
```

```
<section id="default-example">
  <p id="example-element">
    Confusion kissed me on the cheek, and left a taste so bittersweet
  </p>
</section>
```

```
p {
  font: 1.5em sans-serif;
  text-decoration-color: red;
}
```

Syntax

```
/* Single keyword */
text-decoration-thickness: auto;
text-decoration-thickness: from-font;

/* length */
text-decoration-thickness: 0.1em;
text-decoration-thickness: 3px;

/* percentage */
text-decoration-thickness: 10%;

/* Global values */
text-decoration-thickness: inherit;
text-decoration-thickness: initial;
text-decoration-thickness: revert;
text-decoration-thickness: revert-layer;
text-decoration-thickness: unset;
```

Values

`auto`

The browser chooses an appropriate width for the text decoration line.

`from-font`

If the font file includes information about a preferred thickness, use that value. If the font file doesn't include this information, behave as if `auto` was set, with the browser choosing an appropriate thickness.

`<length>`

Specifies the thickness of the text decoration line as a `<length>`, overriding the font file suggestion or the browser default.

`<percentage>`

Specifies the thickness of the text decoration line as a `<percentage>` of **1em** in the current font. A percentage inherits as a relative value, and so therefore scales with changes in the font. The browser must use a minimum of 1 device pixel. For a given application of this property, the thickness is constant across the whole box it is applied to, even if there are child elements with a different font size.

Formal definition

Initial value	`auto`
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Percentages	refer to the font size of the element itself
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
text-decoration-thickness =
  auto                  |
  from-font             |
  <length-percentage>   |
  <line-width>

<length-percentage> =
  <length>      |
  <percentage>
```

```
<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Text Decoration Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Varying thickness

HTML

```
<p class="thin">Here's some text with a 1px red underline.</p>
<p class="thick">This one has a 5px red underline.</p>
<p class="shorthand">This uses the equivalent shorthand.</p>
```

CSS

```
.thin {
  text-decoration-line: underline;
  text-decoration-style: solid;
  text-decoration-color: red;
  text-decoration-thickness: 1px;
}

.thick {
  text-decoration-line: underline;
  text-decoration-style: solid;
  text-decoration-color: red;
  text-decoration-thickness: 5px;
}

.shorthand {
  text-decoration: underline solid red 5px;
}
```

Results

> **Note:** The property used to be called `text-decoration-width`, but was updated in 2019 to `text-decoration-thickness`.

See also

- `text-decoration`
- `text-underline-offset`

text-emphasis CSS property

The **`text-emphasis`** CSS shorthand property applies emphasis marks to text (except spaces and control characters).

Try it

```
text-emphasis: none;
```

```
text-emphasis: filled red;
```

```
text-emphasis: "x";
```

```
text-emphasis: filled double-circle #ffb703;
```

```
<section id="default-example">
  <p>
    I'd far rather be
    <span class="transition-all" id="example-element">happy than right</span>
    any day.
  </p>
</section>
```

```
p {
  font: 1.5em sans-serif;
}
```

The `text-emphasis` property is quite different from `text-decoration`. The `text-decoration` property does not inherit, and the decoration specified is applied across the whole element. However, text-emphasis does inherit, which means it is possible to change emphasis marks for descendants.

The size of the emphasis symbol, like ruby symbols, is about 50% of the size of the font, and `text-emphasis` may affect line height when the current leading is not enough for the marks.

> **Note:** `text-emphasis` doesn't reset the value of `text-emphasis-position`. This is because if the style and the color of emphasis marks may vary in a text, it is extremely unlikely that their position will. In the very rare cases when this is needed, use the property `text-emphasis-position`.

Constituent properties

This property is a shorthand for the following CSS properties:

- `text-emphasis-color`
- `text-emphasis-style`

Syntax

```
/* Initial value */
text-emphasis: none; /* No emphasis marks */
```

```
/* <string> value */
text-emphasis: "x";
text-emphasis: "点";
text-emphasis: "\25B2";
text-emphasis: "*" #555555;
text-emphasis: "foo"; /* Should NOT use. It may be computed to or rendered as 'f' only */

/* Keywords value */
text-emphasis: filled;
text-emphasis: open;
text-emphasis: filled sesame;
text-emphasis: open sesame;

/* Keywords value combined with a color */
text-emphasis: filled sesame #555555;

/* Global values */
text-emphasis: inherit;
text-emphasis: initial;
text-emphasis: revert;
text-emphasis: revert-layer;
text-emphasis: unset;
```

Values

`none`

No emphasis marks.

`filled`

The shape is filled with solid color. If neither `filled` nor `open` is present, this is the default.

`open`

The shape is hollow.

`dot`

Display small circles as marks. The filled dot is `'•'` (U+2022), and the open dot is `'◦'` (U+25E6).

`circle`

Display large circles as marks. The filled circle is `'●'` (U+25CF), and the open circle is `'○'` (U+25CB). This is the default shape in horizontal writing modes when no other shape is given.

`double-circle`

Display double circles as marks. The filled double-circle is `'◉'` (U+25C9), and the open double-circle is `'◎'` (U+25CE).

`triangle`

Display triangles as marks. The filled triangle is `'▲'` (U+25B2), and the open triangle is `'△'` (U+25B3).

`sesame`

Display sesames as marks. The filled sesame is `'﹅'` (U+FE45), and the open sesame is `'﹆'` (U+FE46). This is the default shape in vertical writing modes when no other shape is given.

`<string>`

Display the given string as marks. Authors should not specify more than one *character* in `<string>`. The UA may truncate or ignore strings consisting of more than one grapheme cluster.

`<color>`

Defines the color of the mark. If no color is present, it defaults to `currentColor`.

Formal definition

Initial value	as each of the properties of the shorthand: • `text-emphasis-style`: `none` • `text-emphasis-color`: `currentcolor`
Applies to	all elements
Inherited	yes
Computed value	as each of the properties of the shorthand: • `text-emphasis-style`: as specified • `text-emphasis-color`: computed color
Animation type	as each of the properties of the shorthand: • `text-emphasis-color`: a color • `text-emphasis-style`: discrete

Formal syntax

```
text-emphasis =
  <'text-emphasis-style'>  ||
  <'text-emphasis-color'>

<text-emphasis-style> =
  none                                                |
  [ [ filled | open ] || [ dot | circle | double-circle | triangle | sesame ] ]  |
  <string>

<text-emphasis-color> =
  <color>
```

This syntax reflects the latest standard as per CSS Text Decoration Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

A heading with emphasis shape and color

This example draws a heading with triangles used to emphasize each character.

CSS

```
h2 {
  text-emphasis: triangle #dd5555;
}
```

HTML

```
<h2>This is important!</h2>
```

Result

See also

- The longhand properties `text-emphasis-style`, `text-emphasis-color`.
- The `text-emphasis-position` property allowing you to define the position of the emphasis marks.

text-emphasis-color CSS property

The **`text-emphasis-color`** CSS property sets the color of emphasis marks. This value can also be set using the `text-emphasis` shorthand.

Try it

```
text-emphasis-color: currentColor;
```

```
text-emphasis-color: red;
```

```
text-emphasis-color: rgb(90 200 160 / 0.8);
```

```
<section id="default-example">
  <p>
    I'd far rather be
    <span class="transition-all" id="example-element">happy than right</span>
    any day.
  </p>
</section>
```

```
p {
  font: 1.5em sans-serif;
}

#example-element {
  text-emphasis: filled;
}
```

Syntax

```
/* Initial value */
text-emphasis-color: currentColor;

/* <color> */
text-emphasis-color: #555555;
text-emphasis-color: blue;
text-emphasis-color: rgb(90 200 160 / 80%);
text-emphasis-color: transparent;

/* Global values */
text-emphasis-color: inherit;
text-emphasis-color: initial;
text-emphasis-color: revert;
text-emphasis-color: revert-layer;
text-emphasis-color: unset;
```

Values

This property is specified as one `<color>` value:

`<color>`

Defines the color of the emphasis marks. If no color is present, it defaults to `currentColor`.

Formal definition

Initial value	`currentcolor`
Applies to	all elements
Inherited	yes
Computed value	computed color
Animation type	a color

Formal syntax

```
text-emphasis-color =
  <color>
```

This syntax reflects the latest standard as per CSS Text Decoration Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Emphasis with a color and custom character

CSS

```
em {
  text-emphasis-color: green;
  text-emphasis-style: "*";
}
```

HTML

```
<p>Here's an example:</p>

<em>This has emphasis marks!</em>
```

Result

See also

- The `<color>` data type
- The other emphasis mark related properties: `text-emphasis-style`, `text-emphasis`, and `text-emphasis-position`.
- Other color-related properties: `color`, `background-color`, `border-color`, `outline-color`, `text-shadow`, `caret-color`, and `column-rule-color`

text-emphasis-position CSS property

The **`text-emphasis-position`** CSS property sets where emphasis marks are drawn. Similar to the text rendered by the `<ruby>` HTML element, if there isn't enough room for emphasis marks, the line height is increased.

Try it

```
text-emphasis-position: auto;
```

```
text-emphasis-position: over right;
```

```
text-emphasis-position: under right;
```

```
text-emphasis-position: auto;
writing-mode: vertical-rl;
```

```
text-emphasis-position: over left;
writing-mode: vertical-rl;
```

```
text-emphasis-position: over right;
writing-mode: vertical-rl;
```

```
<section id="default-example">
  <p>
    I'd far rather be
    <span class="transition-all" id="example-element">happy than right</span>
    any day.
  </p>
</section>
```

```
p {
  font: 1.5em sans-serif;
}

#example-element {
  text-emphasis: filled double-circle #ffb703;
}
```

Syntax

```
/* Initial value */
text-emphasis-position: auto;

/* Keyword values */
text-emphasis-position: over;
text-emphasis-position: under;

text-emphasis-position: over right;
text-emphasis-position: over left;
text-emphasis-position: under right;
text-emphasis-position: under left;

text-emphasis-position: left over;
text-emphasis-position: right over;
text-emphasis-position: right under;
text-emphasis-position: left under;

/* Global values */
text-emphasis-position: inherit;
text-emphasis-position: initial;
text-emphasis-position: revert;
text-emphasis-position: revert-layer;
text-emphasis-position: unset;
```

Values

The property accepts one or two values:

- If only one value is provided, it can be `auto`, `over`, or `under`. When only `over` or `under` is used, `right` is assumed as the default position.
- If two values are provided, they must include one of `over` or `under` and one of `right` or `left`. Their order does not matter.

The values include:

`auto`

Draws marks over the text in horizontal writing mode and to the right of the text in vertical writing mode.

`over`

Draws marks over the text in horizontal writing mode.

`under`

Draws marks under the text in horizontal writing mode.

`right`

Draws marks to the right of the text in vertical writing mode.

`left`

Draws marks to the left of the text in vertical writing mode.

Description

The preferred position of emphasis marks depends on the language. In Japanese for example, the preferred position is `over right`. In Chinese, on the other hand, the preferred position is `under right`. The informative table below summarizes the preferred emphasis mark positions for Chinese, Mongolian and Japanese:

Preferred emphasis mark and ruby position

Language	Preferred position		Illustration
	Horizontal	Vertical	
Japanese	over	right	Korean			
Mongolian			
Chinese	under	right	
> **Note:** The `text-emphasis-position` cannot be set, and therefore are not reset either, using the `text-emphasis` shorthand property.

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
text-emphasis-position =
  [ over | under ]  &&
  [ right | left ]?
```

This syntax reflects the latest standard as per CSS Text Decoration Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Adding emphasis mark positions

Use the dropdown menu to change the position of the emphasis marks. This will change the class on the `<section>` element, which in turn, will update the position of the emphasis marks on the text.

HTML

```
<p class="unsupported">
  The <code>auto</code> value is not supported in your browser.
</p>
<label for="position">Emphasis position:</label>
<select id="position">
  <option value="auto">auto</option>
  <option value="over-right">over right</option>
  <option value="over-left">over left</option>
  <option value="under-right">under right</option>
  <option value="under-left">under left</option>
  <option value="preferred">preferred</option>
</select>
```

```
<section id="setting" class="auto">
  <p class="horizontal" lang="zh">你好世界</p>
  <!-- Hello World in Chinese -->
  <p class="vertical" lang="ja">世界、こんにちは。</p>
  <!-- Hello World in Japanese -->
</section>
```

CSS

```
.unsupported {
  color: red;
}
@supports (text-emphasis-position: auto) {
  .unsupported {
    display: none;
  }
}
.horizontal {
  writing-mode: horizontal-tb;
```

```
}
.vertical {
  writing-mode: vertical-rl;
}
section {
  display: flex;
  justify-content: space-around;
}
```

```
section p {
  text-emphasis: filled circle tomato;
  text-emphasis-position: auto;
}
.over-right p,
.preferred p [lang="ja"] {
  text-emphasis-position: over right;
}
.over-left p {
  text-emphasis-position: over left;
}
.under-right p,
.preferred p [lang="zh"] {
  text-emphasis-position: under right;
}
.under-left p {
  text-emphasis-position: under left;
}
.preferred p [lang="ja"] {
}
```

```
const position = document.querySelector("#position");
const setting = document.querySelector("#setting");
const updateClass = () => {
  const currentClass = setting.classList;
  setting.classList.replace(currentClass, position.value);
};
position.addEventListener("change", updateClass);
```

Result

Use the "Emphasis position" dropdown to choose the location of the emphasis marks. The `preferred` option in the dropdown uses the preferred positions, as explained in the Description section.

Preferring ruby over emphasis marks

Some editors prefer to hide emphasis marks when they conflict with ruby. In HTML, this can be done with the following style rule:

```
ruby {
  text-emphasis: none;
}
```

Preferring emphasis marks over ruby

Some other editors prefer to hide ruby when they conflict with emphasis marks. In HTML, this can be done with the following pattern:

```
em {
  text-emphasis: dot; /* Set text-emphasis for <em> elements */
}

em rt {
  display: none; /* Hide ruby inside <em> elements */
}
```

See also

- `text-underline-position`
- `text-emphasis-style`

- `text-emphasis` shorthand property
- `writing-mode`

text-emphasis-style CSS property

The **`text-emphasis-style`** CSS property sets the appearance of emphasis marks. It can also be set, and reset, using the `text-emphasis` shorthand.

Try it

```
text-emphasis-style: none;
```

```
text-emphasis-style: triangle;
```

```
text-emphasis-style: "x";
```

```
text-emphasis-style: filled double-circle;
```

```
<section id="default-example">
  <p>
    I'd far rather be
    <span class="transition-all" id="example-element">happy than right</span>
    any day.
  </p>
</section>
```

```
p {
  font: 1.5em sans-serif;
}
```

Syntax

```
/* Initial value */
text-emphasis-style: none; /* No emphasis marks */

/* <string> values */
text-emphasis-style: "x";
text-emphasis-style: "\25B2";
text-emphasis-style: "*";

/* Keyword values */
text-emphasis-style: filled;
text-emphasis-style: open;
text-emphasis-style: dot;
text-emphasis-style: circle;
text-emphasis-style: double-circle;
text-emphasis-style: triangle;
text-emphasis-style: filled sesame;
text-emphasis-style: open sesame;

/* Global values */
text-emphasis-style: inherit;
text-emphasis-style: initial;
text-emphasis-style: revert;
text-emphasis-style: revert-layer;
text-emphasis-style: unset;
```

Values

`none`

No emphasis marks.

`filled`

The shape is filled with solid color. If neither `filled` nor `open` is present, this is the default.

`open`

The shape is hollow.

`dot`

Display small circles as marks. The filled dot is `'•'` (`U+2022`), and the open dot is `'◦'` (`U+25E6`).

`circle`

Display large circles as marks. The filled circle is `'●'` (`U+25CF`), and the open circle is `'○'` (`U+25CB`).

`double-circle`

Display double circles as marks. The filled double-circle is `'◉'` (`U+25C9`), and the open double-circle is `'◎'` (`U+25CE`).

`triangle`

Display triangles as marks. The filled triangle is `'▲'` (`U+25B2`), and the open triangle is `'△'` (`U+25B3`).

`sesame`

Display sesames as marks. The filled sesame is `'﹅'` (`U+FE45`), and the open sesame is `'﹆'` (`U+FE46`).

`<string>`

Display the given string as marks. Authors should not specify more than one *character* in `<string>`. The UA may truncate or ignore strings consisting of more than one grapheme cluster.

Formal definition

Initial value	none
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
text-emphasis-style =
  none                                          |
  [ [ filled | open ] || [ dot | circle | double-circle | triangle | sesame ] ]  |
  <string>
```

This syntax reflects the latest standard as per CSS Text Decoration Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

```
h2 {
  -webkit-text-emphasis-style: sesame;
  text-emphasis-style: sesame;
}
```

See also

- The related properties `text-emphasis-color`, `text-emphasis`.
- The `text-emphasis-position` property allowing you to define the position of the emphasis marks.

text-fit CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`text-fit`** CSS property can be used to scale the rendered font size of text nodes (and other inline content) so that they fit exactly within the inline dimension of their containing boxes, optionally limited by a maximum or minimum **scaling factor**.

Syntax

```
/* One keyword */
text-fit: none;
text-fit: grow;
text-fit: shrink;

/* Two keywords */
text-fit: grow consistent;
text-fit: shrink per-line-all;

/* Keywords and <percentage> */
text-fit: grow 300%;
text-fit: shrink 80%;
text-fit: grow per-line-all 300%;

/* Global values */
text-fit: inherit;
text-fit: initial;
text-fit: revert;
text-fit: revert-layer;
text-fit: unset;
```

Values

This property is specified as a space-separated list of one to three values from the following list:

`none`

The default value. No text scaling is applied.

`grow`

The text node's rendered font size is scaled up until it exactly fits inside its containing box's inline dimension.

`shrink`

The text node's rendered font size is scaled down until it exactly fits inside its containing box's inline dimension.

`consistent`

All of the lines of the text node are scaled using the same scaling factor. This keyword has no effect if `none` is specified as the first keyword. If a second keyword is not specified, `consistent` is assumed.

`per-line`

All of the lines of the text node are scaled with their own scaling factor. The last line of the text node, and any lines that end in a forced break (for example, due to a `<br>` element) have no text scaling applied. This keyword has no effect if `none` is specified as the first keyword.

`per-line-all`

All of the lines of the text node are scaled with their own scaling factor, including the last line and lines that end in a forced break. This keyword has no effect if `none` is specified as the first keyword.

`<percentage>`

Specifies the maximum (when `grow` is specified) or minimum (when `shrink` is specified) scaling factor. This must be `100%` or greater if `grow` is specified, or between `0%` and `100%` inclusive if `shrink` is specified, otherwise the percentage has no effect.

The mandatory first value can be `none`, `grow`, or `shrink`. The optional second value can be `consistent`, `per-line`, or `per-line-all`. The optional `<percentage>` value is declared last. The components must be specified in this order.

Description

A common web design challenge is getting headings and other text features to fit neatly within their containing boxes, regardless of layout or viewport size. The most typical use case is getting a horizontal text heading to fit the width of its containing box perfectly. Complex `font-size` calculations and JavaScript workarounds were historically used to achieve this.

The `text-fit` property provides a convenient CSS-only solution, adjusting the rendered font size of the text by a specific scaling factor to fit the space available, rather than justifying it like the `text-align` property's `justify` value does.

The basic form of `text-fit` uses a single keyword:

- You can specify `grow` to scale the font size up so that the text fits exactly inside its containing box. This works well for the use case described previously.
- You can specify `shrink` to scale the font size down so that the text fits exactly inside its containing box. This works well in cases where you have a line of text that is longer than its containing box, maybe due to a really long word, and you want to shrink it to avoid overflow.

Specifically, the parts of a text node that are affected by this scaling (the **scalable parts**) are the text itself, excluding trailing whitespace, and spacing whose inline size is proportional to the text's `font-size`, such as percentage-based `letter-spacing` and `word-spacing`, and `text-autospace`. Other parts, including inline `border`, `margin`, and `padding`, are not scaled.

The `text-fit` property does not affect a container's intrinsic size, which means that the text content cannot grow in cases where the container is sized by its content, for example using the `fit-content` keyword. Setting `text-fit` also doesn't change an element's computed `font-size`: the size adjustment is applied after the final rendering.

How is the scaling factor calculated?

The scaling factor is the ratio by which the scalable parts of a text line must be scaled in order for its inline content to fit exactly inside its containing box. The scaling factor for each line of a text node is calculated using a formula along these lines (the exact method for determining the scaling factor may differ between implementations):

```
(A + B) / A
```

where:

- `A` is the total inline size of the text line's scalable parts.

- `B` is the remaining space inside the text line, including any trailing whitespace, which may be negative if the text overflows.

The scaling factor for a text line with no scalable parts is `1`.

Specifying scaling factor limits

To limit the amount by which the text can grow, you can specify a `<percentage>` value after the `grow` or `shrink` keyword.

If `grow` is specified, the percentage has to be `100%` or greater, and acts as a maximum scaling factor. For example:

```
text-fit: grow 300%;
```

Any text this is applied to will grow to fit its containing box, but will not scale to a size greater than 300% of its original `font-size`.

If `shrink` is specified, the percentage has to be between `0%` and `100%` inclusive, and acts as a minimum scaling factor. For example:

```
text-fit: shrink 50%;
```

Any text this is applied to will shrink to fit its containing box, but will not scale to a size less than 50% of its original `font-size`.

> **Note:** In many situations, word breaking behavior results in `text-fit: shrink` having no effect — the words wrap onto new lines rather than shrinking. In these cases, you need to stop the breaking behavior using something like a `white-space` value of `nowrap` to see it working. See this in action in our basic example.

Specifying how scaling factor is applied to multiple text lines

By default, a text node with multiple lines scales all of the lines by the same scaling factor. Each line has its scaling factor calculated separately, and the smallest scaling factor is then applied to all of the lines. This is usually the behavior you'll want, to ensure that each line grows or shrinks by the same proportion.

If you want to adjust this behavior, you can specify a second value after the first keyword and before the percentage, if specified. This value can be specified as the default `consistent` keyword, which keeps the behavior described previously, but you can also specify `per-line` or `per-line-all`. Both of these cause the lines of the text node to be scaled with their own scaling factors. The difference is that, with `per-line`, the last line of the text node, and any lines that end in a forced break (for example, due to a `<br>` element) have no text scaling applied, whereas with `per-line-all` scaling is applied to these lines.

For example, this declaration will grow all lines of a text node by their own scaling factor to fit the containing box.

```
text-fit: grow per-line-all;
```

This declaration on the other hand will shrink all lines of a text node by their own scaling factor to fit the containing box, but not the last line or lines with forced breaks, and not below `50%` of the original `font-size`.

```
text-fit: shrink per-line 50%;
```

Accessibility

When using `text-fit`, designs must be tested carefully at different viewport sizes to make sure the rendered font size doesn't become too small (or too large). This can lead to content becoming illegible, especially for people with visual impairments or in low vision conditions.

In any case, text content should be resizable without loss of content or functionality; see WCAG Success Criterion 1.4.4 Resize Text.

Related guidance:

- MDN Understanding WCAG, Guideline 1.4: Make it easier for users to see and hear content including separating foreground from background

Formal definition

Initial value	none
Applies to	block container elements
Inherited	yes
Computed value	specified keyword, or computed `<percentage>`
Animation type	discrete

Formal syntax

```
text-fit =
  [ none | grow | shrink ] [ consistent | per-line | per-line-all ]? <percentage>?
```

This syntax reflects the latest standard as per CSS Text Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic <code>text-fit</code> usage

This example demonstrates basic usage of `text-fit` to grow and shrink text nodes to fit their containers.

HTML

We include two text elements, an `<h1>` and an `<h2>`, nested inside a `<div>`.

```
<input
  type="range"
  min="0.4"
  max="1"
  value="1"
  step="0.01"
  aria-label="adjust the width of the page" />
```

```
<div>
  <h1>My heading</h1>

  <h2>My subtitle: a bit longer, may need shrinking</h2>
</div>
```

```
const divElem = document.querySelector("div");
const slider = document.querySelector("input");
```

```
let maxWidth;

function setMaxWidth() {
  maxWidth = document.documentElement.clientWidth;
}

function setWidth() {
  divElem.style.width = `${maxWidth * slider.value}px`;
}

slider.addEventListener("input", setWidth);
window.addEventListener("resize", () => {
  setMaxWidth();
  setWidth();
});

setMaxWidth();
setWidth();
```

We also include an `<input type="range">` element to enable adjusting the content width to emulate a changing viewport width. The range input, plus the JavaScript that powers it, have been hidden for brevity.

CSS

We give the container `<div>` a `padding` value of `20px` to give the text some space.

```
* {
  box-sizing: border-box;
}

html {
  font-family: sans-serif;
  background-color: white;
}

div {
  margin: 0 auto;
  background-color: coral;
}

input {
  width: 99%;
}
```

```
div {
  padding: 20px;
}
```

We give the `<h1>` a `text-fit` value of `grow`, so that it will grow to fill its container's available inline space. We give the longer `<h2>` a `white-space` value of `nowrap` so that ordinarily, it would all stay on a single line and overflow its container rather than wrapping, if it reaches the container edge. We then set `text-fit: shrink` on it so that, instead of overflowing, it will shrink to fit inside its container's available inline space.

```
h1 {
  text-fit: grow;
}

h2 {
  white-space: nowrap;
  text-fit: shrink;
}
```

Result

Adjust the slider and note how the `<h1>` grows automatically so that it always fills the available space inside its parent `<div>`. Also note how the `<h2>` shrinks so that it always fills the available space inside the `<div>` at narrower widths; at wider widths where it fits inside the `<div>`, it maintains its natural width.

Without `text-fit`, the `<h1>` wouldn't fill the available space, and the `<h2>` would overflow it at narrower widths.

Setting scaling factor percentage limits

This example is very similar to the previous one, except that in this case we limit the amount that our headings can grow or shrink using `<percentage>` values.

The HTML and JavaScript are identical to the previous example.

CSS

We give the `<h1>` a `text-fit` value of `grow 300%`, so that it will grow to fill its container's available inline space, up to 300% of its natural `font-size`:

```
h1 {
  text-fit: grow 300%;
}
```

We give the `<h2>` a `white-space` value of `nowrap` so that it will all stay on a single line and overflow its container rather than wrapping, when it touches the container edge. We then set `text-fit: shrink 80%` on it so that, instead of overflowing, it will shrink to fit inside its container's available inline space, down to `80%` of its natural `font-size`.

```
h2 {
  white-space: nowrap;
  text-fit: shrink 80%;
}
```

One issue that presents itself at this point is that, when the `<div>`'s `width` gets smaller than about `400px`, the `<h2>` will start to overflow its container. To avoid this, we want to set the text to wrap onto new lines normally at this point. To solve the problem, we first give the containing `<div>` a `container-type` of `inline-size`, so that we can use container queries to selectively apply CSS depending on its width.

```
div {
  padding: 20px;
}
```

```
div {
  container-type: inline-size;
}
```

We then use a container query to change the `<h2>`'s `white-space` value to `wrap` when the `<div>`'s `width` gets smaller than `400px`:

```
@container (width < 400px) {
  h2 {
    white-space: wrap;
  }
}
```

Result

Adjust the slider. Note how the `<h1>` grows automatically so that it always fills the available space inside its parent `<div>`, but only up to a certain width. Note how the `<h2>` shrinks so that it always fills the available space inside the `<div>` at narrower widths. When the `<div>` gets narrower than `400px`, the container query kicks in and we set `white-space: wrap`, meaning that the `<h2>` starts to wrap onto multiple lines.

Demonstrating multi-line scaling behavior keywords

This example demonstrates the difference in effect between setting the `consistent`, `per-line`, and `per-line-all` keywords in the `text-fit` property values of different paragraphs.

HTML

The HTML features three `<p>` elements containing the same filler text, each with different `id` values set on them:

```
<div>
  <p id="consistent">
    Lorem ipsum dolor sit amet consectetur adipisicing elit. Iste vitae in id
    esse odit autem quisquam saepe repellendus.
  </p>

  <p id="per-line">
    Lorem ipsum dolor sit amet consectetur adipisicing elit. Iste vitae in id
    esse odit autem quisquam saepe repellendus.
  </p>

  <p id="per-line-all">
    Lorem ipsum dolor sit amet consectetur adipisicing elit. Iste vitae in id
    esse odit autem quisquam saepe repellendus.
  </p>
</div>
```

The HTML and JavaScript for the width adjustment slider are also included in this example.

CSS

We give each paragraph a `text-fit` value with the first keyword set to `grow`; the second keyword in each case is set to a different value — `consistent`, `per-line`, and `per-line-all`, respectively.

```
#consistent {
  text-fit: grow consistent;
}

#per-line {
  text-fit: grow per-line;
}

#per-line-all {
  text-fit: grow per-line-all;
}
```

```
* {
  box-sizing: border-box;
}

:root {
  overflow: hidden;
}

div {
  padding: 20px;
}

p {
  padding: 20px;
  background-color: rgb(0 0 0 / 0.2);
  position: relative;
  margin-bottom: 40px;
}

p::before {
  content: attr(id);
  background-color: black;
  color: white;
  padding: 5px 10px;
  position: absolute;
  top: -28px;
  left: 0px;
}
```

Result

Adjust the slider up and down the scale, taking careful note of the behavior of each paragraph. You should note that:

- The `consistent` paragraph's text lines always have the same `font-size` as one another throughout.
- The `per-line` paragraph's text lines vary in `font-size` somewhat, which becomes more noticeable at narrower widths. The last line's `font-size` is not scaled.
- The `per-line-all` paragraph's text lines vary in `font-size` somewhat, which includes the last line. This is very noticeable at widths that cause only one or two words to wrap onto the last line.

```
@supports not (text-fit: grow) {
  body::before {
    content: "Your browser does not support text-fit.";
    background-color: wheat;
    text-align: center;
    padding: 1rem 0;
```

```
    z-index: 1;
    position: fixed;
    inset: 40% 0 auto;
  }
}
```

text-indent CSS property

The **`text-indent`** CSS property sets the length of empty space (indentation) that is put before lines of text in a block.

Try it

```
text-indent: 0;
```

```
text-indent: 30%;
```

```
text-indent: -3em;
```

```
text-indent: 3em each-line;
```

```
text-indent: 3em hanging;
```

```
text-indent: 3em hanging each-line;
```

```
<section id="default-example">
  <div id="example-element">
    <p>
      This text is contained within a single paragraph. This paragraph is two
      sentences long.
    </p>
    <p>
      This is a new paragraph. There is a line break element
      <code>&lt;br&gt;</code> after this sentence.<br />There it is! Notice how
      it affects the indentation.
    </p>
  </div>
</section>
```

```
section {
  font-size: 1.25em;
  background-color: darkslateblue;
  align-items: start;
}

#example-element {
  text-align: left;
  margin-left: 3em;
  background-color: slateblue;
  color: white;
}
```

Syntax

```
/* <length-percentage> values */
text-indent: 3mm;
text-indent: 40px;
text-indent: 15%;

/* with keyword values */
text-indent: 5em each-line;
text-indent: 5vb hanging;
text-indent: 5% hanging each-line;

/* Global values */
text-indent: inherit;
text-indent: initial;
text-indent: revert;
text-indent: revert-layer;
text-indent: unset;
```

Values

`<length>`

Indentation is specified as an absolute `<length>`. Negative values are allowed. See `<length>` values for possible units.

`<percentage>`

Indentation is a `<percentage>`. The percentage is relative to the container's own inner inline size.

`each-line`

Indentation affects the first line of the block container as well as each line after a *forced line break*, but does not affect lines after a *soft wrap break*.

`hanging`

Inverts which lines are indented. All lines *except* the first line will be indented.

Description

The `text-indent` CSS property sets the length of empty space (indentation) that is put before lines of text in a block container. The indentation set by the property occurs at the inline-start edge of the content box. The value is a `<length-percentage>`, optionally with one or both of the keywords `each-line` and/or `hanging`. The initial value is `0`.

Percent values are relative to the block container's inline-axis inner size, which is the dimension of the content-area only, excluding the container's padding and border.

The `<length-percentage>` can be a positive or negative value. A negative value creates an outdent equal to the absolute value of the `<length-percentage>` equivalent positive value. A negative value effectively pushes the text the size of the value, but in the opposite direction. For example, `text-indent: 3%;` indents the first line of text, adding white space that is 3% of the container's inner-size before the text, pushing the first line of content toward the inline-end direction. Setting `text-indent: -3%` outdents the first line of text, pushing the start of the first line of text 3% of the container's inner-size past the inline-start of the content area, into the padding and border, possibly overflowing the container.

A negative value is different from adding the `hanging` keyword to a positive value. Continuing with the same example, `text-indent: 3% hanging` doesn't outdent the first line of text. Rather, it indents all the lines of text *except* the first line, by 3% of the container's inner-size.

Formal definition

Initial value	`0`
Applies to	block containers
Inherited	yes
Percentages	refer to the width of the containing block
Computed value	the percentage as specified or the absolute length, plus any keywords as specified
Animation type	a length, percentage or calc();

Formal syntax

```
text-indent =
  [ <length-percentage> ]  &&
  hanging?                 &&
  each-line?

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Text Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates the basic usage of the `text-indent` property.

HTML

We include two paragraphs of text.

```
<p>
  Lorem ipsum dolor sit amet, consectetuer adipiscing elit, sed diam nonummy
  nibh euismod tincidunt ut laoreet dolore magna aliquam erat volutpat.
</p>
<p>
  Lorem ipsum dolor sit amet, consectetuer adipiscing elit, sed diam nonummy
  nibh euismod tincidunt ut laoreet dolore magna aliquam erat volutpat.
</p>
```

CSS

We use the `text-indent` property to indent the first line of each paragraph by `5em`.

```
p {
  text-indent: 5em;
  background: powderblue;
}
```

Result

Percentage indent

Using the same HTML as in the previous example, here we demonstrate using percentage values and how percentage values are relative to the element's content area in the inline direction.

```
<p>
  Lorem ipsum dolor sit amet, consectetuer adipiscing elit, sed diam nonummy
  nibh euismod tincidunt ut laoreet dolore magna aliquam erat volutpat.
</p>
<p>
  Lorem ipsum dolor sit amet, consectetuer adipiscing elit, sed diam nonummy
  nibh euismod tincidunt ut laoreet dolore magna aliquam erat volutpat.
</p>
```

CSS

We set the `text-indent` to a percentage value. We also added padding and vertical stripes to better enable gauging the size of the indentation relative to the element's box model.

```
p {
  text-indent: 30%;

  padding: 30px;
  background-image: repeating-linear-gradient(
    to right,
    transparent 0 9.5%,
    #dedede 9.5% 10%
  );
  background-color: plum;
}
```

Result

Skipping indentation on the first paragraph

A common typographic practice when paragraph indentation is present is to skip the indentation for the first paragraph. As *The Chicago Manual of Style* puts it, "the first line of text following a subhead may begin flush left or be indented by the usual paragraph indention."

Treating first paragraphs differently from subsequent paragraphs can be done using the next-sibling combinator, as in the following example:

HTML

```
<h2>Lorem ipsum</h2>

<p>
  Lorem ipsum dolor sit amet, consectetur adipiscing elit. Suspendisse eu
  venenatis quam. Vivamus euismod eleifend metus vitae pharetra. In vel tempor
  metus. Donec dapibus feugiat euismod. Vivamus interdum tellus dolor. Vivamus
  blandit eros et imperdiet auctor. Mauris sapien nunc, condimentum a efficitur
  non, elementum ac sapien. Cras consequat turpis non augue ullamcorper, sit
  amet porttitor dui interdum.
</p>

<p>
  Sed laoreet luctus erat at rutrum. Proin velit metus, luctus in sapien in,
  tincidunt mattis ex. Praesent venenatis orci at sagittis eleifend. Nulla
  facilisi. In feugiat vehicula magna iaculis vehicula. Nulla suscipit tempor
  odio a semper. Donec vitae dapibus ipsum. Donec libero purus, convallis eu
  efficitur id, pulvinar elementum diam. Maecenas mollis blandit placerat. Ut
  gravida pellentesque nunc, in eleifend ante convallis sit amet.
</p>

<h2>Donec ullamcorper elit nisl</h2>

<p>
  Donec ullamcorper elit nisl, sagittis bibendum massa gravida in. Fusce tempor
  in ante gravida iaculis. Integer posuere tempor metus. Vestibulum lacinia,
  nunc et dictum viverra, urna massa aliquam tellus, id mollis sem velit
  vestibulum nulla. Pellentesque habitant morbi tristique senectus et netus et
  malesuada fames ac turpis egestas. Donec vulputate leo ut iaculis ultrices.
  Cras egestas rhoncus lorem. Nunc blandit tempus lectus, rutrum hendrerit orci
  eleifend id. Ut at quam velit.
</p>

<p>
  Aenean rutrum tempor ligula, at luctus ligula auctor vestibulum. Sed
  sollicitudin velit in leo fringilla sollicitudin. Proin eu gravida arcu. Nam
  iaculis malesuada massa, eget aliquet turpis sagittis sed. Sed mollis tellus
  ac dui ullamcorper, nec lobortis diam pellentesque. Quisque dapibus accumsan
  libero, sed euismod ipsum ullamcorper sed.
</p>
```

CSS

```
p {
  text-align: justify;
  margin: 1em 0 0 0;
}
p + p {
  text-indent: 2em;
  margin: 0;
}
```

text-justify CSS property

The **`text-justify`** CSS property sets what type of justification should be applied to text when `text-align: justify;` is set on an element.

Syntax

```
text-justify: none;
text-justify: auto;
text-justify: inter-word;
text-justify: inter-character;
text-justify: distribute; /* Deprecated value */

/* Global values */
text-justify: inherit;
text-justify: initial;
text-justify: revert;
text-justify: revert-layer;
text-justify: unset;
```

Values

This property is specified as one of the following keyword values:

`none`

The text justification is turned off. This has the same effect as not setting `text-align` at all, although it is useful if you need to turn justification on and off for some reason.

`auto`

The browser chooses the best type of justification for the current situation based on a balance between performance and quality, but also on what is most appropriate for the language of the text (e.g., English, CJK languages, etc.). This is the default justification used if `text-justify` is not set at all.

`inter-word`

The text is justified by adding space between words (effectively varying `word-spacing`), which is most appropriate for languages that separate words using spaces, like English or Korean.

`inter-character`

The text is justified by adding space between characters (effectively varying `letter-spacing`), which is most appropriate for languages like Japanese.

`distribute`

Exhibits the same behavior as `inter-character`; this value is kept for backwards compatibility.

Formal definition

Initial value	`auto`
Applies to	inline-level and table-cell elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
text-justify =
  [ auto | none | inter-word | inter-character | ruby ]  ||
  no-compress
```

This syntax reflects the latest standard as per CSS Text Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Demonstration of the different values of text-justify

```
<p class="none">
  <code>text-justify: none</code> —<br />Lorem ipsum dolor sit amet, consectetur
  adipiscing elit. Nunc ornare maximus vehicula. Duis nisi velit, dictum id
  mauris vitae, lobortis pretium quam. Quisque sed nisi pulvinar, consequat
  justo id, feugiat leo. Cras eu elementum dui.
</p>
<p class="auto">
  <code>text-justify: auto</code> —<br />Lorem ipsum dolor sit amet, consectetur
  adipiscing elit. Nunc ornare maximus vehicula. Duis nisi velit, dictum id
  mauris vitae, lobortis pretium quam. Quisque sed nisi pulvinar, consequat
  justo id, feugiat leo. Cras eu elementum dui.
</p>
<p class="dist">
  <code>text-justify: distribute</code> —<br />Lorem ipsum dolor sit amet,
  consectetur adipiscing elit. Nunc ornare maximus vehicula. Duis nisi velit,
  dictum id mauris vitae, lobortis pretium quam. Quisque sed nisi pulvinar,
  consequat justo id, feugiat leo. Cras eu elementum dui.
</p>
<p class="word">
  <code>text-justify: inter-word</code> —<br />Lorem ipsum dolor sit amet,
  consectetur adipiscing elit. Nunc ornare maximus vehicula. Duis nisi velit,
  dictum id mauris vitae, lobortis pretium quam. Quisque sed nisi pulvinar,
  consequat justo id, feugiat leo. Cras eu elementum dui.
</p>
<p class="char">
  <code>text-justify: inter-character</code> —<br />Lorem ipsum dolor sit amet,
  consectetur adipiscing elit. Nunc ornare maximus vehicula. Duis nisi velit,
  dictum id mauris vitae, lobortis pretium quam. Quisque sed nisi pulvinar,
  consequat justo id, feugiat leo. Cras eu elementum dui.
</p>
```

```
p {
  font-size: 1.5em;
  border: 1px solid black;
  padding: 10px;
  width: 95%;
  margin: 10px auto;
  text-align: justify;
}

.none {
  text-justify: none;
}

.auto {
  text-justify: auto;
}

- `text-align`

text-orientation CSS property

The **`text-orientation`** CSS property sets the orientation of the text characters in a line. It only affects text in vertical mode (when `writing-mode` is not `horizontal-tb`). It is useful for controlling the display of languages that use vertical script, and also for making vertical table headers.

Try it

```
writing-mode: vertical-rl;
text-orientation: mixed;
```

```
writing-mode: vertical-rl;
text-orientation: upright;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    <p>
      In another moment down went Alice after it, never once considering how in
      the world she was to get out again.
    </p>
  </div>
</section>
```

Syntax

```
/* Keyword values */
text-orientation: mixed;
text-orientation: upright;
text-orientation: sideways-right;
text-orientation: sideways;
text-orientation: use-glyph-orientation;

/* Global values */
text-orientation: inherit;
text-orientation: initial;
text-orientation: revert;
text-orientation: revert-layer;
text-orientation: unset;
```

Values

This property is specified as one of the following keyword values:

`mixed`

> Rotates the characters of horizontal scripts 90° clockwise. Lays out the characters of vertical scripts naturally. Default value.

`upright`

> Lays out the characters of horizontal scripts naturally (upright), as well as the glyphs for vertical scripts. Note that this keyword causes all characters to be considered as left-to-right: the used value of `direction` is forced to be `ltr`.

`sideways`

> Causes characters to be laid out as they would be horizontally, but with the whole line rotated 90° clockwise.

`sideways-right`

> An alias to `sideways` that is kept for compatibility purposes.

`use-glyph-orientation`

> On SVG elements, this keyword leads to use the value of the deprecated SVG properties `glyph-orientation-vertical` and `glyph-orientation-horizontal`.

Formal definition

Initial value	`mixed`
Applies to	all elements, except table row groups, rows, column groups, and columns
Inherited	yes
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
text-orientation =
  mixed     |
  upright   |
  sideways
```

This syntax reflects the latest standard as per CSS Writing Modes Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<p>Lorem ipsum dolet semper quisquam.</p>
```

CSS

```
p {
  writing-mode: vertical-rl;
  text-orientation: upright;
}
```

Result

text-overflow CSS property

The **`text-overflow`** CSS property sets how hidden overflow content is signaled to users.

Try it

```
text-overflow: clip;
```

```
text-overflow: ellipsis;
```

```
text-overflow: "-";
```

```
text-overflow: "";
```

```
<section id="default-example">
  <div id="example-element-container">
    <p id="example-element">"Is there any tea on this spaceship?" he asked.</p>
  </div>
</section>
```

```
#example-element-container {
  width: 100%;
  max-width: 18em;
}

#example-element {
  line-height: 50px;
  border: 1px solid #c5c5c5;
  overflow: hidden;
  white-space: nowrap;
  font-family: sans-serif;
  padding: 0 0.5em;
  text-align: left;
}
```

Syntax

```
text-overflow: clip;
text-overflow: ellipsis ellipsis;
text-overflow: ellipsis " [..]";

/* Global values */
text-overflow: inherit;
text-overflow: initial;
text-overflow: revert;
text-overflow: revert-layer;
text-overflow: unset;
```

Values

This property is specified as one or two space-separated values, including:

`clip`

> The default for this property. This keyword value will truncate the text at the limit of the content area, therefore the truncation can happen in the middle of a character. To clip at the transition between characters you can specify `text-overflow` as an empty string, if that is supported in your target browsers: `text-overflow: '';`.

`ellipsis`

> This keyword value will display an ellipsis (`'…'`, `U+2026 HORIZONTAL ELLIPSIS`) to represent clipped text. The ellipsis is displayed inside the content area, decreasing the amount of text displayed. If there is not enough space to display the ellipsis, it is clipped.

`<string>`

> The `<string>` to be used to represent clipped text. The string is displayed inside the content area, shortening the size of the displayed text. If there is not enough space to display the string itself, it is clipped.

Description

The `text-overflow` property sets how hidden overflow content is signaled to users. It can be clipped, display an ellipsis (…), or display a custom string.

The `text-overflow` property doesn't force an overflow to occur. To make text overflow its container, you have to set other CSS properties: `overflow` and `white-space`. For example:

```
overflow: hidden;
white-space: nowrap;
```

The `text-overflow` property only affects content that is overflowing a block container element in its *inline* progression direction (not text overflowing at the bottom of a box, for example).

The `text-overflow` property may be specified using one or two values. If one value is given, it specifies overflow behavior for the end of the line (the right end for left-to-right text, the left end for right-to-left text). If two values are given, the first specifies overflow behavior for the left end of the line, and the second specifies it for the right end of the line.

<code>ellipsis</code> behaving as <code>clip</code> for editable elements

When `text-overflow: ellipsis` is applied to editable elements such as textual `<input>`, `<textarea>`, and `contenteditable` elements, browsers generally treat it as `text-overflow: clip`, either all the time or when the element is focused. The exact behavior differs across browsers; see Browser compatibility.

This behavior is to ensure that the text can be moved through and edited, even when overflowing. If the overflowing text remained covered by an ellipsis, it would not be visible or editable.

You can see the behavior in the following live example, which has this CSS applied:

```
p[contenteditable],
input,
textarea {
  width: 150px;
  white-space: nowrap;
  overflow: hidden;
  text-overflow: ellipsis;
}
```

```
<p contenteditable>
  contenteditable paragraph. The text in here is overflowing.
</p>

<hr />

<input type="text" value="Text input. The text in here is overflowing." />

<hr />

<textarea>Textarea. The text in here is overflowing.</textarea>
```

Focus the different elements and try editing their text content.

Formal definition

Initial value	`clip`
Applies to	block container elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
text-overflow =
  [ clip | ellipsis | <string> | fade | <fade()> ]{1,2}

<fade()> =
  fade( [ <length-percentage> ] )

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Overflow Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

One-value syntax

This example shows different values for `text-overflow` applied to a paragraph, for left-to-right and right-to-left text.

HTML

```
<div class="ltr">
  <h2>Left to right text</h2>
  <pre>clip</pre>
  <p class="overflow-clip">
    Lorem ipsum dolor sit amet, consectetur adipisicing elit.
  </p>
  <pre>ellipsis</pre>
  <p class="overflow-ellipsis">
    Lorem ipsum dolor sit amet, consectetur adipisicing elit.
  </p>
  <pre>" [..]"</pre>
  <p class="overflow-string">
    Lorem ipsum dolor sit amet, consectetur adipisicing elit.
  </p>
</div>

<div class="rtl">
  <h2>Right to left text</h2>
  <pre>clip</pre>
  <p class="overflow-clip">
    Lorem ipsum dolor sit amet, consectetur adipisicing elit.
  </p>
  <pre>ellipsis</pre>
  <p class="overflow-ellipsis">
    Lorem ipsum dolor sit amet, consectetur adipisicing elit.
  </p>
  <pre>" [..]"</pre>
  <p class="overflow-string">
    Lorem ipsum dolor sit amet, consectetur adipisicing elit.
  </p>
</div>
```

CSS

```
p {
  width: 200px;
  border: 1px solid;
  padding: 2px 5px;

  /* Both of the following are required for text-overflow */
  white-space: nowrap;
  overflow: hidden;
}

.overflow-clip {
```

```
  text-overflow: clip;
}

.overflow-ellipsis {
  text-overflow: ellipsis;
}

.overflow-string {
  text-overflow: " [..]";
}

body {
  display: flex;
  justify-content: space-around;
}

.ltr > p {
  direction: ltr;
}

.rtl > p {
  direction: rtl;
}
```

Result

Two-value syntax

This example shows the two-value syntax for `text-overflow`, where you can define different overflow behavior for the start and end of the text. To show the effect we have to scroll the line so the start of the line is also hidden.

HTML

```
<pre>clip clip</pre>
<p class="overflow-clip-clip">
  Lorem ipsum dolor sit amet, consectetur adipisicing elit.
</p>
<pre>clip ellipsis</pre>
<p class="overflow-clip-ellipsis">
  Lorem ipsum dolor sit amet, consectetur adipisicing elit.
</p>
<pre>ellipsis ellipsis</pre>
<p class="overflow-ellipsis-ellipsis">
  Lorem ipsum dolor sit amet, consectetur adipisicing elit.
</p>
<pre>ellipsis " [..]"</pre>
<p class="overflow-ellipsis-string">
  Lorem ipsum dolor sit amet, consectetur adipisicing elit.
</p>
```

CSS

```
p {
  width: 200px;
  border: 1px solid;
  padding: 2px 5px;

  /* Both of the following are required for text-overflow */
  white-space: nowrap;
  overflow: scroll;
}

.overflow-clip-clip {
  text-overflow: clip clip;
}

.overflow-clip-ellipsis {
  text-overflow: clip ellipsis;
}

.overflow-ellipsis-ellipsis {
  text-overflow: ellipsis ellipsis;
}

.overflow-ellipsis-string {
  text-overflow: ellipsis " [..]";
}
```

JavaScript

```
// Scroll each paragraph so the start is also hidden
const paras = document.querySelectorAll("p");

for (const para of paras) {
  para.scroll(100, 0);
}
```

Result

A previous version of this interface reached the *Candidate Recommendation* status. As some not-listed-at-risk features needed to be removed, the spec was demoted to the *Working Draft* level, explaining why browsers implemented this property unprefixed, though not at the CR state.

text-rendering CSS property

The **`text-rendering`** CSS property provides information to the rendering engine about what to optimize for when rendering text.

The browser makes trade-offs among speed, legibility, and geometric precision.

> **Note:** The `text-rendering` property is an SVG property that is not defined in any CSS standard. However, Gecko and WebKit browsers let you apply this property to HTML and XML content on Windows, macOS, and Linux.

One very visible effect is `optimizeLegibility`, which enables ligatures (ff, fi, fl, etc.) in text smaller than 20px for some fonts (for example, Microsoft's *Calibri*, *Candara*, *Constantia*, and *Corbel*, or the *DejaVu* font family).

Syntax

```
/* Keyword values */
text-rendering: auto;
text-rendering: optimizeSpeed;
text-rendering: optimizeLegibility;
text-rendering: geometricPrecision;

/* Global values */
text-rendering: inherit;
text-rendering: initial;
text-rendering: revert;
text-rendering: revert-layer;
text-rendering: unset;
```

Values

`auto`

The browser makes educated guesses about when to optimize for speed, legibility, and geometric precision while drawing text. For differences in how this value is interpreted by the browser, see the compatibility table.

The `auto` value is a good default for balancing quality and performance, especially for extended bodies of plain text.

`optimizeSpeed`

The browser emphasizes rendering speed over legibility and geometric precision when drawing text. It disables kerning and ligatures.

The `optimizeSpeed` value is preferable in resource-constrained rendering scenarios, such as slow processors or low battery.

`optimizeLegibility`

The browser emphasizes legibility over rendering speed and geometric precision. This enables kerning and optional ligatures.

The `optimizeLegibility` value is preferable for texts that are large in size but short in content, such as headers or banners, to enhance their readability. It could also be used for high-quality professional typography such as published articles. It's not recommended for typical articles due to potential performance impacts.

`geometricPrecision`

The browser emphasizes geometric precision over rendering speed and legibility. Certain aspects of fonts — such as kerning — don't scale linearly. So this value can make text using those fonts look good.

In SVG, when text is scaled up or down, browsers calculate the final size of the text (which is determined by the specified font size and the applied scale) and request a font of that computed size from the platform's font system. But if you request a font size of, say, 9 with a scale of 140%, the resulting font size of 12.6 doesn't explicitly exist in the font system, so the browser rounds the font size to 12 instead. This results in stair-step scaling of text.

But the `geometricPrecision` property — when fully supported by the rendering engine — lets you scale your text fluidly. For large scale factors, you might see less-than-beautiful text rendering, but the size is what you would expect—neither rounded up nor down to the nearest font size supported by Windows or Linux.

The `geometricPrecision` value optimizes neither readability nor performance. It usually makes sense in SVG, where you want your graphic to scale faithfully without distorting the text dimensions.

> **Note:** WebKit precisely applies the specified value, but Gecko treats the value the same as `optimizeLegibility`.

Formal definition

Initial value	`auto`
Applies to	text elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
text-rendering =
  auto               |
  optimizeSpeed      |
  optimizeLegibility |
  geometricPrecision
```

This syntax reflects the latest standard as per CSS Specification. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Automatic application of optimizeLegibility

This demonstrates how `optimizeLegibility` is used by browsers automatically when the `font-size` is smaller than `20px`.

HTML

```
<p class="small">LYoWAT - ff fi fl ffl</p>
<p class="big">LYoWAT - ff fi fl ffl</p>
```

CSS

```
.small {
  font:
    19.9px "Constantia",
    "Times New Roman",
```

```
    "Georgia",
    "Palatino",
    serif;
}
.big {
  font:
    20px "Constantia",
    "Times New Roman",
    "Georgia",
    "Palatino",
    serif;
}
```

Result

optimizeSpeed vs. optimizeLegibility

This example shows the difference between the appearance of `optimizeSpeed` and `optimizeLegibility` (in your browser; other browsers may vary).

HTML

```
<p class="speed">LYoWAT - ff fi fl ffl</p>
<p class="legibility">LYoWAT - ff fi fl ffl</p>
```

CSS

```
p {
  font:
    1.5em "Constantia",
    "Times New Roman",
    "Georgia",
    "Palatino",
    serif;
}

.speed {
  text-rendering: optimizeSpeed;
}
.legibility {
  text-rendering: optimizeLegibility;
}
```

- SVG and CSS

text-shadow CSS property

The **`text-shadow`** CSS property adds shadows to text. It accepts a comma-separated list of shadows to be applied to the text and any of its `text-decoration`. Each shadow is described by some combination of X and Y offsets from the element, blur radius, and color.

Try it

```
text-shadow: 1px 1px 2px pink;
```

```
text-shadow: #ffcc00 1px 0 10px;
```

```
text-shadow: 5px 5px #558abb;
```

```
text-shadow: red 2px 5px;
```

```
text-shadow: 5px 10px;
```

```
text-shadow:
  1px 1px 2px red,
  0 0 1em blue,
  0 0 0.2em blue;
```

```
<section id="default-example">
  <p id="example-element">
    Far out in the uncharted backwaters of the unfashionable end of the western
    spiral arm of the Galaxy...
  </p>
</section>
```

```
p {
  font:
    1.5em "Georgia",
    serif;
}
```

Syntax

```
/* offset-x | offset-y | blur-radius | color */
text-shadow: 1px 1px 2px black;

/* color | offset-x | offset-y | blur-radius */
text-shadow: #ffcc00 1px 0 10px;

/* offset-x | offset-y | color */
text-shadow: 5px 5px #558abb;

/* color | offset-x | offset-y */
text-shadow: white 2px 5px;

/* offset-x | offset-y
/* Use defaults for color and blur-radius */
text-shadow: 5px 10px;

/* Global values */
text-shadow: inherit;
text-shadow: initial;
text-shadow: revert;
text-shadow: revert-layer;
text-shadow: unset;
```

This property is specified as a comma-separated list of shadows.

Each shadow is specified as two or three `<length>` values, followed optionally by a `<color>` value. The first two `<length>` values are the `<offset-x>` and `<offset-y>` values. The third, optional, `<length>` value is the `<blur-radius>`. The `<color>` value is the shadow's color.

When more than one shadow is given, shadows are applied front-to-back, with the first-specified shadow on top.

This property applies to both `::first-line` and `::first-letter` pseudo-elements.

Values

`<color>`

> Optional. The color of the shadow. It can be specified either before or after the offset values. If unspecified, the color's value is left up to the user agent, so when consistency across browsers is desired you should define it explicitly.

`<offset-x> <offset-y>`

> Required. These `<length>` values specify the shadow's distance from the text. `<offset-x>` specifies the horizontal distance; a negative value places the shadow to the left of the text. `<offset-y>` specifies the vertical distance; a negative value places the shadow above the text. If both values are `0`, the shadow is placed directly behind the text, although it may be partly visible due to the effect of `<blur-radius>`.

`<blur-radius>`

> Optional. This is a `<length>` value. The higher the value, the bigger the blur; the shadow becomes wider and lighter. If not specified, it defaults to `0`.

Formal definition

Initial value	none
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	a color plus three absolute lengths
Animation type	a shadow list

Formal syntax

```
text-shadow =
  none       |
  <shadow>#

<shadow> =
  <color>?                                  &&
  [ <length>{2} [ <length [0,∞]> <length>? ]? ]  &&
  inset?
```

This syntax reflects the latest standard as per CSS Backgrounds and Borders Module Level 3, CSS Text Decoration Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic shadow

```
.red-text-shadow {
  text-shadow: red 0 -2px;
}
```

```
<p class="red-text-shadow">
  Sed ut perspiciatis unde omnis iste natus error sit voluptatem accusantium
  doloremque laudantium, totam rem aperiam, eaque ipsa quae ab illo inventore.
</p>
```

Multiple shadows

```
.white-text-with-blue-shadow {
  text-shadow:
    1px 1px 2px black,
    0 0 1em blue,
    0 0 0.2em blue;
  color: white;
  font:
    1.5em "Georgia",
    serif;
}
```

```
<p class="white-text-with-blue-shadow">
  Sed ut perspiciatis unde omnis iste natus error sit voluptatem accusantium
  doloremque laudantium, totam rem aperiam, eaque ipsa quae ab illo inventore.
</p>
```

text-size-adjust CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`text-size-adjust`** CSS property controls the text inflation algorithm used on some smartphones and tablets. Other browsers will ignore this property.

Because many websites have not been developed with small devices in mind, mobile browsers differ from desktop browsers in the way they render web pages. Instead of laying out pages at the width of the device screen, they lay them out using a viewport that is much wider, usually 800 or 1000 pixels. To map the extra-wide layout back to the original device size, they either show only part of the whole render or scale the viewport down to fit.

Since text that has been scaled down to fit a mobile screen may be very small, many mobile browsers apply a text inflation algorithm to enlarge the text to make it more readable. When an element containing text uses 100% of the screen's width, the algorithm increases its text size, but without modifying the layout. The `text-size-adjust` property allows web authors to disable or modify this behavior, as web pages designed with small screens in mind do not need it.

Syntax

```
/* Keyword values */
text-size-adjust: none;
text-size-adjust: auto;

/* <percentage> value */
text-size-adjust: 80%;

/* Global values */
text-size-adjust: inherit;
text-size-adjust: initial;
text-size-adjust: revert;
text-size-adjust: revert-layer;
text-size-adjust: unset;
```

Values

This property is specified as one of the following values:

`none`

Disables the browser's inflation algorithm.

`auto`

Enables the browser's inflation algorithm. This value is used to cancel a `none` value previously set with CSS.

`<percentage>`

Enables the browser's inflation algorithm, specifying a percentage value with which to increase the font size.

Formal definition

Initial value	`auto` for smartphone browsers supporting inflation, `none` in other cases (and then not modifiable).
Applies to	all elements
Inherited	yes
Percentages	yes, refer to the corresponding size of the text font
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
text-size-adjust =
  auto               |
  none               |
  <percentage [0,∞]>
```

This syntax reflects the latest standard as per CSS Mobile Text Size Adjustment Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic disabling usage

As hinted at above, on a properly designed responsive site the `text-size-adjust` behavior is not needed, so developers can elect to turn it off by specifying a value of none:

```
p {
  -webkit-text-size-adjust: none;
  text-size-adjust: none;
}
```

text-spacing-trim CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`text-spacing-trim`** CSS property controls the internal spacing set on Chinese/Japanese/Korean (CJK) punctuation characters between adjacent characters (kerning) and at the start or end of text lines.

Syntax

```
/* Keyword values */
text-spacing-trim: normal;
text-spacing-trim: space-all;
text-spacing-trim: space-first;
text-spacing-trim: trim-start;

/* Global values */
text-spacing-trim: inherit;
text-spacing-trim: initial;
text-spacing-trim: revert;
text-spacing-trim: revert-layer;
text-spacing-trim: unset;
```

Values

`<spacing-trim>`

Defines the different spacing trim options. Available values are:

`normal`

Sets CJK full-width opening punctuation characters to be full-width at the start of each line. Sets CJK full-width closing punctuation characters to be full-width at the end of each line, or half-width if they do not fit on the line before justification. Collapses spacing between punctuation characters.

`space-all`

All CJK full-width punctuation characters are set to be full-width.

`space-first`

Behaves as `normal`, except that CJK full-width opening punctuation characters are set to be full-width at the start of the first line of the text's block container, and the start of every subsequent line coming after an explicit line break such as a newline character.

`trim-start`

Behaves as `normal`, except that CJK full-width opening punctuation characters are set to be half-width at the start of each line.

> **Note:** The CSS Text module also defines `trim-both`, `trim-all`, and `auto` values. However, these are not currently implemented in any browser.

Description

The `text-spacing-trim` property applies spacing/kerning to CJK punctuation characters to produce visually pleasing typography as defined by the Requirements for Japanese text layout (JLREQ) and the Requirements for Chinese text layout (CLREQ).

Many CJK punctuation characters include glyph-internal spacing. For example, the CJK full stop and the CJK close parenthesis usually have glyph-internal spacing on their right-hand side, to give them a constant advance measure consistent with other ideographic characters. However, when they appear in a row, the glyph-internal spacing can become excessive.

`text-spacing-trim` can be used to adjust such excessive spacing between adjacent characters (kerning) and at the start or end of text lines. Generally speaking:

- If a full-width punctuation character is set to be full-width, it has internal spacing set on both sides and is the full width of an ideograph.
- If a full-width punctuation character is set to be half-width, it has internal spacing set on one side only, and its other side is flush to the start (in the case of opening punctuation characters) or end (in the case of closing punctuation characters). Half-width characters are typically half the width of an ideograph.

> **Note:** To avoid the risk of excessive kerning, fonts must have the OpenType Alternate Half Widths (`halt`) feature, the Contextual Half-width Spacing (`chws`) feature, or both. If the font doesn't have either feature, `text-spacing-trim` is disabled.

Full-width punctuation collapsing

When pairs of punctuation characters are adjacent to one another, the space between them is collapsed according to the following rules:

- Set a full-width opening punctuation character to half-width if the previous character is a fullwidth opening punctuation character, a fullwidth middle dot, an ideographic space (U+3000), a fullwidth closing punctuation character of an equivalent or larger font size, or a character belonging to Unicode general category "Open punctuation" Ps. Otherwise, set it to full-width.
- Set a full-width closing punctuation character to half-width if the next character is a fullwidth closing punctuation character, a fullwidth middle dot, an ideographic space (U+3000), a fullwidth opening punctuation character with larger font size, or a character belonging to Unicode general category "Close punctuation" (Pe). Otherwise, set it to full-width.

Formal definition

Initial value	`normal`
Applies to	text elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
text-spacing-trim =
  <spacing-trim>  |
  auto

<spacing-trim> =
  space-all    |
```

```
  normal       |
  space-first  |
  trim-start   |
  trim-both    |
  trim-all
```

This syntax reflects the latest standard as per CSS Text Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

<code>text-spacing-trim</code> value comparison

This example compares the effect of four different `text-spacing-trim` properties, applying them to four identical paragraphs so you can see the visual differences between each one.

HTML

```
<main>
  <div id="normal">
    <h2>normal</h2>
    <p>
      (東)、【「(東)」】。<br />
      「東」「東」「東」東東東「東」。
    </p>
  </div>
  <div id="space-all">
    <h2>space-all</h2>
    <p>
      (東)、【「(東)」】。<br />
      「東」「東」「東」東東東「東」。
    </p>
  </div>
  <div id="space-first">
    <h2>space-first</h2>
    <p>
      (東)、【「(東)」】。<br />
      「東」「東」「東」東東東「東」。
    </p>
  </div>
  <div id="trim-start">
    <h2>trim-start</h2>
    <p>
      (東)、【「(東)」】。<br />
      「東」「東」「東」東東東「東」。
    </p>
  </div>
</main>
```

CSS

```
main {
  font-family:
    "Yu Gothic", "YuGothic", "Noto Sans JP", "Hiragino Sans",
    "Hiragino Kaku Gothic ProN", sans-serif;
  display: grid;
  gap: 0.5em;
  grid-template-columns: 1fr 1fr;
  width: 70%;
  margin: 0 auto;
}
h2 {
  font-size: 80%;
  margin: 0;
}
p {
  font-size: 20px;
  border: 1px solid blue;
  margin: 0;
}
#normal {
  text-spacing-trim: normal;
  grid-column: 1;
  grid-row: 1;
}
#space-all {
  text-spacing-trim: space-all;
  grid-column: 2;
  grid-row: 1;
}
#space-first {
  text-spacing-trim: space-first;
  grid-column: 1;
  grid-row: 2;
}
#trim-start {
  text-spacing-trim: trim-start;
  grid-column: 2;
  grid-row: 2;
}
```

Result

text-transform CSS property

The **`text-transform`** CSS property specifies how to capitalize an element's text. It can be used to make text appear in all-uppercase or all-lowercase, or with each word capitalized. It also can help improve legibility for ruby.

Try it

```
text-transform: capitalize;
```

```
text-transform: uppercase;
```

```
text-transform: lowercase;
```

```
text-transform: none;
```

```
text-transform: full-width;
```

```
text-transform: full-size-kana;
```

```
text-transform: math-auto;
```

```
<section id="default-example">
  <div class="transition-all" id="example-element">
    <p>
      LONDON. Michaelmas term lately over, and the Lord Chancellor sitting in
      Lincoln's Inn Hall.
    </p>
    <p lang="el">
      Σ is a Greek letter and appears in ΟΔΥΣΣΕΥΣ. Θα πάμε στο "Θεϊκό φαΐ" ή στη
      "Νεράιδα"
    </p>
    <p lang="ja">アイウエ オカクケ</p>
  </div>
</section>
```

```
#example-element {
  font-size: 1.2em;
}
```

The `text-transform` property takes into account language-specific case mapping rules such as the following:

- In Turkic languages, like Turkish (`tr`), Azerbaijani (`az`), Crimean Tatar (`crh`), Volga Tatar (`tt`), and Bashkir (`ba`), there are two kinds of `i`, with and without the dot, and two case pairings: `i`/`İ` and `ı`/`I`.
- In German (`de`), the `ß` becomes `SS` in uppercase.
- In Dutch (`nl`), the `ij` digraph becomes `IJ`, even with `text-transform: capitalize`, which only puts the first letter of a word in uppercase.
- In Greek (`el`), vowels lose their accent when the whole word is in uppercase (`ά`/`Α`), except for the disjunctive eta (`ή`/`Η`). Also, diphthongs with an accent on the first vowel lose the accent and gain a diaeresis on the second vowel (`άι`/`ΑΪ`).
- In Greek (`el`), the lowercase sigma character has two forms: `σ` and `ς`. `ς` is used only when sigma terminates a word. When applying `text-transform: lowercase` to an uppercase sigma (`Σ`), the browser needs to choose the right lowercase form based on context.
- in Irish (`ga`), certain prefixed letters remain in lowercase when the base initial is capitalized, so for example `text-transform: uppercase` will change `ar aon tslí` to `AR AON tSLÍ` and not, as one might expect, `AR AON TSLÍ` (Firefox only). In some cases, a hyphen is also removed upon uppercasing: `an t-uisce` transforms to `AN tUISCE` (and the hyphen is correctly reinserted by `text-transform: lowercase`).

The language is defined by the `lang` HTML attribute or the `xml:lang` XML attribute.

> **Note:** Support for language-specific cases varies between browsers, so check the browser compatibility table.

Syntax

```
/* Keyword values */
text-transform: none;
text-transform: capitalize;
text-transform: uppercase;
text-transform: lowercase;
text-transform: full-width;
text-transform: full-size-kana;
text-transform: math-auto;

/* Global values */
text-transform: inherit;
text-transform: initial;
text-transform: revert;
text-transform: revert-layer;
text-transform: unset;
```

`capitalize`

Is a keyword that converts the first *letter* of each word to uppercase. Other characters remain unchanged (they retain their original case as written in the element's text). A letter is defined as a character that is part of Unicode's Letter or Number general categories; thus, any punctuation marks or symbols at the beginning of a word are ignored.

> **Warning:** In many languages, it is considered incorrect to capitalize every word in a sentence, even in titles and names. If you don't know the language of the text the style will be applied to, you should avoid using `capitalize`. Furthermore, `capitalize` does not create title casing, because it does not apply language-specific rules such as skipping articles in English.

> **Note:** The `capitalize` keyword was under-specified in CSS 1 and CSS 2.1. This resulted in differences between browsers in the way the first letter was calculated (Firefox considered `-` and `_` as letters, but other browsers did not. Both WebKit and Gecko incorrectly considered letter-based symbols like ⓐ to be real letters.) By precisely defining the correct behavior, CSS Text Level 3 cleans this mess up. The `capitalize` line in the browser compatibility table contains the version the different engines started to support this now precisely-defined behavior.

`uppercase`

Is a keyword that converts all characters to uppercase.

`lowercase`

Is a keyword that converts all characters to lowercase.

`none`

Is a keyword that prevents the case of all characters from being changed.

`full-width`

Is a keyword that forces the writing of a character — mainly ideograms and Latin scripts — inside a square, allowing them to be aligned in the usual East Asian scripts (like Chinese or Japanese).

`full-size-kana`

Generally used for `<ruby>` annotation text, the keyword converts all small Kana characters to the equivalent full-size Kana, to compensate for legibility issues at the small font sizes typically used in ruby.

`math-auto`

Used to automatically render text in math italic where appropriate. It transforms Latin and Greek letters, and a few other math-related symbols, to italic mathematical symbols but only if it's applied on a text node containing a single character. For example, "x" will become "x" (U+1D465), but "exp" will stay as "exp". It is primarily used to specify the behavior of `<mi>` elements in MathML. You should generally use MathML markup which automatically applies the right styling.

Accessibility

Large sections of text set with a `text-transform` value of `uppercase` may be difficult for people with cognitive concerns such as Dyslexia to read.

- MDN Understanding WCAG, Guideline 1.4 explanations
- W3C Understanding WCAG 2.2

Formal definition

Initial value	none
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
text-transform =
  none                                          |
  [ capitalize | uppercase | lowercase ] || full-width || full-size-kana  |
  math-auto
```

This syntax reflects the latest standard as per CSS Text Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Example using "none"

```
<p>
  Initial String
  <strong>Lorem ipsum dolor sit amet, consectetur adipisicing elit…</strong>
</p>
<p>
  text-transform: none
  <strong
    ><span
      >Lorem ipsum dolor sit amet, consectetur adipisicing elit…</span
    ></strong
  >
</p>
```

```
span {
  text-transform: none;
}
strong {
  float: right;
}
```

This demonstrates no text transformation.

Example using "capitalize" (general)

```
<p>
  Initial String
  <strong>Lorem ipsum dolor sit amet, consectetur adipisicing elit…</strong>
</p>
<p>
  text-transform: capitalize
  <strong
    ><span
      >Lorem ipsum dolor sit amet, consectetur adipisicing elit…</span
    ></strong
  >
</p>
```

```
span {
  text-transform: capitalize;
}
strong {
  float: right;
}
```

This demonstrates text capitalization.

Example using "capitalize" (punctuation)

```
<p>
  Initial String
  <strong
    >(this) "is" [a] -short- -test- «for» *the* _css_ ¿capitalize?
    ?¡transform!</strong
  >
</p>
<p>
```

```
  text-transform: capitalize
  <strong
    ><span
      >(this) "is" [a] -short- -test- «for» *the* _css_ ¿capitalize?
      ?¡transform!</span
    ></strong
  >
</p>
```

```
span {
  text-transform: capitalize;
}
strong {
  float: right;
}
```

This demonstrates how initial punctuations of a word are ignored. The keyword target the first letter, that is the first Unicode character part of the Letter or Number general category.

Example using "capitalize" (Symbols)

```
<p>
  Initial String
  <strong>ⓐⓑⓒ (ⓓⓔⓕ) —Ⓖⓗⓘ— ⓙkl</strong>
</p>
<p>
  text-transform: capitalize
  <strong><span>ⓐⓑⓒ (ⓓⓔⓕ) —Ⓖⓗⓘ— ⓙkl</span></strong>
</p>
```

```
span {
  text-transform: capitalize;
}
strong {
  float: right;
}
```

This demonstrates how initial symbols are ignored. The keyword target the first letter, that is the first Unicode character part of the Letter or Number general category.

Example using "capitalize" (Dutch ij digraph)

```
<p>
  Initial String
  <strong lang="nl">The Dutch word: "ijsland" starts with a digraph.</strong>
</p>
<p>
  text-transform: capitalize
  <strong
    ><span lang="nl"
      >The Dutch word: "ijsland" starts with a digraph.</span
    ></strong
  >
</p>
```

```
span {
  text-transform: capitalize;
}
strong {
  float: right;
}
```

This demonstrates how the Dutch *ij* digraph must be handled like one single letter.

Example using "uppercase" (general)

```
<p>
  Initial String
  <strong>Lorem ipsum dolor sit amet, consectetur adipisicing elit…</strong>
</p>
<p>
  text-transform: uppercase
  <strong
    ><span
      >Lorem ipsum dolor sit amet, consectetur adipisicing elit…</span
    ></strong
  >
</p>
```

```
span {
  text-transform: uppercase;
}
strong {
  float: right;
}
```

This demonstrates transforming the text to uppercase.

Example using "uppercase" (Greek vowels)

```
<p>
  Initial String
  <strong>Θα πάμε στο "Θεϊκό φαΐ" ή στη "Νεράιδα"</strong>
</p>
<p>
  text-transform: uppercase
  <strong
    ><span lang="el">Θα πάμε στο "Θεϊκό φαΐ" ή στη "Νεράιδα"</span></strong
  >
</p>
```

```
span {
  text-transform: uppercase;
}
strong {
  float: right;
}
```

This demonstrates how Greek vowels except disjunctive *eta* should have no accent, and the accent on the first vowel of a vowel pair becomes a diaeresis on the second vowel.

Example using "lowercase" (general)

```
<p>
  Initial String
  <strong>Lorem ipsum dolor sit amet, consectetur adipisicing elit…</strong>
</p>
<p>
  text-transform: lowercase
  <strong
    ><span
      >Lorem ipsum dolor sit amet, consectetur adipisicing elit…</span
    ></strong
  >
</p>
```

```
span {
  text-transform: lowercase;
}
strong {
  float: right;
}
```

This demonstrates transforming the text to lowercase.

Example using "lowercase" (Greek Σ)

```
<p>
  Initial String
  <strong>Σ IS A greek LETTER that appears SEVERAL TIMES IN ΟΔΥΣΣΕΥΣ.</strong>
</p>
<p>
  text-transform: lowercase
  <strong
    ><span
      >Σ IS A greek LETTER that appears SEVERAL TIMES IN ΟΔΥΣΣΕΥΣ.</span
    ></strong
  >
</p>
```

```
span {
  text-transform: lowercase;
}
strong {
  float: right;
}
```

This demonstrates how the Greek character sigma (Σ) is transformed into the regular lowercase sigma (σ) or the word-final variant (ς), according the context.

Example using "lowercase" (Lithuanian)

```
<p>
  Initial String
  <strong>Į is a Lithuanian LETTER as is j́</strong>
</p>
<p>
  text-transform: lowercase
  <strong><span lang="lt">Į is a Lithuanian LETTER as is j́</span></strong>
</p>
```

```
span {
  text-transform: lowercase;
}
strong {
  float: right;
}
```

This demonstrates how the Lithuanian letters į and j́ retain their dot when transformed to lowercase.

Example using "full-width" (general)

```
<p>
  Initial String
  <strong
    >0123456789abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ!"#$%&()*+,-./:;&lt;=&gt;?@{|}~</strong
  >
</p>
<p>
  text-transform: full-width
  <strong
    ><span
      >0123456789abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ!"#$%&()*+,-./:;&lt;=&gt;?@{|}~</span
    ></strong
  >
</p>
```

```
span {
  text-transform: full-width;
}
strong {
  width: 100%;
```

```
  float: right;
}
```

Some characters exist in two formats: normal width and a full-width, with different Unicode code points. The full-width version is used to mix them smoothly with Asian ideographic characters.

Example using "full-width" (Japanese half-width katakana)

```
<p>
  Initial String
  <strong>ｳｪﾌﾞ ﾌﾟﾛｸﾞﾗﾐﾝｸﾞ の勉強</strong>
</p>
<p>
  text-transform: full-width
  <strong><span>ｳｪﾌﾞ ﾌﾟﾛｸﾞﾗﾐﾝｸﾞ の勉強</span></strong>
</p>
```

```
span {
  text-transform: full-width;
}
strong {
  width: 100%;
  float: right;
}
```

The Japanese half-width katakana was used to represent katakana in 8-bit character codes. Unlike regular (full-width) katakana characters, a letter with dakuten (voiced sound mark) is represented as two code points, the body of letter and dakuten. The `full-width` combines these into a single code point when converting these characters into full-width.

Example using "full-size-kana"

```
<p>ｱｲｳｴ ｵｶｸｹ ｼｽｿ ﾇﾊﾋﾌ ﾍﾎﾑﾔ ﾕﾖﾗﾘ ﾙﾚﾛﾜ</p>
<p>ｱｲｳｴ ｵｶｸｹ ｼｽｿ ﾇﾊﾋﾌ ﾍﾎﾑﾔ ﾕﾖﾗﾘ ﾙﾚﾛﾜ</p>
```

```
p:nth-of-type(2) {
  text-transform: full-size-kana;
}
```

Example using "math-auto"

In this example, we use pure HTML markup to create a math formula:

```
<div>
  (<span class="math-id">sin</span> <span class="math-id">x</span>)<sup
    >2</sup
  >
  + (<span class="math-id">cos</span> <span class="math-id">x</span>)<sup
    >2</sup
  >
  = 1
</div>
```

We give every `.math-id` element `text-transform: math-auto`. However, note how only the `x` characters become italic, while the `sin` and `cos` remain unchanged.

```
.math-id {
  text-transform: math-auto;
}
```

However, you are encouraged to use MathML for mathematical formulas, as it provides a more robust and accessible way to represent mathematical content. Here's the same formula using MathML:

```
<math xmlns="http://www.w3.org/1998/Math/MathML" display="block">
  <semantics>
    <mrow>
      <mo stretchy="false">(</mo>
      <mo lspace="0em" rspace="0em">sin</mo>
      <mspace width="0.16666666666666666em"></mspace>
      <mi>x</mi>
      <msup>
        <mo stretchy="false">)</mo>
        <mn>2</mn>
      </msup>
      <mo>+</mo>
      <mo stretchy="false">(</mo>
      <mo lspace="0em" rspace="0em">cos</mo>
      <mspace width="0.16666666666666666em"></mspace>
      <mi>x</mi>
      <msup>
        <mo stretchy="false">)</mo>
        <mn>2</mn>
      </msup>
      <mo>=</mo>
      <mn>1</mn>
    </mrow>
    <annotation encoding="TeX">(\sin\,x)^2+(\cos\,x)^2=1</annotation>
  </semantics>
</math>
```

- `font-variant`

text-underline-offset CSS property

The **`text-underline-offset`** CSS property sets the offset distance of an underline text decoration line (applied using `text-decoration`) from its original position.

`text-underline-offset` is not part of the `text-decoration` shorthand. While an element can have multiple `text-decoration` lines, `text-underline-offset` only impacts underlining, and **not** other possible line decoration options such as `overline` or `line-through`.

Try it

```
text-underline-offset: auto;
```

```
text-underline-offset: 8px;
```

```
text-underline-offset: -0.5rem;
```

```
<section id="default-example">
  <p id="example-element">And after all we are only ordinary</p>
</section>
```

```
p {
  font: 1.5em sans-serif;
  text-decoration-line: underline;
  text-decoration-color: red;
}
```

Syntax

```
/* Single keyword */
text-underline-offset: auto;

/* length */
text-underline-offset: 0.1em;
text-underline-offset: 3px;

/* percentage */
text-underline-offset: 20%;

/* Global values */
text-underline-offset: inherit;
text-underline-offset: initial;
text-underline-offset: revert;
text-underline-offset: revert-layer;
text-underline-offset: unset;
```

Values

This property is specified as one of the following values:

`auto`

The browser chooses the appropriate offset for underlines.

`<length>`

Specifies the offset of underlines as a `<length>`, overriding the font file suggestion and the browser default. It is recommended to use `em` units so the offset scales with the font size.

`<percentage>`

Specifies the offset of underlines as a `<percentage>` of **1 em** in the element's font. A percentage inherits as a relative value, and so therefore scales with changes in the font. For a given application of this property, the offset is constant across the whole box that the underline is applied to, even if there are child elements with different font sizes or vertical alignment.

Formal definition

Initial value	`auto`
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Percentages	refer to the font size of the element itself
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
text-underline-offset =
  auto                |
  <length-percentage>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Text Decoration Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Demonstration of text-underline-offset

```
<p class="one-line">Here's some text with an offset wavy red underline!</p>
<br />
<p class="two-lines">
  This text has lines both above and below it. Only the bottom one is offset.
</p>
```

```
p {
  text-decoration: underline wavy red;
  text-underline-offset: 1em;
}

.two-lines {
  text-decoration-color: purple;
  text-decoration-line: underline overline;
}
```

See also

- `text-decoration`
- `text-decoration-thickness`

text-underline-position CSS property

The **`text-underline-position`** CSS property specifies the position of the underline which is set using the `text-decoration` property's `underline` value.

Try it

```
text-underline-position: auto;
```

```
text-underline-position: under;
```

```
<section id="default-example">
  <p>
    <span class="transition-all" id="example-element"
      >C<sub>8</sub>H<sub>10</sub>N<sub>4</sub>O<sub>2</sub></span
    >
    is the chemical formula for caffeine.
  </p>
</section>
```

```
p {
  font: 1.5em sans-serif;
}

#example-element {
  text-decoration-line: underline;
}
```

Syntax

```
/* Single keyword */
text-underline-position: auto;
text-underline-position: under;
text-underline-position: left;
text-underline-position: right;

/* Multiple keywords */
text-underline-position: under left;
text-underline-position: right under;

/* Global values */
text-underline-position: inherit;
text-underline-position: initial;
text-underline-position: revert;
text-underline-position: revert-layer;
text-underline-position: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

> The user agent uses its own algorithm to place the line at or under the alphabetic baseline.

`from-font`

> If the font file includes information about a preferred position, use that value. If the font file doesn't include this information, behave as if `auto` was set, with the browser choosing an appropriate position.

`under`

> Forces the line to be set below the alphabetic baseline, at a position where it won't cross any descenders. This is useful for ensuring legibility with chemical and mathematical formulas, which make a large use of subscripts.

`left`

> In vertical writing-modes, this keyword forces the line to be placed on the *left* side of the text. In horizontal writing-modes, it is a synonym of `auto`.

`right`

> In vertical writing-modes, this keyword forces the line to be placed on the *right* side of the text. In horizontal writing-modes, it is a synonym of `auto`.

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
text-underline-position =
  auto                                |
  [ from-font | under ] || [ left | right ]
```

This syntax reflects the latest standard as per CSS Text Decoration Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

A basic example

We create two example paragraphs:

```
<p class="horizontal">
  Lorem ipsum dolor sit amet, consectetur adipiscing elit. Nullam consectetur ac
  turpis vel laoreet. Nullam volutpat pharetra lorem, sit amet feugiat tortor
  volutpat quis. Nam eget sodales quam. Aliquam accumsan tellus ac erat posuere.
</p>

<p class="vertical">
  Lorem ipsum dolor sit amet, consectetur adipiscing elit. Nullam consectetur ac
  turpis vel laoreet. Nullam volutpat pharetra lorem, sit amet feugiat tortor
  volutpat quis. Nam eget sodales quam. Aliquam accumsan tellus ac erat posuere.
</p>
```

Our CSS looks like this:

```
p {
  font-size: 1.5rem;
  text-transform: capitalize;
  text-decoration: underline;
  text-decoration-thickness: 2px;
}

.horizontal {
  text-underline-position: under;
}

.vertical {
  writing-mode: vertical-rl;
  text-underline-position: left;
}
```

In this example we set both the paragraphs to have a thick underline. In the horizontal text we use `text-underline-position: under;` to put the underline below all the descenders.

In the text with a vertical `writing-mode` set, we can then use values of `left` or `right` to make the underline appear on the left or right of the text as required.

The live example looks like this:

Setting text-underline-position globally

Because the `text-underline-position` property inherits and is not reset by the `text-decoration` shorthand property, it may be appropriate to set its value at a global level. For example, the `under` value may be appropriate for a document with lots of chemical and mathematical formulas, which make a large use of subscripts.

```
:root {
  text-underline-position: under;
}
```

See also

- The `text-decoration` property is a shorthand for setting most text-decoration properties, including `text-decoration-line`, `text-decoration-color`, and `text-decoration-style`. However, it does not set `text-underline-position`.

text-wrap CSS property

The **`text-wrap`** CSS shorthand property controls how text inside an element is wrapped. The different values provide:

- Typographic improvements, for example more balanced line lengths across broken headings
- A way to turn text wrapping off completely.

Try it

```
text-wrap: wrap;
```

```
text-wrap: nowrap;
```

```
text-wrap: balance;
```

```
text-wrap: pretty;
```

```
text-wrap: stable;
```

```
<section class="default-example" id="default-example">
  <div class="whole-content-wrapper">
    <p>Edit the text in the box:</p>
    <div class="transition-all" id="example-element">
      <p contenteditable>
        Lorem ipsum dolor sit amet consectetur adipisicing elit. Voluptatem aut
        cum eum id quos est.
      </p>
    </div>
  </div>
</section>
```

```
.whole-content-wrapper {
  display: flex;
  flex-direction: column;
  align-items: center;
  width: 100%;
}

#example-element {
  border: 1px solid #c5c5c5;
  width: 250px;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `text-wrap-mode`
- `text-wrap-style`

Syntax

```
/* Keyword values */
text-wrap: wrap;
text-wrap: nowrap;
text-wrap: balance;
text-wrap: pretty;
text-wrap: stable;

/* Global values */
text-wrap: inherit;
text-wrap: initial;
text-wrap: revert;
text-wrap: revert-layer;
text-wrap: unset;
```

Values

This property is specified as one of the following keyword values:

`wrap`

Text is wrapped across lines at appropriate characters (for example spaces, in languages like English that use space separators) to minimize overflow. This is the default value.

`nowrap`

Text does not wrap across lines. It will overflow its containing element rather than breaking onto a new line.

`balance`

Text is wrapped in a way that best balances the number of characters on each line, enhancing layout quality and legibility. Because counting characters and balancing them across multiple lines is computationally expensive, this value is only supported for blocks of text spanning a limited number of lines (six or less for Chromium and ten or less for Firefox).

`pretty`

Results in the same behavior as `wrap`, except that the user agent will use a slower algorithm that favors better layout over speed. This is intended for body copy where good typography is favored over performance (for example, when the number of orphans should be kept to a minimum).

`stable`

Results in the same behavior as `wrap`, except that when the user is editing the content, the lines that come before the lines they are editing remain static rather than the whole block of text re-wrapping.

Description

There are 2 ways that text can flow across lines within a block of content, such as a paragraph (`<p>`) or headings (`<h1>`–`<h6>`). These are *forced line breaks*, that are controlled by the user, and *soft line breaks*, that are controlled by the browser. The `text-wrap` property can be used to prompt the browser how to control the *soft line breaks*.

The value you choose, for `text-wrap`, depends on how many lines of text you anticipate styling, whether the text is `contenteditable`, and whether you need to prioritize appearance or performance.

When the styled content will be limited to a short number of lines, such as headings, captions, and blockquotes, `text-wrap: balance` can be added to balance the number of characters on each line, enhancing layout quality and legibility. As browsers limit the number of lines impacted by this property, this value's impact on performance is negligible.

For longer sections of text, `text-wrap: pretty` can be used. Note that `pretty` has a negative effect on performance, so it should be only used for longer blocks of text when the layout is more important than speed.

The `stable` value improves user experience when used on content that is `contenteditable`. This value ensures that, as the user is editing text, the previous lines in the area being edited remain stable.

Formal definition

Initial value	`wrap`
Applies to	text and block containers
Inherited	yes
Percentages	as each of the properties of the shorthand: • `text-wrap-mode`: no • `text-wrap-style`: no
Computed value	as each of the properties of the shorthand: • `text-wrap-mode`: as specified • `text-wrap-style`: as specified
Animation type	as each of the properties of the shorthand: • `text-wrap-mode`: discrete • `text-wrap-style`: discrete

Formal syntax

```
text-wrap =
  <'text-wrap-mode'>   ||
  <'text-wrap-style'>

<text-wrap-mode> =
  wrap    |
  nowrap

<text-wrap-style> =
  auto                  |
  balance               |
  stable                |
  pretty                |
  avoid-short-last-line
```

This syntax reflects the latest standard as per CSS Text Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic text wrap value comparison

HTML

```
<h2 class="wrap" contenteditable="true">
  The default behavior; the text in the heading wraps "normally"
</h2>

<h2 class="nowrap" contenteditable="true">
  In this case the text in the heading doesn't wrap, and overflows the container
</h2>

<h2 class="balance" contenteditable="true">
  In this case the text in the heading is nicely balanced across lines
</h2>
```

CSS

```
.wrap {
  text-wrap: wrap;
}

.nowrap {
  text-wrap: nowrap;
}

.balance {
  text-wrap: balance;
}

h2 {
  font-size: 2rem;
  font-family: sans-serif;
}
```

Result

The text in the example is editable. Change the text, adding long words, to view how the different line and word lengths impact wrapping.

text-wrap-mode CSS property

The **`text-wrap-mode`** CSS property controls whether the text inside an element is wrapped.

Try it

```
text-wrap-mode: wrap;
```

```
text-wrap-mode: nowrap;
```

```
<section class="default-example" id="default-example">
  <div class="whole-content-wrapper">
    <p>Edit the text in the box:</p>
    <div class="transition-all" id="example-element">
      <p contenteditable>
        You can edit this lorem ipsum dolor sit amet consectetur adipisicing
        elit. Voluptatem aut cum eum id quos est text.
      </p>
    </div>
  </div>
</section>
```

```
.whole-content-wrapper {
  display: flex;
  flex-direction: column;
  align-items: center;
  width: 100%;
}

#example-element {
  border: 1px solid #c5c5c5;
  width: 250px;
}
```

Syntax

```
/* Keyword values */
text-wrap-mode: wrap;
text-wrap-mode: nowrap;

/* Global values */
text-wrap-mode: inherit;
text-wrap-mode: initial;
text-wrap-mode: revert;
text-wrap-mode: revert-layer;
text-wrap-mode: unset;
```

Values

The `text-wrap-mode` property is specified as one of the following keyword values:

`wrap`

Text is wrapped across lines at appropriate characters (for example spaces, in languages like English that use space separators) to minimize overflow. This is the default value.

`nowrap`

Text does not wrap across lines. It will overflow its containing element rather than breaking onto a new line.

Description

The `text-wrap-mode` property can be used to control text wrapping inside an element. The different values provide alternate ways of wrapping the content of a block element, specifying whether lines may wrap at unforced soft wrap opportunities (`wrap`), or not (`nowrap`).

When set to `nowrap`, text will overflow rather than break onto multiple lines. As the `overflow` property defaults to `visible`, when content is larger than the container's inline-size, it will overflow in the inline direction. To enable scrolling in the inline direction, instead of overflow, set the `overflow-inline` property to `auto` or `scroll`. To ensure the container at least as wide as the longest word, set the `min-inline-size` to `min-content`.

When set to `wrap`, content flows onto new lines as necessary, wrapping at word break opportunities, such as `<wbr>` and hyphens, and other language-specific soft-wrap opportunities. The property does not prevent non-breakable pieces of content from overflowing in the inline direction if larger than the container's inline-size.

The `text-wrap-mode` is part of two shorthand properties. The `text-wrap-mode`, along with the `white-space-collapse` property, can be declared using the `white-space` shorthand. It can also be set and reset, along with the `text-wrap-style` property, using the `text-wrap` shorthand.

Formal definition

Initial value	`wrap`
Applies to	text and block containers
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
text-wrap-mode =
  wrap    |
  nowrap
```

This syntax reflects the latest standard as per CSS Text Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

In this example, we compare the effect of the `text-wrap-mode` property's two values.

HTML

We include two `<div>` elements that are the same except for their class names.

```
<div class="wrap">CSS IS AWESOME</div>
<div class="nowrap">CSS IS AWESOME</div>
```

CSS

We apply the same styles to both containers, limiting their width.

```
div {
  font-family: "Arial", sans-serif;
  font-weight: bold;
  font-size: 4rem;
  box-sizing: border-box;
  border: 0.25rem solid black;
  padding: 0 4px;
  width: 14rem;
  margin: 1rem;
}
```

We give the examples different `text-wrap-mode` values:

```
.wrap {
  text-wrap-mode: wrap;
}
.nowrap {
  text-wrap-mode: nowrap;
}
```

Result

In the `wrap` example, the content flows over to the next line so that it fits in the box. "Awesome" is wider than the containing box, and contains no soft break opportunities, so it overflows.

In the `nowrap` example, the content does **not** flow to the next line as the content has been specifically set to not wrap, so it is all on one line, overflowing the container.

text-wrap-style CSS property

The **`text-wrap-style`** CSS property controls how text inside an element is wrapped, providing alternate ways of determining where to create line breaks in order to fit the content within a block element.

Try it

```
text-wrap-style: auto;
```

```
text-wrap-style: balance;
```

```
text-wrap-style: pretty;
```

```
text-wrap-style: stable;
```

```
<section class="default-example" id="default-example">
  <div class="whole-content-wrapper">
    <p>Edit the text in the box:</p>
    <div class="transition-all" id="example-element">
      <p contenteditable>
        Lorem ipsum dolor sit amet consectetur adipisicing elit. Voluptatem aut
        cum eum id quos est.
      </p>
    </div>
  </div>
</section>
```

```
.whole-content-wrapper {
  display: flex;
  flex-direction: column;
  align-items: center;
  width: 100%;
}

#example-element {
  border: 1px solid #c5c5c5;
  width: 250px;
}
```

Syntax

```
/* Keyword values */
text-wrap-style: auto;
text-wrap-style: balance;
text-wrap-style: pretty;
text-wrap-style: stable;

/* Global values */
text-wrap-style: inherit;
text-wrap-style: initial;
text-wrap-style: revert;
text-wrap-style: revert-layer;
text-wrap-style: unset;
```

Values

The `text-wrap-style` property is specified as one of the following keyword values:

`auto`

> Text is wrapped in the most performant way for the browser and does not take into account the number of characters.

`balance`

> Text is wrapped in a way that best balances the number of characters on each line, enhancing layout quality and legibility. Because counting characters and balancing them across multiple lines is computationally expensive, this value is only supported for blocks of text spanning a limited number of lines (six or less for Chromium and ten or less for Firefox).

`pretty`

> Text is wrapped using a slower algorithm that favors better layout over speed. This is intended for body copy where good typography is favored over performance (for example, when the number of orphans should be kept to a minimum).

`stable`

> Text is wrapped such that when the user is editing the content, the lines that come before the lines they are editing remain static rather than the whole block of text re-wrapping.

The specification also defines an `avoid-orphans` value in which browsers consider more than one line when making break decisions to avoid excessively short last lines. This value is not yet supported in any browser.

Description

The `text-wrap-style` property can be used to provide a hint as to how the user agent should insert soft line breaks when the content is allowed to wrap. Each value defines a different approach to wrapping lines, balancing speed, quality, layout style, and stability, providing alternative ways to wrap the content of a block element.

When the content is allowed to wrap — the usual behavior because the default value of the `text-wrap-mode` property is `wrap` — the single keyword value of the `text-wrap-style` property specifies *how* the developer would like the text to be wrapped. The values have no effect on where a soft wrap opportunity exists, just how the browser should selects among them. If `text-wrap-mode` is set to `nowrap`, this property has no effect.

Selecting a value

The value you choose, for `text-wrap-style`, depends on how many lines of text you anticipate styling, whether the text is `contenteditable`, and whether you need to prioritize appearance or performance.

When the styled content will be limited to a short number of lines, such as headings, captions, and blockquotes, `text-wrap-style: balance` can be added to balance the number of characters on each line, enhancing layout quality and legibility. As browsers limit the number of lines impacted by this property, this value's impact on performance is negligible.

For longer sections of text, `text-wrap-style: pretty` can be used. Note that `pretty` has a negative effect on performance, so it should be only used for longer blocks of text when the layout is more important than speed.

The `stable` value improves user experience when used on content that is `contenteditable`. This value ensures that, as the user is editing text, the previous lines in the area being edited remain stable.

Formal definition

Initial value	`auto`
Applies to	text and block containers
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
text-wrap-style =
  auto                  |
  balance               |
  stable                |
  pretty                |
  avoid-short-last-line
```

This syntax reflects the latest standard as per CSS Text Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Balanced text

This example has two paragraphs, the first is the default `auto` and the second is `balance`.

HTML

```
<h2>Unbalanced</h2>
<p>
  Lorem ipsum dolor sit amet consectetur adipisicing elit. Velit, ad. Impedit
  adipisci rerum modi praesentium atque aperiam vitae nesciunt consectetur
  assumenda deleniti repudiandae perferendis sed odio doloremque, aliquid natus
  laboriosam?
</p>
<h2>Balanced</h2>
<p class="balanced">
  Lorem ipsum dolor sit amet consectetur adipisicing elit. Velit, ad. Impedit
  adipisci rerum modi praesentium atque aperiam vitae nesciunt consectetur
  assumenda deleniti repudiandae perferendis sed odio doloremque, aliquid natus
  laboriosam?
</p>
```

CSS

```
p {
  max-width: 60ch;
}
.balanced {
  text-wrap-style: balance;
}
```

timeline-scope CSS property

The **`timeline-scope`** CSS property modifies the scope of a named animation timeline.

Syntax

```
/* Keyword values */
timeline-scope: all;
timeline-scope: none;

/* Custom name values */
timeline-scope: --custom_name_for_timeline;
timeline-scope: --timeline_name_one, --timeline_name_two;

/* Global values */
timeline-scope: inherit;
timeline-scope: initial;
timeline-scope: revert;
timeline-scope: revert-layer;
timeline-scope: unset;
```

Values

This property is specified as a keyword or a comma-separated list of custom timeline names:

`none`

Applies no change to the timeline scope. This is the default.

`all`

Sets the scope so that any timeline names set on the element or in its subtree are matched only by elements within the same subtree.

`<dashed-ident>`

Specifies one or more comma-separated timeline names that are declared using `scroll-timeline-name` or `view-timeline-name`. Sets the scope so that when the specified `scroll-timeline-name` or `view-timeline-name` values are set on the element or in its subtree, they are matched only by elements within the same subtree.

Description

The `timeline-scope` property modifies the scope of a named animation timeline. By default, a named timeline (i.e., declared using `scroll-timeline-name` or `view-timeline-name`) can only be set as the controlling timeline of a direct descendant element (i.e., by setting `animation-timeline` on it with the timeline name as its value). This is the default "scope" for the timeline.

The value of the `timeline-scope` is the name of a timeline defined on a descendant element; this changes the scope of the timeline to include the targeted element and its descendants. In other words, that element on which the `timeline-scope` property is defined, and all of its descendant elements, can be controlled using that timeline.

If no timeline (or more than one timeline) exists with the name given for the `timeline-scope` value, an inactive timeline with the specified name is created. The `timeline-scope` property only works with named timelines, and therefore cannot be used in conjunction with anonymous timelines created using the `view()` or `scroll()` animation timeline functions.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	none or an ordered list of identifiers
Animation type	Not animatable

Formal syntax

```
timeline-scope =
  none             |
  all              |
  <dashed-ident>#
```

This syntax reflects the latest standard as per Scroll-driven Animations. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

In this example, we animated an element in response to the scrolling of another element by increasing the timeline scope with the `timeline-scope` property.

HTML

The HTML includes an element to animate and an element to scroll:

```
<div class="content">
  <div class="box animation"></div>
</div>

<div class="scroller">
  <div class="long-element"></div>
</div>
```

CSS

A scroll timeline named `--my-scroller` is defined using the `scroll-timeline-name` property on a scrolling element. This scroll timeline name is used in two other places: it is applied as the `animation-timeline` on the element we want to animate, and as `timeline-scope` on an ancestor of both the scroller and the animated element, increasing the scope.

We set the `<body>`'s height to `100vh`, and lay its two child elements out as two equal columns using flexbox. To increase the timeline scope from the `<div class="scroller">` element to the whole `<body>`, we set `timeline-scope: --my-scroller` on it. By doing so, the `--my-scroller` timeline can be set as the controlling timeline for an animation set on the `<body>` or any element nested inside it.

```
body {
  margin: 0;
  height: 100vh;
  display: flex;

  timeline-scope: --my-scroller;
}

.content,
.scroller {
  flex: 1;
}
```

We set `--my-scroller` as the `scroll-timeline-name` on the scrolling element that should provide the scroll progress timeline for our animated element. We add `overflow` to enable scrolling, adding a background color to make its boundary visible. We set a large `height` on the contents of our scrolling element so the element actually scrolls.

```
.scroller {
  overflow: scroll;
  scroll-timeline-name: --my-scroller;
  background: deeppink;
}

.long-element {
  height: 2000px;
}
```

Next, we give the animated element some rudimentary styles and apply an animation to it using the `animation` shorthand property. We set the `animation-timeline` to the named scroll timeline: `--my-scroller`. To reiterate, animating the element based on the scroll progress of its cousin element is only possible because we set `timeline-scope` on a mutual ancestor; the animated element is **not** a descendant of the scrolling element.

```
.box {
  width: 100px;
  height: 100px;
  border-radius: 10px;
  background-color: rebeccapurple;
}

.animation {
  animation: rotate-appear 1ms linear;
  animation-timeline: --my-scroller;
}

@keyframes rotate-appear {
  from {
```

```
    rotate: 0deg;
    translate: 0;
  }

  to {
    rotate: 720deg;
    translate: 100%;
  }
}
```

```
@layer supports {
  @supports not (timeline-scope: none) {
    body::before {
      content: "Your browser does not support the 'timeline-scope' property.";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem;
    }
  }
}
```

Result

Scroll the vertical bar on the pink area to see the square animate.

The key point to note here is that the animated element is not a descendant of the scrolling element — to make this work, we increase the scope of the `--my-scroller` timeline by setting `timeline-scope: --my-scroller` on the `<body>`.

timeline-trigger CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`timeline-trigger`** CSS shorthand property defines a scroll-triggered animation trigger on an element.

Constituent properties

This property is a shorthand for the following CSS properties:

- `timeline-trigger-name`
- `timeline-trigger-source`
- `timeline-trigger-activation-range`
- `timeline-trigger-active-range`

Syntax

```
/* Keyword */
timeline-trigger: none;

/* Name | source */
timeline-trigger: --t view();
timeline-trigger: --t --my-timeline;

/* Name | source | activation range */
timeline-trigger: --t view() contain;
timeline-trigger: --t --my-timeline entry exit 50%;

/* Name | source | activation range | active range */
timeline-trigger: --t view() contain / cover;
timeline-trigger: --t --my-timeline entry / entry exit 50%;

/* Multiple triggers */
timeline-trigger:
  --t view(),
  --other-trigger --my-timeline entry / entry 50% exit 50%;

/* Global values */
timeline-trigger: inherit;
timeline-trigger: initial;
timeline-trigger: revert;
timeline-trigger: revert-layer;
timeline-trigger: unset;
```

Values

This property is specified as the keyword `none` or a comma-separated list of `<timeline-trigger>` values:

`none`

Specifies that the element does not create a trigger, resetting all four longhand properties to their default values.

`<timeline-trigger>`

Specified as a space-separated list of the following values:

`<'timeline-trigger-name'>`

Specifies the `timeline-trigger-name` value representing the trigger's identifying name. Defaults to `none`.

`<'timeline-trigger-source'>`

Specifies the `timeline-trigger-source` value representing the trigger's timeline. Defaults to `auto`.

`<'timeline-trigger-activation-range'>` Optional

Specifies the `timeline-trigger-activation-range` value representing the trigger's activation range. Defaults to `normal`, which is equivalent to `cover 0% cover 100%` for a view progress timeline `timeline-trigger-source`, and `0% 100%` for a scroll progress timeline `timeline-trigger-source`.

`<'timeline-trigger-active-range'>` Optional

Preceded by a slash (`/`), specifies the `timeline-trigger-active-range` value representing the trigger's activation range. Defaults to `auto`, which sets the `<'timeline-trigger-active-range'>` to the same value as the `<'timeline-trigger-activation-range'>`.

Description

The `timeline-trigger` property can be used to set all the longhand properties used to create a CSS scroll-triggered animation trigger in a single declaration. Component properties not specified within the comma-separated list of `timeline-trigger` values are set to their default values.

Shorthand property order

Because some of the component properties share value types, the order of those component properties within the shorthand is important. The values must be given in the specified order.

- `timeline-trigger-name`
- `timeline-trigger-source`
- `timeline-trigger-activation-range`
- `timeline-trigger-active-range`, preceded by a forward slash.

The `timeline-trigger-active-range` value can only be included if the `timeline-trigger-activation-range` value is included; the two values are separated by a slash (`/`).

For example:

```
.trigger {
  timeline-trigger: --my-trigger view() entry / contain;
}
```

An element with this declaration set will have:

- An identifying `timeline-trigger-name` of `--my-trigger`.
- A `timeline-trigger-source` value of `view()`, which selects the element's nearest ancestor scrolling element to define its timeline trigger.
- An activation range of `entry`, meaning that the trigger will activate when its tracked element moves into the `entry` range. This is the range between the element's start edge crossing the scrollport's end edge and the element's end edge crossing the scrollport's end edge.
- An active range of `contain`, meaning that once activated, the trigger will stay active until its tracked element leaves the `contain` range: the range in which any part of the tracked element is visible in the scrollport.

To trigger an animated element via the previously described trigger, reference the `timeline-trigger-name` in the animated element's `animation-trigger` property. Set both the `timeline-trigger` and `animation-trigger` properties on the animated element to enable it to create its own trigger.

The <code>none</code> value

The `none` keyword specifies that the element does not create a scroll-triggered animation trigger. Setting `none` is equivalent to setting `none auto normal / normal`, which effectively resets all four equivalent longhand properties to their default values.

Formal definition

Initial value	as each of the properties of the shorthand:
	• `timeline-trigger-name`: `none`
	• `timeline-trigger-source`: `auto`
	• `timeline-trigger-activation-range`: as each of the properties of the shorthand:
	  ◦ `timeline-trigger-activation-range-start`: `normal`
	  ◦ `timeline-trigger-activation-range-end`: `normal`
	• `timeline-trigger-active-range`: as each of the properties of the shorthand:
	  ◦ `timeline-trigger-active-range-start`: `auto`
	  ◦ `timeline-trigger-active-range-end`: `auto`

Applies to	all elements
Inherited	no

Computed value	as each of the properties of the shorthand:
	• `timeline-trigger-name`: as specified
	• `timeline-trigger-source`: A list, with each item being either the keyword `none`, the keyword `auto`, a case-sensitive `<ident>`, a computed `scroll()` function, or a computed `view()` function.
	• `timeline-trigger-activation-range`: as each of the properties of the shorthand:
	  ◦ `timeline-trigger-activation-range-start`: A list where each item may be 'normal', a length percentage, or a timeline range name and a length percentage
	  ◦ `timeline-trigger-activation-range-end`: A list where each item may be 'normal', a length percentage, or a timeline range name and a length percentage
	• `timeline-trigger-active-range`: as each of the properties of the shorthand:
	  ◦ `timeline-trigger-active-range-start`: A list where each item may be 'normal', a length percentage, or a timeline range name and a length percentage
	  ◦ `timeline-trigger-active-range-end`: A list where each item may be 'normal', a length percentage, or a timeline range name and a length percentage

Animation type	as each of the properties of the shorthand: • `timeline-trigger-name`: Not animatable • `timeline-trigger-source`: Not animatable • `timeline-trigger-activation-range`: Not animatable • `timeline-trigger-active-range`: Not animatable

Formal syntax

```
timeline-trigger =
  none                                          |
  [ <'timeline-trigger-name'> <'timeline-trigger-source'> [ <'timeline-trigger-range'> ]? ]#

<timeline-trigger-name> =
```

```
  none             |
  <dashed-ident>#

<timeline-trigger-source> =
  [ none | auto | [ <dashed-ident> | <scroll()> | <view()> ]+ ]#

<timeline-trigger-range> =
  [ <'timeline-trigger-activation-range'> [ / <'timeline-trigger-active-range'> ]? ]#

<scroll()> =
  scroll( [ <scroller> || <axis> ]? )

<view()> =
  view( [ <axis> || <'view-timeline-inset'> ]? )

<timeline-trigger-activation-range> =
  [ <'timeline-trigger-activation-range-start'> <'timeline-trigger-activation-range-end'>? ]#

<timeline-trigger-active-range> =
  [ <'timeline-trigger-active-range-start'> <'timeline-trigger-active-range-end'>? ]#

<scroller> =
  root     |
  nearest  |
  self

<axis> =
  block   |
  inline  |
  x       |
  y

<view-timeline-inset> =
  [ [ auto | <length-percentage> ]{1,2} ]#

<timeline-trigger-activation-range-start> =
  [ normal | <length-percentage> | <timeline-range-name> <length-percentage>? ]#

<timeline-trigger-activation-range-end> =
  [ normal | <length-percentage> | <timeline-range-name> <length-percentage>? ]#

<timeline-trigger-active-range-start> =
  [ auto | normal | <length-percentage> | <timeline-range-name> <length-percentage>? ]#

<timeline-trigger-active-range-end> =
  [ auto | normal | <length-percentage> | <timeline-range-name> <length-percentage>? ]#

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per Animation Triggers, CSS Values and Units Module Level 4, Scroll-driven Animations. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates using the `timeline-trigger` shorthand property to create a scroll-triggered animation.

HTML

We include two `<div>` elements, one to animate and one on which to create a trigger. The basic text content that causes the page to scroll has been hidden for brevity.

```
<div class="animated">I am animated</div>

...

<div class="trigger">I create the trigger</div>

...
```

```
<div class="animated">I am animated</div>

<p>

</p>
```

CSS

The `.animated` element's `position` is set to `fixed`, positioning it near the top-left of the scrollport to enable us to see when its animation starts and stops.

```
body {
  width: 80%;
  margin: 0 auto;
  font-family: "Helvetica", "Arial";
  font-size: 1.3rem;
}

div {
  height: 100px;
  border: 5px solid black;
}

.animated {
  width: 100px;
  background: orange;
}

.trigger {
  background: wheat;
}
```

```
.animated {
  position: fixed;
  top: 25px;
  left: 25px;
}
```

Next, we define the `@keyframes` to create a `rotate` animation:

```
@keyframes rotate {
  from {
    rotate: 0deg;
  }

  to {
    rotate: 360deg;
  }
}
```

Using the `animation` shorthand, we apply the `rotate` animation to the `.animated` element. Without a trigger, animations start on page load. We include the `animation-trigger` property, which references a `timeline-trigger-name` of `--t` and specifies two `<animation-action>` values — `play` and `pause`. This causes the animation to play on activation and pause on deactivation.

```
.animated {
  animation: rotate 3s infinite linear;
  animation-trigger: --t play pause;
}
```

The `.trigger` element creates the `.animated` element's trigger using a `timeline-trigger` value of `--t view() entry / cover`. This specifies the following, all in a single declaration:

- A `timeline-trigger-name` value of `--t`, which is equal to the identifier referenced in the `.animated` element's `animation-trigger` property value, associating the two together.
- A `timeline-trigger-source` value of `view()`, which sets the timeline trigger as a view progress timeline, and the element providing the timeline trigger as the nearest scrolling ancestor element.
- A `timeline-trigger-activation-range` of `entry`, which means that the trigger will activate when the tracked element's block start edge enters the scrollport.
- A `timeline-trigger-active-range` of `cover`, which means that, once activated, the trigger will stay active until the tracked element completely leaves the scrollport.

```
.trigger {
  timeline-trigger: --t view() entry / cover;
}
```

Result

Try scrolling the content. The rotation will start when the tracked element enters the `entry` range: when the `.trigger` element first enters the bottom of the scrollport. The animation won't stop until the `.trigger` element has completely exited the scrollport.

Multiple timeline-trigger values

This example builds on the previous one; it demonstrates how multiple `timeline-trigger` values can be set on the same element, creating multiple triggers that can be used to trigger multiple animations.

HTML

The markup is similar to the previous example, with an extra animated `<div>` element with a `class` of `animated2`. This example has two animated elements and one element on which to create triggers.

```
<div class="animated2">I am animated as well</div>
```

CSS

The animated elements are `fixed` in `position`, as in the previous example, with different `left` values so they don't overlap.

```
body {
  width: 80%;
  margin: 0 auto;
  font-family: "Helvetica", "Arial";
  font-size: 1.3rem;
}

div {
  height: 100px;
  border: 5px solid black;
}

.animated,
.animated2 {
  width: 100px;
  background: orange;
}

.trigger {
  background: wheat;
}
```

```
.animated,
.animated2 {
  position: fixed;
  top: 25px;
}

.animated {
  left: 25px;
}

.animated2 {
  left: 150px;
}
```

We define two sets of animation `@keyframes`:

```
@keyframes rotate {
  from {
    rotate: 0deg;
  }

  to {
    rotate: 360deg;
  }
}

@keyframes up-down {
  0% {
    translate: 0 0;
  }

  25% {
    translate: 0 25px;
  }

  50% {
    translate: 0 0;
  }

  75% {
    translate: 0 -25px;
  }

  100% {
    translate: 0 0;
  }
}
```

Each animated element has a different animation set, triggered by a separate timeline trigger, and different `<animation-action>` values applied. We apply the same `animation` to the `.animated` element as in the previous example, and a different `animation` to the `.animated2` element. Both have the `animation-trigger` property applied, but with different values. The first animation plays on activation and reverses on deactivation, whereas the second one plays on activation and pauses on deactivation.

```
.animated {
  animation: rotate 3s infinite linear both;
  animation-trigger: --t play-forwards play-backwards;
}

.animated2 {
  animation: up-down 1s infinite linear;
  animation-trigger: --t2 play pause;
}
```

We set a `timeline-trigger` value on `.trigger` that contains two values. Each value contains different `timeline-trigger-name`, `timeline-trigger-activation-range`, and `timeline-trigger-active-range` values. As a result, the animated elements start and stop their animations at different offsets.

```
.trigger {
  timeline-trigger:
```

```
    --t view() entry / cover,
    --t2 view() contain;
}
```

```
@supports not (timeline-trigger: --t view() entry / cover) {
  body::before {
    content: "Your browser does not support the timeline-trigger property.";
    background-color: wheat;
    text-align: center;
    padding: 1rem 0;

    z-index: 1;
    position: fixed;
    inset: 40% 0 auto;
  }
}
```

Result

Try scrolling the content. The first animated element starts rotating when the tracked element enters the `entry` range down at the bottom of the scrollport, then rotates in reverse when the tracked element has completely exited the scrollport. The second animated element starts moving up and down when the tracked element has completely entered the scrollport, and stops when the tracked element begins exiting the scrollport.

timeline-trigger-activation-range CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`timeline-trigger-activation-range`** CSS shorthand property specifies the start and end of a scroll-triggered animation trigger's activation range.

Constituent properties

This property is a shorthand for the following CSS properties:

- `timeline-trigger-activation-range-start`
- `timeline-trigger-activation-range-end`

Syntax

```
/* Keyword */
timeline-trigger-activation-range: normal;

/* Range start only */
/* Offset only */
timeline-trigger-activation-range: 40%;
timeline-trigger-activation-range: 200px;
/* Named timeline only */
timeline-trigger-activation-range: contain;
timeline-trigger-activation-range: entry;
/* Named timeline and offset value */
timeline-trigger-activation-range: exit 50%;
timeline-trigger-activation-range: contain 150px;

/* Range start and end */
timeline-trigger-activation-range: 20% 80%;
timeline-trigger-activation-range: entry exit;
timeline-trigger-activation-range: normal 20%;
timeline-trigger-activation-range: 20% normal;
/* Offset on start only */
timeline-trigger-activation-range: entry 10% 90%;
/* Offset on end only */
timeline-trigger-activation-range: 200px exit 300px;
/* Named timeline and offset for both start and end */
timeline-trigger-activation-range: entry 0% exit 50%;
timeline-trigger-activation-range: contain 100px contain 90%;

/* Multiple ranges */
timeline-trigger-activation-range:
  contain,
  entry 0% exit 50%;

/* Global values */
timeline-trigger-activation-range: inherit;
timeline-trigger-activation-range: initial;
timeline-trigger-activation-range: revert;
timeline-trigger-activation-range: revert-layer;
timeline-trigger-activation-range: unset;
```

Values

This property is specified as a comma-separated list of animation ranges. Each animation range is specified as a `timeline-trigger-activation-range-start` value and, optionally, a `timeline-trigger-activation-range-end` value.

`<'timeline-trigger-activation-range-start'>`

> The keyword `normal`, a `<length-percentage>`, a `<timeline-range-name>`, or a `<timeline-range-name>` followed by a `<length-percentage>`, representing the `timeline-trigger-activation-range-start`. If a `<timeline-range-name>` is set without a `<length-percentage>`, the `<length-percentage>` defaults to `0%`.

<'timeline-trigger-activation-range-end'>

The keyword `normal`, a `<length-percentage>`, a `<timeline-range-name>`, or a `<timeline-range-name>` followed by a `<length-percentage>`, representing the `timeline-trigger-activation-range-end`. If a `<timeline-range-name>` is set without a `<length-percentage>`, the `<length-percentage>` defaults to `100%`.

Percentages are relative to the length of the named timeline range if one is specified, or the timeline represented by `normal` if not.

Description

The `timeline-trigger-activation-range` property can be used to explicitly specify the start or start and end of a trigger's activation range. The property sets both the `timeline-trigger-activation-range-start` and `timeline-trigger-activation-range-end` properties in one declaration, with each specified as a timeline range, offset, or both. Start and end offsets are both measured from the start of their ranges. If only the `timeline-trigger-activation-range-start` value is specified, the `timeline-trigger-activation-range-end` value defaults to `normal`, which is either `contain 100%` or `scroll 100%`, depending on the `timeline-trigger-source` value.

A trigger's activation range is the range along the associated scrollport within which a CSS scroll-triggered animation trigger will activate. Activation occurs when the tracked element enters the *activation range*, and deactivation occurs when it leaves the *active range*.

The default value is `normal`, which sets the activation range to the default named range. The default named range depends on the `timeline-trigger-source`: it is equivalent to `cover` for a view progress timeline and `scroll` for a scroll progress timeline. The default offset values are `0%` for activation start and `100%` for activation end. Therefore, `normal` resolves to either `cover 0% cover 100%` or `scroll 0% scroll 100%`.

Other `timeline-trigger-activation-range` values can be used to set:

Start and end offsets from the `normal` range

A `<length>` or `<percentage>` value specifies an offset from the beginning of the `normal` timeline, which again defaults to `cover` for a `view()` progress timeline source, and `scroll` for a `scroll()` progress timeline source. Negative values outset the start and end, resulting in a longer activation range. Positive values inset the start and end of the activation range, shortening it.

Specific named ranges

If a `<timeline-range-name>` values is set without including an offset, the offset defaults to `0%` for start and `100%` for end values. The named timeline ranges include `cover`, `contain`, `entry`, `exit`, `entry-crossing`, `exit-crossing`, and `scroll`. See Understanding timeline range names.

Offsets from specific named ranges

When both a `<timeline-range-name>` and `<length>` or `<percentage>` value are specified for the start or end, the value is specified as a length or percentage offset from the start of the named range. Percentage values are relative to the full length of the named range specified. See Setting insets using percentages.

In each component of a `timeline-trigger-activation-range` value, the `<timeline-range-name>` value must come before the `<length>` or `<percentage>` offset. In the following example, you might think `timeline-trigger-activation-range-start` is set to `contain` and `timeline-trigger-activation-range-end` is set to `50%`, but that is not the case. Instead, `timeline-trigger-activation-range-start` is set to `contain 50%` while `timeline-trigger-activation-range-end` defaults to `normal`:

```
timeline-trigger-activation-range: contain 50%;
```

To set `timeline-trigger-activation-range-start` to `contain` and `timeline-trigger-activation-range-end` to `50%`, explicitly set `0%`, which is the default start offset:

```
timeline-trigger-activation-range: contain 0% 50%;
```

By default, the active range is the same as the activation range. To make the active range longer than the activation range, use the `timeline-trigger-active-range-start` and `timeline-trigger-active-range-end` properties, or the `timeline-trigger-active-range` shorthand. Making the active range longer than the activation range is useful when you want to trigger an animation in a small activation range but keep the trigger active over a larger range.

The `timeline-trigger-activation-range` property, along with the `timeline-trigger-name`, `timeline-trigger-source`, and `timeline-trigger-active-range` properties, can also be set using the `timeline-trigger` shorthand.

Explicit and default values for <code>timeline-trigger-activation-range</code>

In terms of explicit and default values, `timeline-trigger-activation-range` works in exactly the same way as the `animation-range` property. See the following for more information:

- Explicitly defining both range start and range end with two values
- Defining range start and defaulting range end

Specifying multiple ranges

When multiple values are specified in a comma-separated `timeline-trigger-activation-range` declaration, each value applies to a timeline trigger in the order in which the names appear in the `timeline-trigger-name` property. When the number of triggers and `timeline-trigger-activation-range` property values do not match, they are applied in the same way as multiple animation property values:

- If the number of `timeline-trigger-activation-range` values exceeds the number of `timeline-trigger-name` values, the excess range values are discarded.
- If the number of trigger names is greater than the number of ranges, the `timeline-trigger-activation-range` values are cycled until every `timeline-trigger-name` value has a `timeline-trigger-activation-range` value set.
- If multiple `timeline-trigger-name` values are set, but only one `timeline-trigger-activation-range` value is set, the `timeline-trigger-activation-range` will apply to all the `timeline-trigger-name`s.

Formal definition

Initial value	as each of the properties of the shorthand: • `timeline-trigger-activation-range-start`: `normal` • `timeline-trigger-activation-range-end`: `normal`
Applies to	all elements
Inherited	no
Percentages	as each of the properties of the shorthand: • `timeline-trigger-activation-range-start`: Relative to the specified named timeline range if specified, otherwise relative to the entire timeline • `timeline-trigger-activation-range-end`: Relative to the specified named timeline range if specified, otherwise relative to the entire timeline
Computed value	as each of the properties of the shorthand: • `timeline-trigger-activation-range-start`: A list where each item may be 'normal', a length percentage, or a timeline range name and a length percentage • `timeline-trigger-activation-range-end`: A list where each item may be 'normal', a length percentage, or a timeline range name and a length percentage
Animation type	Not animatable

Formal syntax

```
timeline-trigger-activation-range =
  [ <'timeline-trigger-activation-range-start'> <'timeline-trigger-activation-range-end'>? ]#

<timeline-trigger-activation-range-start> =
  [ normal | <length-percentage> | <timeline-range-name> <length-percentage>? ]#

<timeline-trigger-activation-range-end> =
  [ normal | <length-percentage> | <timeline-range-name> <length-percentage>? ]#

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per Animation Triggers, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

In this example, we inset a scroll-triggered animation trigger's activation range by setting a custom `timeline-trigger-activation-range` value.

HTML

Our markup contains two `<div>` elements—one to animate and one to create a trigger on—and some text content to make the page scroll. We have hidden the text content for brevity.

```
<div class="animated">I am animated</div>

...

<div class="trigger">I create the trigger</div>

...
```

```
<div class="animated">I am animated</div>

<p>
  Fusce dictum ex quis ipsum consectetur placerat. Cras sed lectus ex. Quisque

  luctus quis. Maecenas scelerisque scelerisque elit eu consequat. Etiam ac
  tristique tellus, sed tincidunt velit.
</p>
```

CSS

The `.animated` element's `position` is set to `fixed`, positioning it near the top-left of the scrollport so we can see when its animation starts and stops.

```
body {
  width: 80%;
  margin: 0 auto;
```

```
  font-family: "Helvetica", "Arial";
  font-size: 1.3rem;
}

div {
  height: 100px;
  border: 5px solid black;
}

.animated {
  width: 100px;
  background: orange;
}

.trigger {
  background: wheat;
}
```

```
.animated {
  position: fixed;
  top: 25px;
  left: 25px;
}
```

Next, we define the `@keyframes` for a `rotate` animation:

```
@keyframes rotate {
  from {
    rotate: 0deg;
  }

  to {
    rotate: 360deg;
  }
}
```

Using the `animation` shorthand, the `rotate` animation is applied to the `.animated` element. Without an associated trigger, the element would start animating when the page loads. The `animation-trigger` property makes it a triggered animation. The value references a `timeline-trigger-name` of `--t` and specifies two `<animation-action>` values — `play` and `pause` — which specify that the animation plays on activation and pauses on deactivation.

```
.animated {
  animation: rotate 3s infinite linear;
  animation-trigger: --t play pause;
}
```

The `.trigger` element creates the `.animated` element's trigger via the following properties:

- A `timeline-trigger-name` with value `--t`, which is equal to the identifier referenced in the `.animated` element's `animation-trigger` property value, associating the two together.
- A `timeline-trigger-source` with value `view()`, which sets the timeline trigger as a view progress timeline, and the element providing the timeline trigger as the nearest scrolling ancestor element.
- A `timeline-trigger-activation-range` of `entry 50% exit 50%`. The `entry` range spans from when the trigger element first starts entering the scrollport to when it has completely entered the scrollport, while the `exit` range spans from when the trigger element first starts leaving the scrollport to when it has completely left the scrollport. This value sets the trigger's activation range to start at `50%` through the `entry` range and end `50%` through the `exit` range.

```
.trigger {
  timeline-trigger-name: --t;
  timeline-trigger-source: view();
  timeline-trigger-activation-range: entry 50% exit 50%;
}
```

Result

Try scrolling the content up and down. The animation starts playing when `50%` of the tracked `.trigger` element has entered the scrollport in either direction and pauses when `50%` of the trigger element has exited the scrollport at either edge.

Comparing multiple range values

This example is identical to the previous example, except that it allows selecting different activation ranges to compare their effects.

The markup is the same as the previous example except we've added a `<select>` element that can be used to change the `timeline-trigger-activation-range` value. When a new value is selected, it is applied to the trigger element using JavaScript. We have hidden the HTML and JavaScript for brevity.

```
<form>
  <label for="range-select">Select activation range</label>
  <select id="range-select">
    <optgroup label="Start value">
      <option>40%</option>
      <option>200px</option>
      <option>contain</option>
      <option selected>cover</option>
      <option>entry</option>
      <option>exit 50%</option>
      <option>contain 150px</option>
    </optgroup>
    <optgroup label="Start and end value">
      <option>20% 80%</option>
      <option>entry exit</option>
      <option>normal 20%</option>
      <option>20% normal</option>
      <option>contain contain 40%</option>
      <option>200px exit 300px</option>
      <option>entry 10% 90%</option>
      <option>entry 0% exit 50%</option>
      <option>contain 100px contain 90%</option>
    </optgroup>
  </select>
</form>
```

```
const selectElem = document.querySelector("select");
const triggerElem = document.querySelector(".trigger");

selectElem.addEventListener("change", () => {
  triggerElem.style.timelineTriggerActivationRange = selectElem.value;
});
```

CSS

The CSS is the same as for the previous example, except we've omitted the `timeline-trigger-activation-range` value. This means that until a range value is selected, the range will default to `normal`, which is `cover 0% cover 100%` in this case.

```
form {
  width: 250px;
  padding: 5px;
  border: 2px solid black;
  background: white;
  position: fixed;
  top: 0;
  right: 0;
}

label,
select {
  font-size: 1rem;
}

select {
  padding: 5px;
  margin-top: 5px;
  width: 100%;
}
```

```
.animated {
  animation: rotate 3s infinite linear;
  animation-trigger: --t play pause;
}

.trigger {
  timeline-trigger-name: --t;
  timeline-trigger-source: view();
}
```

```
@supports not (timeline-trigger-activation-range: entry 50% exit 50%) {
  body::before {
    content: "Your browser does not support the timeline-trigger-activation-range property.";
    background-color: wheat;
    text-align: center;
    padding: 1rem 0;

    z-index: 1;
    position: fixed;
    inset: 40% 0 auto;
  }
}
```

Result

Select different range values then scroll the tracked element up and down the scrollport to see where the animated element starts and stops rotating.

timeline-trigger-activation-range-end CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`timeline-trigger-activation-range-end`** CSS property specifies the end of a scroll-triggered animation trigger's activation range.

Syntax

```
/* Keyword */
timeline-trigger-activation-range-end: normal;

/* <length-percentage> */
timeline-trigger-activation-range-end: 80%;
timeline-trigger-activation-range-end: 400px;

/* Named timeline range */
timeline-trigger-activation-range-end: contain;
timeline-trigger-activation-range-end: exit;

/* Named timeline with <length-percentage> */
timeline-trigger-activation-range-end: entry 110%;
timeline-trigger-activation-range-end: contain 600px;

/* Multiple range end values */
timeline-trigger-activation-range-end:
```

```
  contain,
  entry 100%;

/* Global values */
timeline-trigger-activation-range-end: inherit;
timeline-trigger-activation-range-end: initial;
timeline-trigger-activation-range-end: revert;
timeline-trigger-activation-range-end: revert-layer;
timeline-trigger-activation-range-end: unset;
```

Values

This property is specified as a comma-separated list of the following values:

`normal`

The default value. Equivalent to `cover 100%` for a view progress timeline `timeline-trigger-source`, and `scroll 100%` for a scroll progress timeline.

`<length-percentage>`

Specifies an offset as a `<length>` or `<percentage>`, measured from the beginning of the `normal` timeline. Percentages are relative to the length of the `normal` timeline range.

`<timeline-range-name>`

Specifies the end (`100%`) of the `cover`, `contain`, `entry`, `exit`, `entry-crossing`, `exit-crossing`, or `scroll` timeline range.

`<timeline-range-name> <length-percentage>`

Specifies a length or percentage offset measured from the beginning of the specified named timeline range. Percentages are relative to the length of the named timeline.

Description

The `timeline-trigger-activation-range-end` property can be used to explicitly specify the end of a trigger's activation range as a timeline range, offset, or both.

A trigger's activation range is the range along the associated scrollport within which a CSS scroll-triggered animation trigger will activate. Activation occurs when the tracked element enters the *activation range*, and deactivation occurs when it leaves the *active range*.

The `normal` value sets the end of the activation range to the end of the default named range. This is equivalent to `cover 100%` for a view progress timeline and `scroll 100%` for a scroll progress timeline.

Other `timeline-trigger-activation-range-end` values can be used to set:

An offset from the `normal` range

A `<length>` or `<percentage>` value specifies an offset from the beginning of the `normal` timeline, which again defaults to `cover 100%` for a view progress timeline source and `scroll 100%` for a scroll progress timeline source. Negative values outset the end, resulting in a longer activation range. Positive values inset the end of the activation range, making it shorter.

The end of a specific named range

A `<timeline-range-name>` value specifies a `100%` offset along the named timeline range, which is either `cover`, `contain`, `entry`, `exit`, `entry-crossing`, `exit-crossing`, or `scroll`. See Understanding timeline range names.

An offset from a specific named range

When both a `<timeline-range-name>` and `<length>` or `<percentage>` value are specified, the end is offset by the distance specified from the start of the named range. Percentage values are relative to the range specified. See Setting insets using percentages.

By default, the active range is the same as the activation range. You can use the `timeline-trigger-active-range-end` or `timeline-trigger-active-range` properties to extend the end of the active range and make the active range longer than the activation range. This is useful when you want to trigger an animation in a small activation range, but you want the trigger to stay active within a larger range.

The `timeline-trigger-activation-range-end` property, along with the `timeline-trigger-activation-range-start` property, can also be set using the `timeline-trigger-activation-range` shorthand, which in turn can be set using the `timeline-trigger` shorthand.

Specifying multiple range end values

When multiple values are specified in a comma-separated `timeline-trigger-activation-range-end` declaration, each value applies to a timeline trigger in the order in which the names appear in the `timeline-trigger-name` property. When the number of triggers and `timeline-trigger-activation-range-end` property values do not match, they are applied in the same way as multiple animation property values:

- If the number of `timeline-trigger-activation-range-end` values exceeds the number of `timeline-trigger-name` values, the excess range values are discarded.
- If the number of trigger names is greater than the number of ranges, the `timeline-trigger-activation-range-end` values are cycled until every `timeline-trigger-name` value has a `timeline-trigger-activation-range-end` value set.
- If multiple `timeline-trigger-name` values are set, but only one `timeline-trigger-activation-range-end` value is set, that `timeline-trigger-activation-range-end` value will apply to all the `timeline-trigger-name`s.

Formal definition

Initial value	`normal`
Applies to	all elements
Inherited	no
Percentages	Relative to the specified named timeline range if specified, otherwise relative to the entire timeline
Computed value	A list where each item may be 'normal', a length percentage, or a timeline range name and a length percentage
Animation type	Not animatable

Formal syntax

```
timeline-trigger-activation-range-end =
  [ normal | <length-percentage> | <timeline-range-name> <length-percentage>? ]#

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per Animation Triggers, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

In this example, we inset the end of a scroll-triggered animation trigger's activation range by setting a custom `timeline-trigger-activation-range-end` value.

HTML

Our markup contains two `<div>` elements — one to animate and one to create a trigger on — plus some basic text content to cause the page to scroll. We have hidden the text content for brevity.

```
<div class="animated">I am animated</div>

...

<div class="trigger">I create the trigger</div>

...
```

```
<div class="animated">I am animated</div>

<p>
  Fusce dictum ex quis ipsum consectetur placerat. Cras sed lectus ex. Quisque
  purus dolor, vulputate ac mi eget, commodo varius odio. Suspendisse faucibus
  ipsum vel libero finibus, in placerat nibh congue. Sed iaculis, metus et
  euismod posuere, mi diam vestibulum felis, ac vulputate eros ipsum id justo.
  Etiam a tincidunt purus. Maecenas semper sed enim at blandit. Aenean ut
  sagittis lorem, eget gravida purus. Phasellus eleifend, lectus nec pulvinar
  facilisis, dui dolor feugiat odio, iaculis tempor felis est non tortor. In
  suscipit lorem efficitur molestie tempus. Integer sit amet neque et risus
  iaculis sodales sed eget diam. Quisque sodales nunc sapien, vitae lacinia ex
  luctus quis. Maecenas scelerisque scelerisque elit eu consequat. Etiam ac
  tristique tellus, sed tincidunt velit.
</p>

<p>

  luctus quis. Maecenas scelerisque scelerisque elit eu consequat. Etiam ac
  tristique tellus, sed tincidunt velit.
</p>
```

CSS

The `.animated` element's `position` is set to `fixed`, positioning it near the top-left of the scrollport to enable us to see when its animation starts and stops.

```
body {
  width: 80%;
  margin: 0 auto;
  font-family: "Helvetica", "Arial";
  font-size: 1.3rem;
}

div {
  height: 100px;
  border: 5px solid black;
}

.animated {
  width: 100px;
  background: orange;
}

.trigger {
  background: wheat;
}
```

```
.animated {
  position: fixed;
  top: 25px;
```

```
  left: 25px;
}
```

Next, we define the `@keyframes` for a `rotate` animation:

```
@keyframes rotate {
  from {
    rotate: 0deg;
  }

  to {
    rotate: 360deg;
  }
}
```

Using the `animation` shorthand, the `rotate` animation is applied to the `.animated` element. Without an associated trigger, the element would start animating when the page loads. The `animation-trigger` property makes it a triggered animation. The value references a `timeline-trigger-name` of `--t` and specifies two `<animation-action>` values — `play` and `pause` — which specify that the animation will play on activation, and pause on deactivation.

```
.animated {
  animation: rotate 3s infinite linear;
  animation-trigger: --t play pause;
}
```

The `.trigger` element creates the `.animated` element's trigger via the following properties:

- A `timeline-trigger-name` with value `--t`, which is equal to the identifier referenced in the `.animated` element's `animation-trigger` property value, associating the two together.
- A `timeline-trigger-source` with value `view()`, which sets the timeline trigger as a view progress timeline, and the element providing the timeline trigger as the nearest scrolling ancestor element.
- A `timeline-trigger-activation-range-end` of `contain 60%`. The `contain` range spans from when the trigger element has fully entered the scrollport to when it starts to leave. This value sets the trigger's activation range's start to `60%` through the `contain` range.

```
.trigger {
  timeline-trigger-name: --t;
  timeline-trigger-source: view();
  timeline-trigger-activation-range-end: contain 60%;
}
```

When not explicitly set, the `timeline-trigger-activation-range-start` value defaults to `normal`, which in this case is `cover 0%`. This is the start of the `cover` range, meaning activation occurs when the tracked element starts to enter the scrollport's end edge.

```
@supports not (timeline-trigger-activation-range-end: contain 60%) {
  body::before {
    content: "Your browser does not support the timeline-trigger-activation-range-end property.";
    background-color: wheat;
    text-align: center;
    padding: 1rem 0;

    z-index: 1;
    position: fixed;
    inset: 40% 0 auto;
  }
}
```

Result

Try scrolling the content up. The animation starts playing when the tracked `.trigger` element first becomes visible at the scrollport end edge and pauses when it has scrolled `60%` of the way up the timeline range. When you scroll down, the effect reverses — the animation restarts playing when the trigger element gets to `60%` of the way up, and pauses again when the trigger element reaches the end edge.

timeline-trigger-activation-range-start CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`timeline-trigger-activation-range-start`** CSS property specifies the start of a scroll-triggered animation trigger's activation range.

Syntax

```
/* Keyword */
timeline-trigger-activation-range-start: normal;

/* <length-percentage> */
timeline-trigger-activation-range-start: 20%;
timeline-trigger-activation-range-start: 350px;

/* Named timeline range */
timeline-trigger-activation-range-start: cover;
timeline-trigger-activation-range-start: exit;

/* Named timeline with <length-percentage> */
timeline-trigger-activation-range-start: entry 40%;
timeline-trigger-activation-range-start: contain -20px;

/* Multiple range start values */
timeline-trigger-activation-range-start:
  contain,
```

```
  entry -10%;

/* Global values */
timeline-trigger-activation-range-start: inherit;
timeline-trigger-activation-range-start: initial;
timeline-trigger-activation-range-start: revert;
timeline-trigger-activation-range-start: revert-layer;
timeline-trigger-activation-range-start: unset;
```

Values

This property is specified as a comma-separated list of the following values:

`normal`

The default value. Equivalent to `cover 0%` for a view progress timeline `timeline-trigger-source`, and `scroll 0%` for a scroll progress timeline.

`<length-percentage>`

Specifies an offset as a `<length>` or `<percentage>`, measured from the beginning of the `normal` timeline. Percentages are relative to the length of the `normal` timeline range.

`<timeline-range-name>`

Specifies the start (`0%`) of the `cover`, `contain`, `entry`, `exit`, `entry-crossing`, `exit-crossing`, or `scroll` timeline range.

`<timeline-range-name> <length-percentage>`

Specifies a length or percentage offset measured from the beginning of the specified named timeline range. Percentages are relative to the length of the named timeline.

Description

The `timeline-trigger-activation-range-start` property can be used to explicitly specify the start of a trigger's activation range. The value is specified as a timeline range, offset, or both.

A trigger's activation range is the range along the associated scrollport within which a CSS scroll-triggered animation trigger will activate. Activation occurs when the tracked element enters the *activation range*, and deactivation occurs when it leaves the *active range*.

The `normal` value sets the start of the activation range to the start of the default named range. This is equivalent to `cover 0%` for a view progress timeline and `scroll 0%` for a scroll progress timeline.

Other `timeline-trigger-activation-range-start` property can be used to set:

An offset from the `normal` range

A `<length>` or `<percentage>` value specifies an offset from the beginning of the `normal` timeline, which again defaults to `cover 0%` for a view progress timeline source, and `scroll 0%` for a scroll progress timeline source. Negative values outset the start, resulting in a longer activation range. Positive values inset the start, making the activation range shorter.

The start of a specific named range

A `<timeline-range-name>` value specifies a `0%` offset along the named timeline range, which is either `cover`, `contain`, `entry`, `exit`, `entry-crossing`, `exit-crossing`, or `scroll`. See Understanding timeline range names.

An offset from a specific named range

When both a `<timeline-range-name>` and `<length>` or `<percentage>` value are specified, the start is the beginning of the named range offset by the distance specified. Percentage values are relative to the length of the range specified. See Setting insets using percentages.

The `timeline-trigger-activation-range-start` property, along with the `timeline-trigger-activation-range-end` property, can also be set using the `timeline-trigger-activation-range` shorthand, which in turn can be set using the `timeline-trigger` shorthand.

Specifying multiple range start values

When multiple values are specified in a comma-separated `timeline-trigger-activation-range-start` declaration, each value applies to a timeline trigger in the order in which the names appear in the `timeline-trigger-name` property. When the number of triggers and `timeline-trigger-activation-range-start` property values do not match, they are applied in the same way as multiple animation property values:

- If the number of `timeline-trigger-activation-range-start` values exceeds the number of `timeline-trigger-name` values, the excess range values are discarded.
- If the number of trigger names is greater than the number of ranges, the `timeline-trigger-activation-range-start` values are cycled until every `timeline-trigger-name` value has a `timeline-trigger-activation-range-start` value set.
- If multiple `timeline-trigger-name` values are set, but only one `timeline-trigger-activation-range-start` value is set, that `timeline-trigger-activation-range-start` value will apply to all the `timeline-trigger-name`s.

Formal definition

Initial value	`normal`
Applies to	all elements
Inherited	no
Percentages	Relative to the specified named timeline range if specified, otherwise relative to the entire timeline
Computed value	A list where each item may be 'normal', a length percentage, or a timeline range name and a length percentage
Animation type	Not animatable

Formal syntax

```
timeline-trigger-activation-range-start =
  [ normal | <length-percentage> | <timeline-range-name> <length-percentage>? ]#

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per Animation Triggers, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

</p>
```

CSS

The `.animated` element's `position` is set to `fixed`, positioning it near the top-left of the scrollport to enable us to see when its animation starts and stops.

```
body {
  width: 80%;
  margin: 0 auto;
  font-family: "Helvetica", "Arial";
  font-size: 1.3rem;
}

div {
  height: 100px;
  border: 5px solid black;
}

.animated {
  width: 100px;
  background: orange;
}

.trigger {
  background: wheat;
}
```

```
.animated {
  position: fixed;
  top: 25px;
  left: 25px;
}
```

Next, we define the `@keyframes` for a `rotate` animation:

```
@keyframes rotate {
  from {
    rotate: 0deg;
  }

  to {
    rotate: 360deg;
  }
}
```

Using the `animation` shorthand, the `rotate` animation is applied to the `.animated` element. Without an associated trigger, the element would start animating when the page loads. The `animation-trigger` property makes it a triggered animation. The value references a `timeline-trigger-name` of `--t` and specifies two `<animation-action>` values — `play` and `pause` — which specify that the animation will play on activation and pause on deactivation.

```
.animated {
  animation: rotate 3s infinite linear;
  animation-trigger: --t play pause;
}
```

The `.trigger` element creates the `.animated` element's trigger via the following properties:

- A `timeline-trigger-name` with value `--t`, which is equal to the identifier referenced in the `.animated` element's `animation-trigger` property value, associating the two together.
- A `timeline-trigger-source` with value `view()`, which sets the timeline trigger as a view progress timeline, and the element providing the timeline trigger as the nearest scrolling ancestor element.
- A `timeline-trigger-activation-range-start` of `entry 50%`. The `entry` range spans from when the trigger element first starts entering the scrollport to when it has completely entered the scrollport. This value sets the trigger's activation range's start to `50%` through the `entry` range, which occurs when `50%` of the tracked `.trigger` element has entered the scrollport via the scrollport's end edge.

```
.trigger {
  timeline-trigger-name: --t;
  timeline-trigger-source: view();
  timeline-trigger-activation-range-start: entry 50%;
}
```

When not explicitly set, the `timeline-trigger-activation-range-end` value defaults to `normal`, which in this case is `cover 100%`. The `timeline-trigger-active-range-end` value defaults to `auto` — the same as `timeline-trigger-activation-range-end`. This means that deactivation occurs at the end of the `cover` range, when the tracked element exits the scrollport's start edge.

```
@supports not (timeline-trigger-activation-range-start: entry 50%) {
  body::before {
    content: "Your browser does not support the timeline-trigger-activation-range-start property.";
    background-color: wheat;
    text-align: center;
    padding: 1rem 0;

    z-index: 1;
    position: fixed;
    inset: 40% 0 auto;
  }
}
```

Result

Try scrolling the content up. The animation starts playing when `50%` of the tracked `.trigger` element has entered the scrollport end edge and pauses when it has completely exited the scrollport at the opposite edge. When you scroll down, the effect reverses — the animation restarts playing when the trigger element starts to enter the top of the scrollport, and pauses again when `50%` of the trigger element has exited the bottom.

timeline-trigger-active-range CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`timeline-trigger-active-range`** CSS shorthand property specifies a scroll-triggered animation trigger's active range.

Constituent properties

This property is a shorthand for the following CSS properties:

- `timeline-trigger-active-range-start`
- `timeline-trigger-active-range-end`

Syntax

```
/* Keywords */
timeline-trigger-active-range: normal;
timeline-trigger-active-range: auto;

/* Range start only */
/* Offset only */
timeline-trigger-active-range: 10%;
timeline-trigger-active-range: 40px;
/* Named timeline only */
timeline-trigger-active-range: cover;
/* Named timeline and offset value */
timeline-trigger-active-range: exit -10%;
timeline-trigger-active-range: contain 50px;

/* Range start and end */
```

```
timeline-trigger-active-range: entry exit;
/* Offset on start only */
timeline-trigger-active-range: 10% normal;
timeline-trigger-active-range: 100px contain;
timeline-trigger-active-range: entry 10% contain;
/* Offset on end only */
timeline-trigger-active-range: normal exit-crossing 90%;
timeline-trigger-active-range: auto 10%;
timeline-trigger-active-range: contain contain 90%;
/* Offset for both start and end */
timeline-trigger-active-range: 5% 95%;
timeline-trigger-active-range: 200px exit 600px;
timeline-trigger-active-range: entry 10% 90%;
/* Named timeline and offset for both start and end */
timeline-trigger-active-range: entry 0% exit 50%;
timeline-trigger-active-range: contain 100px contain 90%;

/* Multiple ranges */
timeline-trigger-active-range:
  cover,
  entry -5% exit 50%;

/* Global values */
timeline-trigger-active-range: inherit;
timeline-trigger-active-range: initial;
timeline-trigger-active-range: revert;
timeline-trigger-active-range: revert-layer;
timeline-trigger-active-range: unset;
```

Values

This property is specified as a comma-separated list of animation ranges. Each animation range is specified as a `timeline-trigger-active-range-start` value, and, optionally, a `timeline-trigger-active-range-end` value.

`<'timeline-trigger-active-range-start'>`

> The keyword `normal`, the keyword `auto`, a `<length-percentage>`, a `<timeline-range-name>`, or a `<timeline-range-name>` followed by a `<length-percentage>`, representing the `timeline-trigger-active-range-start`. If a `<timeline-range-name>` is set without a `<length-percentage>`, the `<length-percentage>` defaults to `0%`.

`<'timeline-trigger-active-range-end'>`

> The keyword `normal`, the keyword `auto`, a `<length-percentage>`, a `<timeline-range-name>`, or a `<timeline-range-name>` followed by a `<length-percentage>`, representing the `timeline-trigger-active-range-end`. If a `<timeline-range-name>` is set without a `<length-percentage>`, the `<length-percentage>` defaults to `100%`.

Percentages are relative to the length of the named timeline range if one is specified, or the timeline represented by `normal` if not.

Description

The `timeline-trigger-active-range` property can be used to explicitly specify the start or both the start and end of a trigger's active range. The property sets both the `timeline-trigger-active-range-start` and `timeline-trigger-active-range-end` properties in one declaration, with each specified as a timeline range, offset, or both. Start and end offsets are both measured from the start of their ranges.

A trigger's *active range* is the range along the associated scrollport within which a CSS scroll-triggered animation trigger will stay active once activated. Activation occurs when the tracked element enters the *activation range*, and deactivation occurs when it leaves the *active range*. The default value is `auto`, which sets the `timeline-trigger-active-range` value to the same as the `timeline-trigger-activation-range`.

Making the active range longer than the activation range is useful when you want to trigger an animation in a small activation range, but you want the trigger to stay active within a larger range. The trigger will only deactivate when the tracked element leaves the active range.

A value of `normal` sets the active range to the default named range. The default named range depends on the `timeline-trigger-source`: it is equivalent to `cover` for a view progress timeline and `scroll` for a scroll progress timeline. The default offset values are `0%` and `100%`. Therefore, `normal` resolves to either `cover 0% cover 100%` or `scroll 0% scroll 100%`.

The `timeline-trigger-active-range` property can be used to set:

Start and end offsets from the `normal` range

> A `<length>` or `<percentage>` value specifies an offset from the beginning of the `normal` timeline, which again defaults to `cover` for a view progress timeline source, and `scroll` for a scroll progress timeline source. Negative values outset the start and end, resulting in a longer active range. Positive values inset the start and end of the active range, making it shorter.

Specific named ranges

> If a `<timeline-range-name>` value is set without including an offset, the offset defaults to `0%` for start and `100%` for the end values. The named timeline ranges include `cover`, `contain`, `entry`, `exit`, `entry-crossing`, `exit-crossing`, and `scroll`. See Understanding timeline range names.

Offsets from specific named ranges

> When both a `<timeline-range-name>` and `<length>` or `<percentage>` value are specified, the start and end values are offset by the distances along the specified named ranges. Percentage values are relative to the range specified. See Setting insets using percentages.

In each component of a `timeline-trigger-active-range` value, the `<timeline-range-name>` value must come before the `<length>` or `<percentage>` offset. In the following example, you might think `timeline-trigger-active-range-start` is set to `contain`, and `timeline-trigger-active-range-end` is set to `50%`, but this is not the case. Instead, `timeline-trigger-active-range-start` is set to `contain 50%` while `timeline-trigger-active-range-end` defaults to `auto`:

```
timeline-trigger-active-range: contain 50%;
```

To set `timeline-trigger-active-range-start` to `contain` and `timeline-trigger-active-range-end` to `50%`, explicitly set `0%`, which is the default start offset:

```
timeline-trigger-active-range: contain 0% 50%;
```

A set active range must be equal to or larger than the activation range. Specifically, the `timeline-trigger-active-range-start` value must come before or at the same position as the `timeline-trigger-activation-range-start` value, and the `timeline-trigger-active-range-end` value must be the same as or come after the `timeline-trigger-activation-range-end` value. If either value is within the activation range, the value will have no effect, and the active range will be equal to the activation range.

The `timeline-trigger-active-range` property, along with the `timeline-trigger-name`, `timeline-trigger-source`, and `timeline-trigger-activation-range` properties, can also be set using the `timeline-trigger` shorthand.

Explicit and default values of <code>timeline-trigger-active-range</code>

In terms of explicit and default values, `timeline-trigger-active-range` works in exactly the same way as the `animation-range` property. See the following for more information:

- Explicitly defining both range start and range end with two values

- Defining range start and defaulting range end

Specifying multiple ranges

When multiple values are specified in a comma-separated `timeline-trigger-active-range` declaration, each value applies to a timeline trigger in the order in which the names appear in the `timeline-trigger-name` property. When the number of triggers and `timeline-trigger-active-range` property values do not match, they are applied in the same way as multiple animation property values:

- If the number of `timeline-trigger-active-range` values exceeds the number of `timeline-trigger-name` values, the excess range values are discarded.
- If the number of trigger names is greater than the number of ranges, the `timeline-trigger-active-range` values are cycled until every `timeline-trigger-name` value has a `timeline-trigger-active-range` value set.
- If multiple `timeline-trigger-name` values are set, but only one `timeline-trigger-active-range` value is set, the `timeline-trigger-active-range` will apply to all the `timeline-trigger-name`s.

Formal definition

Initial value	as each of the properties of the shorthand: • `timeline-trigger-active-range-start`: `auto` • `timeline-trigger-active-range-end`: `auto`
Applies to	all elements
Inherited	no
Percentages	as each of the properties of the shorthand: • `timeline-trigger-active-range-start`: Relative to the specified named timeline range if specified, otherwise relative to the entire timeline • `timeline-trigger-active-range-end`: Relative to the specified named timeline range if specified, otherwise relative to the entire timeline
Computed value	as each of the properties of the shorthand: • `timeline-trigger-active-range-start`: A list where each item may be 'normal', a length percentage, or a timeline range name and a length percentage • `timeline-trigger-active-range-end`: A list where each item may be 'normal', a length percentage, or a timeline range name and a length percentage
Animation type	Not animatable

Formal syntax

```
timeline-trigger-active-range =
  [ <'timeline-trigger-active-range-start'> <'timeline-trigger-active-range-end'>? ]#

<timeline-trigger-active-range-start> =
  [ auto | normal | <length-percentage> | <timeline-range-name> <length-percentage>? ]#

<timeline-trigger-active-range-end> =
  [ auto | normal | <length-percentage> | <timeline-range-name> <length-percentage>? ]#

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per Animation Triggers, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates the effect of extending a trigger's active range by comparing a triggered animation with a longer active range than its activation range against an identical triggered animation with no `timeline-trigger-active-range` property set.

HTML

The markup contains four `<div>` elements — two to animate and two to create a trigger on — plus some content that causes the page to scroll. We have hidden the extra content for brevity.

```
<div class="animated">I am animated</div>
<div class="animated longer">I am animated longer</div>

...
<section>
  <div class="trigger">I create the trigger</div>
  <div class="trigger longer">I create a longer trigger</div>
</section>
...
```

```
<div class="animated">I am animated</div>
<div class="animated longer">I am animated longer</div>
<p>

  tristique tellus, sed tincidunt velit.
</p>
```

CSS

The `.animated` elements' `position` is set to `fixed`, positioning them near the top-left of the scrollport to enable us to see when their animations start and stop.

```
body {
  width: 80%;
  margin: 0 auto;
  font-family: "Helvetica", "Arial";
  font-size: 1.3rem;
}

div {
  height: 100px;
  border: 5px solid black;
}

.animated {
  width: 100px;
  background: orange;
}

.trigger {
  background: wheat;
}
```

```
.animated {
  position: fixed;
  top: 25px;
  left: 25px;
}
.animated.longer {
  left: 150px;
}
section {
  display: flex;
  gap: 20px;
}
```

Next, we define the `@keyframes` for a `rotate` animation:

```
@keyframes rotate {
  from {
    rotate: 0deg;
  }

  to {
    rotate: 360deg;
  }
}
```

Using the `animation` shorthand, the `rotate` animation is applied to the `.animated` elements. Without an associated trigger, the elements would start animating when the page loads. The `animation-trigger` property makes it a triggered animation. The values reference a `timeline-trigger-name` of `--t` and `--longer-t`, respectively, and define the same `<animation-action>` values on each — `play` and `pause` — which specify that the animations will play on activation and pause on deactivation.

```
.animated {
  animation: rotate 3s infinite linear;
  animation-trigger: --t play pause;
}
.animated.longer {
  animation-trigger: --longer-t play pause;
}
```

The `.trigger` element creates the `.animated` element's trigger via the following properties:

- A `timeline-trigger-name` with value `--t`, which is equal to the identifier referenced in the `.animated` element's `animation-trigger` property value, associating the two together.

- A `timeline-trigger-source` with value `view()`, which sets the timeline trigger as a view progress timeline, and the element providing the timeline trigger as the nearest scrolling ancestor element.
- A `timeline-trigger-activation-range` of `contain 25% contain 75%`. The `contain` range spans from when the trigger element has completely entered the scrollport to when it starts to leave. This value sets the trigger's activation range to start `25%` of the way through the `contain` range and end `75%` of the way through the range. In other words, the activation range is the middle half of the scrollport.

The `.trigger.longer` element creates the `.animated.longer` element's trigger via the following properties:

- A `timeline-trigger-name` with value `--longer-t` (overriding the `--t`), which is equal to the identifier referenced in the `.animated.longer` element's `animation-trigger` property value, associating the two together.
- A `timeline-trigger-active-range` of `cover 0% cover 100%`. The `cover` range spans from when the trigger element starts to enter the scrollport to when it has completely left. In other words, the active range is when any part of the tracked element is in the scrollport.

```
.trigger {
  timeline-trigger-name: --t;
  timeline-trigger-source: view();
  timeline-trigger-activation-range: contain 25% contain 75%;
}
.trigger.longer {
  timeline-trigger-name: --longer-t;
  timeline-trigger-active-range: cover 0% cover 100%;
}
```

```
@supports not (timeline-trigger-active-range: contain 0%) {
  body::before {
    content: "Your browser does not support the timeline-trigger-active-range property.";
    background-color: wheat;
    text-align: center;
    padding: 1rem 0;

    z-index: 1;
    position: fixed;
    inset: 40% 0 auto;
  }
}
```

Result

Try scrolling the content up. Both animations start playing when the tracked `.trigger` elements are about a quarter of the way up the scrollport. Continue scrolling. The first animation pauses when its trigger element gets to 75% through the scrollport, whereas the second animation doesn't pause until its trigger element has completely left the scrollport.

This is because the active range extends how long the trigger remains active, but doesn't change where activation occurs.

timeline-trigger-active-range-end CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`timeline-trigger-active-range-end`** CSS property specifies the end of a scroll-triggered animation trigger's active range.

Syntax

```
/* Keywords */
timeline-trigger-active-range-end: auto;
timeline-trigger-active-range-end: normal;

/* <length-percentage> */
timeline-trigger-active-range-end: 80%;
timeline-trigger-active-range-end: 400px;

/* Named timeline range */
timeline-trigger-active-range-end: contain;
timeline-trigger-active-range-end: exit;

/* Named timeline with <length-percentage> */
timeline-trigger-active-range-end: exit -10px;
timeline-trigger-active-range-end: contain 110%;

/* Multiple range end values */
timeline-trigger-active-range-end:
  contain 110%,
  exit -10px;

/* Global values */
timeline-trigger-active-range-end: inherit;
timeline-trigger-active-range-end: initial;
timeline-trigger-active-range-end: revert;
timeline-trigger-active-range-end: revert-layer;
timeline-trigger-active-range-end: unset;
```

Values

This property is specified as a comma-separated list of the following values:

`auto`

Specifies the value of the `timeline-trigger-activation-range-end` property. This is the default value.

`normal`

Specifies the end, or `100%`, of the `normal` range. Equivalent to `cover 100%` for a view progress timeline `timeline-trigger-source`, and `scroll 100%` for a scroll progress timeline.

`<length-percentage>`

Specifies a length or percentage value measured from the beginning of the `normal` timeline. Percentages are relative to the length of the `normal` timeline range.

`<timeline-range-name>`

Specifies the end, or `100%`, of the `cover`, `contain`, `entry`, `exit`, `entry-crossing`, `exit-crossing`, or `scroll` timeline range.

`<timeline-range-name> <length-percentage>`

Specifies a length or percentage value measured from the beginning of the specified named timeline range. Percentages are relative to the length of the named range.

Description

The `timeline-trigger-active-range-end` property can be used to explicitly set the end of a trigger's active range to a value equal to or further along the timeline than the `timeline-trigger-activation-range-end`, which specifies the end of the trigger's activation range.

The *active range* is the range within which a trigger remains activated once activation has occurred. Activation occurs when the tracked element enters the *activation range* and deactivation occurs when it leaves the *active* range. By default, the active range ends where the activation range ends. This property creates a buffer zone and is used to prevent premature resetting when a user scrolls back and forth across the activation range's endpoint. Only when a tracked element moves out of the active range does the trigger become inactive.

The default value of `timeline-trigger-active-range-end` is `auto`, which sets the value to the same named range and offset as the `timeline-trigger-activation-range-end`. When specified as a timeline range, offset, or both, this property sets the end of the active range to a point that is independent of the `timeline-trigger-activation-range-end` value. If the value doesn't extend the end of the activation range, it has no effect.

The value of `normal` sets the end of the active range to the end of the default named range, resolving to either `cover 100%` for a view progress timeline (the `timeline-trigger-source` is set to a `view()` function) or `scroll 100%` for a scroll progress timeline (the `timeline-trigger-source` is set to a `scroll()` function).

Other values of the `timeline-trigger-active-range-end` property can be used to set:

An offset from the `normal` range

A `<length>` or `<percentage>` value specifies an offset from the beginning of the `normal` timeline, which again defaults to either `cover` or `scroll`. Negative values outset the end, resulting in a longer active range. Positive values inset the end of the active range, making it shorter.

The end of a specific named range

A `<timeline-range-name>` value specifies a `100%` offset from the start of the named timeline range, which is either `cover`, `contain`, `entry`, `exit`, `entry-crossing`, `exit-crossing`, or `scroll`. See Understanding timeline range names.

An offset from a specific named range

When both a `<timeline-range-name>` and `<length>` or `<percentage>` value are specified, the end is offset by the distance specified from the start of the named range. Percentage values are relative to the range specified. See Setting insets using percentages.

If the value is set to a point prior to the end of the activation range, the value of the `timeline-trigger-activation-range-end` is used, as if the value were set to `auto`.

The `timeline-trigger-active-range-end` property, along with the `timeline-trigger-active-range-start` property, can also be set using the `timeline-trigger-active-range` shorthand, which in turn can be set using the `timeline-trigger` shorthand.

Specifying multiple range end values

When you specify multiple comma-separated values in a single `timeline-trigger-active-range-end` declaration, they apply to the timeline triggers in the order in which they appear in the `timeline-trigger-name` property. When the number of triggers and `timeline-trigger-active-range-end` property values do not match, they are applied in the same way as multiple animation property values.

For example, if multiple `timeline-trigger-name` values are set, but only a single `timeline-trigger-active-range-end` value is set, the `timeline-trigger-active-range-end` will apply to all the `timeline-trigger-name`s. If two or more `timeline-trigger-active-range-end` values are set, they will cycle between the `timeline-trigger-name`s until every timeline trigger has a `timeline-trigger-active-range-end` value set.

Consider these declarations:

```
timeline-trigger-name: --my-trigger, --my-other-trigger, --another-trigger;
timeline-trigger-active-range-end:
  110%,
  exit 300px;
```

In this case, `--my-trigger` will use the `110%` range end and `--my-other-trigger` will use the `exit 300px` range end. As there are three names but only two range ends, the range ends are cycled, so the third trigger name, `--another-trigger`, will use the `110%` range end.

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	no
Percentages	Relative to the specified named timeline range if specified, otherwise relative to the entire timeline
Computed value	A list where each item may be 'normal', a length percentage, or a timeline range name and a length percentage
Animation type	Not animatable

Formal syntax

```
timeline-trigger-active-range-end =
  [ auto | normal | <length-percentage> | <timeline-range-name> <length-percentage>? ]#

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per Animation Triggers, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates the effect of extending a trigger's active range. It compares two identical triggered animations, with the end of one animation trigger's active range outset using the `timeline-trigger-active-range-end` property.

HTML

The markup contains four `<div>` elements — two to animate and two to create a trigger on — plus some basic text content to cause the page to scroll. The text content is hidden for brevity.

```
<div class="animated">I am animated</div>
<div class="animated longer">I am animated longer</div>

...
<section>
  <div class="trigger">I create the trigger</div>
  <div class="trigger longer">I create a longer trigger</div>
</section>
...
```

```
<div class="animated">I am animated</div>
<div class="animated longer">I am animated longer</div>

  luctus quis. Maecenas scelerisque scelerisque elit eu consequat. Etiam ac
  tristique tellus, sed tincidunt velit.
</p>
```

CSS

The `.animated` elements' `position` is set to `fixed`, positioning them near the top-left of the scrollport to enable us to see when their animations start and stop.

```
body {
  width: 80%;
  margin: 0 auto;
  font-family: "Helvetica", "Arial";
  font-size: 1.3rem;
}

div {
  height: 100px;
  border: 5px solid black;
}

.animated {
  width: 100px;
```

```
  background: orange;
}

.trigger {
  background: wheat;
}
```

```
.animated {
  position: fixed;
  top: 25px;
  left: 25px;
}
.animated.longer {
  left: 150px;
}
section {
  display: flex;
  gap: 20px;
}
```

Next, we define the `@keyframes` for a `rotate` animation:

```
@keyframes rotate {
  from {
    rotate: 0deg;
  }

  to {
    rotate: 360deg;
  }
}
```

Using the `animation` shorthand, the `rotate` animation is applied to the `.animated` elements. Without an associated trigger, the elements would start animating when the page loads. The `animation-trigger` property makes it a triggered animation. The values reference a `timeline-trigger-name` of `--t` and `--longer-t`, respectively, and define two `<animation-action>` values — `play` and `pause` — which specify that the animation will play on activation and pause on deactivation.

```
.animated {
  animation: rotate 3s infinite linear;
  animation-trigger: --t play pause;
}
.animated.longer {
  animation-trigger: --longer-t play pause;
}
```

The `.trigger` element creates the `.animated` element's trigger via the following properties:

- A `timeline-trigger-name` with value `--t`, which is equal to the identifier referenced in the `.animated` element's `animation-trigger` property value, associating the two together.
- A `timeline-trigger-source` with value `view()`, which sets the timeline trigger as a view progress timeline, and the element providing the timeline trigger as the nearest scrolling ancestor element.
- A `timeline-trigger-activation-range-end` of `contain 50%`. The `contain` range spans from when the trigger element has completely entered the scrollport to when it starts to leave. This value sets the trigger's activation range to end `50%` through it, which occurs when it is vertically centered in the scrollport.

The `.trigger.longer` element creates the `.animated.longer` element's trigger via the following properties:

- A `timeline-trigger-name` with value `--longer-t` (overriding the `--t`), which is equal to the identifier referenced in the `.animated.longer` element's `animation-trigger` property value, associating the two together.
- A `timeline-trigger-active-range-end` of `cover 100%`. The `cover` range spans from when the trigger element first starts to enter the scrollport to when it has completely left it.

```
.trigger {
  timeline-trigger-name: --t;
  timeline-trigger-source: view();
  timeline-trigger-activation-range-end: contain 50%;
}
.trigger.longer {
  timeline-trigger-name: --longer-t;
  timeline-trigger-active-range-end: cover 100%;
}
```

```
@supports not (timeline-trigger-active-range-end: cover 100%) {
  body::before {
    content: "Your browser does not support the timeline-trigger-active-range-end property.";
    background-color: wheat;
    text-align: center;
    padding: 1rem 0;

    z-index: 1;
    position: fixed;
    inset: 40% 0 auto;
  }
}
```

Result

Try scrolling the content up. Both animations start playing when the tracked `.trigger` elements first enter into view. The animation of one element pauses when the trigger is at `50%` of the `contain` timeline. The other element only pauses when the trigger has fully exited the viewport.

When you scroll downward again, after both animations have paused, both animations will restart when the trigger elements reach the `50%` point. This is because the active range extends how long the trigger remains active, but does not change where activation occurs.

timeline-trigger-active-range-start CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`timeline-trigger-active-range-start`** CSS property specifies the start of a scroll-triggered animation trigger's active range.

Syntax

```
/* Keywords */
timeline-trigger-active-range-start: auto;
timeline-trigger-active-range-start: normal;

/* <length-percentage> */
timeline-trigger-active-range-start: 10%;
timeline-trigger-active-range-start: 50px;

/* Named timeline range */
timeline-trigger-active-range-start: contain;
timeline-trigger-active-range-start: exit;

/* Named timeline with <length-percentage> */
timeline-trigger-active-range-start: entry -5%;
timeline-trigger-active-range-start: contain 100px;

/* Multiple range start values */
timeline-trigger-active-range-start:
  contain -10px,
  entry 5%;

/* Global values */
timeline-trigger-active-range-start: inherit;
timeline-trigger-active-range-start: initial;
timeline-trigger-active-range-start: revert;
timeline-trigger-active-range-start: revert-layer;
timeline-trigger-active-range-start: unset;
```

Values

This property is specified as a comma-separated list of the following values:

`auto`

Specifies the value of the `timeline-trigger-activation-range-start` property. This is the default value.

`normal`

Specifies the start, or `0%`, of the `normal` range. Equivalent to `cover 0%` for a view progress timeline `timeline-trigger-source`, and `scroll 0%` for a scroll progress timeline.

`<length-percentage>`

Specifies a length or percentage value measured from the beginning of the `normal` timeline. Percentages are relative to the length of the `normal` timeline range.

`<timeline-range-name>`

Specifies the start, or `0%`, of the `cover`, `contain`, `entry`, `exit`, `entry-crossing`, `exit-crossing`, or `scroll` timeline range.

`<timeline-range-name> <length-percentage>`

Specifies a length or percentage value measured from the beginning of the specified named timeline range. Percentages are relative to the length of the named range.

Description

The `timeline-trigger-active-range-start` property can be used to explicitly set the start of a trigger's active range to a value equal to or preceding the `timeline-trigger-activation-range-start`, which specifies the start of the trigger's activation range.

The *active range* is the range in which a trigger remains activated once activation has occurred. Activation occurs when the tracked element enters the *activation range*, and deactivation occurs when it leaves the *active range*. By default, the active range starts where the activation range starts. This property creates a buffer zone and is used to prevent premature resetting when a user scrolls back and forth across the activation's starting point. Only when a tracked element moves out of the *active range* does the trigger become inactive.

The default value of `timeline-trigger-active-range-start` is `auto`, which sets the value to the same named range and offset as the `timeline-trigger-activation-range-start`. When specified as a timeline range, offset, or both, this property sets the start of the active range to a point that is independent of the `timeline-trigger-activation-range-start` value. If the range start position doesn't extend the activation range, it has no effect.

The value of `normal` sets the start of the active range to the start of the default named range, resolving to either `cover 0%` for a view progress timeline (the `timeline-trigger-source` is set to a `view()` function) or `scroll 0%` for a scroll progress timeline (the `timeline-trigger-source` is set to a `scroll()` function).

Other values of the `timeline-trigger-active-range-start` property can be used to set:

An offset from the `normal` range

A `<length>` or `<percentage>` value specifies an offset from the beginning of the `normal` timeline of `cover` or `scroll`. Negative values outset the start, resulting in a longer active range. Positive values inset the start of the active range, making it shorter.

The start of a specific named range

A `<timeline-range-name>` value specifies a `0%` offset along the named timeline range, which is either `cover`, `contain`, `entry`, `exit`, `entry-crossing`, `exit-crossing`, or `scroll`. See Understanding timeline range names.

An offset from a specific named range

When both a `<timeline-range-name>` and `<length>` or `<percentage>` value are specified, the start is offset by the distance specified from the start of the named range. Percentage values are relative to the range specified. See Setting insets using percentages.

The `timeline-trigger-active-range-start` property, along with the `timeline-trigger-active-range-end` property, can also be set using the `timeline-trigger-active-range` shorthand, which in turn can be set using the `timeline-trigger` shorthand.

Specifying multiple range start values

When you specify multiple comma-separated values in a single `timeline-trigger-active-range-start` declaration, they apply to the timeline triggers in the order in which they appear in the `timeline-trigger-name` property. When the number of triggers and `timeline-trigger-active-range-start` property values do not match, they are applied in the same way as multiple animation property values.

For example, if multiple `timeline-trigger-name` values are set, but only a single `timeline-trigger-active-range-start` value is set, the `timeline-trigger-active-range-start` will apply to all the `timeline-trigger-names`. If two or more `timeline-trigger-active-range-start` values are set, they will cycle between the `timeline-trigger-names` until every timeline trigger has a `timeline-trigger-active-range-start` value set.

Consider these declarations:

```
timeline-trigger-name: --my-trigger, --my-other-trigger, --another-trigger;
timeline-trigger-active-range-start:
  contain,
  entry 5%;
```

In this case, `--my-trigger` will use the `contain` range start and `--my-other-trigger` will use the `entry 5%` range start. As there are three names but only two range starts, the range starts are cycled, so the third trigger name, `--another-trigger`, will use the `contain` range start.

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	no
Percentages	Relative to the specified named timeline range if specified, otherwise relative to the entire timeline
Computed value	A list where each item may be 'normal', a length percentage, or a timeline range name and a length percentage
Animation type	Not animatable

Formal syntax

```
timeline-trigger-active-range-start =
  [ auto | normal | <length-percentage> | <timeline-range-name> <length-percentage>? ]#

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per Animation Triggers, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates the effect of extending a trigger's active range. It compares two identical triggered animations, with the start of one animation trigger's active range outset using the `timeline-trigger-active-range-start` property.

HTML

The markup contains four `<div>` elements — two to animate and two to create a trigger on — plus some basic text content to cause the page to scroll. The text content is hidden for brevity.

```
<div class="animated">I am animated</div>
<div class="animated longer">I am animated longer</div>

...
<section>
  <div class="trigger">I create the trigger</div>
  <div class="trigger longer">I create a longer trigger</div>
</section>
...
```

```
<div class="animated">I am animated</div>
<div class="animated longer">I am animated longer</div>
<p>

  tristique tellus, sed tincidunt velit.
</p>
```

CSS

The `.animated` elements' `position` is set to `fixed`, positioning them near the top-left of the scrollport to enable us to see when their animations start and stop.

```
body {
  width: 80%;
  margin: 0 auto;
  font-family: "Helvetica", "Arial";
  font-size: 1.3rem;
}

div {
  height: 100px;
  border: 5px solid black;
}

.animated {
  width: 100px;
  background: orange;
}

.trigger {
  background: wheat;
}
```

```
.animated {
  position: fixed;
  top: 25px;
  left: 25px;
}
.animated.longer {
  left: 150px;
}
section {
  display: flex;
  gap: 20px;
}
```

Next, we define the `@keyframes` for a `rotate` animation:

```
@keyframes rotate {
  from {
    rotate: 0deg;
  }

  to {
    rotate: 360deg;
  }
}
```

Using the `animation` shorthand, the `rotate` animation is applied to the `.animated` elements. Without an associated trigger, the elements would start animating when the page loads. The `animation-trigger` property makes it a triggered animation. The values reference a `timeline-trigger-name` of `--t` and `--longer-t`, respectively, and define the same two `<animation-action>` values — `play` and `pause` — which specify that the animations will play on activation and pause on deactivation.

```
.animated {
  animation: rotate 3s infinite linear;
  animation-trigger: --t play pause;
}
.animated.longer {
  animation-trigger: --longer-t play pause;
}
```

The `.trigger` element creates the `.animated` element's trigger via the following properties:

- A `timeline-trigger-name` with value `--t`, which is equal to the identifier referenced in the `.animated` element's `animation-trigger` property value, associating the two together.
- A `timeline-trigger-source` with value `view()`, which sets the timeline trigger as a view progress timeline, and the element providing the timeline trigger as the nearest scrolling ancestor element.
- A `timeline-trigger-activation-range` of `contain 50% contain 100%`. The `contain` range spans from when the trigger element has completely entered the scrollport to when it starts to leave. This value sets the trigger's activation range to start at `50%` through the `contain` range (when the tracked element's bottom edge is halfway through the scrollport), and end at `100%`, when the element's top edge first exits the scrollport.

The `.trigger.longer` element creates the `.animated.longer` element's trigger via the following properties:

- A `timeline-trigger-name` with value `--longer-t` (overriding the `--t`), which is equal to the identifier referenced in the `.animated.longer` element's `animation-trigger` property value, associating the two together.

- A `timeline-trigger-active-range-start` of `contain 0%`, which occurs when the trigger's bottom edge is at the bottom edge of the scrollport.

```
.trigger {
  timeline-trigger-name: --t;
  timeline-trigger-source: view();
  timeline-trigger-activation-range: contain 50% contain 100%;
}
.trigger.longer {
  timeline-trigger-name: --longer-t;
  timeline-trigger-active-range-start: contain 0%;
}
```

```
@supports not (timeline-trigger-active-range-start: contain 0%) {
  body::before {
    content: "Your browser does not support the timeline-trigger-active-range-start property.";
    background-color: wheat;
    text-align: center;
    padding: 1rem 0;

    z-index: 1;
    position: fixed;
    inset: 40% 0 auto;
  }
}
```

Result

Try scrolling the content up. Both animations start playing when the tracked `.trigger` elements get to the middle of the scrollport and stop playing when they start to leave the top edge of the scrollport.

If you then scroll downward, both animations start playing when they are fully in the scrollport, with the top edge of the tracked elements meeting the top edge of the scrollport. The first animation pauses when the tracked element exits the activation range, when it passes the center of the scrollport. The second animation doesn't pause until its trigger element starts to leave the scrollport at its bottom edge. This is because the active range on the second animation extends how long the trigger remains active.

timeline-trigger-name CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`timeline-trigger-name`** CSS property specifies a scroll-triggered animation trigger's identifier(s).

Syntax

```
/* Keyword */
timeline-trigger-name: none;

/* Single dashed ident */
timeline-trigger-name: --my-trigger;
timeline-trigger-name: --my-other-trigger;

/* Multiple dashed idents */
timeline-trigger-name: --my-trigger, --my-other-name;

/* Global values */
timeline-trigger-name: inherit;
timeline-trigger-name: initial;
timeline-trigger-name: revert;
timeline-trigger-name: revert-layer;
timeline-trigger-name: unset;
```

Values

Specified as one or more `<dashed-ident>` values separated by commas, or the keyword `none`.

`none`

Specifies that the element does not define any scroll-triggered animation triggers.

`<dashed-ident>`

Specifies the name of the timeline trigger.

Description

The `timeline-trigger-name` property specifies one or more identifying names for a CSS scroll-triggered animation trigger. This identifier is used within the `animation-trigger` property value.

For example:

```
.trigger {
  timeline-trigger-name: --my-trigger;
  timeline-trigger-source: view();
}
```

An element with these declarations set will create a trigger with the name `--my-trigger`. The `timeline-trigger-source` declaration is needed to create a timeline to control triggering animations; in this case, the value of `view()` creates an anonymous view progress timeline.

The resulting `ViewTimeline` tracks the position of the `.trigger` element across the block-axis of the nearest ancestor scroller. The trigger is activated and deactivated when the tracked element is scrolled to specific positions inside the scrollport.

Any animated element with its `animation-trigger` property set to `--my-trigger` will have its animation controlled by the `--my-trigger` trigger:

```
.animated {
  animation: rotate 3s infinite linear both;
  animation-trigger: --my-trigger play-once;
}
```

Each `animation-trigger` value includes two or three components: the `<dashed-ident>` identifying the trigger, and one or two `<animation-action>` keywords specifying what should happen when the trigger is activated and, optionally, when it's deactivated. In this case, the animation will play once when activated.

The animated element can create its own trigger: to achieve this, set its `timeline-trigger-name` and `animation-trigger` properties to include the same `<dashed-ident>` value:

```
.animatedAndTrigger {
  animation: rotate 3s infinite linear both;
  animation-trigger: --my-trigger play-once;

  timeline-trigger-name: --my-trigger;
  timeline-trigger-source: view();
}
```

The `timeline-trigger-name` property, along with the `timeline-trigger-source`, `timeline-trigger-activation-range`, and `timeline-trigger-active-range` properties, can also be set using the `timeline-trigger` shorthand property.

Multiple trigger names

You can specify multiple, comma-separated `<dashed-ident>` values in the same trigger's `timeline-trigger-name` value, meaning that it can be referenced by multiple identifiers. This can be useful in a situation where you have multiple components dropped into a page that you want to trigger animations on, but which use predefined `animation-trigger` values that you can't edit.

You could use multiple `timeline-trigger-name` values to create a trigger for all the animations:

```
.trigger {
  timeline-trigger-name: --animation-trigger-1, --animation-trigger-2;
  timeline-trigger-source: view();
}
```

If you specify the same `<dashed-ident>` multiple times in the same `timeline-trigger-name` list, only the last instance will define a trigger. The preceding ones will have no effect.

If multiple elements define triggers with the same trigger name, the trigger defined by the last element in the source order is used, unless scoped. See `trigger-scope` for more details.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
timeline-trigger-name =
  none             |
  <dashed-ident>#
```

This syntax reflects the latest standard as per Animation Triggers. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example shows how to create a basic scroll-triggered animation. We use the `timeline-trigger-name` property to name a trigger and reference that name within an animated element's `animation-trigger` property.

HTML

Our markup contains two `<div>` elements, one to animate and one on which to create a trigger, plus some basic text content to cause the page to scroll. We have hidden the text content for brevity.

```
<div class="animated">I am animated</div>

...

<div class="trigger">I create the trigger</div>

...
```

```
<div class="animated">I am animated</div>

</p>
```

CSS

The animated `<div>` element's `position` is set to `fixed`, positioning it near the top-left of the scrollport to enable us to see when its animation starts and stops.

```
body {
  width: 80%;
  margin: 0 auto;
  font-family: "Helvetica", "Arial";
  font-size: 1.3rem;
}

div {
  height: 100px;
  border: 5px solid black;
}

.animated {
  width: 100px;
  background: orange;
}

.trigger {
  background: wheat;
}
```

```
.animated {
  position: fixed;
  top: 25px;
  left: 25px;
}
```

Next, we define the `@keyframes` for the `rotate` animation we will use later:

```
@keyframes rotate {
  from {
    rotate: 0deg;
  }

  to {
    rotate: 360deg;
  }
}
```

Using the `animation` shorthand, we apply the `rotate` animation to the `.animated` element. Without an associated trigger, the element would start animating when the page loads. The `animation-trigger` property makes it a triggered animation. The value references a `timeline-trigger-name` of `--t` and specifies two `<animation-action>` values — `play` and `pause` — which specify that the animation will play on activation, and pause on deactivation.

```
.animated {
  animation: rotate 3s infinite linear;
  animation-trigger: --t play pause;
}
```

The `.trigger` element creates the `.animated` element's trigger via the following properties:

- A `timeline-trigger-name` with value `--t`, which is equal to the identifier referenced in the animated element's `animation-trigger` property value, associating the two together.
- A `timeline-trigger-source` with value `view()`, which sets the timeline trigger as a view progress timeline, and the element providing the timeline trigger as the nearest scrolling ancestor element.

```
.trigger {
  timeline-trigger-name: --t;
  timeline-trigger-source: view();
}
```

Result

Try scrolling the content up. When any part of the tracked `.trigger` element appears in the scrollport, the animation plays; when it has completely left the scrollport at either edge, the animation pauses.

Making the animated element the trigger

This example demonstrates how an animated element can create its own trigger.

HTML

This time, our markup contains a single `<div>` element.

```
<div>I create my own trigger</div>
```

The text content that causes the page to scroll has been hidden for brevity.

```

```

CSS

We define an `invert-colors` keyframe animation that inverts the foreground and background colors:

```
body {
  width: 80%;
  margin: 0 auto;
  font-family: "Helvetica", "Arial";
  font-size: 1.3rem;
}

div {
  height: 100px;
  background: orange;
  border: 5px solid black;
}
```

```
@keyframes invert-colors {
  from {
    background: orange;
    color: black;
```

```
  }

  to {
    background: black;
    color: orange;
  }
}
```

We set an `animation-trigger` value that references a `timeline-trigger-name` of `--t`. We also specify two `<animation-action>` values — `play-forwards` and `play-backwards` — which set the animation to play forwards on activation and in reverse on deactivation.

We then specify the following properties on the same `<div>`:

- A `timeline-trigger-name` with value `--t`. This specifies that the `<div>` creates the trigger for its own animation.
- A `timeline-trigger-source` with value `view()`. This sets the timeline trigger as a view progress timeline, and the element providing the timeline trigger as the nearest scrolling ancestor element.
- A `timeline-trigger-activation-range` with value `contain`. This means the trigger will activate when the tracked element is fully inside the scrollport. Because `timeline-trigger-active-range` defaults to `auto`, the active range is the same as the activation range; therefore, the trigger will deactivate when it stops being fully inside the scrollport. This is in contrast to the default activation and active range, `cover`, which would cause the trigger to activate when any part of the element enters the scrollport and deactivate only when it has fully left the scrollport. This would make the reverse animation occur when the element is out of view.

```
div {
  animation: invert-colors 0.6s ease-in both;

  animation-trigger: --t play-forwards play-backwards;

  timeline-trigger-name: --t;
  timeline-trigger-source: view();
  timeline-trigger-activation-range: contain;
}
```

```
@supports not (timeline-trigger-name: --t) {
  body::before {
    content: "Your browser does not support the timeline-trigger-name property.";
    background-color: wheat;
    text-align: center;
    padding: 1rem 0;

    z-index: 1;
    position: fixed;
    inset: 40% 0 auto;
  }
}
```

Result

Try scrolling the content up. The tracked element's animation plays after it has fully entered the scrollport, and pauses when it starts to leave the scrollport.

timeline-trigger-source CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`timeline-trigger-source`** CSS property specifies the timeline that will trigger a scroll-triggered animation.

Syntax

```
/* Keywords */
timeline-trigger-source: none;
timeline-trigger-source: auto;

/* Named timeline */
timeline-trigger-source: --my-timeline;

/* Anonymous scroll progress timeline */
timeline-trigger-source: scroll();
timeline-trigger-source: scroll(x root);

/* Anonymous view progress timeline */
timeline-trigger-source: view();
timeline-trigger-source: view(inline);
timeline-trigger-source: view(x 200px auto);

/* Multiple source values */
timeline-trigger-source: view(), none, --my-timeline;
timeline-trigger-source: scroll(x), auto, scroll(y root);

/* Global values */
timeline-trigger-source: inherit;
timeline-trigger-source: initial;
timeline-trigger-source: revert;
timeline-trigger-source: revert-layer;
timeline-trigger-source: unset;
```

Values

This property is specified as a comma-separated list of the following values:

`none`

The element's trigger does not have a source: it is not associated with any timeline and the animation does not happen.

`auto`

The element's trigger source is the document's default time-based `DocumentTimeline`. This is the default value.

`<dashed-ident>`

The element creates a scroll-triggered animation trigger as a named view progress timeline.

`scroll()`

The element creates a scroll-triggered animation trigger as an anonymous scroll progress timeline.

`view()`

The element creates a scroll-triggered animation trigger as an anonymous view progress timeline.

Description

The `timeline-trigger-source` property specifies the timeline trigger that will control a scroll-triggered animation.

For example:

```
.trigger {
  timeline-trigger-name: --my-trigger;
  timeline-trigger-source: view();
}
```

The resulting `ViewTimeline` tracks the position of the `.trigger` element across the block-axis of the nearest ancestor scroller. The trigger activates and deactivates when the tracked element is scrolled to certain positions inside the scrollport. By default, when `timeline-trigger-source` is set to `view()`, activation occurs when the tracked element starts to enter the scrollport, and deactivation occurs when the tracked element completely exits the scrollport.

An animated element can be triggered by the previously described trigger by referencing its `timeline-trigger-name` in its `animation-trigger` property. The `animation-trigger` value consists of a comma-separated list, each containing the name of a trigger and one or two `<animation-action>` keywords that specify what the animation should do when its trigger activates and deactivates.

For example:

```
.animated {
  animation: rotate 3s infinite linear both;
  animation-trigger: --my-trigger play-once;
}
```

The animated element and the element that creates the trigger can be the same element. In this case, the animated element creates its own trigger:

```
.animatedAndTrigger {
  animation: rotate 3s infinite linear both;
  animation-trigger: --my-trigger play-once;

  timeline-trigger-name: --my-trigger;
  timeline-trigger-source: view();
}
```

The `timeline-trigger-source` property, along with the `timeline-trigger-name`, `timeline-trigger-activation-range`, and `timeline-trigger-active-range` properties, can also be set using the `timeline-trigger` shorthand property.

Trigger source types

To create a triggered animation, set the `timeline-trigger-source` property to one of three main value types:

- A `view()` function referencing an anonymous view progress timeline trigger. This is created on the nearest scrolling ancestor of the element that creates the trigger. As shown earlier, this allows you to create functionality whereby an element will start animating when it (or another element) reaches a certain scroll offset in the scrollport, and stop animating (or some other action) when it (or another element) reaches a different scroll offset. For example:

  ```
  timeline-trigger-name: --t;
  timeline-trigger-source: view();
  ```

- A `scroll()` function referencing an anonymous scroll progress timeline trigger. You can create this on the root element or the nearest scroller of the element that creates the trigger. This allows you to create functionality whereby an element will start animating when it (or another element) reaches an absolute scroll offset (for example, it scrolls upwards by `600px`), and stop animating (or some other action) when it (or another element) reaches a different offset. For example:

  ```
  timeline-trigger-name: --t;
  timeline-trigger-source: scroll();
  timeline-trigger-activation-range: 600px;
  ```

  > **Note:** See the `scroll()` example.

- A `<dashed-ident>` referencing a named view progress timeline or named scroll progress timeline. This involves setting a `view-timeline-name` or `scroll-timeline-name` on the element that creates the trigger, and then referring to that name in the value of the `timeline-trigger-source` property, for example:

  ```
  view-timeline-name: --my-timeline;
  timeline-trigger-source: --my-timeline;
  ```

Scroll progress timelines are arguably less useful for scroll-triggered animations than view progress timelines. You are more likely to want an animation to start at a scroll offset relative to the scrollport, not after an arbitrary amount of scrolling, where the animation may well be triggered offscreen on smaller screens.

Other values

It is also possible to set `timeline-trigger-source` to a keyword of `auto` or `none`. Both result in a non-scroll-triggered animation, but their effects differ.

- The default value, `auto`, sets the element's trigger source to the document's default time-based `DocumentTimeline`. This results in any animations applied to the element playing on page load.
- The `none` value results in the element's trigger having no source, which means that any animations applied to the element will not play at all.

Multiple sources

When you specify multiple comma-separated values on a single `timeline-trigger-source` property, they are applied to the timeline triggers in the order in which the `timeline-trigger-name`s appear. When the number of triggers and `timeline-trigger-source` property values do not match, they are applied in the same way as multiple animation property values.

For example, if multiple `timeline-trigger-name` values are set, but only a single `timeline-trigger-source` value is set, the `timeline-trigger-source` will apply to all the `timeline-trigger-name`s. If two `timeline-trigger-source` values are set, they will cycle between the `timeline-trigger-name`s until all of them have a `timeline-trigger-source` value set. And so on.

Consider these declarations:

```
timeline-trigger-name: --my-trigger, --my-other-trigger, --another-trigger;
timeline-trigger-source: view(), --my-source;
```

In this case, the first name will use the `view()` source, and the second name will use the `--my-source` source. The third name will cycle back to using the `view()` source again.

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	no
Computed value	A list, with each item being either the keyword `none`, the keyword `auto`, a case-sensitive `<ident>`, a computed `scroll()` function, or a computed `view()` function.
Animation type	Not animatable

Formal syntax

```
timeline-trigger-source =
  [ none | auto | [ <dashed-ident> | <scroll()> | <view()> ]+ ]#

<scroll()> =
  scroll( [ <scroller> || <axis> ]? )

<view()> =
  view( [ <axis> || <'view-timeline-inset'> ]? )

<scroller> =
  root     |
  nearest  |
  self

<axis> =
  block   |
  inline  |
  x       |
  y

<view-timeline-inset> =
  [ [ auto | <length-percentage> ]{1,2} ]#

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per Animation Triggers, CSS Values and Units Module Level 4, Scroll-driven Animations. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic view progress timeline source usage

In this example, we create a basic scroll-triggered animation that uses an anonymous view progress timeline trigger source.

HTML

The markup contains two `<div>` elements: one to animate and one to create a trigger, plus basic text content to make the page scroll. The text is hidden for brevity.

```
<div class="animated">I am animated</div>

...

<div class="trigger">I create the trigger</div>

...
```

```
<div class="animated">I am animated</div>

<p>
  Fusce dictum ex quis ipsum consectetur placerat. Cras sed lectus ex. Quisque
  purus dolor, vulputate ac mi eget, commodo varius odio. Suspendisse faucibus
  ipsum vel libero finibus, in placerat nibh congue. Sed iaculis, metus et
  euismod posuere, mi diam vestibulum felis, ac vulputate eros ipsum id justo.
  Etiam a tincidunt purus. Maecenas semper sed enim at blandit. Aenean ut
  sagittis lorem, eget gravida purus. Phasellus eleifend, lectus nec pulvinar
  facilisis, dui dolor feugiat odio, iaculis tempor felis est non tortor. In
  suscipit lorem efficitur molestie tempus. Integer sit amet neque et risus
  iaculis sodales sed eget diam. Quisque sodales nunc sapien, vitae lacinia ex
  luctus quis. Maecenas scelerisque scelerisque elit eu consequat. Etiam ac
  tristique tellus, sed tincidunt velit.
</p>

<p>
  Fusce dictum ex quis ipsum consectetur placerat. Cras sed lectus ex. Quisque
  purus dolor, vulputate ac mi eget, commodo varius odio. Suspendisse faucibus
  ipsum vel libero finibus, in placerat nibh congue. Sed iaculis, metus et
  euismod posuere, mi diam vestibulum felis, ac vulputate eros ipsum id justo.
  Etiam a tincidunt purus. Maecenas semper sed enim at blandit. Aenean ut
  sagittis lorem, eget gravida purus. Phasellus eleifend, lectus nec pulvinar
```

```
  facilisis, dui dolor feugiat odio, iaculis tempor felis est non tortor. In
  suscipit lorem efficitur molestie tempus. Integer sit amet neque et risus
  iaculis sodales sed eget diam. Quisque sodales nunc sapien, vitae lacinia ex
  luctus quis. Maecenas scelerisque scelerisque elit eu consequat. Etiam ac
  tristique tellus, sed tincidunt velit.
</p>

<div class="trigger">I create the trigger</div>

<p>
  Fusce dictum ex quis ipsum consectetur placerat. Cras sed lectus ex. Quisque
  purus dolor, vulputate ac mi eget, commodo varius odio. Suspendisse faucibus
  ipsum vel libero finibus, in placerat nibh congue. Sed iaculis, metus et

  iaculis sodales sed eget diam. Quisque sodales nunc sapien, vitae lacinia ex
  luctus quis. Maecenas scelerisque scelerisque elit eu consequat. Etiam ac
  tristique tellus, sed tincidunt velit.
</p>
```

CSS

The animated `<div>` element's `position` is set to `fixed`, positioning it near the top-left of the scrollport to enable us to see when its animation starts and stops.

```
body {
  width: 80%;
  margin: 0 auto;
  font-family: "Helvetica", "Arial";
  font-size: 1.3rem;
}

div {
  height: 100px;
  border: 5px solid black;
}

.animated {
  width: 100px;
  background: orange;
}

.trigger {
  background: wheat;
}
```

```
.animated {
  position: fixed;
  top: 25px;
  left: 25px;
}
```

Next, we define the `@keyframes` for the `rotate` animation we will use later:

```
@keyframes rotate {
  from {
    rotate: 0deg;
  }

  to {
    rotate: 360deg;
  }
}
```

Using the `animation` shorthand, the `.animated` element has the `rotate` animation applied. Without an associated trigger, the element would start animating when the page loads. The `animation-trigger` property makes it a triggered animation. The value references a `timeline-trigger-name` of `--t` and specifies two `<animation-action>` values — `play` and `pause` — which specify that the animation will play on activation and pause on deactivation.

```
.animated {
  animation: rotate 3s infinite linear;
  animation-trigger: --t play pause;
}
```

The `.trigger` element creates the animated `<div>`'s trigger via the following properties:

- A `timeline-trigger-name` with value `--t`, which is equal to the identifier referenced in the `.animated` element's `animation-trigger` property value, associating the two together.
- A `timeline-trigger-source` with value `view()`, which sets the timeline trigger as a view progress timeline, and the element providing the timeline trigger as the nearest scrolling ancestor element.

```
.trigger {
  timeline-trigger-name: --t;
  timeline-trigger-source: view();
}
```

Result

Try scrolling the content up. When any part of the `.trigger` appears in the scrollport, the animation will play; when it has completely left the scrollport at either edge, the animation will pause.

Basic scroll progress timeline source usage

This example is nearly identical to the previous one, except that this time we set `timeline-trigger-source` to an anonymous scroll progress timeline instead of an anonymous view progress timeline.

The HTML and CSS are nearly identical, except that this time we have set our `.trigger` element's `timeline-trigger-source` to `scroll()` instead of `view()`. This creates the trigger as an anonymous scroll progress timeline on the element's nearest scrolling ancestor.

We have also set a `timeline-trigger-activation-range` of `600px`, which means that the trigger will activate (meaning the animation will start playing) when the tracked element scrolls upwards by `600px`. If we didn't set this, the trigger would activate immediately on page load.

```
.animated {
  animation: rotate 3s infinite linear;
  animation-trigger: --t play pause;
}
```

```
.trigger {
  timeline-trigger-name: --t;
  timeline-trigger-source: scroll();
  timeline-trigger-activation-range: 600px;
}
```

```
@supports not (timeline-trigger-source: scroll()) {
  body::before {
    content: "Your browser does not support the timeline-trigger-source property.";
    background-color: wheat;
    text-align: center;
    padding: 1rem 0;

    z-index: 1;
    position: fixed;
    inset: 40% 0 auto;
  }
}
```

Result

The animation will start when the tracked element scrolls `600px` upwards.

top CSS property

The **`top`** CSS property sets the vertical position of a positioned element. This inset property has no effect on non-positioned elements.

Try it

```
top: 0;
```

```
top: 4em;
```

```
top: 10%;
```

```
top: 20px;
```

```
<section id="default-example">
  <div class="example-container">
    <div id="example-element">I am absolutely positioned.</div>
    <p>
      As much mud in the streets as if the waters had but newly retired from the
      face of the earth, and it would not be wonderful to meet a Megalosaurus,
      forty feet long or so, waddling like an elephantine lizard up Holborn
      Hill.
    </p>
  </div>
</section>
```

```
.example-container {
  border: 0.75em solid;
  padding: 0.75em;
  text-align: left;
  position: relative;
  width: 100%;
  min-height: 200px;
}

#example-element {
  background-color: #264653;
  border: 4px solid #ffb500;
  color: white;
  position: absolute;
  width: 140px;
  height: 60px;
}
```

The effect of `top` depends on how the element is positioned (i.e., the value of the `position` property):

- When `position` is set to `absolute` or `fixed`, the `top` property specifies the distance between the element's outer margin of the top edge and the inner border of the top edge of its containing block, or, in the case of anchor positioned elements when the `anchor()` function is used within the value, relative to the specified `<anchor-side>` edge. The `top` property is compatible with the `top`, `bottom`, `start`, `end`, `self-start`, `self-end`, `center`, and `<percentage>` values.
- When `position` is set to `relative`, the `top` property specifies the distance the element's top edge is moved below its normal position.
- When `position` is set to `sticky`, the `top` property is used to compute the sticky-constraint rectangle.
- When `position` is set to `static`, the `top` property has *no effect*.

When both `top` and `bottom` values are specified, there are three different cases:

- If `position` is set to `absolute` or `fixed` and `height` is unspecified (either `auto` or `100%`), both the `top` and `bottom` values are respected.
- If `position` is set to `relative` or `height` is constrained, the `top` property takes precedence and the `bottom` property is ignored.
- If `position` is set to `sticky`, both `top` and `bottom` values are considered. This means that a sticky element can potentially move up and down within its containing block based on the values of these two properties as long as the element's position box remains contained within its containing block.

Syntax

```
/* <length> values */
top: 3px;
top: 2.4em;
top: anchor(bottom);
top: anchor-size(--my-anchor self-block, 10%);

/* <percentage>s of the height of the containing block */
top: 10%;

/* Keyword value */
top: auto;

/* Global values */
top: inherit;
top: initial;
top: revert;
top: revert-layer;
top: unset;
```

Values

`<length>`

A negative, null, or positive `<length>`:

- for *absolutely positioned elements*, it represents the distance to the top edge of the containing block.
- for *anchor-positioned elements*, the `anchor()` function resolves to a `<length>` value relative to the position of the associated *anchor element*'s top or bottom edge (see Using inset properties with `anchor()` function values), and the `anchor-size()` function resolves to a `<length>` value relative to the associated anchor element's width or height (see Setting element position based on anchor size).
- for *relatively positioned elements*, it represents the distance that the element is moved below its normal position.

`<percentage>`

A `<percentage>` of the containing block's height.

`auto`

Specifies that:

- for *absolutely positioned elements*, the position of the element is based on the `bottom` property, while `height: auto` is treated as a height based on the content; or if `bottom` is also `auto`, the element is positioned where it should vertically be positioned if it were a static element.
- for *relatively positioned elements*, the distance of the element from its normal position is based on the `bottom` property; or if `bottom` is also `auto`, the element is not moved vertically at all.

Formal definition

Initial value	`auto`
Applies to	positioned elements
Inherited	no
Percentages	refer to the height of the containing block
Computed value	if specified as a length, the corresponding absolute length; if specified as a percentage, the specified value; otherwise, `auto`
Animation type	a length, percentage or calc();

Formal syntax

```
top =
  auto                |
  <length-percentage>  |
  <anchor()>           |
  <anchor-size()>

<length-percentage> =
  <length>      |
  <percentage>

<anchor()> =
  anchor( <anchor-name>?                 &&
  <anchor-side> , <length-percentage>? )

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<anchor-name> =
  <dashed-ident>

<anchor-side> =
  inside        |
  outside       |
  top           |
  left          |
  right         |
```

```
  bottom        |
  start         |
  end           |
  self-start    |
  self-end      |
  <percentage>  |
  center

<anchor-size> =
  width         |
  height        |
  block         |
  inline        |
  self-block    |
  self-inline
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Positioned Layout Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

A positioned element set 10% from the top

```
body {
  background: beige;
}

div {
  position: absolute;
  top: 10%;
  right: 40%;
  bottom: 20%;
  left: 15%;
  background: gold;
  border: 1px solid blue;
}
```

```
<div>The size of this content is determined by the position of its edges.</div>
```

touch-action CSS property

The **`touch-action`** CSS property sets how an element's region can be manipulated by a touchscreen user (for example, by zooming features built into the browser).

By default, panning (scrolling) and pinching gestures are handled exclusively by the browser. An application using Pointer events will receive a `pointercancel` event when the browser starts handling a touch gesture. By explicitly specifying which gestures should be handled by the browser, an application can supply its own behavior in `pointermove` and `pointerup` listeners for the remaining gestures. Applications using Touch events disable the browser handling of gestures by calling `preventDefault()`, but should also use `touch-action` to ensure the browser knows the intent of the application before any event listeners have been invoked.

When a gesture is started, the browser intersects the `touch-action` values of the touched element and its ancestors, up to the one that implements the gesture (in other words, the first containing scrolling element). This means that in practice, `touch-action` is typically applied only to top-level elements which have some custom behavior, without needing to specify `touch-action` explicitly on any of that element's descendants.

> **Note:** After a gesture starts, changes to `touch-action` will not have any impact on the behavior of the current gesture.

Syntax

```
/* Keyword values */
touch-action: auto;
touch-action: none;
touch-action: pan-x;
touch-action: pan-left;
touch-action: pan-right;
touch-action: pan-y;
touch-action: pan-up;
touch-action: pan-down;
touch-action: pinch-zoom;
touch-action: manipulation;

/* Global values */
touch-action: inherit;
touch-action: initial;
touch-action: revert;
touch-action: revert-layer;
touch-action: unset;
```

The `touch-action` property may be specified as either:

- One of the keywords `auto`, `none`, `manipulation`, *or*
- One of the keywords `pan-x`, `pan-left`, `pan-right`, and/or one of the keywords `pan-y`, `pan-up`, `pan-down`, plus optionally the keyword `pinch-zoom`.

Values

`auto`

Enable browser handling of all panning and zooming gestures.

`none`

Disable browser handling of all panning and zooming gestures.

`pan-x`

Enable single-finger horizontal panning gestures. May be combined with **pan-y**, **pan-up**, **pan-down** and/or **pinch-zoom**.

`pan-y`

Enable single-finger vertical panning gestures. May be combined with **pan-x**, **pan-left**, **pan-right** and/or **pinch-zoom**.

`manipulation`

Enable panning and pinch zoom gestures, but disable additional non-standard gestures such as double-tap to zoom. Disabling double-tap to zoom removes the need for browsers to delay the generation of **click** events when the user taps the screen. This is an alias for "**pan-x pan-y pinch-zoom**" (which, for compatibility, is itself still valid).

`pan-left, pan-right, pan-up, pan-down`

Enable single-finger gestures that begin by scrolling in the given direction(s). Once scrolling has started, the direction may still be reversed. Note that scrolling "up" (**pan-up**) means that the user is dragging their finger downward on the screen surface, and likewise **pan-left** means the user is dragging their finger to the right. Multiple directions may be combined except when there is a simpler representation (for example, **"pan-left pan-right**" is invalid since "**pan-x**" is simpler, but "**pan-left pan-down**" is valid).

`pinch-zoom`

Enable multi-finger panning and zooming of the page. This may be combined with any of the **pan-** values.

Accessibility

A declaration of `touch-action: none;` may inhibit operating a browser's zooming capabilities. This will prevent people experiencing low vision conditions from being able to read and understand page content.

- MDN Understanding WCAG, Guideline 1.4 explanations
- Understanding Success Criterion 1.4.4 | Understanding WCAG 2.0

Formal definition

Initial value	`auto`
Applies to	all elements except: non-replaced inline elements, table rows, row groups, table columns, and column groups
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
touch-action =
  auto                                          |
  none                                          |
  [ [ pan-x | pan-left | pan-right ] || [ pan-y | pan-up | pan-down ] || pinch-zoom ]  |
  manipulation
```

This syntax reflects the latest standard as per Compatibility. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Disabling all gestures

The most common usage is to disable all gestures on an element (and its non-scrollable descendants) that provides its own dragging and zooming behavior – such as a map or game surface.

HTML

```
<div id="map"></div>
```

CSS

```
#map {
  height: 150vh;
  width: 70vw;
  background: linear-gradient(blue, green);
  touch-action: none;
}
```

transform CSS property

The **`transform`** CSS property lets you rotate, scale, skew, or translate an element. It modifies the coordinate space of the CSS visual formatting model.

If the property has a value different from `none`, a stacking context will be created. In that case, the element will act as a containing block for any `position: fixed;` or `position: absolute;` elements that it contains.

You can also use the individual transform properties: `translate`, `rotate`, and `scale`. These properties are applied in the order: `translate`, `rotate`, `scale`, and finally `transform`.

> **Warning:** Only transformable elements can be `transform`ed. That is, all elements whose layout is governed by the CSS box model except for: non-replaced inline boxes, table-column boxes, and table-column-group boxes.

Try it

```
transform: matrix(1, 2, 3, 4, 5, 6);
```

```
transform: translate(120px, 50%);
```

```
transform: scale(2, 0.5);
```

```
transform: rotate(0.5turn);
```

```
transform: skew(30deg, 20deg);
```

```
transform: scale(0.5) translate(-100%, -100%);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

Syntax

```
/* Keyword value */
transform: none;

/* Function values */
transform: matrix(1, 2, 3, 4, 5, 6);
transform: matrix3d(1, 0, 0, 0, 0, 1, 0, 0, 0, 0, 1, 0, 0, 0, 0, 1);
transform: perspective(17px);
transform: rotate(0.5turn);
transform: rotate3d(1, 2, 3, 10deg);
transform: rotateX(10deg);
transform: rotateY(10deg);
transform: rotateZ(10deg);
transform: translate(12px, 50%);
transform: translate3d(12px, 50%, 3em);
transform: translateX(2em);
transform: translateY(3in);
transform: translateZ(2px);
transform: scale(2, 0.5);
transform: scale3d(2.5, 1.2, 0.3);
transform: scaleX(2);
transform: scaleY(0.5);
transform: scaleZ(0.3);
transform: skew(30deg, 20deg);
transform: skewX(30deg);
transform: skewY(1.07rad);

/* Multiple function values */
transform: translateX(10px) rotate(10deg) translateY(5px);
transform: perspective(500px) translate3d(10px, 0, 20px) rotateY(30deg);

/* Global values */
transform: inherit;
transform: initial;
transform: revert;
transform: revert-layer;
transform: unset;
```

Values

This property is specified as either the keyword value `none` or as a space-separated list of `<transform-function>` values:

`<transform-function>`

> One or more of the CSS transform functions to be applied. The transform functions are combined from left to right – each function establishes a new coordinate space for the next function and so on – so the visual result matches the written order of the functions. Alternatively, keeping the parent coordinate space fixed, the same transformation can be described as applying the functions in reverse order (right to left).

`none`

> Specifies that no transform should be applied.

Accessibility

Scaling/zooming animations are problematic for accessibility, as they are a common trigger for certain types of migraine. If you need to include such animations on your website, you should provide a control to allow users to turn off animations, preferably site-wide.

Also, consider making use of the `prefers-reduced-motion` media feature — use it to write a media query that will turn off animations if the user has reduced animation specified in their system preferences.

Formal definition

Initial value	none
Applies to	transformable elements
Inherited	no
Percentages	refer to the size of bounding box
Computed value	as specified, but with relative lengths converted into absolute lengths
Animation type	a transform
Creates stacking context	yes

Formal syntax

```
transform =
  none              |
  <transform-list>

<transform-list> =
```

```
  <transform-function>+

<transform-function> =
  <scale3d()>      |
  <scale()>        |
  <scaleX()>       |
  <scaleY()>       |
  <scaleZ()>       |
  <translate3d()>  |
  <translate()>    |
  <translateX()>   |
  <translateY()>   |
  <translateZ()>   |
  <rotate3d()>     |
  <rotate()>       |
  <rotateX()>      |
  <rotateY()>      |
  <rotateZ()>      |
  <skew()>         |
  <skewX()>        |
  <skewY()>        |
  <matrix3d()>     |
  <matrix()>       |
  <perspective()>

<scale3d()> =
  scale3d( [ <number> | <percentage> ]#{3} )

<scale()> =
  scale( <number> , <number>? )

<scaleX()> =
  scaleX( <number> )

<scaleY()> =
  scaleY( <number> )

<scaleZ()> =
  scaleZ( [ <number> | <percentage> ] )

<translate3d()> =
  translate3d( <length-percentage> , <length-percentage> , <length> )

<translate()> =
  translate( <length-percentage> , <length-percentage>? )

<translateX()> =
  translateX( <length-percentage> )

<translateY()> =
  translateY( <length-percentage> )

<translateZ()> =
  translateZ( <length> )

<rotate3d()> =
  rotate3d( <number> , <number> , <number> , [ <angle> | <zero> ] )

<rotate()> =
  rotate( [ <angle> | <zero> ] )

<rotateX()> =
  rotateX( [ <angle> | <zero> ] )

<rotateY()> =
  rotateY( [ <angle> | <zero> ] )

<rotateZ()> =
  rotateZ( [ <angle> | <zero> ] )

<skew()> =
  skew( [ <angle> | <zero> ] , [ <angle> | <zero> ]? )

<skewX()> =
  skewX( [ <angle> | <zero> ] )

<skewY()> =
  skewY( [ <angle> | <zero> ] )

<matrix3d()> =
  matrix3d( <number>#{16} )

<matrix()> =
  matrix( <number>#{6} )

<perspective()> =
  perspective( [ <length [0,∞]> | none ] )

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Transforms Module Level 1, CSS Transforms Module Level 2, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Translating and rotating an element

HTML

```
<div>Transformed element</div>
```

CSS

```
div {
  border: solid red;
  transform: translate(30px, 20px) rotate(20deg);
```

```
  width: 140px;
  height: 60px;
}
```

Result

Comparing the order of transform functions

The order of transform functions matters.

In this example, two boxes are rotated and translated by the same values, but the functions are in the opposite order. The dotted lines mark the X-axis before and after rotation.

HTML

```
<div class="original"></div>
<div class="one">1</div>
<div class="two">2</div>
```

CSS

```
div {
  height: 200px;
  width: 200px;
  position: absolute;
  left: 200px;
  top: 50px;
  font-size: 4rem;
  line-height: 200px;
  text-align: center;
}
.original {
  border: 1px dashed;
}
.original::before,
.original::after {
  content: "";
  position: absolute;
  top: 100px;
  width: 500px;
  left: -150px;
  height: 1px;
  border-top: 2px dotted;
}
.original::after {
  transform: rotate(135deg);
}
.one {
  background-color: #cccccc;
}
.two {
  background-color: #d6bb72;
}
```

```
.one {
  transform: translateX(200px) rotate(135deg);
}
.two {
  transform: rotate(135deg) translateX(200px);
}
```

Result

- Box 1 (first `translateX()`, then `rotate()`): The coordinate space first shifts `200px` along the X axis, then rotates `135deg` within that shifted space, so the element ends up to the right of its original position, rotated.
- Box 2 (first `rotate()`, then `translateX()`): The coordinate space first rotates `135deg`, so the element then moves `200px` along the rotated axis, in the direction shown by the dotted lines. Please see Using CSS transforms and `<transform-function>` for more examples.

transform-box CSS property

The **`transform-box`** CSS property defines the layout box to which the `transform`, individual transform properties `translate`, `scale`, and `rotate`, and `transform-origin` properties relate.

Syntax

```
/* Keyword values */
transform-box: content-box;
transform-box: border-box;
transform-box: fill-box;
transform-box: stroke-box;
transform-box: view-box;

/* Global values */
transform-box: inherit;
transform-box: initial;
transform-box: revert;
transform-box: revert-layer;
transform-box: unset;
```

The `transform-box` property is specified as one of the keyword values listed below.

Values

`content-box`

The content box is used as the reference box. The reference box of a `<table>` is the border box of its table wrapper box, not its table box.

`border-box`

The border box is used as the reference box. The reference box of a `<table>` is the border box of its table wrapper box, not its table box.

`fill-box`

The object bounding box is used as the reference box. For elements with associated CSS layout box, acts as `content-box`.

`stroke-box`

The stroke bounding box is used as the reference box. For elements with associated CSS layout box, acts as `border-box`.

`view-box`

The nearest SVG viewport is used as the reference box. If a `viewBox` attribute is specified for the SVG viewport creating element, the reference box is positioned at the origin of the coordinate system established by the `viewBox` attribute, and the dimension of the reference box is set to the width and height values of the `viewBox` attribute. For elements with associated CSS layout box, acts as `border-box`.

Formal definition

Initial value	`view-box`
Applies to	transformable elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
transform-box =
  content-box  |
  border-box   |
  fill-box     |
  stroke-box   |
  view-box
```

This syntax reflects the latest standard as per CSS Transforms Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

SVG transform-origin scoping

In this example we have an SVG:

```
<svg id="svg" xmlns="http://www.w3.org/2000/svg" viewBox="0 0 50 50">
  <g>
    <circle id="center" fill="red" r="1" transform="translate(25 25)" />
    <circle id="boxcenter" fill="blue" r=".5" transform="translate(15 15)" />
    <rect
      id="box"
      x="10"
      y="10"
      width="10"
      height="10"
      rx="1"
      ry="1"
      stroke="black"
      fill="none" />
  </g>
</svg>
```

In the CSS we have an animation that uses a transform to rotate the rectangle infinitely. `transform-box: fill-box` is used to make the `transform-origin` the center of the bounding box, so the rectangle spins in place. Without it, the transform origin is the center of the SVG canvas, and so you get a very different effect.

```
svg {
  width: 80vh;
  border: 1px solid #d9d9d9;
  position: absolute;
  margin: auto;
  inset: 0;
}

#box {
  transform-origin: 50% 50%; /* anything other than `0 0` to see the effect */
  transform-box: fill-box;
  animation: rotate-box 3s linear infinite;
}

@keyframes rotate-box {
  to {
    transform: rotate(360deg);
  }
}
```

See also

- Using CSS transforms
- `transform`, `transform-origin`
- Individual transform properties:
  - `translate`
  - `scale`
  - `rotate`

transform-origin CSS property

The **`transform-origin`** CSS property sets the origin for an element's transformations.

Try it

```
transform-origin: center;
```

```
transform-origin: top left;
```

```
transform-origin: 50px 50px;
```

```
/* 3D rotation with z-axis origin */
transform-origin: bottom right 60px;
```

```
<section id="default-example">
  <div id="example-container">
    <div id="example-element">Rotate me!</div>
    <img
      alt=""
      id="crosshair"
      src="/shared-assets/images/examples/crosshair.svg"
      width="24px" />
    <div id="static-element"></div>
  </div>
</section>
```

```
@keyframes rotate {
  from {
    transform: rotate(0);
  }

  to {
    transform: rotate(30deg);
  }
}

@keyframes rotate3d {
  from {
    transform: rotate3d(0, 0, 0, 0);
  }

  to {
    transform: rotate3d(1, 2, 0, 60deg);
  }
}

#example-container {
  width: 160px;
  height: 160px;
  position: relative;
}

#example-element {
  width: 100%;
  height: 100%;
  display: flex;
  position: absolute;
  align-items: center;
  justify-content: center;
  background: #f7ebee;
  color: black;
  font-size: 1.2rem;
  text-transform: uppercase;
}

#example-element.rotate {
  animation: rotate 1s forwards;
}

#example-element.rotate3d {
  animation: rotate3d 1s forwards;
}

#crosshair {
  width: 24px;
  height: 24px;
  opacity: 0;
  position: absolute;
}

#static-element {
  width: 100%;
  height: 100%;
  position: absolute;
  border: dotted 3px #ff1100;
}
```

```
const crosshair = document.getElementById("crosshair");
const el = document.getElementById("example-element");

function update() {
  const selected = document.querySelector(".selected");

  /* Restart the animation
          https://developer.mozilla.org/en-US/docs/Web/API/Web_Animations_API/Tips */
  el.className = "";
  window.requestAnimationFrame(() => {
    window.requestAnimationFrame(() => {
      el.className =
```

```
        el.style.transformOrigin.split(" ")[2] === "60px"
          ? "rotate3d"
          : "rotate";
    });
  });

  const transformOrigin = getComputedStyle(el).transformOrigin;
  const pos = transformOrigin.split(/\s+/);
  crosshair.style.left = `calc(${pos[0]} - 12px)`;
  crosshair.style.top = `calc(${pos[1]} - 12px)`;
}

const observer = new MutationObserver(() => {
  update();
});

observer.observe(el, {
  attributes: true,
  attributeFilter: ["style"],
});

update();
crosshair.style.opacity = "1";
```

The transform origin is the point around which a transformation is applied. For example, the transform origin of the `rotate()` function is the center of rotation.

In effect, this property wraps a pair of translations around the element's other transformations. The first translation moves the transform origin to the true origin at $(0, 0)$. Then the other transformations are applied, and because the transform origin is at $(0, 0)$, those transformations act about the transform origin. Finally, the opposite translation is applied, moving the transform origin back to its original location. Consequently, this definition

```
transform-origin: -100% 50%;
transform: rotate(45deg);
```

results in the same transformation as

```
transform-origin: 0 0;
transform: translate(-100%, 50%) rotate(45deg) translate(100%, -50%);
```

Reading from right to left, `translate(100%, -50%)` is the translation to bring the transform origin to the true origin, `rotate(45deg)` is the original transformation, and `translate(-100%, 50%)` is the translation to restore the transform origin to its original location.

By default, the origin of a transform is `center`.

Syntax

```
/* One-value syntax */
transform-origin: 2px;
transform-origin: bottom;

/* x-offset | y-offset */
transform-origin: 3cm 2px;

/* x-offset-keyword | y-offset */
transform-origin: left 2px;

/* x-offset-keyword | y-offset-keyword */
transform-origin: right top;

/* y-offset-keyword | x-offset-keyword */
transform-origin: top right;

/* x-offset | y-offset | z-offset */
transform-origin: 2px 30% 10px;

/* x-offset-keyword | y-offset | z-offset */
transform-origin: left 5px -3px;

/* x-offset-keyword | y-offset-keyword | z-offset */
transform-origin: right bottom 2cm;

/* y-offset-keyword | x-offset-keyword | z-offset */
transform-origin: bottom right 2cm;

/* Global values */
transform-origin: inherit;
transform-origin: initial;
transform-origin: revert;
transform-origin: revert-layer;
transform-origin: unset;
```

The `transform-origin` property may be specified using one, two, or three values, where each value represents an offset. Offsets that are not explicitly defined are reset to their corresponding initial values.

If a single `<length>` or `<percentage>` value is defined, it represents the horizontal offset.

If two or more values are defined and either no value is a keyword, or the only used keyword is `center`, then the first value represents the horizontal offset and the second represents the vertical offset.

- One-value syntax:
  - The value must be a `<length>`, a `<percentage>`, or one of the keywords `left`, `center`, `right`, `top`, and `bottom`.
- Two-value syntax:
  - One value must be a `<length>`, a `<percentage>`, or one of the keywords `left`, `center`, and `right`.
  - The other value must be a `<length>`, a `<percentage>`, or one of the keywords `top`, `center`, and `bottom`.
- Three-value syntax:
  - The first two values are the same as for the two-value syntax.
  - The third value must be a `<length>`. It always represents the Z offset.

Values

x-offset

Is a `<length>` or a `<percentage>` describing how far from the left edge of the box the origin of the transform is set.

offset-keyword

Is one of the `left`, `right`, `top`, `bottom`, or `center` keyword describing the corresponding offset.

y-offset

Is a `<length>` or a `<percentage>` describing how far from the top edge of the box the origin of the transform is set.

x-offset-keyword

Is one of the `left`, `right`, or `center` keyword describing how far from the left edge of the box the origin of the transform is set.

y-offset-keyword

Is one of the `top`, `bottom`, or `center` keyword describing how far from the top edge of the box the origin of the transform is set.

z-offset

Is a `<length>` (and never a `<percentage>` which would make the statement invalid) describing how far from the user eye the z=0 origin is set.

The keywords are convenience shorthands and match the following `<percentage>` values:

Keyword	Value
`left`	`0%`
`center`	`50%`
`right`	`100%`
`top`	`0%`
`bottom`	`100%`

Formal definition

Initial value	`50% 50% 0`
Applies to	transformable elements
Inherited	no
Percentages	refer to the size of bounding box
Computed value	for `<length>` the absolute value, otherwise a percentage
Animation type	simple list of length, percentage, or calc

> **Note:** The initial value of `transform-origin` is `0 0` for all SVG elements except for root `<svg>` elements and `<svg>` elements that are a direct child of a foreignObject, and whose `transform-origin` is `50% 50%`, like other CSS elements. See the SVG transform-origin attribute for more information.

Formal syntax

```
transform-origin =
  [ left | center | right | top | bottom | <length-percentage> ]  |
  [ left | center | right | <length-percentage> ] [ top | center | bottom | <length-percentage> ] <length>?  |
  [ [ center | left | right ] && [ center | top | bottom ] ] <length>?

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Transforms Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

A demonstration of various transform values

This example shows the effect of choosing different `transform-origin` values for a variety of transformation functions.

```
<div class="container">
  <div class="example">
    <div class="box box1">&amp;nbsp;</div>
    <div class="box original">&amp;nbsp;</div>
  </div>

  <pre>
transform: none;
  </pre>

  <div class="example">
    <div class="box box2">&amp;nbsp;</div>
    <div class="box original">&amp;nbsp;</div>
  </div>

  <pre>
transform: rotate(30deg);
  </pre>

  <div class="example">
    <div class="box box3">&amp;nbsp;</div>
    <div class="box original">&amp;nbsp;</div>
  </div>

  <pre>
transform: rotate(30deg);
```

```
transform-origin: 0 0;
  </pre>

  <div class="example">
    <div class="box box4">&amp;nbsp;</div>
    <div class="box original">&amp;nbsp;</div>
  </div>

  <pre>
transform: rotate(30deg);
transform-origin: 100% 100%;
  </pre>

  <div class="example">
    <div class="box box5">&amp;nbsp;</div>
    <div class="box original">&amp;nbsp;</div>
  </div>

  <pre>
transform: rotate(30deg);
transform-origin: -1em -3em;
  </pre>

  <div class="example">
    <div class="box box6">&amp;nbsp;</div>
    <div class="box original">&amp;nbsp;</div>
  </div>

  <pre>
transform: scale(1.7);
  </pre>

  <div class="example">
    <div class="box box7">&amp;nbsp;</div>
    <div class="box original">&amp;nbsp;</div>
  </div>

  <pre>
transform: scale(1.7);
transform-origin: 0 0;
  </pre>

  <div class="example">
    <div class="box box8">&amp;nbsp;</div>
    <div class="box original">&amp;nbsp;</div>
  </div>

  <pre>
transform: scale(1.7);
transform-origin: 100% -30%;
  </pre>

  <div class="example">
    <div class="box box9">&amp;nbsp;</div>
    <div class="box original">&amp;nbsp;</div>
  </div>

  <pre>
transform: skewX(50deg);
transform-origin: 100% -30%;
  </pre>

  <div class="example">
    <div class="box box10">&amp;nbsp;</div>
    <div class="box original">&amp;nbsp;</div>
  </div>

  <pre>
transform: skewY(50deg);
transform-origin: 100% -30%;
  </pre>
</div>
```

```
.container {
  display: grid;
  grid-template-columns: 200px 100px;
  gap: 20px;
}

.example {
  position: relative;
  margin: 0 2em 4em 5em;
}

.box {
  display: inline-block;
  width: 3em;
  height: 3em;
  border: solid 1px;
  background-color: palegreen;
}

.original {
  position: absolute;
  left: 0;
  opacity: 20%;
}

.box1 {
  transform: none;
}

.box2 {
```

```
  transform: rotate(30deg);
}

.box3 {
  transform: rotate(30deg);
  transform-origin: 0 0;
}

.box4 {
  transform: rotate(30deg);
  transform-origin: 100% 100%;
}

.box5 {
  transform: rotate(30deg);
  transform-origin: -1em -3em;
}

.box6 {
  transform: scale(1.7);
}

.box7 {
  transform: scale(1.7);
  transform-origin: 0 0;
}

.box8 {
  transform: scale(1.7);
  transform-origin: 100% -30%;
}

.box9 {
  transform: skewX(50deg);
  transform-origin: 100% -30%;
}

.box10 {
  transform: skewY(50deg);
  transform-origin: 100% -30%;
}
```

transform-style CSS property

The **`transform-style`** CSS property sets whether children of an element are positioned in the 3D space or are flattened in the plane of the element.

Try it

```
transform-style: flat;
```

```
transform-style: preserve-3d;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all layer" id="example-element">
    <p>Parent</p>
    <div class="numeral"><code>rotate3d(1, 1, 1, 45deg)</code></div>
  </div>
</section>
```

```
.layer {
  background: #623e3f;
  border-radius: 0.75rem;
  color: white;
  transform: perspective(200px) rotateY(30deg);
}

.numeral {
  background-color: #ffba08;
  border-radius: 0.2rem;
  color: black;
  margin: 1rem;
  padding: 0.2rem;
  transform: rotate3d(1, 1, 1, 45deg);
}
```

If flattened, the element's children will not exist on their own in the 3D-space.

As this property is not inherited, it must be set for all non-leaf descendants of the element.

Syntax

```
/* Keyword values */
transform-style: flat;
transform-style: preserve-3d;

/* Global values */
transform-style: inherit;
transform-style: initial;
transform-style: revert;
transform-style: revert-layer;
transform-style: unset;
```

Values

This property is specified as one of the following keyword values:

`flat`

Indicates that the children of the element are lying in the plane of the element itself.

`preserve-3d`

Indicates that the children of the element should be positioned in the 3D-space.

Description

The spec lists some grouping property values, which require the user agent to create a flattened representation of the descendant elements before they can be applied, and therefore force the element to have a used value of `transform-style: flat`, even when `preserve-3d` is specified. These property values include:

- `overflow`: any value other than `visible` or `clip`.
- `opacity`: any value less than `1`.
- `filter`: any value other than `none`.
- `clip`: any value other than `auto`.
- `clip-path`: any value other than `none`.
- `isolation`: used value of `isolate`.
- `mask-image`: any value other than `none`.
- `mask-border-source`: any value other than `none`.
- `mix-blend-mode`: any value other than `normal`.
- `contain`: `paint` and any other property/value combination that causes paint containment. This includes any property that affect the used value of the `contain` property, such as `content-visibility: hidden`.

Formal definition

Initial value	`flat`
Applies to	transformable elements
Inherited	no
Computed value	as specified
Animation type	discrete
Creates stacking context	yes

Formal syntax

```
transform-style =
  flat         |
  preserve-3d
```

This syntax reflects the latest standard as per CSS Transforms Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Transform style demonstration

In this example we have a 3D cube created using transforms. The parent container of the cube faces has `transform-style: preserve-3d` set on it by default, so it is transformed in the 3D space and you can see it as intended.

We also provide a checkbox allowing you to toggle between this, and `transform-style: flat`. In this alternative state, the cube faces are all flattened onto the plane of their parent, and you might not be able to see them at all, depending on the browser you are using.

HTML

```
<section id="example-element">
  <div class="face front">1</div>
  <div class="face back">2</div>
  <div class="face right">3</div>
  <div class="face left">4</div>
  <div class="face top">5</div>
  <div class="face bottom">6</div>
</section>

<div class="checkbox">
  <label for="preserve"><code>preserve-3d</code></label>
  <input type="checkbox" id="preserve" checked />
</div>
```

CSS

```
#example-element {
  margin: 50px;
  width: 100px;
  height: 100px;
  transform-style: preserve-3d;
  transform: rotate3d(1, 1, 1, 30deg);
}

.face {
  display: flex;
  align-items: center;
  justify-content: center;
  width: 100%;
  height: 100%;
  position: absolute;
  backface-visibility: inherit;
  font-size: 60px;
  color: white;
}

.front {
  background: rgb(90 90 90 / 70%);
  transform: translateZ(50px);
```

```
}

.back {
  background: rgb(0 210 0 / 70%);
  transform: rotateY(180deg) translateZ(50px);
}

.right {
  background: rgb(210 0 0 / 70%);
  transform: rotateY(90deg) translateZ(50px);
}

.left {
  background: rgb(0 0 210 / 70%);
  transform: rotateY(-90deg) translateZ(50px);
}

.top {
  background: rgb(210 210 0 / 70%);
  transform: rotateX(90deg) translateZ(50px);
}

.bottom {
  background: rgb(210 0 210 / 70%);
  transform: rotateX(-90deg) translateZ(50px);
}
```

JavaScript

```
const cube = document.getElementById("example-element");
const checkbox = document.getElementById("preserve");

checkbox.addEventListener("change", () => {
  cube.style.transformStyle = checkbox.checked ? "preserve-3d" : "flat";
});
```

transition CSS property

The **`transition`** CSS shorthand property for `transition-property`, `transition-duration`, `transition-timing-function`, `transition-delay`, and `transition-behavior`.

Transitions enable you to define the transition between two states of an element. Different states may be defined using pseudo-classes like `:hover` or `:active` or dynamically set using JavaScript.

Try it

```
transition: margin-right 2s;
```

```
transition: margin-right 2s 0.5s;
```

```
transition: margin-right 2s ease-in-out;
```

```
transition: margin-right 2s ease-in-out 0.5s;
```

```
transition:
  margin-right 2s,
  color 1s;
```

```
transition: all 1s ease-out;
```

```
<section id="default-example">
  <div id="example-element">Hover to see<br />the transition.</div>
</section>
```

```
#example-element {
  background-color: #e4f0f5;
  color: black;
  padding: 1rem;
  border-radius: 0.5rem;
  font: 1em monospace;
  width: 100%;
  transition: margin-right 2s;
}

#default-example:hover > #example-element {
  background-color: #990099;
  color: white;
  margin-right: 40%;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `transition-behavior`
- `transition-delay`
- `transition-duration`
- `transition-property`
- `transition-timing-function`

Syntax

```
/* Apply to 1 property */
/* property name | duration */
```

```
transition: margin-right 4s;

/* property name | duration | delay */
transition: margin-right 4s 1s;

/* property name | duration | easing function */
transition: margin-right 4s ease-in-out;

/* property name | duration | easing function | delay */
transition: margin-right 4s ease-in-out 1s;

/* property name | duration | behavior */
transition: display 4s allow-discrete;

/* Apply to 2 properties */
transition:
  margin-right 4s,
  color 1s;

/* Apply to all changed properties */
transition: all 0.5s ease-out allow-discrete;
transition: 200ms linear 50ms;

/* Global values */
transition: inherit;
transition: initial;
transition: revert;
transition: revert-layer;
transition: unset;
```

The `transition` property value is specified as one of the following:

- The special value `none`, which specifies that no transitions will occur on this element. This is the default value.
- One or more single-property transitions, separated by commas.

Each single-property transition describes the transition that should be applied to a single property or all properties. It includes:

- zero or one value representing the property or properties to which the transition should apply. This can be set as:
  - A `<custom-ident>` representing a single property.
  - The special value `all`, which specifies that the transition will be applied to all properties that change as the element changes state.
  - No value, in which case a value of `all` will be inferred and the specified transition will still apply to all changing properties.
- zero or one `<easing-function>` value representing the easing function to use
- zero, one, or two `<time>` values. The first value that can be parsed as a time is assigned to the `transition-duration`, and the second value that can be parsed as a time is assigned to `transition-delay`.
- zero or one value declaring whether to start transitions for properties whose animation behavior is discrete. The value, if present, is either the keyword `allow-discrete` or the keyword `normal`.

If you specify `all` as the transition property for one single-property transition, but then specify subsequent single-property transitions with `<custom-ident>` values, those subsequent transitions will override the first one. For example:

```
transition:
  all 200ms,
  opacity 400ms;
```

In this case, all the properties that change as the element changes state will transition with a duration of 200ms except for `opacity`, which will take 400ms to transition.

See how things are handled when lists of property values aren't the same length. In short, extra transition descriptions beyond the number of properties actually being animated are ignored.

Formal definition

Initial value	as each of the properties of the shorthand: • `transition-delay`: `0s` • `transition-duration`: `0s` • `transition-property`: `all` • `transition-timing-function`: `ease` • `transition-behavior`: `normal`
Applies to	all elements, `::before` and `::after` pseudo-elements
Inherited	no
Computed value	as each of the properties of the shorthand: • `transition-delay`: as specified • `transition-duration`: as specified • `transition-property`: as specified • `transition-timing-function`: as specified • `transition-behavior`: as specified
Animation type	Not animatable

Formal syntax

```
transition =
  <single-transition>#

<single-transition> =
  [ none | <single-transition-property> ]  ||
  <time>                                   ||
  <easing-function>                        ||
  <time>                                   ||
  <transition-behavior-value>

<single-transition-property> =
  all             |
  <custom-ident>

<easing-function> =
  <linear-easing-function>        |
  <cubic-bezier-easing-function>  |
```

```
  <step-easing-function>

<transition-behavior-value> =
  normal          |
  allow-discrete

<linear-easing-function> =
  linear      |
  <linear()>

<cubic-bezier-easing-function> =
  ease              |
  ease-in           |
  ease-out          |
  ease-in-out       |
  <cubic-bezier()>

<step-easing-function> =
  step-start  |
  step-end    |
  <steps()>

<linear()> =
  linear( [ <number> && <percentage>{0,2} ]# )

<cubic-bezier()> =
  cubic-bezier( [ <number [0,1]> , <number> ]#{2} )

<steps()> =
  steps( <integer> , <step-position>? )

<integer> =
  <number-token>

<step-position> =
  jump-start  |
  jump-end    |
  jump-none   |
  jump-both   |
  start       |
  end
```

This syntax reflects the latest standard as per CSS Easing Functions Level 2, CSS Transitions Module Level 1, CSS Transitions Module Level 2, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

In this example, when the user hovers over the element, there is a half-second (`500ms`) delay before a two-second `background-color` transition occurs.

HTML

```
<a class="target">Hover over me</a>
```

CSS

We include two `<time>` values. In the `transition` shorthand, the first `<time>` value is the `transition-duration`. The second time value is the `transition-delay`. Both default to `0s` if omitted.

```
.target {
  font-size: 2rem;
  background-color: palegoldenrod;
  transition: background-color 2s 500ms;
}

.target:hover {
  background-color: darkorange;
}
```

See also

- CSS transitions module
- Using CSS transitions
- `TransitionEvent`

transition-behavior CSS property

The **`transition-behavior`** CSS property specifies whether transitions will be started for properties whose animation behavior is discrete.

Syntax

```
/* Keyword values */
transition-behavior: allow-discrete;
transition-behavior: normal;

/* Global values */
transition-behavior: inherit;
transition-behavior: initial;
transition-behavior: revert;
transition-behavior: revert-layer;
transition-behavior: unset;
```

Values

`allow-discrete`

Transitions will be started on the element for discrete animated properties.

`normal`

Transitions will *not* be started on the element for discrete animated properties.

Description

The `transition-behavior` property is only relevant when used in conjunction with other transition properties, notably `transition-property` and `transition-duration`, as no transition occurs if no properties are animated over a non-zero duration of time.

```
.card {
  transition-property: opacity, display;
  transition-duration: 0.25s;
  transition-behavior: allow-discrete;
}

.card.fade-out {
  opacity: 0;
  display: none;
}
```

The `transition-behavior` value can be included as part of a shorthand `transition` declaration. When included in the shorthand, when using or defaulting to all properties, the `allow-discrete` value has no impact on regular animatable properties. The following CSS is equivalent to the longhand declarations above:

```
.card {
  transition: all 0.25s;
  transition: all 0.25s allow-discrete;
}

.card.fade-out {
  opacity: 0;
  display: none;
}
```

In the above snippet we include the `transition` property twice. The first instance does not include the `allow-discrete` value — this provides cross-browser support, ensuring the card's other properties still transition in browsers that don't support `transition-behavior`.

Discrete animation behavior

Discrete-animated properties generally flip between two values 50% through animating between the two.

There is an exception, however, which is when animating to or from `display: none` or `content-visibility: hidden`. In this case, the browser will flip between the two values so that the transitioned content is shown for the entire animation duration.

So for example:

- When animating `display` from `none` to `block` (or another visible `display` value), the value will flip to `block` at `0%` of the animation duration so it is visible throughout.
- When animating `display` from `block` (or another visible `display` value) to `none`, the value will flip to `none` at `100%` of the animation duration so it is visible throughout.

Formal definition

Initial value	`normal`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
transition-behavior =
  <transition-behavior-value>#

<transition-behavior-value> =
  normal          |
  allow-discrete
```

This syntax reflects the latest standard as per CSS Transitions Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Transitioning a popover

In this example, a popover is animated as it transitions from hidden to shown and back again.

HTML

The HTML contains a `<div>` element declared as a popover using the popover attribute, and a `<button>` element designated as the popover's display control using its popovertarget attribute.

```
<button popovertarget="mypopover">Show the popover</button>
<div popover="auto" id="mypopover">I'm a Popover! I should animate.</div>
```

CSS

```
html {
  font-family: "Helvetica", "Arial", sans-serif;
}

[popover] {
  font-size: 1.2rem;
  padding: 10px;
}
```

```
[popover]:popover-open {
  opacity: 1;
  transform: scaleX(1);
}

[popover] {
  /* Final state of the exit animation */
  opacity: 0;
  transform: scaleX(0);
```

```
  transition-property: opacity, transform, overlay, display;
  transition-duration: 0.7s;
  transition-behavior: allow-discrete;
  /* Using the shorthand transition property, we could write:
    transition:
      opacity 0.7s,
      transform 0.7s,
      overlay 0.7s allow-discrete,
      display 0.7s allow-discrete;

    or even:
    transition: all 0.7s allow-discrete;
  */
}

/* Needs to be included after the previous [popover]:popover-open
   rule to take effect, as the specificity is the same */
@starting-style {
  [popover]:popover-open {
    opacity: 0;
    transform: scaleX(0);
  }
}
```

The two properties we want to animate are `opacity` and `transform`: we want the popover to fade in and out while growing and shrinking in the horizontal direction. We set a starting state for these properties on the default hidden state of the popover element (selected via `[popover]`), and an end state on the open state of the popover (selected via the `:popover-open` pseudo-class). We then set a `transition` property to animate between the two.

Because the animated element is being promoted to the top layer when shown and removed from the top layer when hidden — which also means that its hidden state has `display: none` set on it — the following properties are added to the list of transitioned elements to get the animation working in both directions. In both cases, `transition-behavior: allow-discrete` is set in the shorthand to enable discrete animation.

- `display`: Required so that the animated element is visible (set to `display: block`) throughout both the entry and exit animation. Without this, the exit animation would not be visible; in effect, the popover would just disappear.
- `overlay`: Required to make sure that the removal of the element from the top layer is deferred until the animation has been completed. This doesn't make a huge difference for basic animations such as this one, but in more complex cases not doing this can result in the element being removed from the overlay too quickly, meaning the animation is not smooth or effective.

In addition, a starting state for the animation is set inside the `@starting-style` at-rule. This is needed to avoid unexpected behavior. By default transitions are not triggered on elements' first style updates, or when the `display` type changes from `none` to another type. `@starting-style` allows you to override that default in a specific controlled fashion. Without this, the entry animation would not occur and the popover would just appear.

Result

The code renders as follows:

> **Note:** Because popovers change from `display: none` to `display: block` each time they are shown, the popover transitions from its `@starting-style` styles to its `[popover]:popover-open` styles every time the entry transition occurs. When the popover closes, it transitions from its `[popover]:popover-open` state to the default `[popover]` state.
>
> It is possible for the style transition on entry and exit to be different in such cases. See our Demonstration of when starting styles are used example for a proof of this.

- `@starting-style`
- CSS transitions module
- Four new CSS features for smooth entry and exit animations on developer.chrome.com (2023)

transition-delay CSS property

The **`transition-delay`** CSS property specifies the duration to wait before starting a property's transition effect when its value changes.

Try it

```
transition-delay: 250ms;
transition-property: margin-right;
```

```
transition-delay: 1s;
transition-property: background-color;
```

```
transition-delay: 1s;
transition-property: margin-right, color;
```

```
transition-delay: 1s, 250ms;
transition-property: margin-right, color;
```

```
<section id="default-example">
  <div id="example-element">Hover to see<br />the transition.</div>
</section>
```

```
#example-element {
  background-color: #e4f0f5;
  color: black;
  padding: 1rem;
  border-radius: 0.5rem;
  font: 1em monospace;
  width: 100%;
  transition: margin-right 2s;
}

#default-example:hover > #example-element {
  background-color: #990099;
  color: white;
  margin-right: 40%;
}
```

The delay may be zero, positive, or negative:

- A value of `0s` (or `0ms`) will begin the transition effect immediately.
- A positive value will delay the start of the transition effect for the given length of time.
- A negative value will begin the transition effect immediately, and partway through the effect. In other words, the effect will be animated as if it had already been running for the given length of time.

You may specify multiple delays, which is useful when transitioning multiple properties. Each delay will be applied to the corresponding property as specified by the `transition-property` property, which acts as a master list. If there are fewer delays specified than in the master list, the list of delay values will be repeated until there are enough. If there are more delays, the list of delay values will be truncated to match the number of properties. In both cases, the CSS declaration remains valid.

Syntax

```
/* <time> values */
transition-delay: 3s;
transition-delay: 2s, 4ms;

/* Global values */
transition-delay: inherit;
transition-delay: initial;
transition-delay: revert;
transition-delay: revert-layer;
transition-delay: unset;
```

Values

`<time>`

Denotes the amount of time to wait between a property's value changing and the start of the transition effect.

Formal definition

Initial value	`0s`
Applies to	all elements, `::before` and `::after` pseudo-elements
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
transition-delay =
  <time>#
```

This syntax reflects the latest standard as per CSS Transitions Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Example showing different delays

HTML

```
<div class="box delay-1">0.5 seconds</div>

<div class="box delay-2">2 seconds</div>

<div class="box delay-3">4 seconds</div>

<button id="change">Change</button>
```

CSS

```
.box {
  margin: 20px;
  padding: 10px;
  display: inline-block;
  width: 100px;
  height: 100px;
  background-color: red;
  font-size: 18px;
  transition-property: background-color, font-size, transform, color;
  transition-timing-function: ease-in-out;
  transition-duration: 3s;
}

.transformed-state {
  transform: rotate(270deg);
  background-color: blue;
  color: yellow;
  font-size: 12px;
  transition-property: background-color, font-size, transform, color;
  transition-timing-function: ease-in-out;
  transition-duration: 3s;
}

.delay-1 {
  transition-delay: 0.5s;
}

.delay-2 {
  transition-delay: 2s;
}

.delay-3 {
  transition-delay: 4s;
}
```

JavaScript

```
function change() {
  const elements = document.querySelectorAll("div.box");
  for (const element of elements) {
    element.classList.toggle("transformed-state");
  }
}

const changeButton = document.querySelector("#change");
changeButton.addEventListener("click", change);
```

- `TransitionEvent` API

transition-duration CSS property

The **`transition-duration`** CSS property sets the length of time a transition animation should take to complete. By default, the value is `0s`, meaning that no animation will occur.

You may specify multiple durations; each duration will be applied to the corresponding property as specified by the `transition-property` property, which acts as a master list. If the number of specified durations is less than in the master list, the user agent repeats the list of durations. If the number of specified durations is more than in the master list, the list is truncated to the right size. In both the cases, the CSS declaration stays valid.

Try it

```
transition-duration: 500ms;
transition-property: margin-right;
```

```
transition-duration: 2s;
transition-property: background-color;
```

```
transition-duration: 2s;
transition-property: margin-right, color;
```

```
transition-duration: 3s, 1s;
transition-property: margin-right, color;
```

```
<section id="default-example">
  <div id="example-element">Hover to see<br />the transition.</div>
</section>
```

```
#example-element {
  background-color: #e4f0f5;
  color: black;
  padding: 1rem;
  border-radius: 0.5rem;
  font: 1em monospace;
  width: 100%;
  transition: margin-right 2s;
}

#default-example:hover > #example-element {
  background-color: #990099;
  color: white;
  margin-right: 40%;
}
```

Syntax

```
/* <time> values */
transition-duration: 6s;
transition-duration: 120ms;
transition-duration: 1s, 15s;
transition-duration: 10s, 30s, 230ms;

/* Global values */
transition-duration: inherit;
transition-duration: initial;
transition-duration: revert;
transition-duration: revert-layer;
transition-duration: unset;
```

Values

`<time>`

Is a `<time>` denoting the amount of time the transition from the old value of a property to the new value should take. A time of `0s` indicates that no transition will happen, that is the switch between the two states will be instantaneous. A negative value for the time renders the declaration invalid.

Formal definition

Initial value	`0s`
Applies to	all elements, `::before` and `::after` pseudo-elements
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
transition-duration =
  <time [0s,∞]>#
```

This syntax reflects the latest standard as per CSS Transitions Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Example showing different durations

HTML

```
<div class="box duration-1">0.5 seconds</div>

<div class="box duration-2">2 seconds</div>

<div class="box duration-3">4 seconds</div>

<button id="change">Change</button>
```

CSS

```
.box {
  margin: 20px;
  padding: 10px;
  display: inline-block;
  width: 100px;
  height: 100px;
  background-color: red;
  font-size: 18px;
  transition-property: background-color, font-size, transform, color;
  transition-timing-function: ease-in-out;
}

.transformed-state {
  transform: rotate(270deg);
  background-color: blue;
  color: yellow;
  font-size: 12px;
  transition-property: background-color, font-size, transform, color;
  transition-timing-function: ease-in-out;
}

.duration-1 {
  transition-duration: 0.5s;
}

.duration-2 {
  transition-duration: 2s;
}

.duration-3 {
  transition-duration: 4s;
}
```

JavaScript

```
function change() {
  const elements = document.querySelectorAll("div.box");
  for (const element of elements) {
    element.classList.toggle("transformed-state");
  }
}

const changeButton = document.querySelector("#change");
changeButton.addEventListener("click", change);
```

transition-property CSS property

The **`transition-property`** CSS property sets the CSS properties to which a transition effect should be applied.

If you specify a shorthand property (e.g., `background`), all of its longhand sub-properties that can be animated will be.

Try it

```
transition-property: margin-right;
```

```
transition-property: margin-right, color;
```

```
transition-property: all;
```

```
transition-property: none;
```

```
<section id="default-example">
  <div id="example-element">Hover to see<br />the transition.</div>
</section>
```

```
#example-element {
  background-color: #e4f0f5;
  color: black;
  padding: 1rem;
```

```
  border-radius: 0.5rem;
  font: 1em monospace;
  width: 100%;
  transition: margin-right 2s;
}

#default-example:hover > #example-element {
  background-color: #990099;
  color: white;
  margin-right: 40%;
}
```

Syntax

```
/* Keyword values */
transition-property: none;
transition-property: all;

/* <custom-ident> values */
transition-property: test_05;
transition-property: -specific;
transition-property: sliding-vertically;

/* Multiple values */
transition-property: test1, animation4;
transition-property: all, height, color;
transition-property:
  all,
  -moz-specific,
  sliding;

/* Global values */
transition-property: inherit;
transition-property: initial;
transition-property: revert;
transition-property: revert-layer;
transition-property: unset;
```

Values

`none`

No properties will transition.

`all`

All properties that can transition will.

`<custom-ident>`

A string identifying the property to which a transition effect should be applied when its value changes.

Formal definition

Initial value	`all`
Applies to	all elements, `::before` and `::after` pseudo-elements
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
transition-property =
  none                        |
  <single-transition-property>#

<single-transition-property> =
  all             |
  <custom-ident>
```

This syntax reflects the latest standard as per CSS Transitions Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

When the button is hovered or focused, it undergoes a one-second color transition; the `transition-property` is `background-color`.

HTML

```
<button class="target">Focus me!</button>
```

CSS

```
html {
  height: 100vh;
}

button {
  font-size: 1.4rem;
  padding: 10px 20px;
  border: 1px solid #cccccc;
  border-radius: 10px;
  outline: none;
}
```

```
.target {
  transition-property: background-color;
  transition-duration: 1s;
```

```
  background-color: #cccccc;
}

.target:hover,
.target:focus {
  background-color: #eeeeee;
}
```

See our Using CSS transitions guide for more `transition-property` examples.

- `transition-delay`
- `TransitionEvent`

transition-timing-function CSS property

The **`transition-timing-function`** CSS property sets how intermediate values are calculated for CSS properties being affected by a transition effect.

Try it

```
transition-timing-function: linear;
```

```
transition-timing-function: ease-in;
```

```
transition-timing-function: steps(6, end);
```

```
transition-timing-function: cubic-bezier(0.29, 1.01, 1, -0.68);
```

```
<section id="default-example">
  <div id="example-element">Hover to see<br />the transition.</div>
</section>
```

```
#example-element {
  background-color: #e4f0f5;
  color: black;
  padding: 1rem;
  border-radius: 0.5rem;
  font: 1em monospace;
  width: 100%;
  transition: margin-right 2s;
}

#default-example:hover > #example-element {
  background-color: #990099;
  color: white;
  margin-right: 40%;
}
```

This, in essence, lets you establish an acceleration curve so that the speed of the transition can vary over its duration.

This acceleration curve is defined using one `<easing-function>` for each property to be transitioned.

You may specify multiple easing functions; each one will be applied to the corresponding property as specified by the `transition-property` property, which acts as a `transition-property` list. If there are fewer easing functions specified than in the `transition-property` list, the user agent must calculate which value is used by repeating the list of values until there is one for each transition property. If there are more easing functions, the list is truncated to the right size. In both cases, the CSS declaration stays valid.

Syntax

```
/* Keyword values */
transition-timing-function: ease;
transition-timing-function: ease-in;
transition-timing-function: ease-out;
transition-timing-function: ease-in-out;
transition-timing-function: linear;
transition-timing-function: step-start;
transition-timing-function: step-end;

/* Function values */
transition-timing-function: steps(4, jump-end);
transition-timing-function: cubic-bezier(0.1, 0.7, 1, 0.1);

/* Steps Function keywords */
transition-timing-function: steps(4, jump-start);
transition-timing-function: steps(10, jump-end);
transition-timing-function: steps(20, jump-none);
transition-timing-function: steps(5, jump-both);
transition-timing-function: steps(6, start);
transition-timing-function: steps(8, end);

/* Multiple easing functions */
transition-timing-function: ease, step-start, cubic-bezier(0.1, 0.7, 1, 0.1);

/* Global values */
transition-timing-function: inherit;
transition-timing-function: initial;
transition-timing-function: revert;
transition-timing-function: revert-layer;
transition-timing-function: unset;
```

Values

`<easing-function>`

Each `<easing-function>` represents the easing function to link to the corresponding property to transition, as defined in `transition-property`.

The non-step keyword values (ease, linear, ease-in-out, etc.) each represent cubic Bézier curve with fixed four point values, with the cubic-bezier() function value allowing for a non-predefined value. The step easing functions divide the input time into a specified number of intervals that are equal in length. It is defined by a number of steps and a step position.

`ease`

Equal to `cubic-bezier(0.25, 0.1, 0.25, 1.0)`, the default value, increases in velocity towards the middle of the transition, slowing back down at the end.

`linear`

Equal to `cubic-bezier(0.0, 0.0, 1.0, 1.0)`, transitions at an even speed.

`ease-in`

Equal to `cubic-bezier(0.42, 0, 1.0, 1.0)`, starts off slowly, with the transition speed increasing until complete.

`ease-out`

Equal to `cubic-bezier(0, 0, 0.58, 1.0)`, starts transitioning quickly, slowing down as the transition continues.

`ease-in-out`

Equal to `cubic-bezier(0.42, 0, 0.58, 1.0)`, starts transitioning slowly, speeds up, and then slows down again.

`cubic-bezier(p1, p2, p3, p4)`

An author-defined cubic-Bezier curve, where the p1 and p3 values must be in the range of 0 to 1.

`steps(n, <jump-term>)`

Displays the transition along *n stops along the transition, displaying each stop for* equal lengths of time. For example, if *n* is 5, there are 5 steps. Whether the transition holds temporarily at 0%, 20%, 40%, 60% and 80%, on the 20%, 40%, 60%, 80% and 100%, or makes 5 stops between the 0% and 100% along the transition, or makes 5 stops including the 0% and 100% marks (on the 0%, 25%, 50%, 75%, and 100%) depends on which of the following jump terms is used:

`jump-start`

Denotes a left-continuous function, so that the first jump happens when the transition begins;

`jump-end`

Denotes a right-continuous function, so that the last jump happens when the animation ends;

`jump-none`

There is no jump on either end. Instead, holding at both the 0% mark and the 100% mark, each for 1/n of the duration

`jump-both`

Includes pauses at both the 0% and 100% marks, effectively adding a step during the transition time.

`start`

Same as `jump-start`.

`end`

Same as `jump-end`.

`step-start`

Equal to `steps(1, jump-start)`

`step-end`

Equal to `steps(1, jump-end)`

Accessibility

Some animations can be helpful such as to guide users to understand what actions are expected, to show relationships within the user interface, and to inform users as to what actions have occurred. Animations can help reduce cognitive load, prevent change blindness, and establish better recall in spatial relationships. However, some animations can be problematic for people with cognitive concerns such as Attention Deficit Hyperactivity Disorder (ADHD) and certain kinds of motion can be a trigger for Vestibular disorders, epilepsy, and migraine and Scotopic sensitivity.

Consider providing a mechanism for pausing or disabling animation, as well as using the Reduced Motion Media Query (or equivalent User Agent client hint `Sec-CH-Prefers-Reduced-Motion`) to create a complementary experience for users who have expressed a preference for less animation.

Formal definition

Initial value	`ease`
Applies to	all elements, `::before` and `::after` pseudo-elements
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
transition-timing-function =
  <easing-function>#

<easing-function> =
  <linear-easing-function>        |
  <cubic-bezier-easing-function>  |
  <step-easing-function>

<linear-easing-function> =
  linear      |
  <linear()>

<cubic-bezier-easing-function> =
  ease              |
  ease-in           |
```

```
  ease-out          |
  ease-in-out       |
  <cubic-bezier()>

<step-easing-function> =
  step-start  |
  step-end    |
  <steps()>

<linear()> =
  linear( [ <number> && <percentage>{0,2} ]# )

<cubic-bezier()> =
  cubic-bezier( [ <number [0,1]> , <number> ]#{2} )

<steps()> =
  steps( <integer> , <step-position>? )

<integer> =
  <number-token>

<step-position> =
  jump-start  |
  jump-end    |
  jump-none   |
  jump-both   |
  start       |
  end
```

This syntax reflects the latest standard as per CSS Easing Functions Level 2, CSS Transitions Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Cubic-Bezier examples

```
<div class="parent">
  <div class="ease">ease</div>
  <div class="ease-in">ease-in</div>
  <div class="ease-out">ease-out</div>
  <div class="ease-in-out">ease-in-out</div>
  <div class="linear">linear</div>
  <div class="cb">cubic-bezier(0.2,-2,0.8,2)</div>
</div>
```

```
.parent {
}
.parent > div[class] {
  width: 12em;
  min-width: 12em;
  margin-bottom: 4px;
  background-color: black;
  border: 1px solid red;
  color: white;
  transition-property: all;
  transition-duration: 7s;
}
.parent > div.box1 {
  width: 90vw;
  min-width: 24em;
  background-color: magenta;
  color: yellow;
  border: 1px solid orange;
  transition-property: all;
  transition-duration: 2s;
}
```

```
function updateTransition() {
  const els = document.querySelectorAll(".parent > div[class]");
  for (const el of els) {
    el.classList.toggle("box1");
  }
}

const intervalID = setInterval(updateTransition, 10000);
```

```
.ease {
  transition-timing-function: ease;
}
.ease-in {
  transition-timing-function: ease-in;
}
.ease-out {
  transition-timing-function: ease-out;
}
.ease-in-out {
  transition-timing-function: ease-in-out;
}
.linear {
  transition-timing-function: linear;
}
.cb {
  transition-timing-function: cubic-bezier(0.2, -2, 0.8, 2);
}
```

Step examples

```
<div class="parent">
  <div class="jump-start">jump-start</div>
  <div class="jump-end">jump-end</div>
  <div class="jump-both">jump-both</div>
  <div class="jump-none">jump-none</div>
  <div class="step-start">step-start</div>
```

```
  <div class="step-end">step-end</div>
</div>
```

```
.parent {
}
.parent > div[class] {
  width: 12em;
  min-width: 12em;
  margin-bottom: 4px;
  background-color: black;
  border: 1px solid red;
  color: white;
  transition-property: all;
  transition-duration: 7s;
}
.parent > div.box1 {
  width: 90vw;
  min-width: 24em;
  background-color: magenta;
  color: yellow;
  border: 1px solid orange;
  transition-property: all;
  transition-duration: 2s;
}
```

```
function updateTransition() {
  const els = document.querySelectorAll(".parent > div[class]");
  for (const el of els) {
    el.classList.toggle("box1");
  }
}

const intervalID = setInterval(updateTransition, 10000);
```

```
.jump-start {
  transition-timing-function: steps(5, jump-start);
}
.jump-end {
  transition-timing-function: steps(5, jump-end);
}
.jump-none {
  transition-timing-function: steps(5, jump-none);
}
.jump-both {
  transition-timing-function: steps(5, jump-both);
}
.step-start {
  transition-timing-function: step-start;
}
.step-end {
  transition-timing-function: step-end;
}
```

translate CSS property

The **`translate`** CSS property allows you to specify translation transforms individually and independently of the `transform` property. This maps better to typical user interface usage, and saves having to remember the exact order of transform functions to specify in the `transform` value.

Try it

```
translate: none;
```

```
translate: 40px;
```

```
translate: 50% -40%;
```

```
translate: 20px 4rem;
```

```
translate: 20px 4rem 150px;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    <div class="face front">1</div>
    <div class="face back">2</div>
    <div class="face right">3</div>
    <div class="face left">4</div>
    <div class="face top">5</div>
    <div class="face bottom">6</div>
  </div>
</section>
```

```
#default-example {
  background: linear-gradient(skyblue, khaki);
  perspective: 800px;
  perspective-origin: 150% 150%;
```

```
}

#example-element {
  width: 100px;
  height: 100px;
  perspective: 550px;
  transform-style: preserve-3d;
}

.face {
  display: flex;
  align-items: center;
  justify-content: center;
  width: 100%;
  height: 100%;
  position: absolute;
  backface-visibility: inherit;
  font-size: 60px;
  color: white;
}

.front {
  background: rgb(90 90 90 / 0.7);
  transform: translateZ(50px);
}

.back {
  background: rgb(0 210 0 / 0.7);
  transform: rotateY(180deg) translateZ(50px);
}

.right {
  background: rgb(210 0 0 / 0.7);
  transform: rotateY(90deg) translateZ(50px);
}

.left {
  background: rgb(0 0 210 / 0.7);
  transform: rotateY(-90deg) translateZ(50px);
}

.top {
  background: rgb(210 210 0 / 0.7);
  transform: rotateX(90deg) translateZ(50px);
}

.bottom {
  background: rgb(210 0 210 / 0.7);
  transform: rotateX(-90deg) translateZ(50px);
}
```

Syntax

```
/* Keyword value */
translate: none;

/* Single values */
translate: 100px;
translate: 50%;

/* Two values */
translate: 100px 200px;
translate: 50% 105px;

/* Three values */
translate: 50% 105px 5rem;

/* Global values */
translate: inherit;
translate: initial;
translate: revert;
translate: revert-layer;
translate: unset;
```

Values

Single `<length-percentage>` value

A `<length>` or `<percentage>` that specifies a translation along the X-axis. Equivalent to a `translate()` (2D translation) function with a single value specified.

Two `<length-percentage>` values

Two `<length>` or `<percentage>` that specify the X and Y axis translation values (respectively) of a 2D translation. Equivalent to a `translate()` (2D translation) function with two values specified.

Three values

Two `<length-percentage>` and single `<length>` values that specify the X, Y, and Z axis translation values (respectively) of a 3D translation. Equivalent to a `translate3d()` (3D translation) function.

`none`

Specifies that no translation should be applied.

Formal definition

Initial value	none
Applies to	transformable elements
Inherited	no
Percentages	refer to the size of bounding box
Computed value	as specified, but with relative lengths converted into absolute lengths

Animation type	a transform
Creates stacking context	yes

Formal syntax

```
translate =
  none                                          |
  <length-percentage> [ <length-percentage> <length>? ]?

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Transforms Module Level 2, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Translating an element on hover

This example shows how to use the `translate` property to move an element in three axes. The first box is moved along the X axis and the second box is moved along the X and Y axes. The third box is moved along the X, Y and Z axes and has the appearance of moving toward the viewer because of the addition of `perspective` to the parent element.

HTML

```
<div class="wrapper">
  <div id="box1">translate X</div>
  <div id="box2">translate X,Y</div>
  <div id="box3">translate X,Y,Z</div>
</div>
```

CSS

```
.wrapper {
  perspective: 100px;
  display: inline-flex;
  gap: 1em;
}
.wrapper > div {
  width: 7em;
  line-height: 7em;
  text-align: center;
  transition: 0.5s ease-in-out;
  border: 3px dotted;
}
#box1:hover {
  translate: 20px;
}

#box2:hover {
  translate: 20px 20px;
}

#box3:hover {
  translate: 5px 5px 30px;
}
```

Result

- `rotate`
- `transform`

Note: skew is not an independent transform value

trigger-scope CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`trigger-scope`** CSS property can be used to limit the scope of a scroll-triggered animation trigger name to a document subtree.

Syntax

```
/* Keywords */
trigger-scope: none;
trigger-scope: all;

/* <dashed-ident> */
trigger-scope: --my-trigger;

/* Multiple values */
trigger-scope: --my-trigger, --another-trigger;

/* Global values */
trigger-scope: inherit;
trigger-scope: initial;
trigger-scope: revert;
trigger-scope: revert-layer;
trigger-scope: unset;
```

Values

Specified as `none`, `all`, or a comma-separated list of `<dashed-ident>` values:

`none`

Specifies that no trigger scoping is set. This is the default value.

`all`

Sets the scope so that *any* `timeline-trigger-name` values set in the subtree can only be associated with animated elements in the same subtree.

`<dashed-ident>`

A trigger name. Sets the scope so that the specified `timeline-trigger-name` values, when set in the subtree, can only be associated with animated elements in the same subtree.

Description

The `trigger-scope` property is used to limit trigger scope to specific element subtrees in scroll-triggered animations.

Trigger names, defined with the `timeline-trigger-name` property, are global by default. When an animated element is associated with a trigger name via its `animation-trigger` property, the browser determines what its trigger element is as follows:

1. It walks up the animated element's ancestor tree until it finds an ancestor with a `timeline-trigger-name` set that is the same as the name referenced in its `animation-trigger` property value. If the animated element is also the trigger, it will be found instantly.
2. If it can't find a suitable ancestor trigger, it will use the *last* element in the HTML source order with that `timeline-trigger-name` value.
3. If it can't find an element anywhere in the DOM with that `timeline-trigger-name` value, the animated element won't be scroll-triggered; having no associated timeline, the animation will not happen.

If multiple elements define triggers with the same trigger name, only the last one in the document tree will be used as the trigger for animated elements referencing that trigger name in their `animation-trigger` properties. This is likely not the desired behavior.

The `trigger-scope` property can solve this problem by limiting the scope of a trigger name to a subtree of the document. This means the trigger is visible only to elements within the same subtree and has no effect on elements outside the subtree. When `trigger-scope` is set on an element, and that element or its descendants are defined as triggers, animated elements are associated with those triggers only if they are within the same subtree.

Which trigger names are included in the scope depends on the `trigger-scope` value set:

- `trigger-scope: all` means that all trigger names are included in the scope.
- `trigger-scope: --my-trigger, --another-trigger` means that only triggers with names of `--my-trigger` and/or `--another-trigger` are included in the scope.
- `trigger-scope: none` means that no trigger scoping is set on the element.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
trigger-scope =
  none            |
  all             |
  <dashed-ident>#
```

This syntax reflects the latest standard as per Animation Triggers. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates using the `trigger-scope` property to limit the scope of an `animation-trigger-name`.

HTML

We include three `<section>` elements, each containing two `<div>` elements: an `.animated` element and a `.trigger` element.

Most of the HTML, including a checkbox toggle that enables or disables the `trigger-scope` property, has been hidden for brevity.

```
<section id="one">
  <div class="animated"></div>
  ...
  <div class="trigger">Trigger for first animation</div>
  ...
</section>
<section id="two">
  <div class="animated"></div>
  ...
  <div class="trigger">Trigger for second animation</div>
  ...
</section>
<section id="three">
  <div class="animated"></div>
  ...
  <div class="trigger">Trigger for third animation</div>
  ...
</section>
```

```
<section id="one">
  <div class="animated"></div>

  <p>
    Fusce dictum ex quis ipsum consectetur placerat. Cras sed lectus ex. Quisque
    purus dolor, vulputate ac mi eget, commodo varius odio. Suspendisse faucibus
    ipsum vel libero finibus, in placerat nibh congue. Sed iaculis, metus et
    euismod posuere, mi diam vestibulum felis, ac vulputate eros ipsum id justo.
    Etiam a tincidunt purus. Maecenas semper sed enim at blandit. Aenean ut
    sagittis lorem, eget gravida purus. Phasellus eleifend, lectus nec pulvinar
    facilisis, dui dolor feugiat odio, iaculis tempor felis est non tortor. In

  </p>
</section>
<label for="trigger-scope"
  >Set <code>trigger-scope</code> to <code>none</code>
  <input id="trigger-scope" type="checkbox" />
</label>
```

CSS

We define three `@keyframes` animations. Each will be applied to a different `.animated` element.

```
@keyframes fade-in {
  from {
    opacity: 1;
  }

  to {
    opacity: 0;
  }
}

@keyframes color-cycle {
```

```
  from {
    background: red;
    scale: 1;
  }

  to {
    background: blue;
    scale: 2;
  }
}

@keyframes move-up-down {
  25% {
    translate: 0 -20px;
  }

  75% {
    translate: 0 20px;
  }
}
```

```
body {
  width: 60%;
  margin: 0 auto;
  font-size: 1.3rem;
  font-family: "Helvetica", "Arial";
}

p {
  line-height: 1.5;
}

section {
  background: #eeeeee;
  padding: 10px 20px;
  margin-top: 20px;
}

.animated {
  width: 50px;
  height: 50px;
  background: red;
  border: 5px solid black;
}

label {
  position: fixed;
  bottom: 2px;
  right: 2px;
  padding: 5px;
  border: 2px solid black;
  background: white;
}
```

The animated elements' `position` is set to `fixed`, positioning them near the top of the scrollport to keep them visible at all times.

Each animated element has the same `animation-trigger` value: their animations are triggered by a trigger with a `timeline-trigger-name` of `--t`, and the animations will play when their trigger activates and then reset when their trigger deactivates.

```
.animated {
  position: fixed;
  top: 10px;
  animation-trigger: --t play reset;
}
```

Using the `animation` shorthand, each `.animated` element is given a different `animation-name`. They each also have a different `left` value so that they are not positioned on top of one another.

```
#one .animated {
  animation: fade-in 1s infinite alternate ease-in;
  left: 10px;
}

#two .animated {
  animation: color-cycle 1s infinite alternate linear;
  left: 110px;
}

#three .animated {
  animation: move-up-down 2s infinite linear;
  left: 210px;
}
```

The `.trigger` elements are set as triggers for the `.animated` elements by giving them a `timeline-trigger-name` value that references the same identifier, `--t`, and a `timeline-trigger-source` of `view()`. We set the `timeline-trigger-activation-range` to `contain` and let the `timeline-trigger-active-range` default to the same value. As a result, activation and deactivation occur while the trigger is still visible. We also set some rudimentary styles to make them stand out from the rest of the text.

```
.trigger {
  timeline-trigger-name: --t;
  timeline-trigger-source: view();
  timeline-trigger-activation-range: contain;

  padding: 10px;
  border: 2px solid black;
  background: black;
  color: white;
}
```

Finally, we set the `trigger-scope` on the `<section>` element to `all`. This limits the effect of each trigger named `--t` to their `<section>` ancestor.

```
section {
  trigger-scope: all;
}
```

```
:has(:checked) section {
  trigger-scope: none;
}

@supports not (trigger-scope: all) {
  body::before {
    content: "Your browser does not support the trigger-scope property.";
    background-color: wheat;
    text-align: center;
    padding: 1rem 0;

    z-index: 1;
    position: fixed;
    inset: 40% 0 auto;
  }
}
```

Result

Scroll down the example. One square animates at a time. This is because each square animates only when the trigger element located in the same scope (the same `<section>`) is visible in the scrollport. Even though the three triggers share the same trigger name, each `.animated` element's animation is triggered by a different trigger.

Now check the checkbox to remove `trigger-scope: all` from the `<section>` elements. Scroll through the content again. None of the squares animate until the third `.trigger` is visible in the scrollport, at which point all of the squares start animating at the same time. Because scoping has been removed, each `.animated` element's animation is activated and deactivated by the last element with `--t` as a `timeline-trigger-name`.

unicode-bidi CSS property

The **`unicode-bidi`** CSS property, together with the `direction` property, determines how bidirectional text in a document is handled. For example, if a block of content contains both left-to-right and right-to-left text, the user-agent uses a complex Unicode algorithm to decide how to display the text. The `unicode-bidi` property overrides this algorithm and allows the developer to control the text embedding.

Try it

```
unicode-bidi: normal;
```

```
unicode-bidi: bidi-override;
```

```
unicode-bidi: plaintext;
```

```
unicode-bidi: isolate-override;
```

```
<section class="default-example" id="default-example">
  <p class="transition-all" id="example-element">
    בְּרֵאשִׁית בָּרָא אֱלֹהִים אֵת הַשָּׁמַיִם וְאֵת הָאָרֶץ.
  </p>
</section>
```

The `unicode-bidi` and `direction` properties are the only properties that are not affected by the `all` shorthand.

> **Warning:** This property is intended for Document Type Definition (DTD) designers. Web designers and similar authors **should not** override it.

Syntax

```
/* Keyword values */
unicode-bidi: normal;
unicode-bidi: embed;
unicode-bidi: isolate;
unicode-bidi: bidi-override;
unicode-bidi: isolate-override;
unicode-bidi: plaintext;

/* Global values */
unicode-bidi: inherit;
unicode-bidi: initial;
unicode-bidi: revert;
unicode-bidi: revert-layer;
unicode-bidi: unset;
```

Values

`normal`

The element does not offer an additional level of embedding with respect to the bidirectional algorithm. For inline elements, implicit reordering works across element boundaries.

`embed`

If the element is inline, this value opens an additional level of embedding with respect to the bidirectional algorithm. The direction of this embedding level is given by the `direction` property.

`bidi-override`

For inline elements this creates an override. For block container elements this creates an override for inline-level descendants not within another block container element. This means that inside the element, reordering is strictly in sequence according to the `direction` property; the implicit part of the bidirectional algorithm is ignored.

`isolate`

This keyword indicates that the element's container directionality should be calculated without considering the content of this element. The element is therefore *isolated* from its siblings. When applying its bidirectional-resolution algorithm, its container element treats it as one or several `U+FFFC Object Replacement Character`, i.e., like an image.

`isolate-override`

This keyword applies the isolation behavior of the `isolate` keyword to the surrounding content and the override behavior of the `bidi-override` keyword to the inner content.

`plaintext`

This keyword makes the elements directionality calculated without considering its parent bidirectional state or the value of the `direction` property. The directionality is calculated using the P2 and P3 rules of the Unicode Bidirectional Algorithm. This value allows the display of data that is already formatted using a tool following the Unicode Bidirectional Algorithm.

Formal definition

Initial value	`normal`
Applies to	all elements, though some values have no effect on non-inline elements
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
unicode-bidi =
  normal           |
  embed            |
  isolate          |
  bidi-override    |
  isolate-override |
  plaintext
```

This syntax reflects the latest standard as per CSS Writing Modes Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

CSS

```
.bible-quote {
  direction: rtl;
  unicode-bidi: embed;
}
```

HTML

```
<div class="bible-quote">A line of text</div>
<div>Another line of text</div>
```

user-modify CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`user-modify`** property has no effect in Firefox. It was originally planned to determine whether or not the content of an element can be edited by a user.

> **Warning:** This property has been replaced by the `contenteditable` attribute.

Syntax

```
/* Keyword values */
user-modify: read-only;
user-modify: read-write;
user-modify: write-only;

/* Global values */
user-modify: inherit;
user-modify: initial;
user-modify: revert;
user-modify: unset;
```

Values

This property is specified as one of the following keyword values:

`read-only`

Default value. Contents are read-only.

`read-write`

The user is able to read and write contents.

`read-write-plaintext-only`

Same as `read-write`, but rich text formatting will be lost.

`write-only`

The user is able to edit the content, but not to read it.

Formal syntax

```
user-modify =
  read-only                |
  read-write               |
  read-write-plaintext-only  |
  write-only
```

Examples

HTML

```
<div class="readwrite">The user is able to change this text.</div>
```

CSS

```
.readwrite {
  -moz-user-modify: read-write;
  -webkit-user-modify: read-write;
}
```

Specifications

Not part of any standard.

See also

- `-moz-user-focus`
- `-moz-user-input`
- `-moz-user-select`

user-select CSS property

The **`user-select`** CSS property controls whether the user can select text. This doesn't have any effect on content loaded as part of a browser's user interface (its chrome), except in textboxes.

Try it

```
user-select: none;
```

```
user-select: text;
```

```
user-select: all;
```

```
<section id="default-example">
  <p id="example-element">Try to select this text</p>
</section>
```

```
#example-element {
  font-size: 1.5rem;
}
```

Syntax

```
/* Keyword values */
user-select: none;
user-select: auto;
user-select: text;
user-select: all;

/* Global values */
user-select: inherit;
user-select: initial;
user-select: revert;
user-select: revert-layer;
user-select: unset;
```

> **Note:** `user-select` is not an inherited property, though the initial `auto` value makes it behave like it is inherited most of the time. WebKit/Chromium-based browsers *do* implement the property as inherited, which violates the behavior described in the spec, and this will bring some issues. Until now, Chromium has chosen to fix the issues to make the final behavior meet the specifications.

Values

`none`

The text of the element and its sub-elements is not selectable. Note that the `Selection` object can contain these elements.

`auto`

The used value of `auto` is determined as follows:

- On the `::before` and `::after` pseudo elements, the used value is `none`
- If the used value of `user-select` on the parent of this element is `none`, the used value is `none`
- Otherwise, if the used value of `user-select` on the parent of this element is `all`, the used value is `all`
- Otherwise, the used value is `text`

`text`

The text can be selected by the user.

`all`

The content of the element shall be selected atomically: If a selection would contain part of the element, then the selection must contain the entire element including all its descendants. If a double-click or context-click occurred in sub-elements, the highest ancestor with this value will be selected.

> **Note:** The CSS basic user interface module defines a `contain` value for the `user-select` property to enable selection to start within the element to be contained by the bounds of that element, however, this is not supported in any browsers.

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
user-select =
  auto     |
  text     |
  none     |
  contain  |
  all
```

This syntax reflects the latest standard as per CSS Basic User Interface Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<p>You should be able to select this text.</p>
<p class="unselectable">Hey, you can't select this text!</p>
<p class="all">Clicking once will select all of this text.</p>
```

CSS

```
.unselectable {
  -webkit-user-select: none; /* Safari */
  user-select: none;
}

.all {
  -webkit-user-select: all;
  user-select: all;
}
```

Result

vector-effect CSS property

The **`vector-effect`** CSS property suppresses specific transformation effects in SVG, thus permitting effects like a road on a map staying the same width no matter how the map is zoomed, or allowing a diagram key to retain its position and size regardless of other transforms. It can only be used with SVG elements that accept the `vector-effect` attribute. When used, the CSS value overrides any values of the element's `vector-effect` attribute.

Syntax

```
/* Keyword values */
vector-effect: none;
vector-effect: non-scaling-stroke;

/* Global values */
vector-effect: inherit;
vector-effect: initial;
vector-effect: revert;
vector-effect: revert-layer;
vector-effect: unset;
```

Values

This property is specified as one of the following keyword values:

`none`

No vector effects are applied to the element, meaning it will be fully affected by transforms as normal.

`non-scaling-stroke`

The element's drawn stroke width will be physically equal in size to its defined stroke width, even if the element has been scaled up or down in size due to transforms of either itself or its coordinate system. This is the case whether the element is scaled with transforms or by physical resizing of the entire image.

> **Note:** The spec defines three other values, `non-scaling-size`, `non-rotation`, and `fixed-position`, but these have no implementations and are considered at-risk.

Formal syntax

```
vector-effect =
  none               |
  non-scaling-stroke |
  non-scaling-size   |
```

```
  non-rotation        |
  fixed-position
```

This syntax reflects the latest standard as per CSS Specification. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Preventing SVG stroke scaling with CSS

Here, we start with a 200x100 SVG image that contains two rectangles inside a group. The group is scaled up and rotated. The second of the two rectangles has a class of `thinned`.

```
<svg xmlns="http://www.w3.org/2000/svg" viewBox="0 0 200 100">
  <g
    transform="scale(2.3) rotate(23)"
    transform-origin="100 50"
    stroke-width="3"
    stroke="orange"
    fill="#ddeeff88">
    <rect x=" 60" y="20" width="30" height="60" />
    <rect x="110" y="20" width="30" height="60" class="thinned" />
  </g>
</svg>
```

To this SVG image, we apply `width: 500px` to make it larger than its intrinsic size, and set the classed `<rect>` to have non-scaled strokes.

```
svg {
  width: 500px;
}
svg rect.thinned {
  vector-effect: non-scaling-stroke;
}
```

The result is that the first of the two rectangles has an apparent (visual) stroke width of approximately 17, whereas the second rectangle still has an apparent stroke width of 3 despite having been scaled up in the same way the first rectangle has.

Overriding SVG stroke scaling values with CSS

In this case, we start with a similar SVG image to the one used in the previous example. Here, the `<g>` element is rotated as before, but no scaling is applied to it. The `<rect>` elements are given a common origin for their transforms, and have their `vector-effect` SVG attributes set to a value of `none`.

```
<svg xmlns="http://www.w3.org/2000/svg" viewBox="0 0 200 100">
  <g
    transform="rotate(23)"
    transform-origin="100 50"
    stroke-width="3"
    stroke="orange"
    fill="#ddeeff88">
    <rect
      x=" 60"
      y="20"
      width="30"
      height="60"
      transform-origin="100 50"
      vector-effect="none" />
    <rect
      x="110"
      y="20"
      width="30"
      height="60"
      transform-origin="100 50"
      vector-effect="none"
      class="thinned" />
  </g>
</svg>
```

As before, the SVG is made larger than its intrinsic size using CSS. This time, scaling is applied to the `<rect>` elements directly, and the second rectangle is set to have its strokes non-scaled.

```
svg {
  width: 500px;
}
svg rect {
  transform: scale(2.3);
}
svg rect.thinned {
  vector-effect: non-scaling-stroke;
}
```

The result is visually identical to that of the previous example. What we can see is that the attribute value of `none` is overridden by the CSS value `non-scaling-stroke`, and that the vector effects are honored even though the scaling was done directly on the `<rect>` rather than on its parent `<g>` element.

vertical-align CSS property

The **`vertical-align`** CSS shorthand property sets the vertical alignment of an inline, inline-block, or table-cell box.

Constituent properties

This property is a shorthand for the following CSS properties:

- `alignment-baseline`
- `baseline-source`
- `baseline-shift`

Try it

```
vertical-align: baseline;
```

```
vertical-align: top;
```

```
vertical-align: middle;
```

```
vertical-align: bottom;
```

```
vertical-align: sub;
```

```
vertical-align: text-top;
```

```
<section class="default-example" id="default-example">
  <p>
    Align the star:
    <img id="example-element" src="/shared-assets/images/examples/star2.png" />
  </p>
</section>
```

```
#default-example > p {
  line-height: 3em;
  font-family: monospace;
  font-size: 1.2em;
  text-decoration: underline overline;
}
```

The `vertical-align` property can be used in two contexts:

- To vertically align an inline-level element's box inside its containing line box. For example, it could be used to vertically position an image in a line of text.
- To vertically align the content of a cell in a table.

Use this shorthand (`vertical-align`) instead of its corresponding longhand properties, unless you need to cascade them independently or (on SVG elements) to support legacy SVG implementations.

Note that `vertical-align` only applies to inline, inline-block and table-cell elements: you can't use it to vertically align block-level elements.

Syntax

```
/* Keyword values */
vertical-align: baseline;
vertical-align: sub;
vertical-align: super;
vertical-align: text-top;
vertical-align: text-bottom;
vertical-align: middle;
vertical-align: top;
vertical-align: bottom;

/* <length> values */
vertical-align: 10em;
vertical-align: 4px;

/* <percentage> values */
vertical-align: 20%;

/* Global values */
vertical-align: inherit;
vertical-align: initial;
vertical-align: revert;
vertical-align: revert-layer;
vertical-align: unset;
```

The `vertical-align` property is specified as one of the values listed below.

Values for inline elements

Parent-relative values

These values vertically align the element relative to its parent element:

`baseline`

> Aligns the baseline of the element with the baseline of its parent. The baseline of some replaced elements, like `<textarea>`, is not specified by the HTML specification, meaning that their behavior with this keyword may vary between browsers.

`sub`

> Aligns the baseline of the element with the subscript-baseline of its parent.

`super`

> Aligns the baseline of the element with the superscript-baseline of its parent.

`text-top`

> Aligns the top of the element with the top of the parent element's font.

`text-bottom`

> Aligns the bottom of the element with the bottom of the parent element's font.

`middle`

> Aligns the middle of the element with the baseline plus half the x-height of the parent.

`<length>`

> Aligns the baseline of the element to the given length above the baseline of its parent. A negative value is allowed.

`<percentage>`

Aligns the baseline of the element to the given percentage above the baseline of its parent, with the value being a percentage of the `line-height` property. A negative value is allowed.

Line-relative values

The following values vertically align the element relative to the entire line:

`top`

Aligns the top of the element and its descendants with the top of the entire line.

`bottom`

Aligns the bottom of the element and its descendants with the bottom of the entire line.

For elements that do not have a baseline, the bottom margin edge is used instead.

Values for table cells

`baseline` (and `sub`, `super`, `text-top`, `text-bottom`, `<length>`, and `<percentage>`)

Aligns the baseline of the cell with the baseline of all other cells in the row that are baseline-aligned.

`top`

Aligns the top padding edge of the cell with the top of the row.

`middle`

Centers the padding box of the cell within the row.

`bottom`

Aligns the bottom padding edge of the cell with the bottom of the row.

Negative values are allowed.

Formal definition

Initial value	`baseline`
Applies to	as each of the properties of the shorthand:. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Computed value	as each of the properties of the shorthand:
Animation type	discrete

Formal syntax

```
vertical-align =
  [ first | last ]       ||
  <'alignment-baseline'>  ||
  <'baseline-shift'>

<alignment-baseline> =
  baseline           |
  <baseline-metric>

<baseline-shift> =
  <length-percentage>  |
  sub                  |
  super                |
  top                  |
  center               |
  bottom

<baseline-metric> =
  text-bottom   |
  alphabetic    |
  ideographic   |
  middle        |
  central       |
  mathematical  |
  hanging       |
  text-top

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Inline Layout Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

HTML

```
<div>
  An <img src="frame_image.svg" alt="link" width="32" height="32" /> image with
  a default alignment.
</div>
<div>
  An
  <img class="top" src="frame_image.svg" alt="link" width="32" height="32" />
  image with a text-top alignment.
</div>
<div>
  An
  <img class="bottom" src="frame_image.svg" alt="link" width="32" height="32" />
  image with a text-bottom alignment.
</div>
```

```
<div>
  An
  <img class="middle" src="frame_image.svg" alt="link" width="32" height="32" />
  image with a middle alignment.
</div>
```

CSS

```
img.top {
  vertical-align: text-top;
}
img.bottom {
  vertical-align: text-bottom;
}
img.middle {
  vertical-align: middle;
}
```

Result

Vertical alignment in a line box

HTML

```
<p>
top:         <img style="vertical-align: top" src="star.png" alt="star"/>
middle:      <img style="vertical-align: middle" src="star.png" alt="star"/>
bottom:      <img style="vertical-align: bottom" src="star.png" alt="star"/>
super:       <img style="vertical-align: super" src="star.png" alt="star"/>
sub:         <img style="vertical-align: sub" src="star.png" alt="star"/>
</p>

<p>
text-top:    <img style="vertical-align: text-top" src="star.png" alt="star"/>
text-bottom: <img style="vertical-align: text-bottom" src="star.png" alt="star"/>
0.2em:       <img style="vertical-align: 0.2em" src="star.png" alt="star"/>
-1em:        <img style="vertical-align: -1em" src="star.png" alt="star"/>
20%:         <img style="vertical-align: 20%" src="star.png" alt="star"/>
-100%:       <img style="vertical-align: -100%" src="star.png" alt="star"/>
</p>
```

```
#* {
  box-sizing: border-box;
}

img {
  margin-right: 0.5em;
}

p {
  height: 3em;
  padding: 0 0.5em;
  font-family: monospace;
  text-decoration: underline overline;
  margin-left: auto;
  margin-right: auto;
  width: 80%;
}
```

Result

Vertical alignment in a table cell

In this example, we have a table with a single row containing six cells. The row sets `vertical-align` to `bottom` as the default value.

- The first four cells each set their own `vertical-align` values, and these override the row's value.
- The fifth cell does not set any `vertical-align` value, so inherits the row's value.

The sixth cell is only used to ensure that the cells are tall enough to see the effect.

HTML

```
<table>
  <tbody>
    <tr class="bottom">
      <td class="baseline">baseline</td>
      <td class="top">top</td>
      <td class="middle">middle</td>
      <td>bottom</td>
      <td>Row's style</td>
      <td>
        Lorem ipsum dolor sit amet, consectetur adipiscing elit. Suspendisse
        pretium felis eu sem mattis vulputate.
      </td>
    </tr>
  </tbody>
</table>
```

CSS

```
table {
  margin-left: auto;
  margin-right: auto;
  width: 80%;
}

table,
th,
td {
  border: 1px solid black;
}
```

```
td {
  padding: 0.5em;
  font-family: monospace;
}

.bottom {
  vertical-align: bottom;
}

.baseline {
  vertical-align: baseline;
}

.top {
  vertical-align: top;
}

.middle {
  vertical-align: middle;
}
```

view-timeline CSS property

The **`view-timeline`** CSS shorthand property defines a named view progress timeline's name, direction, and inset values.

Constituent properties

This property is a shorthand for the following CSS properties:

- `view-timeline-axis`
- `view-timeline-inset`
- `view-timeline-name`

Syntax

```
/* One component */
view-timeline: none;
view-timeline: --custom_name_for_timeline;

/* Two components */
view-timeline: --custom_name_for_timeline block;
view-timeline: --custom_name_for_timeline y;
view-timeline: none inline;
view-timeline: none x;

/* Three components */
view-timeline: --custom_name_for_timeline block auto;
view-timeline: --custom_name_for_timeline block 20% 200px;

/* Global values */
view-timeline: inherit;
view-timeline: initial;
view-timeline: revert;
view-timeline: revert-layer;
view-timeline: unset;
```

Values

`<view-timeline-name>`

See `view-timeline-name`. The default value is `none`.

`<view-timeline-inset>`

See `view-timeline-inset`. The default value is `auto`.

`<view-timeline-axis>`

See `view-timeline-axis`. The default value is `block`.

Description

The `view-timeline` shorthand property defines a *named view progress timeline*, which progresses based on changes to the visibility of an element (the *subject*) within a scrollable element (*scroller*). The `view-timeline` property is set on the subject. If the scroller element does not overflow its container in the axis dimension or if the overflow is hidden or clipped, no scroll progress timeline will be created.

The subject's visibility inside the scroller is tracked — by default, the timeline is at `0%` when the subject is first visible at one edge of the scroller and `100%` when it reaches the opposite edge.

The `view-timeline` can contain three constituent values: a name for the named view progress timeline, a scroll axis value, and up to two timeline inset values. If only one value is declared, the value is the `view-timeline-name`. The name is then referenced in an `animation-timeline` declaration to indicate the element that will be animated as the timeline progresses. This can be the subject element, but it doesn't have to be — you can animate a different element as the subject moves through the scrolling area.

The `view-timeline` shorthand property can be applied to a container element to set a combination of the `<view-timeline-name>`, `<view-timeline-inset>`, and `<view-timeline-axis>` values. At least one value must be specified. If all values are specified, the order must be `<view-timeline-name>` followed by `<view-timeline-axis>` and/or `<view-timeline-inset>`.

The names specified in the `<view-timeline-name>` component must be a list of comma-separated `<dashed-ident>` values (which means they must start with `--`) or the keyword `none`.

Formal definition

Initial value	as each of the properties of the shorthand:

	• view-timeline-name: none • view-timeline-axis: block
Applies to	all elements
Inherited	no
Computed value	as each of the properties of the shorthand: • view-timeline-name: none or an ordered list of identifiers • view-timeline-axis: as specified
Animation type	as each of the properties of the shorthand: • view-timeline-name: Not animatable • view-timeline-axis: Not animatable

Formal syntax

```
view-timeline =
  [ <'view-timeline-name'> [ <'view-timeline-axis'> || <'view-timeline-inset'> ]? ]#

<view-timeline-name> =
  [ none | <dashed-ident> ]#

<view-timeline-axis> =
  [ block | inline | x | y ]#

<view-timeline-inset> =
  [ [ auto | <length-percentage> ]{1,2} ]#

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4, Scroll-driven Animations. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Creating a named view progress timeline

A view progress timeline named `--subject-reveal` is defined using the `view-timeline` property on a subject element with a `class` of `animation`. This is then set as the timeline for the same element using `animation-timeline: --subject-reveal`. The result is that the subject element animates as it moves upwards through the document as it is scrolled.

HTML

The HTML for the example is shown below.

```
<div class="content">
  <h1>Content</h1>

  <p>
    Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod
    tempor incididunt ut labore et dolore magna aliqua. Risus quis varius quam
    quisque id. Et ligula ullamcorper malesuada proin libero nunc consequat
    interdum varius. Elit ullamcorper dignissim cras tincidunt lobortis feugiat
    vivamus at augue.
  </p>

  <p>
    Dolor sed viverra ipsum nunc aliquet. Sed sed risus pretium quam vulputate
    dignissim. Tortor aliquam nulla facilisi cras. A erat nam at lectus urna
    duis convallis convallis. Nibh ipsum consequat nisl vel pretium lectus.
    Sagittis aliquam malesuada bibendum arcu vitae elementum. Malesuada bibendum
    arcu vitae elementum curabitur vitae nunc sed velit.
  </p>

  <div class="subject animation"></div>

  <p>
    Adipiscing enim eu turpis egestas pretium aenean pharetra magna ac. Arcu
    cursus vitae congue mauris rhoncus aenean vel. Sit amet cursus sit amet
    dictum. Augue neque gravida in fermentum et. Gravida rutrum quisque non
    tellus orci ac auctor augue mauris. Risus quis varius quam quisque id diam
    vel quam elementum. Nibh praesent tristique magna sit amet purus gravida
    quis. Duis ultricies lacus sed turpis tincidunt id aliquet. In egestas erat
    imperdiet sed euismod nisi. Eget egestas purus viverra accumsan in nisl nisi
    scelerisque. Netus et malesuada fames ac.
  </p>
</div>
```

CSS

The `subject` element and its containing `content` element are styled minimally, and the text content is given some basic font settings:

```
.subject {
  width: 300px;
  height: 200px;
  margin: 0 auto;
  background-color: deeppink;
}

.content {
  width: 75%;
  max-width: 800px;
  margin: 0 auto;
}

p,
h1 {
```

```
  font-family: "Helvetica", "Arial", sans-serif;
}

h1 {
  font-size: 3rem;
}

p {
  font-size: 1.5rem;
  line-height: 1.5;
}
```

The `<div>` with the class of `subject` is also given a class of `animation` — this is where `view-timeline` is set to define a named view progress timeline. It is also given an `animation-timeline` name with the same value to declare that this will be the element animated as the view progress timeline progresses.

Lastly, an animation is specified on the element that animates its opacity and scale, causing it to fade in and grow as it moves up the scroller.

```
.animation {
  view-timeline: --subject-reveal block;
  animation-timeline: --subject-reveal;

  animation-name: appear;
  animation-fill-mode: both;
  animation-duration: 1ms; /* Firefox requires this to apply the animation */
}

@keyframes appear {
  from {
    opacity: 0;
    transform: scaleX(0);
  }

  to {
    opacity: 1;
    transform: scaleX(1);
  }
}
```

```
@layer no-support {
  @supports not (view-timeline: none) {
    body::before {
      content: "Your browser doesn't support the `view-timeline` property.";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

Result

Scroll to see the subject element being animated.

- Guide: CSS scroll driven animation timelines
- CSS scroll-driven animations

view-timeline-axis CSS property

The **`view-timeline-axis`** CSS property specifies the scroll direction to be used for a named view progress timeline.

Syntax

```
/* Logical property values */
view-timeline-axis: block;
view-timeline-axis: inline;

/* Physical property values */
view-timeline-axis: y;
view-timeline-axis: x;

/* Global values */
view-timeline-axis: inherit;
view-timeline-axis: initial;
view-timeline-axis: revert;
view-timeline-axis: revert-layer;
view-timeline-axis: unset;
```

Values

`<axis>`

Specifies the scroll direction used by the view progress timeline. The value can be one of the `<axis>` keywords: `block`, `inline`, `x`, or `y`. The default value is `block`.

Description

The `view-timeline-axis` property specifies the direction, or `<axis>`, of named view progress timelines that are based on the element's box.

By default, CSS `@keyframes` animations progress along the time-based default timeline. When you set the animation progress via a view progress timeline instead, `view-timeline-axis` specifies the direction that controls the timeline progression.

For view progress timelines, progression of the animation along the timelines is based on the visibility of the element, or *subject*. The `view-timeline-axis` property is set on the subject.

The subject must be nested inside a scrollable element. If the scrollable element does not overflow its container in the axis dimension or if the overflow is hidden or clipped, no scroll progress timeline will be created.

The `view-timeline-axis`, along with the `view-timeline-inset` and `view-timeline-name` properties, is a component of the `view-timeline` shorthand property.

Formal definition

Initial value	`block`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
view-timeline-axis =
  [ block | inline | x | y ]#
```

This syntax reflects the latest standard as per Scroll-driven Animations. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Defining the axis of the view progress timeline

In this example, a view progress timeline named `--subject-reveal` is defined using the `view-timeline-name` property on a subject element with a class of "animation". This timeline is then applied to the animation on the same element, using `animation-timeline: --subject-reveal;`.

To demonstrate the effect of `view-timeline-axis`, a horizontal (non-default) scrollbar is used in this example to drive the animation.

HTML

The HTML for the example is shown below.

```
<div class="content">
  <p>
    Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod
    tempor incididunt ut labore et dolore magna aliqua.
  </p>

  <p>
    Risus quis varius quam quisque id. Et ligula ullamcorper malesuada proin
    libero nunc consequat interdum varius. Elit ullamcorper dignissim cras
    tincidunt lobortis feugiat vivamus at augue.
  </p>

  <p>
    Dolor sed viverra ipsum nunc aliquet. Sed sed risus pretium quam vulputate
    dignissim. Tortor aliquam nulla facilisi cras.
  </p>

  <p>
    A erat nam at lectus urna duis convallis convallis. Nibh ipsum consequat
    nisl vel pretium lectus.
  </p>

  <p>
    Sagittis aliquam malesuada bibendum arcu vitae elementum. Malesuada bibendum
    arcu vitae elementum curabitur vitae nunc sed velit.
  </p>

  <div class="subject animation"></div>

  <p>
    Adipiscing enim eu turpis egestas pretium aenean pharetra magna ac. Arcu
    cursus vitae congue mauris rhoncus aenean vel. Sit amet cursus sit amet
    dictum. Augue neque gravida in fermentum et. Gravida rutrum quisque non
    tellus orci ac auctor augue mauris.
  </p>
</div>
```

CSS

In the CSS, we set the `subject` element as the source of a view progress timeline named `--subject-reveal` using the `view-timeline-name` property. The scroll axis is set using `view-timeline-axis: x;`. We also include `view-timeline-axis: horizontal;` for browsers that support the non-standard legacy `horizontal` and `vertical` values, rather than `x` and `y`.

The `content` ancestor element is made to overflow horizontally by laying out its contents using `display: flex;` and `flex-flow: column wrap;`.

```
.subject {
  width: 300px;
  height: 200px;
  margin: 0 auto;
  background-color: deeppink;
}

.content {
  width: 50%;
  height: 400px;
  margin-top: 30px;
  display: flex;
  flex-flow: column wrap;
  gap: 10px;
}

p {
  font-family: "Helvetica", "Arial", sans-serif;
}

p {
  font-size: 1.3rem;
  line-height: 1.4;
}
```

```
.animation {
  view-timeline-name: --subject-reveal;
  view-timeline-axis: x;
  view-timeline-axis: horizontal;

  animation: appear 1ms linear both;
  animation-timeline: --subject-reveal;
}

@keyframes appear {
  from {
    opacity: 0;
    transform: scaleX(0);
  }

  to {
    opacity: 1;
    transform: scaleX(1);
  }
}
```

```
@layer no-support {
  body::before {
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
  @supports not (view-timeline-axis: inherit) {
    body::before {
      content: "Your browser doesn't support the `view-timeline-axis` property.";
      background-color: wheat;
    }
  }
  @supports (view-timeline-axis: horizontal) {
    body::before {
      content: "Your browser supports legacy values for the `view-timeline-axis` property.";
      background-color: yellow;
    }
  }
}
```

Result

Scroll the horizontal bar at the bottom to see the subject element animate as you scroll.

- Guide: Scroll-driven animation timelines
- CSS scroll-driven animations module
- CSS animations module

view-timeline-inset CSS property

The **`view-timeline-inset`** CSS property is used to specify one or two values representing an adjustment to the position of the scrollport (see Scroll container for more details) in which the subject element of a *named view progress timeline* animation is deemed to be visible. Put another way, this allows you to specify start and/or end inset (or outset) values that offset the position of the timeline.

This can be combined with or used instead of `animation-range` and its longhand properties, which can be used to set the attachment range of an animation along its timeline. See CSS scroll-driven animations for more details.

> **Note:** If the scroller element does not overflow its container in the axis dimension or if the overflow is hidden or clipped, no scroll progress timeline will be created.

The `view-timeline-inset`, `view-timeline-axis`, and `view-timeline-name` properties can also be set using the `view-timeline` shorthand property.

Syntax

```
/* Single value */
view-timeline-inset: auto;
view-timeline-inset: 200px;
view-timeline-inset: 20%;

/* Two values */
view-timeline-inset: 20% auto;
view-timeline-inset: auto 200px;
view-timeline-inset: 20% 200px;
```

Values

Allowed values for `view-timeline-inset` are:

`auto`

> If set, the corresponding `scroll-padding` (or equivalent longhand value) for that edge of the scrollport is used. If this is not set (or set to `auto`), the value will usually be 0, although some user agents may use heuristics to determine a different default value if appropriate.

`<length-percentage>`

> Any valid `<length-percentage>` value is accepted as an inset/outset value.
>
> - If the value is positive, the position of the animation's start/end will be moved inside the scrollport by the specified length or percentage.
> - If the value is negative, the position of the animation's start/end will be moved outside the scrollport by the specified length or percentage, i.e., it will start animating before it appears in the scrollport, or finish animating after it leaves the scrollport.

If two values are provided, the first value represents the start inset/outset in the relevant axis (where the animation begins) and the second value represents the end inset/outset (where the animation ends). If only one value is provided, the start and end inset/outset are both set to the same value.

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	no
Percentages	Relative to the corresponding dimension of the relevant scrollport
Computed value	A list where each item may be either 'auto' or a length percentage
Animation type	by computed value type

Formal syntax

```
view-timeline-inset =
  [ [ auto | <length-percentage> ]{1,2} ]#

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4, Scroll-driven Animations. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Creating a named view progress timeline with inset

A view progress timeline named `--subject-reveal` is defined using the `view-timeline` property on a subject element with a `class` of `animation`. This is then set as the timeline for the same element using `animation-timeline: --subject-reveal;`. The result is that the subject element animates as it moves upwards through the document as it is scrolled.

A `view-timeline-inset` declaration is also set to make the animation begin later than expected, and finish earlier.

HTML

The HTML for the example is shown below.

```
<div class="content">
  <h1>Content</h1>

  <p>
    Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod
    tempor incididunt ut labore et dolore magna aliqua. Risus quis varius quam
    quisque id. Et ligula ullamcorper malesuada proin libero nunc consequat
    interdum varius. Elit ullamcorper dignissim cras tincidunt lobortis feugiat
    vivamus at augue.
  </p>

  <p>
    Dolor sed viverra ipsum nunc aliquet. Sed sed risus pretium quam vulputate
    dignissim. Tortor aliquam nulla facilisi cras. A erat nam at lectus urna
    duis convallis convallis. Nibh ipsum consequat nisl vel pretium lectus.
    Sagittis aliquam malesuada bibendum arcu vitae elementum. Malesuada bibendum
    arcu vitae elementum curabitur vitae nunc sed velit.
  </p>

  <div class="subject animation"></div>

  <p>
    Adipiscing enim eu turpis egestas pretium aenean pharetra magna ac. Arcu
    cursus vitae congue mauris rhoncus aenean vel. Sit amet cursus sit amet
    dictum. Augue neque gravida in fermentum et. Gravida rutrum quisque non
    tellus orci ac auctor augue mauris. Risus quis varius quam quisque id diam
    vel quam elementum. Nibh praesent tristique magna sit amet purus gravida
    quis. Duis ultricies lacus sed turpis tincidunt id aliquet. In egestas erat
    imperdiet sed euismod nisi. Eget egestas purus viverra accumsan in nisl nisi
    scelerisque. Netus et malesuada fames ac.
  </p>
</div>
```

CSS

The `subject` element and its containing `content` element are styled minimally, and the text content is given some basic font settings:

```
.subject {
  width: 300px;
  height: 200px;
  margin: 0 auto;
  background-color: deeppink;
}

.content {
  width: 75%;
  max-width: 800px;
  margin: 0 auto;
}

p,
h1 {
  font-family: "Helvetica", "Arial", sans-serif;
}

h1 {
  font-size: 3rem;
}

p {
  font-size: 1.5rem;
  line-height: 1.5;
}
```

The `<div>` with the class of `subject` is also given a class of `animation` — this is where `view-timeline` is set to define a named view progress timeline. We also give it a `view-timeline-inset` declaration to make the animation begin later than expected, and finish earlier. It is also given an `animation-timeline` name with the same value to declare that this will be the element animated as the view progress timeline is progressed.

Last, an animation is specified on the element that animates its opacity and scale, causing it to fade in and size up as it moves up the scroller.

```
.animation {
  view-timeline: --subject-reveal block;
  view-timeline-inset: 70% -100px;
  animation-timeline: --subject-reveal;

  animation-name: appear;
  animation-fill-mode: both;
  animation-duration: 1ms; /* Firefox requires this to apply the animation */
}

@keyframes appear {
  from {
    opacity: 0;
    transform: scaleX(0);
  }

  to {
    opacity: 1;
    transform: scaleX(1);
  }
}
```

Result

Scroll to see the subject element being animated.

view-timeline-name CSS property

The **`view-timeline-name`** CSS property specifies the names of one or more named view progress timelines associated with the element.

Syntax

```
/* Keyword value */
view-timeline-name: none;

/* Custom identifier */
view-timeline-name: --custom_name_for_timeline;

/* Multiple identifiers */
view-timeline-name: --first_timeline_name, --another_timeline_name;

/* Global values */
view-timeline-name: inherit;
view-timeline-name: initial;
view-timeline-name: revert;
view-timeline-name: revert-layer;
view-timeline-name: unset;
```

Values

`none`

Indicates that the timeline has no name. This is the default value.

`<dashed-ident>`

Specifies a comma-separated list of `<dashed-ident>` custom name identifiers. All `<dashed-ident>` values must start with `--`, which helps avoid name clashes with standard CSS keywords.

Description

The `view-timeline-name` property is used to set the name of a view progress timeline. A view progress timeline is progressed through based on the change in visibility of an element, called the *subject*, inside a scrollable element, called the *scroller*. The `view-timeline-name` property is set on the subject. You can also set `view-timeline-name` by using the `view-timeline` shorthand property.

If the subject's named scroller element does not overflow its container in the axis dimension or if the overflow is hidden or clipped, no scroll progress timeline will be created.

Once created, the `<dashed-ident>` name values specified can be referenced in `animation-timeline` declarations to indicate the element that will be animated as the timeline progresses.

Formal definition

Initial value	`none`
Applies to	all elements
Inherited	no
Computed value	`none` or an ordered list of identifiers
Animation type	Not animatable

Formal syntax

```
view-timeline-name =
  [ none | <dashed-ident> ]#
```

This syntax reflects the latest standard as per Scroll-driven Animations. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Creating a named view progress timeline

A view progress timeline named `--subject-reveal` is defined using the `view-timeline-name` property on a subject element with a `class` of `animation`. This is then set as the timeline for the same element using `animation-timeline: --subject-reveal;`. The result is that the subject element animates as it moves upwards through the document as it is scrolled.

HTML

The HTML for the example is shown below.

```
<div class="content">
  <h1>Content</h1>

  <p>
    Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod
    tempor incididunt ut labore et dolore magna aliqua. Risus quis varius quam
    quisque id. Et ligula ullamcorper malesuada proin libero nunc consequat
    interdum varius. Elit ullamcorper dignissim cras tincidunt lobortis feugiat
    vivamus at augue.
  </p>

  <p>
    Dolor sed viverra ipsum nunc aliquet. Sed sed risus pretium quam vulputate
    dignissim. Tortor aliquam nulla facilisi cras. A erat nam at lectus urna
    duis convallis convallis. Nibh ipsum consequat nisl vel pretium lectus.
    Sagittis aliquam malesuada bibendum arcu vitae elementum. Malesuada bibendum
    arcu vitae elementum curabitur vitae nunc sed velit.
  </p>

  <div class="subject animation"></div>

  <p>
    Adipiscing enim eu turpis egestas pretium aenean pharetra magna ac. Arcu
    cursus vitae congue mauris rhoncus aenean vel. Sit amet cursus sit amet
    dictum. Augue neque gravida in fermentum et. Gravida rutrum quisque non
    tellus orci ac auctor augue mauris. Risus quis varius quam quisque id diam
    vel quam elementum. Nibh praesent tristique magna sit amet purus gravida
    quis. Duis ultricies lacus sed turpis tincidunt id aliquet. In egestas erat
    imperdiet sed euismod nisi. Eget egestas purus viverra accumsan in nisl nisi
    scelerisque. Netus et malesuada fames ac.
  </p>
</div>
```

CSS

The `subject` element and its containing `content` element are styled minimally, and the text content is given some basic font settings:

```
.subject {
  width: 300px;
  height: 200px;
  margin: 0 auto;
  background-color: deeppink;
}

.content {
  width: 75%;
  max-width: 800px;
  margin: 0 auto;
}

p,
h1 {
  font-family: "Helvetica", "Arial", sans-serif;
}

h1 {
  font-size: 3rem;
}

p {
  font-size: 1.5rem;
  line-height: 1.5;
}
```

The `<div>` with the class of `subject` is also given a class of `animation` — this is where `view-timeline-name` is set to define a named view progress timeline. It is also given an `animation-timeline` name with the same value to declare that this will be the element animated as the view progress timeline is progressed.

Last, an animation is specified on the element that animates its opacity and scale, causing it to fade in and size up as it moves up the scroller.

```
.animation {
  view-timeline-name: --subject-reveal;
  animation-timeline: --subject-reveal;

  animation-name: appear;
  animation-fill-mode: both;
  animation-duration: 1ms; /* Firefox requires this to apply the animation */
}

@keyframes appear {
  from {
    opacity: 0;
    transform: scaleX(0);
  }

  to {
    opacity: 1;
    transform: scaleX(1);
  }
}
```

```
@layer no-support {
  @supports not (view-timeline-name: none) {
    body::before {
      content: "Your browser doesn't support the `view-timeline-name` property.";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

Result

Scroll to see the subject element being animated.

view-transition-class CSS property

The **`view-transition-class`** CSS property provides the selected elements with one or more identifying classes (`<custom-ident>`s), providing an additional method of styling the view transitions for those elements.

Syntax

```
/* <custom-ident> value examples */
view-transition-class: card;
view-transition-class: card fast-slide;

/* Keyword value */
view-transition-class: none;

/* Global values */
view-transition-class: inherit;
view-transition-class: initial;
view-transition-class: revert;
view-transition-class: revert-layer;
view-transition-class: unset;
```

Values

`<custom-ident>`

> An identifying name used to select view transition pseudo-elements for styling. Unlike `view-transition-name`, a class does not need to be unique and does not cause the element to participate in a separate view transition group.

`none`

> No class would apply to the named view transition pseudo-elements generated for this element.

Description

The `view-transition-class` value provides a styling hook, similar to a CSS class name, which can be used to apply the same styles to multiple view transition pseudo-elements. It does not mark an element for capturing. Each individual element still needs its own unique `view-transition-name`; the `view-transition-class` is only used as an additional way to style elements that already have a `view-transition-name`. Support for determining the `view-transition-name` automatically is being discussed in the CSS View Transitions Module Level 2 spec.

The `view-transition-class` applies styles using the view transition pseudo-elements, including `::view-transition-group()`, `::view-transition-image-pair()`, `::view-transition-old()`, and `::view-transition-new()`. This is different from the `view-transition-name`, which matches view transitions between the element in the old state with its corresponding element in the new state.

Until the `view-transition-class` property is fully supported in all browsers supporting view transitions, include a custom `::view-transition-group()` for each element.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
view-transition-class =
  none            |
  <custom-ident>+
```

This syntax reflects the latest standard as per CSS View Transitions Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Styling a shared class across multiple elements

In this example, three cards each have a unique `view-transition-name` (required for pairing old and new states), but they all share the same `view-transition-class`. This lets you write a single rule that styles all their transitions at once, rather than repeating styles for each name individually. Unlike `view-transition-name`, a `view-transition-class` does not need to be unique.

```
<div class="card" id="card1">Card 1</div>
<div class="card" id="card2">Card 2</div>
<div class="card" id="card3">Card 3</div>
```

```
/* Each element must have a unique view-transition-name */
#card1 {
  view-transition-name: card-1;
```

```
}

#card2 {
  view-transition-name: card-2;
}

#card3 {
  view-transition-name: card-3;
}

/* But they can all share the same view-transition-class */
.card {
  view-transition-class: card;
}

/* This single rule applies to all three cards' transitions */
::view-transition-group(.card) {
  animation-duration: 0.5s;
  animation-timing-function: ease-in-out;
}
```

Using multiple classes on a single element

A `view-transition-class` value can be a space-separated list of identifiers, letting you compose several "atomic" styles on the same element and target each one independently of your view transition pseudo-elements. In this example, both cards share the same two classes — `slide` controls the animation, and `fast-transition` controls its duration — while each card still has its own unique `view-transition-name`.

```
<div class="card" id="card1">Card 1</div>
<div class="card" id="card2">Card 2</div>
```

```
.card {
  view-transition-class: slide fast-transition;
}

#card1 {
  view-transition-name: card-1;
}

#card2 {
  view-transition-name: card-2;
}

/* The `slide` class drives which animation runs... */
::view-transition-new(.slide) {
  animation-name: slide-in;
}

::view-transition-old(.slide) {
  animation-name: slide-out;
}

/* ...while the `fast-transition` class drives how long it runs. */
::view-transition-group(.fast-transition) {
  animation-duration: 0.5s;
}
```

view-transition-name CSS property

The **`view-transition-name`** CSS property specifies the view transition snapshot that selected elements will participate in. This enables you to animate those elements separately from the rest of the page, which uses the default cross-fade animation during a view transition. You can then define custom animation styles for these elements.

Syntax

```
/* <custom-ident> value examples */
view-transition-name: header;
view-transition-name: figure-caption;

/* Keyword values */
view-transition-name: none;
view-transition-name: match-element;

/* Global values */
view-transition-name: inherit;
view-transition-name: initial;
view-transition-name: revert;
view-transition-name: revert-layer;
view-transition-name: unset;
```

Values

`<custom-ident>`

An identifying name that causes the selected element to participate in a separate snapshot from the root snapshot. The `<custom-ident>` cannot be `auto`, `match-element`, `none`, or a CSS-wide keyword value.

`match-element`

The browser automatically assigns a unique name to the selected element. This name is used to snapshot the element separately from all other elements on the page. (This name is internal and cannot be read from the DOM.)

`none`

The selected element will not participate in a separate snapshot, unless it has a parent element with a `view-transition-name` set, in which case it will be snapshotted as part of that element.

Description

By default, when a view transition is applied to a web app, all changes to the UI that occur during that transition are snapshotted and animated together. This is the default — or `root` — snapshot (see The view transition pseudo-element tree). By default, this animation is a smooth cross-fade, which can be seen in action in the View Transitions SPA demo.

If you want certain elements to be animated differently from the `root` snapshot during the view transition, you can do so by giving them a different `view-transition-name`, for example:

```
figcaption {
  view-transition-name: figure-caption;
}
```

You can then specify which animations you want for the before and after snapshots using the relevant view transition pseudo-elements — `::view-transition-old()` and `::view-transition-new()`. For example:

```
::view-transition-old(figure-caption) {
  animation: 0.25s linear both shrink-x;
}

::view-transition-new(figure-caption) {
  animation: 0.25s 0.25s linear both grow-x;
}
```

If you don't want an element to be snapshotted separately, you can specify a `view-transition-name` value of `none`:

```
.dont-animate-me {
  view-transition-name: none;
}
```

The `view-transition-name` `<custom-ident>` must be unique for each rendered element taking part in the view transition. If two rendered elements have the same `view-transition-name` at the same time, the `ViewTransition.ready` `Promise` will reject and the transition will be skipped.

Specifying <code>view-transition-name</code> values automatically

Sometimes you will want to animate multiple UI elements separately in a view transition. This is often the case when you have a list of elements on a page and want to rearrange them in some way:

```
<ul>
  <li>Item 1</li>
  <li>Item 2</li>
  <li>Item 3</li>
  <li>Item 4</li>

  <!-- ... -->

  <li>Item 99</li>
</ul>
```

Giving each one a unique name can be inconvenient, especially as the number of elements gets larger:

```
li:nth-child(1) {
  view-transition-name: item1;
}
li:nth-child(2) {
  view-transition-name: item2;
}
li:nth-child(3) {
  view-transition-name: item3;
}
li:nth-child(4) {
  view-transition-name: item4;
}

/* ... */

li:nth-child(99) {
  view-transition-name: item99;
}
```

To get around this problem, you can use the `match-element` value, which causes the browser to give each selected element a unique internal `view-transition-name`:

```
li {
  view-transition-name: match-element;
}
```

Because `match-element` assigns automatic `view-transition-name` values based on element identity, it can only be used for same-document view transitions. The auto-generated internal identifiers are not transferrable across different elements or documents.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
view-transition-name =
  none            |
  <custom-ident>
```

This syntax reflects the latest standard as per CSS View Transitions Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic <code>view-transition-name</code> usage

This example comes from the View Transitions SPA demo, which is a basic image gallery. The Basic SPA view transition provides a more detailed explanation of how this demo works.

Most of the UI changes are animated using the `root` transition snapshot. However, the `<figcaption>` is given a `view-transition-name` of `figure-caption` to allow it to be animated differently from the rest of the page:

```
figcaption {
  view-transition-name: figure-caption;
}
```

The following code applies a custom animation just to the `<figcaption>`:

```
@keyframes grow-x {
  from {
    transform: scaleX(0);
  }
  to {
    transform: scaleX(1);
  }
}

@keyframes shrink-x {
  from {
    transform: scaleX(1);
  }
  to {
    transform: scaleX(0);
  }
}

::view-transition-group(figure-caption) {
  height: auto;
  right: 0;
  left: auto;
  transform-origin: right center;
}

::view-transition-old(figure-caption) {
  animation: 0.25s linear both shrink-x;
}

::view-transition-new(figure-caption) {
  animation: 0.25s 0.25s linear both grow-x;
}
```

We create a custom CSS animation and apply it to the `::view-transition-old(figure-caption)` and `::view-transition-new(figure-caption)` pseudo-elements. We also apply other styles to keep them both in the same place and to stop the default styling from interfering with our custom animations.

Using the <code>match-element</code> value

This example contains a list of technologies–HTML, CSS, SVG, and JS–that are displayed in a sidebar next to a main content area, which starts out empty. Clicking a technology's heading animates its content into the adjoining content area that shows more details.

HTML

The `<main>` element contains an unordered list and an `<article>` element. The multiple child `<li>` elements inside the list each contain an `<a>` element inside a heading.

```
<main class="match-element-applied">
  <ul>
    <li>
      <h2><a href="#">HTML</a></h2>
      <h3>HyperText Markup Language</h3>
      <p>
        HyperText Markup Language (HTML) is the most basic building block of the
        web. It defines the meaning and structure of web content. HTML provides
        the fundamental building blocks for structuring web documents and apps.
      </p>
    </li>
    <li>
      <h2><a href="#">CSS</a></h2>
      <h3>Cascading Style Sheets</h3>
      <p>
        Cascading Style Sheets (CSS) is a stylesheet language used to describe
        the presentation of a document written in HTML or XML (including XML
        dialects such as SVG, MathML or XHTML). CSS describes how elements
        should be rendered on screen, on paper, in speech, or on other media.
      </p>
    </li>
    <li>
      <h2><a href="#">SVG</a></h2>
      <h3>Scalable Vector Graphics</h3>
      <p>
        Scalable Vector Graphics (SVG) is an XML-based markup language for
        describing two-dimensional based vector graphics.
      </p>
    </li>
    <li>
      <h2><a href="#">JS</a></h2>
      <h3>JavaScript</h3>
      <p>
        JavaScript (JS) is the web's native programming language. JavaScript is
        a lightweight, interpreted (or just-in-time compiled) programming
        language with first-class functions. While it is most well-known as the
        scripting language for web pages, many non-browser environments, such as
        Node.js, also use it.
      </p>
    </li>
  </ul>
```

```
  <article></article>
</main>
```

```
<form>
  <label for="match-element-checkbox">
    Apply <code>match-element</code> to list items?
  </label>
  <input type="checkbox" id="match-element-checkbox" checked />
</form>
```

CSS

We use flexbox to lay out the `<li>` and the `<article>` side by side, and to make the list items share equal amount of space in the first column. The list takes up 35% of the container's width, while the `<article>` fills the remaining available horizontal space.

```
/* General styles and resets */
* {
  box-sizing: border-box;
  font-size: 0.9rem;
}

html {
  font-family: "Helvetica", "Arial", sans-serif;
  height: 100%;
}

body {
  margin: 0;
  height: inherit;
  display: flex;
  flex-direction: column;
  justify-content: space-around;
}
li h2 {
  margin: 0;
}

ul {
  padding: 0;
  margin: 0;
  list-style-type: none;
}

li {
  overflow: hidden;
  container-type: inline-size;
}

li p {
  display: none;
}

li.active-item p {
  display: block;
}

li:nth-child(1) {
  background-color: #cbc0d3;
  border: 20px solid #cbc0d3;
}

li:nth-child(2) {
  background-color: #efd3d7;
  border: 20px solid #efd3d7;
}

li:nth-child(3) {
  background-color: #feeafa;
  border: 20px solid #feeafa;
}

li:nth-child(4) {
  background-color: #dee2ff;
  border: 20px solid #dee2ff;
}

/* Links */

a {
  text-decoration: none;
  color: rgb(0 0 255 / 0.8);
}

a:hover,
a:focus {
  color: rgb(100 100 255);
}

/* Form and checkbox styles */
form {
  position: absolute;
  bottom: 0;
  right: 0;
  z-index: 2;
  background-color: white;
  padding: 10px;
  border: 1px solid black;
}
```

```
main {
  container-type: inline-size;
```

```
  width: 100%;
  height: 100%;
  display: flex;
  gap: 2cqw;
  position: relative;
}

ul {
  width: 35cqw;
  display: flex;
  flex-direction: column;
  gap: 1cqw;
}

article {
  flex: 1;
}

li {
  flex: 1;
}
```

We also define a rule that selects elements with the `active-item` class. When this class is applied to an element, the rule causes it to be positioned exactly over the top of the `<article>` element. This class will be applied to the list items via JavaScript when their links are clicked, which will initiate a view transition.

```
.active-item {
  position: absolute;
  z-index: 1;
  translate: 37cqw;
  width: calc(100% - 37cqw);
  height: 100%;
}
```

By default, all elements in a view transition are animated together in a single cross-fade. In this example, however, we don't want this — we want each list item to have its own movement animation. We can achieve this by applying `view-transition-name: match-element` to every list item:

```
.match-element-applied li {
  view-transition-name: match-element;
}
```

The `match-element-applied` class is applied to the `<main>` element by default, which is why the checkbox in the Result frame is initially selected. If you uncheck it, the class is removed and the default cross-fade animation comes into effect instead. You can toggle the checkbox to compare the default animation with the one applied when `view-transition-name: match-element` is used.

Next, we customize the animation by using the `::view-transition-group()` pseudo-element to apply an `animation-duration` to all the view transition groups (signified by the `*` identifier) and give all the old and new snapshots a `height` of `100%`. This works around differences in the aspect ratios of the old and new snapshots and makes the animations look smoother:

```
::view-transition-group(*) {
  animation-duration: 0.5s;
}

html::view-transition-old(*),
html::view-transition-new(*) {
  height: 100%;
}
```

JavaScript

In this example, the `active-item` class is applied to the list items when their links are clicked; this is achieved via the `updateActiveItem()` function:

```
const mainElem = document.querySelector("main");
let prevElem;
let checkboxElem = document.querySelector("input");

// View transition code
function updateActiveItem(event) {
  // Get the list item that contains the clicked link
  const clickedElem = event.target.parentElement.parentElement;

  // Set the active-item class on the list item
  clickedElem.className = "active-item";

  // Keep track of the previous item that was clicked, if any.
  // Remove the active-item class from the previous item so that only
  // one list item is placed over the <article> at any one time
  if (prevElem === clickedElem) {
    prevElem.className = "";
    prevElem = undefined;
  } else if (prevElem) {
    prevElem.className = "";
    prevElem = clickedElem;
  } else {
    prevElem = clickedElem;
  }
}

mainElem.addEventListener("click", (event) => {
  event.preventDefault(); // Prevent iframe from scrolling when clicked
  // Do nothing unless a link is clicked inside the <main> element
  if (event.target.tagName !== "A") {
    return;
  }

  // Run updateActiveItem() on its own if view transitions are not supported
  if (!document.startViewTransition) {
    updateActiveItem(event);
  } else {
    // Run updateActiveItem() via startViewTransition()
    const transition = document.startViewTransition(() =>
      updateActiveItem(event),
    );
```

```
  }
});

// Toggle the class on <main> to control whether or not match-element is applied

checkboxElem.addEventListener("change", () => {
  mainElem.classList.toggle("match-element-applied");
});
```

Running the `updateActiveItem()` function via the `startViewTransition()` function animates the display of technology details smoothly.

Result

Click a technology heading in the sidebar and notice the animation effect of its content into the main content area.

There is also a checkbox, which is selected by default, so `view-transition-name: match-element` is applied. Uncheck the checkbox and click a heading again to see how the view-transition works without `view-transition-name: match-element`.

view-transition-scope CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`view-transition-scope`** CSS property enables the discoverability of elements with `view-transition-name` values set on them (and therefore the creation of view transition snapshots) to be isolated to a specific element subtree.

Syntax

```
/* Keyword values */
view-transition-scope: none;
view-transition-scope: all;

/* Global values */
view-transition-scope: inherit;
view-transition-scope: initial;
view-transition-scope: revert;
view-transition-scope: revert-layer;
view-transition-scope: unset;
```

Values

This property is specified as one of the following keyword values:

`none`

The initial value. Discoverability of elements to snapshot during a view transition is not limited to any specific subtree.

`all`

Limits the discoverability of elements to snapshot during a view transition to the subtree of the element on which this property is set. Only elements with a non-`none` `view-transition-name` are considered.

Description

During the view transition process, the browser captures snapshots of elements that have a non-`none` `view-transition-name` set on them. These snapshots are then animated via CSS animations.

One issue that can arise during this process is naming collisions between elements involved in a view transition. You can't have the same `view-transition-name` set on multiple elements — if you do, the browser throws an `InvalidStateError` when the `Element.startViewTransition()` method is called to start the transition.
