You could solve this problem by setting a `view-transition-name` of `match-element` on the elements to let the browser auto-assign internal unique names. However, this won't work if you are including multiple components from different sources that you don't control. A naming collision might still occur.

The `view-transition-scope` property allows view transitions to be self-contained. When `view-transition-scope: all` is set on an element, it limits the transition scope to that element and its descendants, which can be used to solve the above problem.

Whenever an element-scoped view transition is triggered, the browser automatically sets `view-transition-scope: all` on the transition root element, ensuring that only elements inside the transition scope are snapshotted and animated.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
view-transition-scope =
  none  |
  all
```

This syntax reflects the latest standard as per CSS View Transitions Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using <code>view-transition-scope</code> to isolate snapshots

This example demonstrates how to use `view-transition-scope` to isolate the scope of document-scoped view transitions, enabling the same `view-transition-name` to be used on multiple elements.

HTML

The HTML includes a `<button>` element to control updating the DOM, plus several components with the class `change-me`, some of which are nested, all wrapped in a `<section>` element.

```
<button>Update DOM</button>
<section>
  <div class="change-me"><span>I can change</span></div>
  <div class="change-me">
    <span>I can change</span>
    <div class="change-me"><span>I can change</span></div>
  </div>
  <div class="change-me"><span>I can change</span></div>
</section>
```

CSS

We start by setting the same `view-transition-name` on all components. We then set `view-transition-scope: all` on all of them, to isolate the view transition process for each one. Next, we set a longer `animation-duration` on all view transitions with this `view-transition-name` via the `::view-transition-group()` pseudo-element.

```
body {
  font: 1.2em / 1.5 sans-serif;
  width: 50%;
  max-width: 700px;
  margin: 0 auto;
}

section,
.change-me {
  border: 2px solid #666666;
  padding: 10px;
}

section {
  background-color: orange;
}
```

```
.change-me {
  background-color: white;
  view-transition-name: para-change;
  view-transition-scope: all;
}

::view-transition-group(para-change) {
  animation-duration: 1s;
}
```

JavaScript

The script starts by grabbing references to the button and the `<div>` elements (our components).

```
const btn = document.querySelector("button");
const divs = document.querySelectorAll("div");
```

Next, we define a function called `updateDivs()`, which toggles the text content of each component's nested `<span>` element between two values, and also toggles the component's foreground and background colors between two values.

```
function updateDivs() {
  divs.forEach((div) => {
    if (div.firstElementChild.textContent === "I can change") {
      div.firstElementChild.textContent = "I have changed";
      div.style.color = "white";
      div.style.backgroundColor = "black";
    } else {
      div.firstElementChild.textContent = "I can change";
      div.style.color = "black";
      div.style.backgroundColor = "white";
    }
  });
}
```

Finally, we add a `click` event listener to the `<button>` element. When the button is clicked, we first check whether `startViewTransition()` exists on the `document` object — if it does not, we run `updateDivs()` and then `return` out of the function. This first part allows browsers that don't support view transitions to still update the DOM without error. Next, we run `updateDivs()` inside a `startViewTransition()` callback to trigger the view transition as the DOM updates.

```
btn.addEventListener("click", handleClick);

function handleClick(e) {
  if (!document.startViewTransition) {
    updateDivs();
    return;
  }
  document.startViewTransition(() => {
    updateDivs();
  });
}
```

Result

Click the "Update DOM" button to see the view transition. Now try the following:

1. Inspect one of the `<div>` elements.
2. In the Styles panel in your browser's developer tools, uncheck the `view-transition-scope: all;` declaration to disable it.

3. Now switch to the JavaScript Console.
4. Click the "Update DOM" button again.

You should see that the view transition animation is not applied when the DOM changes, and an `InvalidStateError` is reported in the console.

visibility CSS property

The **`visibility`** CSS property shows or hides an element without changing the layout of a document. The property can also hide rows or columns in a `<table>`.

To both hide an element *and remove it from the document layout*, set the `display` property to `none` instead of using `visibility`.

Try it

```
visibility: visible;
```

```
visibility: hidden;
```

```
visibility: collapse;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">Hide me</div>
    <div>Item 2</div>
    <div>Item 3</div>
  </div>
</section>
```

```
.example-container {
  border: 1px solid #c5c5c5;
  padding: 0.75em;
  width: 80%;
  max-height: 300px;
  display: flex;
}

.example-container > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
  margin: 10px;
  flex: 1;
}

#example-element {
  background-color: rgb(255 0 200 / 0.2);
  border: 3px solid rebeccapurple;
}
```

Syntax

```
/* Keyword values */
visibility: visible;
visibility: hidden;
visibility: collapse;

/* Global values */
visibility: inherit;
visibility: initial;
visibility: revert;
visibility: revert-layer;
visibility: unset;
```

The `visibility` property is specified as one of the keyword values listed below.

Values

`visible`

> The element box is visible.

`hidden`

> The element box is invisible (not drawn), but still affects layout as normal. Descendants of the element will be visible if they have `visibility` set to `visible`. The element cannot receive focus (such as when navigating through tab indexes).

`collapse`

> The `collapse` keyword has different effects for different elements:
>
> - For `<table>` rows, columns, column groups, and row groups, the row(s) or column(s) are hidden and the space they would have occupied is removed (as if `display: none` were applied to the column/row of the table). However, the size of other rows and columns is still calculated as though the cells in the collapsed row(s) or column(s) are present. This value allows for the fast removal of a row or column from a table without forcing the recalculation of widths and heights for the entire table.
> - Collapsed flex items and ruby annotations are hidden, and the space they would have occupied is removed.
> - For other elements, `collapse` is treated the same as `hidden`.

Accessibility

Using a `visibility` value of `hidden` on an element will remove it from the accessibility tree. This will cause the element and all its descendant elements to no longer be announced by screen reading technology.

Interpolation

When animated, visibility values are interpolated between *visible* and *not-visible*. One of the start or ending values must therefore be `visible` or no interpolation can happen. The value is interpolated as a discrete step, where values of the easing function between `0` and `1` map to `visible` and other values of the easing function (which occur only at the start/end of the transition or as a result of `cubic-bezier()` functions with y values outside of [0, 1]) map to the closer endpoint.

Notes

- Support for `visibility: collapse` is missing or partially incorrect in some modern browsers. It may not be correctly treated like `visibility: hidden` on elements other than table rows and columns.
- When applied to table rows, if the table contains cells (`<td>` and `<th>` elements) that span both visible and collapsed rows, the cell may render in unexpected ways. If the spanning cell is defined in a collapsed row, browsers do not render the table cell, as if the cells in subsequent rows were present with `visibility: collapse` applied. When the cell is defined in a visible row and spans a collapsed row, the cell contents are not reflowed, but the presentation of the cell itself varies by browser. Most browsers reduce the block size of the cell by the block size of the hidden row. This means the contents may be larger than the cell in the block-size direction. Depending on the browser, the overflowing contents are either cropped, as if `overflow: hidden` were set, while the content bleeds into the subsequent row in other browsers as if `overflow: visible` were set. In other browsers, the cell is rendered as if the row were not collapsed, with all the other cells in the row hidden as if `visibility: collapse` were set on individual cells rather than the row itself.
- `visibility: collapse` may change the layout of a table if the table has nested tables within the cells that are collapsed, unless `visibility: visible` is specified explicitly on nested tables.

Formal definition

Initial value	`visible`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
visibility =
  visible       |
  hidden        |
  force-hidden  |
  collapse
```

This syntax reflects the latest standard as per CSS Display Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

HTML

```
<p class="visible">The first paragraph is visible.</p>
<p class="not-visible">The second paragraph is NOT visible.</p>
<p class="visible">
  The third paragraph is visible. Notice the second paragraph is still occupying
  space.
</p>
```

CSS

```
.visible {
  visibility: visible;
}

.not-visible {
  visibility: hidden;
}
```

Table example

HTML

```
<table>
  <tbody>
    <tr>
      <td>1.1</td>
      <td class="collapse">1.2</td>
      <td>1.3</td>
    </tr>
    <tr class="collapse">
      <td>2.1</td>
      <td>2.2</td>
      <td>2.3</td>
    </tr>
    <tr>
      <td>3.1</td>
      <td>3.2</td>
      <td>3.3</td>
    </tr>
  </tbody>
</table>
```

CSS

```
.collapse {
  visibility: collapse;
}

table {
  border: 1px solid red;
}

td {
  border: 1px solid gray;
}
```

white-space CSS property

The **`white-space`** CSS shorthand property sets how white space inside an element is handled.

Try it

```
white-space: normal;
```

```
white-space: pre;
```

```
white-space: pre-wrap;
```

```
white-space: pre-line;
```

```
white-space: wrap;
```

```
white-space: collapse;
```

```
white-space: preserve nowrap;
```

```
<section class="default-example" id="default-example">
  <div id="example-element">
    <p>
      But ere she from the church-door stepped She smiled and told us why: 'It
      was a wicked woman's curse,' Quoth she, 'and what care I?' She smiled, and
      smiled, and passed it off Ere from the door she stept—
    </p>
  </div>
</section>
```

```
#example-element {
  width: 16rem;
}

#example-element p {
  border: 1px solid #c5c5c5;
  padding: 0.75rem;
  text-align: left;
}
```

The property specifies two things:

- Whether and how white space is collapsed.
- Whether and how lines wrap.

> **Note:** To make words break *within themselves*, use `overflow-wrap`, `word-break`, or `hyphens` instead.

Constituent properties

This property is a shorthand for the following CSS properties:

- `white-space-collapse`
- `text-wrap-mode`

> **Note:** The spec defines a third constituent property: `white-space-trim`, which is not implemented in any browser yet.

Syntax

```
/* Single keyword values */
white-space: normal;
white-space: pre;
white-space: pre-wrap;
white-space: pre-line;

/* white-space-collapse and text-wrap-mode shorthand values */
white-space: nowrap;
white-space: wrap;
white-space: break-spaces;
white-space: collapse;
white-space: preserve nowrap;

/* Global values */
white-space: inherit;
white-space: initial;
white-space: revert;
white-space: revert-layer;
white-space: unset;
```

Values

The `white-space` property values can be specified as one or two keywords representing the values for the `white-space-collapse` and `text-wrap-mode` properties, or the following special keywords:

`normal`

Sequences of white space are collapsed. Newline characters in the source are handled the same as other white spaces. Lines are broken as necessary to fill line boxes. Equivalent to `collapse wrap`.

`pre`

Sequences of white space are preserved. Lines are only broken at newline characters in the source and at `<br>` elements. Equivalent to `preserve nowrap`.

`pre-wrap`

Sequences of white space are preserved. Lines are broken at newline characters, at `<br>`, and as necessary to fill line boxes. Equivalent to `preserve wrap`.

`pre-line`

Sequences of white space are collapsed. Lines are broken at newline characters, at `<br>`, and as necessary to fill line boxes. Equivalent to `preserve-breaks wrap`.

> **Note:** The `white-space` property as a shorthand is a relatively new feature (see browser compatibility). Originally, it had six keyword values; now, the value `nowrap` is instead interpreted as a value for `text-wrap-mode`, while the value `break-spaces` is interpreted as a value for `white-space-collapse`. The above four keywords are still specific to `white-space`, but they have longhand equivalents. The change to make `white-space` a shorthand expands acceptable values to even more keywords and combinations, such as `wrap` and `collapse`.

The following table summarizes the behavior of these four `white-space` keyword values:

	New lines	Spaces and tabs	Text wrapping	End-of-line spaces	End-of-line other space separators
`normal`	Collapse	Collapse	Wrap	Remove	Hang
`pre`	Preserve	Preserve	No wrap	Preserve	No wrap
`pre-wrap`	Preserve	Preserve	Wrap	Hang	Hang
`pre-line`	Preserve	Collapse	Wrap	Remove	Hang

A tab defaults to 8 spaces and can be configured using the `tab-size` property. In the case of `normal`, `nowrap`, and `pre-line` values, every tab is converted to a space (U+0020) character.

> **Note:** There is a distinction made between **spaces** and **other space separators**. These are defined as follows:
>
> spaces
>
> Spaces (U+0020), tabs (U+0009), and segment breaks (such as newlines).
>
> other space separators
>
> All other space separators defined in Unicode, other than those already defined as spaces.
>
> Where white space is said to *hang*, this can affect the size of the box when measured for intrinsic sizing.

Formal definition

Initial value	`normal`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
white-space =
  normal                                          |
  pre                                             |
  pre-wrap                                        |
  pre-line                                        |
  <'white-space-collapse'> || <'text-wrap-mode'> || <'white-space-trim'>

<white-space-collapse> =
  collapse          |
  discard           |
  preserve          |
  preserve-breaks   |
  preserve-spaces   |
  break-spaces

<text-wrap-mode> =
  wrap    |
  nowrap

<white-space-trim> =
  none                                          |
  discard-before || discard-after || discard-inner
```

This syntax reflects the latest standard as per CSS Text Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

```
code {
  white-space: pre;
}
```

Line breaks inside <pre> elements

```
pre {
  white-space: pre-wrap;
}
```

In action

```
<div id="css-code" class="box">
  p { white-space:
  <select>
    <option>normal</option>
    <option>nowrap</option>
    <option>pre</option>
```

```
    <option>pre-wrap</option>
    <option>pre-line</option>
    <option>break-spaces</option>
  </select>
  }
</div>
<div id="results" class="box">
  <p>
    Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod
    tempor incididunt ut labore et dolore magna aliqua. Ut enim ad minim veniam,
    quis nostrud exercitation ullamco laboris nisi ut aliquip ex ea commodo
    consequat. Duis aute irure dolor in reprehenderit in voluptate velit esse
    cillum dolore eu fugiat nulla pariatur. Excepteur sint occaecat cupidatat
    non proident, sunt in culpa qui officia deserunt mollit anim id est laborum.
  </p>
</div>
```

```
.box {
  width: 350px;
  padding: 16px;
}

#css-code {
  background-color: gainsboro;
  font-size: 16px;
  font-family: monospace;
}

#css-code select {
  font-family: inherit;
  width: 100px;
}

#results {
  background-color: rgb(230 230 230);
  overflow-x: scroll;
  white-space: normal;
  font-size: 14px;
}
```

```
const select = document.querySelector("#css-code select");
const results = document.querySelector("#results p");
select.addEventListener("change", (e) => {
  results.style.setProperty("white-space", e.target.value);
});
```

Controlling line wrapping in tables

HTML

```
<table>
  <tbody>
    <tr>
      <td></td>
      <td>Very long content that splits</td>
      <td class="nw">Very long content that don't split</td>
    </tr>
    <tr>
      <td class="nw">white-space:</td>
      <td>normal</td>
      <td>nowrap</td>
    </tr>
  </tbody>
</table>
```

CSS

```
table {
  border-collapse: collapse;
  border: solid black 1px;
  width: 250px;
  height: 150px;
}
td {
  border: solid 1px black;
  text-align: center;
}
.nw {
  white-space: nowrap;
}
```

Result

Multiple lines in SVG text element

The `white-space` CSS property can be used to create multiple lines in a `<text>` element, which does not wrap by default.

HTML

The text inside the `<text>` element needs to be split into multiple lines for the new lines to be detected. After the first line the rest need to have their whitespace removed.

```
<svg viewBox="0 0 320 150">
  <text y="20" x="10">Here is an English paragraph
that is broken into multiple lines
in the source code so that it can
be more easily read and edited
in a text editor.
  </text>
</svg>
```

CSS

```
text {
  white-space: break-spaces;
}
```

Result

- Properties that define how words break *within themselves*: `overflow-wrap`, `word-break`, `hyphens`
- `tab-size`
- Handling whitespace in CSS

white-space-collapse CSS property

The **`white-space-collapse`** CSS property controls how white space inside an element is collapsed.

> **Note:** The `white-space-collapse` and `text-wrap-mode` properties can be declared together using the `white-space` shorthand property.

Syntax

```
/* Keyword values */
white-space-collapse: collapse;
white-space-collapse: preserve;
white-space-collapse: preserve-breaks;
white-space-collapse: preserve-spaces;
white-space-collapse: break-spaces;

/* Global values */
white-space-collapse: inherit;
white-space-collapse: initial;
white-space-collapse: revert;
white-space-collapse: revert-layer;
white-space-collapse: unset;
```

The `white-space-collapse` property is specified as a single keyword chosen from the list of values below.

Values

`collapse`

White space sequences are collapsed.

`preserve`

White space sequences and segment break characters are preserved.

`preserve-breaks`

White space sequences are collapsed, while segment break characters are preserved.

`preserve-spaces`

White space sequences are preserved, while tabs and segment break characters are converted to spaces.

`break-spaces`

The behavior is identical to `preserve`, except that:

- Any sequence of preserved white space always takes up space, including at the end of the line.
- A line-breaking opportunity exists after every preserved white space character, including between white space characters.
- Preserved spaces take up space and do not hang, thus affecting the box's intrinsic sizes (`min-content` size and `max-content` size).

> **Note:** *Segment break characters* are characters such as line feeds that cause text to break onto new lines.

> **Note:** The CSS text module defines a `discard` value for the `white-space-collapse` property to discard all white space in the element, however, this is not supported in any browsers.

Formal definition

Initial value	`collapse`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
white-space-collapse =
  collapse         |
  discard          |
  preserve         |
  preserve-breaks  |
  preserve-spaces  |
  break-spaces
```

This syntax reflects the latest standard as per CSS Text Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<h2 class="collapse">Default behavior;
  all   whitespace   is   collapsed
  in    the          heading       .</h2>

<h2 class="preserve">In this case
  all   whitespace   is   preserved
  in    the          heading       .</h2>

<h2 class="preserve-breaks">In this case only
  the   line breaks  are  preserved
  in    the          heading       .</h2>

<h2 class="preserve-spaces">In this case only
  the   spaces       are  preserved
  in    the          heading       .</h2>
```

CSS

```
.collapse {
  white-space-collapse: collapse;
}

.preserve {
  white-space-collapse: preserve;
}

.preserve-breaks {
  white-space-collapse: preserve-breaks;
}

.preserve-spaces {
  white-space-collapse: preserve-spaces;
}

h2 {
  font-size: 1.6rem;
  font-family: monospace;
  border-bottom: 1px dotted #cccccc;
}
```

Result

- Shorthand for `white-space-collapse` and `text-wrap-mode`: The `white-space` property.
- CSS text module
- Handling whitespace in CSS

widows CSS property

The **`widows`** CSS property sets the minimum number of lines in a block container that must be shown at the *top* of a page, region, or column.

In typography, a *widow* is the last line of a paragraph that appears alone at the top of a page. (The paragraph is continued from a prior page.)

Syntax

```
/* <integer> values */
widows: 2;
widows: 3;

/* Global values */
widows: inherit;
widows: initial;
widows: revert;
widows: revert-layer;
widows: unset;
```

Values

This property is specified as one `<integer>`:

`<integer>`

The minimum number of lines that can stay by themselves at the top of a new fragment after a fragmentation break. The value must be positive.

Formal definition

Initial value	2
Applies to	block container elements
Inherited	yes
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
widows =
  <integer [1,∞]>

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Fragmentation Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Controlling column widows

This example uses a checkbox to switch `widows` between `2` and `1`. With `widows: 2`, at least two lines of a paragraph must appear at the top of a column. With `widows: 1`, the paragraph can be broken anywhere.

HTML

```
<div>
  <p>This is the first paragraph containing some text.</p>
  <p>
    This is the second paragraph containing some more text than the first one.
    It is used to demonstrate how widows work.
  </p>
  <p>
    This is the third paragraph. It has a little bit more text than the first
    one.
  </p>
</div>
<form>
  <input type="checkbox" id="widows" checked />
  <label for="widows">Apply widows: 2</label>
</form>
```

CSS

```
div {
  background-color: #8cffa0;
  width: 400px;
  height: 160px;
  columns: 3;
  column-fill: auto;
  orphans: 1;
  widows: 1;
}

div:has(~ form input:checked) {
  widows: 2;
}

p {
  background-color: #8ca0ff;
}

p:first-child {
  margin-top: 0;
}
```

Result

In Firefox, which does not support `widows`, the behavior in this example is essentially equivalent to `widows: 1`, regardless of the checkbox state. The following screenshot shows the result with `widows: 2` in a supporting browser:

- `orphans`
- Paged media

width CSS property

The **`width`** CSS property sets an element's width. By default, it sets the width of the content area, but if `box-sizing` is set to `border-box`, it sets the width of the border area.

Try it

```
width: 150px;
```

```
width: 20em;
```

```
width: 75%;
```

```
width: auto;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box where you can change the width.
  </div>
</section>
```

```
#example-element {
  display: flex;
  flex-direction: column;
  background-color: #5b6dcd;
  height: 80%;
  justify-content: center;
  color: white;
}
```

The specified value of `width` applies to the content area so long as its value remains within the values defined by `min-width` and `max-width`.

- If the value for `width` is less than the value for `min-width`, then `min-width` overrides `width`.
- If the value for `width` is greater than the value for `max-width`, then `max-width` overrides `width`.

> **Note:** As a geometric property, `width` also applies to the `<svg>`, `<rect>`, `<image>`, and `<foreignObject>` SVG elements, with `auto` resolving to `100%` for `<svg>` and `0` for other elements, and percent values being relative to the SVG viewport width for `<rect>`. The CSS `width` property value overrides any SVG `width` attribute value set on the SVG element.

Syntax

```
/* <length> values */
width: 300px;
width: 25em;

/* <percentage> value */
width: 75%;

/* Keyword values */
width: max-content;
width: min-content;
width: fit-content;
width: auto;
width: stretch;

/* function values */
width: fit-content(20em);
width: anchor-size(width);
width: anchor-size(--my-anchor inline, 120%);
width: calc-size(max-content, size / 2);

/* Global values */
width: inherit;
width: initial;
width: revert;
width: revert-layer;
width: unset;
```

Values

`<length>`

Defines the width as a distance value.

`<percentage>`

Defines the width as a percentage of the containing block's width.

`auto`

The browser will calculate and select a width for the specified element.

`max-content`

The intrinsic preferred width.

`min-content`

The intrinsic minimum width.

`fit-content`

Use the available space, but not more than max-content, i.e., `min(max-content, max(min-content, stretch))`.

`anchor-size()`

Sets the width relative to a dimension of an anchor element. When defining the `width` of an anchor-positioned element, the first parameter defaults to the associated anchor's width. If applied to a non-anchor-positioned element, it sets the width to the fallback value. If no fallback is defined, the declaration is ignored.

`calc-size()`

Sets the width to a modified intrinsic size.

`fit-content(<length-percentage>)`

Uses the fit-content formula with the available space replaced by the specified argument, clamping the width according to the formula `min(maximum size, max(minimum size, <length-percentage>))`.

`stretch`

Sets the width of the element's margin box to the width of its containing block. It attempts to make the margin box fill the available space in the containing block, so in a way behaving similar to `100%` but applying the resulting size to the margin box rather than the box determined by box-sizing.

Accessibility

Ensure that elements set with a `width` aren't truncated and/or don't obscure other content when the page is zoomed to increase text size.

- Understanding Success Criterion 1.4.4 | W3C Understanding WCAG 2.0

Formal definition

Initial value	`auto`
Applies to	all elements but non-replaced inline elements, table rows, and row groups
Inherited	no
Percentages	refer to the width of the containing block
Computed value	a percentage or `auto` or the absolute length
Animation type	a length, percentage or calc();

Formal syntax

```
width =
  auto            |
  <box-size>      |
  <anchor-size()>

<box-size> =
  <length-percentage [0,∞]>               |
  stretch                                 |
  contain                                 |
  min-content                             |
  max-content                             |
  fit-content                             |
  stretch( <length-percentage [0,∞]> )    |
  fit-content( <length-percentage [0,∞]> ) |
  <calc-size()>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<length-percentage> =
  <length>     |
  <percentage>

<calc-size()> =
  calc-size( <calc-size-basis> , <calc-sum> )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width       |
  height      |
  block       |
  inline      |
  self-block  |
  self-inline

<calc-size-basis> =
  <size-keyword>  |
  <calc-sum>      |
  <calc-size()>   |
  any

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>       |
  <dimension>    |
  <percentage>   |
  <calc-keyword> |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Sizing Module Level 3, CSS Box Sizing Module Level 4, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Default width

This example demonstrates basic usage and the default `auto` value.

HTML

We include two paragraphs; one with a class name.

```
<p>The MDN community writes really great documentation.</p>
<p class="has-width">The MDN community writes really great documentation.</p>
```

CSS

We make all paragraphs have a gold background, explicitly setting the second paragraph's `width` to `auto`.

```
p {
  background: gold;
}
p.has-width {
  width: auto;
}
```

Results

As `width` defaults to `auto`, both paragraphs are the same width.

Using length units

This example demonstrates length width values.

HTML

We include two `<div>` elements with some text.

```
<div class="px_length">Width measured in px</div>
<div class="em_length">Width measured in em</div>
```

CSS

The `px_length` element is set to `200px` while the `em_length` element is set to be `20em` wide. Both elements also have different `background-color`, `color`, and `border` values to enable differentiating between the two when rendered.

```
.px_length {
  width: 200px;

  background-color: red;
  color: white;
  border: 1px solid black;
}

.em_length {
  width: 20em;

  background-color: white;
  color: red;
  border: 1px solid black;
}
```

Results

The `px_length` element will always be 200px wide. The rendered width of the `em_length` element depends on the font size.

Using percentages

This example demonstrates using percentage values.

HTML

We include one `<div>` element with some text.

```
<div class="percent">Width in percentage</div>
```

CSS

We set the `width` of the element to be `20%` of the width of its parent container.

```
.percent {
  width: 20%;

  background-color: silver;
  border: 1px solid red;
}
```

Results

Using intrinsic sizes

This example compares `max-content` and `min-content`, and introduces `calc-size`.

HTML

We include three paragraphs with the same content; just their class names differ.

```
<p class="max-green">The MDN community writes really great documentation.</p>
<p class="min-blue">The MDN community writes really great documentation.</p>
<p class="min-pink">The MDN community writes really great documentation.</p>
```

CSS

We set one paragraph's `width` to `max-content`, the second to `min-content`, and the third to be twice the size of the `min-content` by using the `calc-size()` function. Each is given a different `background-color` and `border-style` to enable differentiating between the two.

```
p.max-green {
  width: max-content;

  background-color: lightgreen;
  border-style: dotted;
}

p.min-blue {
```

```
  width: min-content;

  background-color: lightblue;
  border-style: dashed;
}

p.min-pink {
  width: calc-size(min-content, size * 2);

  background-color: pink;
  border-style: solid;
}
```

```
@supports not (width: calc-size(min-content, size * 2)) {
  body::before {
    content: "Your browser doesn't support the calc-size() function yet.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

Results

The `max-content` example is as wide as the text. The `min-content` example is as wide as the widest word. The `calc-size()` example is set to be twice as wide as the `min-content`.

Using the stretch keyword

This example demonstrates the `stretch` value within a flex container.

HTML

We include a parent container with two child elements.

```
<div class="parent">
  <div class="child">text</div>
  <div class="child stretch">stretch</div>
</div>
```

CSS

We use the `display` property to make the parent a flex container, and set the second child's `width` the `stretch`.

```
.parent {
  border: solid;
  margin: 1rem;
  display: flex;
}

.child {
  background: #00999999;
  margin: 1rem;
}

.stretch {
  width: stretch;
}
```

```
@supports not (width: stretch) {
  body::before {
    content: "Your browser doesn't support the stretch value yet.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

Result

By default, flex items are as wide as their content. The `stretch` value makes the element as wide as the available space allows, with the element's margin box otherwise clamped to the width of its containing block.

Using the anchor-size() function

This example demonstrates using the `anchor-size()` function to define the width of an anchor-positioned element; we defined its width as a multiple of its anchor's height.

HTML

We specify two `<div>` elements: one `anchor` element and one `infobox` element that we'll position relative to the anchor.

```
<div class="anchor">⚓</div>

<div class="infobox">
  <p>Infobox.</p>
</div>
```

CSS

We declare the `anchor` `<div>` as an anchor element by giving it an `anchor-name`. The positioned element has its `position` property set to `absolute`, and is associated with the anchor element via its `position-anchor` property. We also set absolute `height` and `width` dimensions on the anchor and define the width of the anchor-positioned element to be the width of the anchor using the `anchor-size()` function as the value of the `width` property. As a bonus, we also use the `anchor-size()` function to define the infobox's `left` position, making the gap between the anchor and the infobox one quarter of the height of the anchor.

```
.anchor {
  anchor-name: --my-anchor;
  width: 120px;
  height: 60px;
```

```
  font-size: 2rem;
  background-color: lightpink;
  text-align: center;
  align-content: center;
  outline: 1px solid black;
}

.infobox {
  position-anchor: --my-anchor;
  position: absolute;
  position-area: right;
  width: anchor-size(width);

  left: calc( anchor-size(height) / 4 )

  align-content: center;
  color: darkblue;
  background-color: azure;
  outline: 1px solid #dddddd;
}
```

```
body {
  padding: 5em;
}

@supports not (width: anchor-size(width)) {
  body::before {
    content: "Your browser doesn't support the anchor-size() function value.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

Results

Note how the infobox's width is always the same as the anchor element's width.

will-change CSS property

The **`will-change`** CSS property enables optimizing animations by providing a rendering hint to a browser about how an element is expected to change.

Syntax

```
/* Keyword values */
will-change: auto;
will-change: scroll-position;
will-change: contents;

/* <custom-ident> values */
will-change: transform;
will-change: opacity;

/* multiple values */
will-change: left, top;

/* Global values */
will-change: inherit;
will-change: initial;
will-change: revert;
will-change: revert-layer;
will-change: unset;
```

Values

The value is either `auto` or one or more comma separated `<animatable-feature>` values:

`auto`

Indicates that the browser applies whatever heuristics and optimizations it normally does. This is the default value.

`<animatable-feature>`

Represents one of the following:

`scroll-position`

Specifies that the scroll position of the element is expected to change in the near future, indicating the browser can optimize the rendering of overflowing content.

`contents`

Specifies that the element's contents, including all the elements in its subtree, are expected to change in the near future, indicating the browser can cache the element less aggressively.

`<custom-ident>`

Specifies the name of a CSS property, as an `<ident>`, whose value is animated or otherwise expected to change in the near future. If the specified `<ident>` represents a property shorthand, all of its longhand components are applied. The value cannot be `will-change`, `none`, `all`, `auto`, `scroll-position`, or `contents`.

Description

The `will-change` property provides a rendering hint to the browser indicating which properties are expected to be animated or otherwise changed. This enables browsers to create the necessary rendering optimizations to enable smoother changes and avoid jank.

The `will-change` property is aimed at improving rendering performance. This property can improve performance for elements with frequent repaints and reflows or for those that use properties such as `box-shadow` and `clip-path` to create complex visual effects.

Applying the property to an element applies the value to the element's entire subtree, indicating that any of the descendants can change. For this reason, applying a non-`auto` value on a large section, such as the `<body>`, can actually be bad for a page's performance. Instead, limit the use of this property to deeply nested elements, containing as little of the document as possible.

> **Warning:** Use the `will-change` property as a last resort to try to deal with existing performance problems. Don't use it to anticipate performance problems.

Proper usage of this property can be a bit tricky. Keep the following guidelines in mind:

- **Don't apply `will-change` to too many elements**: The browser already tries as hard as it can to optimize everything. Some of the stronger optimizations that are likely to be tied to `will-change` end up using a lot of a machine's resources. Overusing the property can cause the page to slow down instead of improving its performance.
- **Use sparingly**: The browser's normal behavior for optimizations is to remove the optimizations as soon as it can and revert to normal state. But adding `will-change` directly to a stylesheet implies that the targeted elements are always a few moments away from changing and the browser will keep the optimizations for a much longer time than it would have otherwise. So it is a good practice to switch `will-change` on and off using script code before and after the change occurs.
- **Don't apply will-change to elements to perform premature optimization**: If your page is performing well, don't add the `will-change` property to elements just to wring out a little more speed. `will-change` is intended to be used as a last resort to try to deal with existing performance problems. It should not be used to anticipate performance problems. Excessive use of `will-change` will result in excessive memory use and will cause more complex rendering to occur as the browser attempts to prepare for the possible change. This will lead to worse performance.
- **Give it sufficient time to work**: This property enables you to signal to the browser about properties that are likely to change, so the browser can choose to apply any ahead-of-time optimizations before the property change occurs. For this reason, you should give the browser some time to do the optimizations. Predict slightly ahead of time that something will change, and then set `will-change`.
- **Be aware that `will-change` may influence the visual appearance of elements**: When used with property values that create a stacking context (e.g., `will-change: opacity`), the stacking context is created up front.

Animations

If applying `will-change` to improve animations, add the property before the animation starts, not within the `@keyframes` animation definitions. Animated properties are treated as if they're already included in a `will-change`, so there's no reason to add them there.

Via stylesheet

It may be appropriate to include `will-change` in your style sheet for an application that does page flips on key presses like an album or a slide deck presentation where the pages are large and complex. This will let browser prepare the transition ahead of time and allow for snappy transitions between the pages as soon as the key is pressed. But use caution with the `will-change` property directly in stylesheets. It may cause the browser to keep the optimization in memory for much longer than it is needed.

```
.slide {
  will-change: transform;
}
```

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
will-change =
  auto                  |
  <animateable-feature>#

<animateable-feature> =
  scroll-position  |
  contents         |
  <custom-ident>
```

This syntax reflects the latest standard as per CSS Will Change Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates the basic CSS application of the `will-change` property.

CSS

We use CSS to apply the `will-change` property to the `#element`, providing a hint to the browser that the `transform` and `opacity` property values will be animated or otherwise change in the near future.

```
#element {
  will-change: transform, opacity;
}
```

Via script

This example shows how to apply the `will-change` property when needed and remove optimizations when done using JavaScript, which is generally how `will-change` should be applied.

JavaScript

We use JavaScript to add the `will-change` property to `#element` when the element is hovered over by using the `mouseenter` event. Setting `will-change` to `transform, opacity` tells the browser to optimize for changes to the `transform` and `opacity` properties. When the `animationend` event occurs, our script sets the value to `auto`.

```
const el = document.getElementById("element");

el.addEventListener("mouseenter", hintBrowser);
el.addEventListener("animationEnd", removeHint);

function hintBrowser() {
```

```
  this.style.willChange = "transform, opacity";
}

function removeHint() {
  this.style.willChange = "auto";
}
```

word-break CSS property

The **`word-break`** CSS property sets whether line breaks appear wherever the text would otherwise overflow its content box.

Try it

```
word-break: normal;
```

```
word-break: break-all;
```

```
word-break: keep-all;
```

```
word-break: break-word;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    Honorificabilitudinitatibus califragilisticexpialidocious
    Taumatawhakatangihangakoauauotamateaturipukakapikimaungahoronukupokaiwhenuakitanatahu
    グレートブリテンおよび北アイルランド連合王国という言葉は本当に長い言葉
  </div>
</section>
```

```
#example-element {
  width: 80%;
  padding: 20px;
  text-align: start;
  border: solid 1px darkgray;
}
```

Syntax

```
/* Keyword values */
word-break: normal;
word-break: break-all;
word-break: keep-all;
word-break: auto-phrase; /* experimental */
word-break: break-word; /* deprecated */

/* Global values */
word-break: inherit;
word-break: initial;
word-break: revert;
word-break: revert-layer;
word-break: unset;
```

The `word-break` property is specified as a single keyword chosen from the list of values below.

Values

`normal`

Use the default line break rule.

`break-all`

To prevent overflow, word breaks should be inserted between any two characters (excluding Chinese/Japanese/Korean text).

`keep-all`

Word breaks should not be used for Chinese/Japanese/Korean (CJK) text. Non-CJK text behavior is the same as for `normal`.

`auto-phrase`

Has the same effect as `word-break: normal` except that language-specific analysis is performed to improve word breaks by not placing them in the middle of natural phrases.

`break-word`

Has the same effect as `overflow-wrap: anywhere` combined with `word-break: normal`, regardless of the actual value of the `overflow-wrap` property.

> **Note:** In contrast to `word-break: break-word` and `overflow-wrap: break-word` (see `overflow-wrap`), `word-break: break-all` will create a break at the exact place where text would otherwise overflow its container (even if putting an entire word on its own line would negate the need for a break).

The specification also lists an additional value, `manual`, which is not currently supported in any browsers. When implemented, `manual` will have the same effect as `word-break: normal` except that breaks won't be automatically inserted in Southeast Asian languages. This is needed because, in such languages, user agents frequently place breaks in suboptimal positions. `manual` will allow you to insert line breaks in optimal positions manually.

Formal definition

Initial value	`normal`
Applies to	all elements

Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
word-break =
  normal      |
  break-all   |
  keep-all    |
  manual      |
  auto-phrase |
  break-word
```

This syntax reflects the latest standard as per CSS Text Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<p>1. <code>word-break: normal</code></p>
<p class="normal narrow">
  This is a long and Honorificabilitudinitatibus califragilisticexpialidocious
  Taumatawhakatangihangakoauauotamateaturipukakapikimaungahoronukupokaiwhenuakitanatahu
  グレートブリテンおよび北アイルランド連合王国という言葉は本当に長い言葉
</p>

<p>2. <code>word-break: break-all</code></p>
<p class="breakAll narrow">
  This is a long and Honorificabilitudinitatibus califragilisticexpialidocious
  Taumatawhakatangihangakoauauotamateaturipukakapikimaungahoronukupokaiwhenuakitanatahu
  グレートブリテンおよび北アイルランド連合王国という言葉は本当に長い言葉
</p>

<p>3. <code>word-break: keep-all</code></p>
<p class="keepAll narrow">
  This is a long and Honorificabilitudinitatibus califragilisticexpialidocious
  Taumatawhakatangihangakoauauotamateaturipukakapikimaungahoronukupokaiwhenuakitanatahu
  グレートブリテンおよび北アイルランド連合王国という言葉は本当に長い言葉
</p>

<p>4. <code>word-break: manual</code></p>
<p class="manual narrow">
  This is a long and Honorificabilitudinitatibus califragilisticexpialidocious
  Taumatawhakatangihangakoauauotamateaturipukakapikimaungahoronukupokaiwhenuakitanatahu
  グレートブリテンおよび北アイルランド連合王国という言葉は本当に長い言葉
</p>

<p>5. <code>word-break: auto-phrase</code></p>
<p class="autoPhrase narrow">
  This is a long and Honorificabilitudinitatibus califragilisticexpialidocious
  Taumatawhakatangihangakoauauotamateaturipukakapikimaungahoronukupokaiwhenuakitanatahu
  グレートブリテンおよび北アイルランド連合王国という言葉は本当に長い言葉
</p>

<p>6. <code>word-break: break-word</code></p>
<p class="breakWord narrow">
  This is a long and Honorificabilitudinitatibus califragilisticexpialidocious
  Taumatawhakatangihangakoauauotamateaturipukakapikimaungahoronukupokaiwhenuakitanatahu
  グレートブリテンおよび北アイルランド連合王国という言葉は本当に長い言葉
</p>
```

CSS

```
.narrow {
  padding: 10px;
  border: 1px solid;
  width: 500px;
  margin: 0 auto;
  font-size: 20px;
  line-height: 1.5;
  letter-spacing: 1px;
}

.normal {
  word-break: normal;
}

.breakAll {
  word-break: break-all;
}

.keepAll {
  word-break: keep-all;
}

.manual {
  word-break: manual;
}

.autoPhrase {
  word-break: auto-phrase;
}

.breakWord {
  word-break: break-word;
}
```

- Guide to wrapping and breaking text

word-spacing CSS property

The **word-spacing** CSS property sets the spacing between words and between tags.

Try it

```
word-spacing: normal;
```

```
word-spacing: 1rem;
```

```
word-spacing: 4px;
```

```
word-spacing: 50%;
```

```
word-spacing: -0.4ch;
```

```
<section id="default-example">
  <p id="example-element">
    As much mud in the streets as if the waters had but newly retired from the
    face of the earth, and it would not be wonderful to meet a Megalosaurus,
    forty feet long or so, waddling like an elephantine lizard up Holborn Hill.
  </p>
</section>
```

```
@font-face {
  src: url("/shared-assets/fonts/variable-fonts/AmstelvarAlpha-VF.woff2");
  font-family: "Amstelvar";
  font-style: normal;
}

section {
  font-size: 1.2em;
  font-family: "Amstelvar", serif;
}
```

Syntax

```
/* Keyword value */
word-spacing: normal;

/* <length> values */
word-spacing: 3px;
word-spacing: 0.3em;
word-spacing: 65%;
word-spacing: -1ex;

/* Global values */
word-spacing: inherit;
word-spacing: initial;
word-spacing: revert;
word-spacing: revert-layer;
word-spacing: unset;
```

Values

This property is specified as the keyword `normal` or a `<length-percentage>`:

`normal`

The normal inter-word spacing, as defined by the current font and/or the browser.

`<length-percentage>`

Specifies extra spacing in addition to the intrinsic inter-word spacing defined by the font. Percentage values are calculated relative to the `font-size` of the text.

Accessibility

A large positive or negative `word-spacing` value will make the sentences the styling is applied to unreadable. For text styled with a very large positive value, the words will be so far apart that it will no longer appear to be a sentence. For text styled with a large negative value, the words can overlap each other to the point where the beginning and end of each word is unrecognizable.

Legible `word-spacing` must be determined on a case-by-case basis, as different font families have different character widths. There is no one value that can ensure all font families automatically maintain their legibility.

- MDN Understanding WCAG, Guideline 1.4 explanations
- Understanding Success Criterion 1.4.8 | W3C Understanding WCAG 2.0

Examples

Basic usage

This example demonstrates basic usage of `word-spacing`.

HTML

Our HTML contains two paragraphs of text:

```
<p id="mozdiv1">Lorem ipsum dolor sit amet.</p>
<p id="mozdiv2">Lorem ipsum dolor sit amet.</p>
```

CSS

Our CSS applies a different `word-spacing` to each paragraph:

```
#mozdiv1 {
  word-spacing: 15px;
}

#mozdiv2 {
  word-spacing: 5em;
}
```

Result

The example renders like so:

Comparing word-spacing set with length and percentage

This example demonstrates that percentage `word-spacing` values are useful for responsive text sizing.

The code displays several paragraphs that have the same `word-spacing` set on text with increasing font size. We provide functionality to switch between a length and a percentage `word-spacing` value, so that you can observe the responsive qualities of using a percentage value.

HTML

The HTML contains several `<p>` elements containing text content, and an `<input type="checkbox">` that we'll use to toggle between a length `word-spacing` and a percentage `word-spacing` value.

```
<p class="x-small">X-small font-size (0.8em)</p>
<p class="small">Small font-size (1.3em)</p>
<p class="medium">Medium font-size (2em)</p>
<p class="large">Large font-size (3em)</p>
<p class="x-large">X-Large (3.5em)</p>

<form>
  <label for="ls-toggle">
    Toggle <code>word-spacing</code> (off: <code>10px</code>, on:
    <code>15%</code>)
  </label>
  <input type="checkbox" id="ls-toggle" />
</form>
```

CSS

Our CSS starts by applying increasing `font-size` values to each successive paragraph:

```
html {
  font-family: "Arial", sans-serif;
}
```

```
.x-small {
  font-size: 0.8em;
}

.small {
  font-size: 1.3em;
}

.medium {
  font-size: 2em;
}

.large {
  font-size: 3em;
}

.x-large {
  font-size: 3.5em;
}
```

We apply a `word-spacing` value of `10px` to all paragraphs by default. When the checkbox is checked, however, we change the `word-spacing` value to `15%`:

```
p {
  word-spacing: 10px;
}

p:has(~ form > input:checked) {
  word-spacing: 15%;
}
```

Result

The rendered result looks like this:

First, note how the initial length letter spacing value looks OK when applied to the larger font sizes, but it doesn't look good on the smaller font sizes. Now toggle the checkbox, and note how the percentage letter spacing looks appropriate on all lines, as it scales with the font size.

Formal definition

Initial value	`normal`
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Percentages	refer to the width of the affected glyph
Computed value	absolute `<length>`
Animation type	a length

Formal syntax

```
word-spacing =
  normal                |
  <length-percentage>
```

```
<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Text Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

writing-mode CSS property

The **`writing-mode`** CSS property sets whether lines of text are laid out horizontally or vertically, as well as the direction in which text flows.

Try it

```
writing-mode: horizontal-tb;
```

```
writing-mode: vertical-lr;
```

```
writing-mode: vertical-rl;
```

```
writing-mode: sideways-rl;
```

```
writing-mode: sideways-lr;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    <div>1</div>
    <div>2</div>
    <div>3</div>
    <div>4</div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  padding: 0.75em;
  width: 80%;
  max-height: 300px;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
  margin: 10px;
}
```

Syntax

```
/* Keyword values */
writing-mode: horizontal-tb;
writing-mode: vertical-rl;
writing-mode: vertical-lr;
writing-mode: sideways-rl;
writing-mode: sideways-lr;

/* Global values */
writing-mode: inherit;
writing-mode: initial;
writing-mode: revert;
writing-mode: revert-layer;
writing-mode: unset;
```

Values

This property is specified as one of the following keywords:

`horizontal-tb`

> For `ltr` scripts, content flows horizontally from left to right. For `rtl` scripts, content flows horizontally from right to left. The next horizontal line is positioned below the previous line.

`vertical-rl`

> For `ltr` scripts, content flows vertically from top to bottom, and the next vertical line is positioned to the left of the previous line. For `rtl` scripts, content flows vertically from bottom to top, and the next vertical line is positioned to the left of the previous line.

`vertical-lr`

> For `ltr` scripts, content flows vertically from top to bottom, and the next vertical line is positioned to the right of the previous line. For `rtl` scripts, content flows vertically from bottom to top, and the next vertical line is positioned to the right of the previous line.

`sideways-rl`

> For `ltr` scripts, content flows vertically from top to bottom. For `rtl` scripts, content flows vertically from bottom to top. All the glyphs, even those in vertical scripts, are set sideways toward the right.

`sideways-lr`

> For `ltr` scripts, content flows vertically from bottom to top. For `rtl` scripts, content flows vertically from top to bottom. All the glyphs, even those in vertical scripts, are set sideways toward the left.

`lr`

> Deprecated except for SVG1 documents. For CSS, use `horizontal-tb` instead.

`lr-tb`

Deprecated except for SVG1 documents. For CSS, use `horizontal-tb` instead.

`rl`

Deprecated except for SVG1 documents. For CSS, use `horizontal-tb` instead.

`tb`

Deprecated except for SVG1 documents. For CSS, use `vertical-lr` instead.

`tb-lr`

Deprecated except for SVG1 documents. For CSS, use `vertical-lr` instead.

`tb-rl`

Deprecated except for SVG1 documents. For CSS, use `vertical-rl` instead.

Description

The `writing-mode` property sets whether lines of text are laid out horizontally or vertically. It specifies the *block flow direction*, which is the direction in which block-level containers are stacked, and the direction in which inline-level content flows within a block container. Thus, it also determines the ordering of block-level content.

The flow direction in horizontal scripts is also affected by the directionality of that script, either left-to-right (`ltr`, like English and most other languages) or right-to-left (`rtl`, like Hebrew or Arabic).

When set for an entire document, it should be set on the root element (`html` element for HTML documents).

Formal definition

Initial value	`horizontal-tb`
Applies to	all elements except table row groups, table column groups, table rows, and table columns
Inherited	yes
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
writing-mode =
  horizontal-tb  |
  vertical-rl    |
  vertical-lr    |
  sideways-rl    |
  sideways-lr
```

This syntax reflects the latest standard as per CSS Writing Modes Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using multiple writing modes

This example demonstrates all of the writing modes, showing each with text in various languages.

HTML

The HTML is a `<table>` with each writing mode in a row with a column showing text in various scripts using that writing mode.

```
<table>
  <caption>
    Using multiple writing modes
  </caption>
  <thead>
    <tr>
      <th>Value</th>
      <th>Vertical script</th>
      <th>Horizontal (LTR) script</th>
      <th>Horizontal (RTL) script</th>
      <th>Mixed script</th>
    </tr>
  </thead>
  <tbody>
    <tr class="text1">
      <th>horizontal-tb</th>
      <td>我家没有电脑。</td>
      <td>Example text</td>
      <td>חלל ארוך לדוגמא</td>
      <td>1994年に至っては</td>
    </tr>
    <tr class="text2">
      <th>vertical-lr</th>
      <td>我家没有电脑。</td>
      <td>Example text</td>
      <td>חלל ארוך לדוגמא</td>
      <td>1994年に至っては</td>
    </tr>
    <tr class="text3">
      <th>vertical-rl</th>
      <td>我家没有电脑。</td>
      <td>Example text</td>
      <td>חלל ארוך לדוגמא</td>
      <td>1994年に至っては</td>
    </tr>
    <tr class="experimental text4">
      <th>sideways-lr</th>
      <td>我家没有电脑。</td>
      <td>Example text</td>
      <td>חלל ארוך לדוגמא</td>
      <td>1994年に至っては</td>
    </tr>
    <tr class="experimental text5">
      <th>sideways-rl</th>
```

```
      <td>我家没有电脑。</td>
      <td>Example text</td>
      <td>מלל ארוך לדוגמא</td>
      <td>1994年に至っては</td>
    </tr>
  </tbody>
</table>
<p class="notice">
  Your browser does not support the <code>sideways-lr</code> or
  <code>sideways-rl</code> values.
</p>
```

CSS

```
table {
  border-collapse: collapse;
}
td,
th {
  border: 2px black solid;
  padding: 4px;
}
th {
  background-color: lightgray;
}

.experimental {
  display: none;
}

.notice {
  display: table-row;
  font-weight: bold;
  text-align: center;
}

@supports (writing-mode: sideways-lr) {
  .experimental {
    display: table-row;
  }
  .notice {
    display: none;
  }
}
```

The CSS that adjusts the directionality of the content looks like this:

```
.text1 td {
  writing-mode: horizontal-tb;
}

.text2 td {
  writing-mode: vertical-lr;
}

.text3 td {
  writing-mode: vertical-rl;
}

.text4 td {
  writing-mode: sideways-lr;
}

.text5 td {
  writing-mode: sideways-rl;
}
```

Result

Using writing-mode with transforms

If your browser doesn't support `sideways-lr`, a workaround is to use `transform` to achieve a similar effect depending on the script direction. The effect of `vertical-rl` is the same as with `sideways-lr`, so no transformation is required for left-to-right scripts. In some cases, rotating the text 180 degrees is sufficient to achieve the effect of `sideways-lr`, but font glyphs may not be designed to be rotated, so this may produce unexpected positioning or rendering.

HTML

```
<table>
  <caption>
    Using writing-mode with transforms
  </caption>
  <thead>
    <tr>
      <th>Vertical LR</th>
      <th>Vertical LR with transform</th>
      <th>Sideways LR</th>
      <th>Only rotate</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <td>
        <span class="vertical-lr">我家没有电脑。</span>
        <span class="vertical-lr">Example text</span>
      </td>
      <td>
        <span class="vertical-lr rotated">我家没有电脑。</span>
        <span class="vertical-lr rotated">Example text</span>
      </td>
      <td>
        <span class="sideways-lr">我家没有电脑。</span>
```

```
        <span class="sideways-lr">Example text</span>
      </td>
      <td>
        <span class="only-rotate">我家没有电脑。</span>
        <span class="only-rotate">Example text</span>
      </td>
    </tr>
  </tbody>
</table>
```

CSS

```
.vertical-lr {
  writing-mode: vertical-lr;
}

.rotated {
  transform: rotate(180deg);
}

.sideways-lr {
  writing-mode: sideways-lr;
}

.only-rotate {
  inline-size: fit-content;
  transform: rotate(-90deg);
}
```

```
table {
  border-collapse: collapse;
}
td,
th {
  border: 2px black solid;
  padding: 4px;
}
th {
  background-color: lightgray;
}
span {
  display: inline-block;
  width: 1.5em;
  text-align: center;
}
```

x CSS property

The **x** CSS property defines the x-axis coordinate of the top left corner of the SVG `<rect>` shape, `<image>` image, `<foreignObject>` viewport or nested `<svg>` viewport relative to the nearest `<svg>` ancestor's user coordinate system. If present, it overrides the element's `x` attribute.

> **Note:** The `x` property only applies to `<rect>`, `<image>`, `<foreignObject>`, and `<svg>` elements nested in an `<svg>`. It has no effect on the outermost `<svg>` elements itself, and does not apply to other SVG elements nor to HTML elements or pseudo-elements.

Syntax

```
/* length and percentage values */
x: 40px;
x: 40%;

/* Global values */
x: inherit;
x: initial;
x: revert;
x: revert-layer;
x: unset;
```

Values

The `<length>` and `<percentage>` values denote the x-axis coordinate position of the top left corner of the SVG element container.

`<length>`

As an absolute or relative length, it can be expressed in any unit allowed by the CSS `<length>` data type.

`<percentage>`

Percentages refer to the width of the SVG `viewBox`, if declared, otherwise, the percentage refers to the width of the current SVG viewport.

Formal definition

Initial value	`0`
Applies to	`<svg>`, `<rect>`, `<image>`, and `<foreignObject>` elements in `<svg>`
Inherited	no
Percentages	refer to the width of the current SVG viewport
Computed value	the percentage as specified or the absolute length
Animation type	by computed value type

Formal syntax

```
x =
  <length-percentage>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Specification, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Defining the x-axis coordinates of SVG shapes

This example demonstrates the basic use case of `x`, and how the CSS `x` property takes precedence over the `x` attribute.

HTML

We include four identical SVG `<rect>` elements; their `x` and `y` attributes values are all `10`, meaning the four rectangles are all in the same location, `10px` from the top and left corner of the SVG viewport.

```
<svg xmlns="http://www.w3.org/2000/svg">
  <rect width="100" height="100" x="10" y="10" />
  <rect width="100" height="100" x="10" y="10" />
  <rect width="100" height="100" x="10" y="10" />
  <rect width="100" height="100" x="10" y="10" />
</svg>
```

CSS

We style all the rectangles to have a black border and be slightly transparent, so overlapping rectangles are visible. We provide each rectangle with different fill and `x` values.

```
svg {
  border: 1px solid;
  width: 300px;
}

rect {
  fill: none;
  stroke: black;
  opacity: 0.8;
}

rect:nth-of-type(2) {
  x: 3em;
  fill: red;
}

rect:nth-of-type(3) {
  x: 180px;
  fill: yellow;
}

rect:nth-of-type(4) {
  x: 50%;
  fill: orange;
}
```

Results

The left edges of the rectangles are at `10` (from the attribute), `3em`, `180px`, and `50%`, respectively. The SVG is `300px` wide, so the last rectangle's left side is at the `150px` mark.

See also

- SVG `x` attribute
- Geometry properties: `x`, `cx`, `cy`, `r`, `rx`, `ry`, `y`, `width`, `height`
- `fill`
- `stroke`
- `paint-order`
- `<basic-shape>` data type

y CSS property

The **`y`** CSS property defines the y-axis coordinate of the top left corner of the SVG `<rect>` shape, `<image>` image, `<foreignObject>` viewport and nested `<svg>` viewport relative to the nearest `<svg>` ancestor's user coordinate system. If present, it overrides the element's `y` attribute.

> **Note:** The `y` property only applies to `<rect>`, `<image>`, `<foreignObject>`, and `<svg>` elements nested in an `<svg>`. It has no effect on outermost `<svg>` elements and does not apply to other SVG elements nor to HTML elements or pseudo-elements.

Syntax

```
/* length and percentage values */
y: 10px;
y: 10%;
```

```
/* Global values */
y: inherit;
y: initial;
y: revert;
y: revert-layer;
y: unset;
```

Values

The `<length>` and `<percentage>` values denote the y-axis coordinate position of the top left corner of the SVG element.

`<length>`

As an absolute or relative length, it can be expressed in any unit allowed by the CSS `<length>` data type.

`<percentage>`

Percentages refer to the height of the SVG `viewBox`, if declared, otherwise, the percentage refers to the height of the current SVG viewport.

Formal definition

Initial value	`0`
Applies to	`<svg>`, `<rect>`, `<image>`, and `<foreignObject>` elements in `<svg>`
Inherited	no
Percentages	refer to the height of the current SVG viewport
Computed value	the percentage as specified or the absolute length
Animation type	by computed value type

Formal syntax

```
y =
  <length-percentage>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Specification, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Defining the y-axis coordinates of SVG shapes

This example demonstrates the basic use case of `y`, and how the CSS `y` property takes precedence over the `y` attribute.

HTML

We include four identical SVG `<rect>` elements; their `x` and `y` attributes values are all `10`, meaning the four rectangles are all in the same location, `10px` from the top and left corner of the SVG viewport.

```
<svg>
  <rect width="40" height="40" x="10" y="10" />
  <rect width="40" height="40" x="10" y="10" />
  <rect width="40" height="40" x="10" y="10" />
  <rect width="40" height="40" x="10" y="10" />
</svg>
```

CSS

We style all the rectangles to have a black border and be slightly transparent, so overlapping rectangles are visible. We provide the rectangle with different `fill` and `y` values.

```
svg {
  border: 1px solid;
}

rect {
  fill: none;
  stroke: black;
  opacity: 0.8;
}

rect:nth-of-type(2) {
  y: -20px;
  fill: red;
}

rect:nth-of-type(3) {
  y: 4em;
  fill: yellow;
}

rect:nth-of-type(4) {
  y: 60%;
  fill: orange;
}
```

Results

The top edges of the rectangles are at `10` (from the attribute), `-20px`, `4em`, and `60%`, respectively. The rectangle is `40px` tall, so the `-20px` places half the red rectangle outside the viewport. The SVG is `150px` tall, so the orange rectangle's top side is `90px` from the top of the SVG viewport.

- `stroke`
- `paint-order`

- `<basic-shape>` data type

z-index CSS property

The **`z-index`** CSS property sets the z-order of a positioned element and its descendants or flex and grid items. Overlapping elements with a larger z-index cover those with a smaller one.

Try it

```
z-index: auto;
```

```
z-index: 1;
```

```
z-index: 3;
```

```
z-index: 5;
```

```
z-index: 7;
```

```
<section class="default-example container" id="default-example">
  <div id="example-element">Change my z-index</div>
  <div class="block blue position1">z-index: 6</div>
  <div class="block blue position2">z-index: 4</div>
  <div class="block blue position3">z-index: 2</div>
  <div class="block red position4">z-index: auto</div>
  <div class="block red position5">z-index: auto</div>
  <div class="block red position6">z-index: auto</div>
</section>
```

```
#example-element {
  top: 15px;
  left: 15px;
  width: 180px;
  height: 230px;
  position: absolute;
  /* center the text so it is visible even when z-index is set to auto */
  line-height: 215px;
  font-family: monospace;
  background-color: #fcfbe5;
  border: solid 5px #e3e0a1;
  z-index: auto;
  color: black;
}

.container {
  display: inline-block;
  width: 250px;
  position: relative;
}

.block {
  width: 150px;
  height: 50px;
  position: absolute;
  font-family: monospace;
  color: black;
}

.blue {
  background-color: #e5e8fc;
  border: solid 5px #112382;
  /* move text to the bottom of the box */
  line-height: 55px;
}

.red {
  background-color: #fce5e7;
  border: solid 5px #e3a1a7;
}

.position1 {
  top: 0;
  left: 0;
  z-index: 6;
}

.position2 {
  top: 30px;
  left: 30px;
  z-index: 4;
}

.position3 {
  top: 60px;
  left: 60px;
  z-index: 2;
}

.position4 {
  top: 150px;
  left: 0;
  z-index: auto;
}

.position5 {
  top: 180px;
  left: 30px;
  z-index: auto;
}

.position6 {
```

```
  top: 210px;
  left: 60px;
  z-index: auto;
}
```

For a positioned box (that is, one with any `position` other than `static`), the `z-index` property specifies:

1. The stack level of the box in the current stacking context.
2. Whether the box establishes a local stacking context.

Syntax

```
/* Keyword value */
z-index: auto;

/* <integer> values */
z-index: 0;
z-index: 3;
z-index: 289;
z-index: -1; /* Negative values to lower the priority */

/* Global values */
z-index: inherit;
z-index: initial;
z-index: revert;
z-index: revert-layer;
z-index: unset;
```

Values

This property is specified as one of the following values:

`auto`

> The box does not establish a new local stacking context. The stack level of the generated box in the current stacking context is `0`.

`<integer>`

> This `<integer>` is the stack level of the generated box in the current stacking context. The box also establishes a local stacking context. This means that the z-indexes of descendants are not compared to the z-indexes of elements outside this element.

Formal definition

Initial value	`auto`
Applies to	positioned elements
Inherited	no
Computed value	as specified
Animation type	an integer
Creates stacking context	yes

Formal syntax

```
z-index =
  auto       |
  <integer>  |
  inherit

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4, Cascading Style Sheets Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Visually layering elements

HTML

```
<div class="wrapper">
  <div class="dashed-box">Dashed box</div>
  <div class="gold-box">Gold box</div>
  <div class="green-box">Green box</div>
</div>
```

CSS

```
.wrapper {
  position: relative;
}

.dashed-box {
  position: relative;
  z-index: 1;
  border: dashed;
  height: 8em;
  margin-bottom: 1em;
  margin-top: 2em;
}
.gold-box {
  position: absolute;
  z-index: 3; /* put .gold-box above .green-box and .dashed-box */
  background: gold;
  width: 80%;
  left: 60px;
  top: 3em;
}
.green-box {
```

```
  position: absolute;
  z-index: 2; /* put .green-box above .dashed-box */
  background: lightgreen;
  width: 20%;
  left: 65%;
  top: -25px;
  height: 7em;
  opacity: 0.9;
}
```

Result

See also

- CSS `position` property
- Understanding CSS z-indexes

zoom CSS property

The **`zoom`** CSS property can be used to control the magnification level of an element. `transform: scale()` can be used as an alternative to this property.

The `zoom` CSS property scales the targeted element, which can affect the page layout. When scaling, the zoomed element scales from `top` and `center` when using the default `writing-mode`.

In contrast, an element scaled using `scale()` will not cause layout recalculation or move other elements on the page. If using `scale()` makes the contents larger than the containing element, then `overflow` comes into effect. Additionally, elements adjusted using `scale()` transform from the `center` by default; this can be changed with the `transform-origin` CSS property.

Syntax

```
/* <percentage> values */
zoom: 50%;
zoom: 200%;

/* <number> values */
zoom: 1.1;
zoom: 0.7;

/* Non-standard keyword values */
zoom: normal;
zoom: reset;

/* Global values */
zoom: inherit;
zoom: initial;
zoom: revert;
zoom: revert-layer;
zoom: unset;
```

Values

`<percentage>`

Zoom factor. `100%` is equivalent to `normal`. Values larger than `100%` zoom in. Values smaller than `100%` zoom out.

`<number>`

Zoom factor. Equivalent to the corresponding percentage (`1.0` = `100%` = `normal`). Values larger than `1.0` zoom in. Values smaller than `1.0` zoom out.

Two non-standard keyword values are not recommended. Check browser compatibility data:

`normal`

Render the element at its normal size; equal to `zoom: 1`. Use the global `unset` keyword value instead.

`reset`

Resets the value to `zoom: 1` and prevents the element from being (de)magnified if the user applies non-pinch-based zooming (e.g., by pressing `Ctrl` - - or `Ctrl` + + keyboard shortcuts) to the document.

Formal definition

Initial value	`1`
Applies to	all elements
Inherited	no
Percentages	Converted to `<number>`
Computed value	as specified, but with `<percentage>` converted to the equivalent `<number>`
Animation type	by computed value type

Formal syntax

```
zoom =
  <number [0,∞]>     |
  <percentage [0,∞]>
```

This syntax reflects the latest standard as per CSS Viewport Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Resizing paragraphs

In this example the paragraph elements are zoomed, on hovering a paragraph the `zoom` value is `unset`.

HTML

```
<p class="small">Small</p>
<p class="normal">Normal</p>
<p class="big">Big</p>
```

CSS

```
body {
  display: flex;
  align-items: center;
  justify-content: space-around;
  height: 100vh;
}
```

```
.small {
  zoom: 75%;
}
.normal {
  zoom: normal;
}
.big {
  zoom: 2.5;
}
p:hover {
  zoom: unset;
}
```

Result

Resizing elements

In this example the `div` elements are zoomed using the `normal`, `<percentage>`, and `<number>` values.

HTML

```
<div id="a" class="circle"></div>
<div id="b" class="circle"></div>
<div id="c" class="circle"></div>
```

CSS

```
div.circle {
  width: 25px;
  height: 25px;
  border-radius: 100%;
  vertical-align: middle;
  display: inline-block;
}
div#a {
  background-color: gold;
  zoom: normal; /* circle is 25px diameter */
}
div#b {
  background-color: green;
  zoom: 200%; /* circle is 50px diameter */
}
div#c {
  background-color: blue;
  zoom: 2.9; /* circle is 72.5px diameter */
}
```

Result

Creating a zoom control

In this example a `select` field is used to change the zoom level of the element.

HTML

In this first block, of HTML, a `select` field is defined with the different `zoom` values to be used.

```
<section class="controls">
  <label for="zoom"
    >Zoom level
    <select name="zoom" id="zoom">
      <option value="0.5">Extra Small</option>
      <option value="0.75">Small</option>
      <option value="normal" selected>Normal</option>
      <option value="1.5">Large</option>
      <option value="2">Extra Large</option>
    </select>
  </label>
</section>
```

In this second block a **not supported** message is added that will be hidden if the browser supports `zoom`.

```
<p class="zoom-notice">CSS zoom is not supported</p>
```

The final block just defines the content that will be zoomed.

```
<section class="content">
  <h1>This is the heading</h1>
  <p>
    Lorem ipsum dolor, sit amet consectetur adipisicing elit. Placeat inventore
    ea eveniet, fugiat in consequatur molestiae nostrum repellendus nam
    provident repellat officiis facilis alias facere obcaecati quos sunt
    voluptas! Iste.
  </p>
  <p>
    Lorem ipsum dolor, sit amet consectetur adipisicing elit. Placeat inventore
    ea eveniet, fugiat in consequatur molestiae nostrum repellendus nam
    provident repellat officiis facilis alias facere obcaecati quos sunt
    voluptas! Iste.
  </p>
</section>
```

CSS

In this first block, of CSS, we are setting the starting value for the `--zoom-level` using custom properties and then using that as the value for `zoom` on the content block.

```
html {
  --zoom-level: normal;
}
.content {
  max-width: 60ch;
  margin: auto;
  zoom: var(--zoom-level);
}
```

```
.controls,
.zoom-notice {
  display: flex;
  justify-content: space-around;
}
.zoom-notice {
  color: red;
}
```

In this final CSS block we are checking to see if the browser supports `zoom` and if so setting the **not supported** message to `display: none;`.

```
@supports (zoom: 1) {
  .zoom-notice {
    display: none;
  }
}
```

JavaScript

This JavaScript watches for a change in the select field and sets the new value for `--zoom-level` on the content `section`, e.g., `style="--zoom-level: 1.5;"`.

```
const zoomControl = document.querySelector("#zoom");
const content = document.querySelector(".content");
const updateZoom = () => {
  content.style = `--zoom-level: ${zoomControl.value}`;
};
zoomControl.addEventListener("change", updateZoom);
```

CSS selectors

CSS selectors are patterns used in CSS rules to target and select specific elements for styling.

> **Note:** This page is an index of all selectors in CSS. The CSS selectors page introduces the module that defines some, but not all, of these selectors.

For example, to style paragraphs, you will use the `p` type selector to select all `<p>` elements and apply a style to them:

```
/* Set font size on all <p> elements */
p {
  font-size: 12px;
  color: rebeccapurple;
}
```

Syntax

```
/* Select elements and apply styles */
selector {
  property: value;
}
```

:-moz-broken CSS pseudo-class

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`:-moz-broken`** CSS pseudo-class is a Mozilla extension that matches elements representing broken image links.

> **Note:** This selector is mainly intended to be used by theme developers.

Syntax

```
:-moz-broken {
  /* ... */
}
```

Examples

HTML

```
<img src="broken.jpg" alt="This image is broken. :-(" />
```

CSS

```
:-moz-broken {
  background: bisque;
  padding: 8px;
}
```

Result

Specifications

Not part of any standard.

:-moz-drag-over CSS pseudo-class

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`:-moz-drag-over`** CSS pseudo-class is a Mozilla extension that matches an element when a `dragover` event is called on it.

Syntax

```
:-moz-drag-over {
  /* ... */
}
```

Examples

HTML

```
<div id="drop-target">
  <p>Drop target</p>
</div>

<div draggable="true">
  <p>Draggable</p>
</div>
```

JavaScript

Most elements are not valid places to drop data, so in order to allow a drop, you must prevent default behavior by canceling `dragenter` or `dragover` (or both) events. In this example, we only need to cancel the `dragenter` event, which is the first event fired when the browser evaluates if an element can be a drop target. For more information, see Drag operations: Specifying drop targets.

```
const target = document.getElementById("drop-target");
/* dragenter event fired on the drop target */
target.addEventListener("dragenter", (event) => {
  // prevent default to allow drop
  event.preventDefault();
});
```

CSS

```
body {
  font-family: "Arial";
}
div {
  display: inline-block;
  width: 150px;
  height: 150px;
  border: 2px dotted black;
  background-color: aquamarine;
```

```
  margin: 1rem;
}
p {
  padding: 1rem;
}
```

The following CSS changes the drop target color to red when the draggable element overlays the drop area.

```
#drop-target {
  background-color: cornflowerblue;
}
#drop-target:-moz-drag-over {
  background-color: red;
}
```

Result

:-moz-first-node CSS pseudo-class

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`:-moz-first-node`** CSS pseudo-class is a Mozilla extension that represents any element that is the first child node of some other element. It differs from `:first-child` because it does not match a first-child element with (non-whitespace) text before it.

> **Note:** Any whitespace at the start of an element is ignored for the determination of `:-moz-first-node`.

Syntax

```
:-moz-first-node {
  /* ... */
}
```

Examples

CSS

```
span:-moz-first-node {
  background-color: lime;
}
```

HTML

```
<p>
  <span>This matches!</span>
  <span>This doesn't match.</span>
</p>

<p>
  Blahblah.
  <span>This doesn't match because it's preceded by text.</span>
</p>
```

:-moz-loading CSS pseudo-class

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`:-moz-loading`** CSS pseudo-class is a Mozilla extension that matches elements that can't be displayed because they have not started loading, such as images that haven't started to arrive yet. Note that images that are *in the process* of loading *are not* matched by this pseudo-class.

> **Note:** This selector is mainly intended to be used by theme developers.

Syntax

```
:-moz-loading {
  /* ... */
}
```

Examples

Setting a background for images that are loading

```
:-moz-loading {
  background: url("loading-animation.gif") center no-repeat;
}
```

Specifications

Not part of any standard.

:-moz-locale-dir(ltr) CSS pseudo-class

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`:-moz-locale-dir(ltr)`** CSS pseudo-class is a Mozilla extension that matches an element if the user interface is being displayed left-to-right. This is determined by the preference `intl.uidirection.locale` (where `locale` is the current locale) being set to "ltr".

> **Note:** This selector is mainly used by extensions and themes to adapt the user interface based on the user's locale. (This can vary from window to window, and even from tab to tab.) It also allows extensions to work even when they don't support the user's default locale, since they can support both left-to-right and right-to-left layouts regardless of locale specifics.

> **Warning:** This selector does not work properly from HTML; it always matches, regardless of whether the UI locale is left-to-right or right-to-left.

Syntax

```
:-moz-locale-dir(ltr) {
  /* ... */
}
```

Examples

This example doesn't work if you're not using Firefox, and may not work even in Firefox due to an issue with the selector not working properly with HTML content. It was designed for use with XUL.

HTML

```
<p>If you're using a left-to-right interface, this should be red.</p>
```

CSS

```
p:-moz-locale-dir(ltr) {
  color: red;
}
```

Result

Specifications

:-moz-locale-dir(rtl) CSS pseudo-class

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`:-moz-locale-dir(rtl)`** CSS pseudo-class is a Mozilla extension that matches an element if the user interface is being displayed right-to-left. This is determined by the preference `intl.uidirection.locale` (where `locale` is the current locale) being set to "rtl".

> **Note:** This selector is mainly used by extensions and themes to adapt the user interface based on the user's locale. (This can vary from window to window, and even from tab to tab.) It also allows extensions to work even when they don't support the user's default locale, since they can support both left-to-right and right-to-left layouts regardless of locale specifics.

> **Warning:** This selector does not work properly from HTML; it never matches, no matter whether the UI locale is left-to-right or right-to-left.

Syntax

```
:-moz-locale-dir(rtl) {
  /* ... */
}
```

Examples

This example will not work if you're not using Firefox, and might not work properly even in Firefox due to an issue with using this selector in HTML.

HTML

```
<p>If you're using a right-to-left interface, this should be red.</p>
```

CSS

```
p:-moz-locale-dir(rtl) {
  color: red;
}
```

Result

Specifications

Not part of any standard.

:-moz-only-whitespace CSS pseudo-class

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

> **Note:** In Selectors Level 4, the `:empty` selector was changed to act like `:-moz-only-whitespace`, but no browser currently supports this yet.

The **`:-moz-only-whitespace`** CSS pseudo-class matches elements that only contain text nodes that only contain whitespace. (This includes elements with empty text nodes and elements with no child nodes.)

Syntax

```
:-moz-only-whitespace {
  /* ... */
}
```

Examples

Basic :-moz-only-whitespace example

HTML

```
<div> </div>
```

CSS

```
div {
  border: 4px solid red;
}

:-moz-only-whitespace {
  border-color: lime;
}
```

Result

Specifications

Briefly defined as `:blank` in Selectors Level 4, but then the functionality was merged into `:empty` and `:blank` redefined to mean empty `<input>`.

- `:blank`
- `:empty`

:-moz-submit-invalid CSS pseudo-class

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`:-moz-submit-invalid`** CSS pseudo-class is a Mozilla extension that represents any submit `<button>` on forms whose contents aren't valid based on their validation constraints.

By default, no style is applied. You can use this pseudo-class to customize the appearance of the submit button when there are invalid form fields.

Syntax

```
:-moz-submit-invalid {
  /* ... */
}
```

Specifications

Not part of any standard.

See also

- `:valid`
- `:invalid`

:-moz-suppressed CSS pseudo-class

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`:-moz-suppressed`** CSS pseudo-class is a Mozilla extension that matches elements representing images that were suppressed because loading images from the specified site has been blocked.

> **Note:** This selector is mainly intended to be used by theme developers.

Syntax

```
:-moz-suppressed {
  /* ... */
}
```

Examples

Styling elements that have been blocked

```
:-moz-suppressed {
  background: yellow;
  padding: 8px;
}
```

Specifications

Not part of any standard.

See also

- `:-moz-broken`, `:-moz-loading`, `:-moz-user-disabled`

:-moz-user-disabled CSS pseudo-class

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`:-moz-user-disabled`** CSS pseudo-class is a Mozilla extension that matches elements representing images that were not loaded because images have been entirely disabled by the user's preferences.

> **Note:** This selector is mainly intended to be used by theme developers.

Syntax

```
:-moz-user-disabled {
  /* ... */
}
```

Examples

Styling user-disabled elements

```
:-moz-user-disabled {
  background-color: lightgray;
```

```
  padding: 8px;
}
```

Specifications

Not part of any standard.

See also

:-moz-window-inactive CSS pseudo-class

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`:-moz-window-inactive`** CSS pseudo-class is a Mozilla extension that matches any element while it's in an inactive window.

`:-moz-window-inactive` works in content HTML documents, too.

> **Note:** Prior to the addition of this pseudo-class, giving different styles to background windows was achieved by setting an attribute (`active="true"`) on the top-level XUL chrome window. This attribute is no longer used.

Syntax

```
:-moz-window-inactive {
  /* ... */
}
```

Examples

This example alters the appearance of a box's background depending on whether its window is active or not.

HTML

```
<div id="my-box">
  <p>This is a box!</p>
</div>
```

CSS

```
#my-box {
  background: linear-gradient(to bottom, yellow, cyan);
  width: 200px;
  height: 200px;
}

#my-box:-moz-window-inactive {
  background: cyan;
}
```

Result

The result of this code is shown below. You can view this as a separate page as well.

Specifications

Not part of any standard.

::-moz-color-swatch CSS pseudo-element

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`::-moz-color-swatch`** CSS pseudo-element is a Mozilla extension that represents the color selected in an `<input>` of `type="color"`.

> **Note:** Using `::-moz-color-swatch` with anything but an `<input type="color">` doesn't match anything and has no effect.

Syntax

```
::-moz-color-swatch {
  /* ... */
}
```

Examples

HTML

```
<input type="color" value="#de2020" />
```

CSS

```
input[type="color"]::-moz-color-swatch {
  border-radius: 10px;
  border-style: none;
}
```

::-moz-focus-inner CSS pseudo-element

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`::-moz-focus-inner`** CSS pseudo-element is a Mozilla extension that represents an inner focus ring of the `<button>` element as well as the button, submit, reset, and color types of the `<input>` element.

> **Note:** Using `::-moz-focus-inner` with anything than the buttons that support it doesn't match anything and has no effect.

Syntax

```
::-moz-focus-inner {
  /* ... */
}
```

Example

HTML

```
<input type="submit" value="Input" /> <button type="submit">Button</button>
```

CSS

```
button::-moz-focus-inner,
input[type="color"]::-moz-focus-inner,
input[type="reset"]::-moz-focus-inner,
input[type="button"]::-moz-focus-inner,
input[type="submit"]::-moz-focus-inner {
  padding-block-start: 0px;
  padding-inline-end: 2px;
  padding-block-end: 0px;
  padding-inline-start: 2px;
  border: 2px dotted red;
}
```

::-moz-list-bullet CSS pseudo-element

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`::-moz-list-bullet`** CSS pseudo-element is a Mozilla extension that represents the marker (typically a bullet) of a list item (`<li>`) in an unordered list (`<ul>`).

Syntax

```
li::-moz-list-bullet {
  /* ... */
}
```

Examples

Styling list item markers

HTML

```
<ul>
  <li>Item 1</li>
  <li>Item 2</li>
  <li>Item 3</li>
</ul>
```

CSS

```
::-moz-list-bullet {
  color: red;
  font-size: 1.5em;
}
```

::-moz-meter-bar CSS pseudo-element

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`::-moz-meter-bar`** CSS pseudo-element represents the meter gauge in a `<meter>` element. It is used for selecting and applying styles to the gauge inside a meter element.

> **Note:** By default, the `<meter>` element uses native styling. To apply your own styles, first set `appearance: none` on the `<meter>` element, and then style using `::-moz-meter-bar`.

Syntax

```
meter {
  appearance: none;
}
::-moz-meter-bar {
  /* ... */
}
```

Examples

HTML

```
Normal: <meter min="0" max="10" value="6">Score 6/10</meter>
<br />
Styled:   <meter class="styled" min="0" max="10" value="6">
  Score 6/10
</meter>
```

CSS

```
meter {
  height: 20px;
  width: 200px;
  vertical-align: -0.4rem;
}

.styled {
  appearance: none;
}

.styled::-moz-meter-bar {
  background: lime;
  box-shadow: 0 2px 3px grey inset;
  border-radius: 5px;
}
```

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`::-moz-progress-bar`** CSS pseudo-element is a Mozilla extension that represents the progress bar inside a `<progress>` element. (The bar represents the amount of progress that has been made.)

If you want to select the unfinished part of `<progress>` in Mozilla, please select the `<progress>` directly.

Syntax

```
::-moz-progress-bar {
  /* ... */
}
```

Examples

HTML

```
<progress value="30" max="100">30%</progress>
<progress max="100">Indeterminate</progress>
```

CSS

```
::-moz-progress-bar {
  background-color: red;
}

/* Force indeterminate bars to have zero width */
:indeterminate::-moz-progress-bar {
  width: 0;
}
```

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`::-moz-range-progress`** CSS pseudo-element is a Mozilla extension that represents the lower portion of the *track* (i.e., groove) in which the indicator slides in an `<input>` of `type="range"`. This portion corresponds to values lower than the value currently selected by the *thumb* (i.e., virtual knob).

> **Note:** Using `::-moz-range-progress` with anything but an `<input type="range">` doesn't match anything and has no effect.

Syntax

```
::-moz-range-progress {
  /* ... */
}
```

Examples

HTML

```
<input type="range" min="0" max="100" step="5" value="50" />
```

CSS

```
input[type="range"]::-moz-range-progress {
  background-color: green;
  height: 1em;
}
```

Result

A progress bar using this style might look something like this:

The pseudo-elements used by WebKit/Blink to style other parts of a `<meter>` element are as follows:

- `::-webkit-meter-inner-element`
- `::-webkit-meter-bar`
- `::-webkit-meter-even-less-good-value`
- `::-webkit-meter-optimum-value`

::-webkit-progress-bar CSS pseudo-element

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`::-webkit-progress-bar`** CSS pseudo-element represents the entire bar of a `<progress>` element. Normally it's only visible as the unfilled portion of the bar, since by default it's rendered below the `::-webkit-progress-value` pseudo-element. It is a child of the `::-webkit-progress-inner-element` pseudo-element and the parent of the `::-webkit-progress-value` pseudo-element.

> **Note:** For `::-webkit-progress-value` to take effect, `appearance` needs to be set to `none` on the `<progress>` element.

Syntax

```
::-webkit-progress-bar {
  /* ... */
}
```

Examples

CSS

```
progress {
  -webkit-appearance: none;
}

::-webkit-progress-bar {
  background-color: orange;
}
```

HTML

```
<progress value="10" max="50"></progress>
```

Result

Result screenshot

The code above results in a progress bar that looks like this when using a WebKit or Blink browser:

Specifications

Not part of any standard.

::-webkit-scrollbar CSS pseudo-element

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The `::-webkit-scrollbar` CSS pseudo-element affects the style of an element's scrollbar when it has scrollable overflow.

The `scrollbar-color` and `scrollbar-width` standard properties may be used as alternatives for browsers that do not support this pseudo-element and the related `::-webkit-scrollbar-*` pseudo-elements (see Browser compatibility).

> **Note:** If an element's computed `scrollbar-color` and `scrollbar-width` values are anything other than `auto`, they will override `::-webkit-scrollbar-*` styling. Because `scrollbar-color` is inherited, an element is affected when an ancestor sets it, even if the element itself doesn't. Setting `scrollbar-color: auto` on the element restores its `::-webkit-scrollbar-*` styling if it was previously removed by a `scrollbar-color` setting on an ancestor. See Adding a fallback for scrollbar styles for more details.

CSS Scrollbar Selectors

You can use the following pseudo-elements to customize various parts of the scrollbar for WebKit browsers:

- `::-webkit-scrollbar` — the entire scrollbar.
- `::-webkit-scrollbar-button` — the buttons on the scrollbar (arrows pointing upwards and downwards that scroll one line at a time).
- `::-webkit-scrollbar:horizontal` — the horizontal scrollbar.
- `::-webkit-scrollbar-thumb` — the draggable scrolling handle.
- `::-webkit-scrollbar-track` — the track (progress bar) of the scrollbar, where there is a gray bar on top of a white bar.
- `::-webkit-scrollbar-track-piece` — the part of the track (progress bar) not covered by the handle.
- `::-webkit-scrollbar:vertical` — the vertical scrollbar.
- `::-webkit-scrollbar-corner` — the bottom corner of the scrollbar, where both horizontal and vertical scrollbars meet. This is often the bottom-right corner of the browser window.
- `::-webkit-resizer` — the draggable resizing handle that appears at the bottom corner of some elements.

Accessibility

Authors should avoid styling scrollbars, as changing the appearance of scrollbars away from the default breaks external consistency which negatively impacts usability. If styling scrollbars, ensure there is enough color contrast and touch targets are at least 44px wide and tall. See Techniques for WCAG 2.0: G183: Using a contrast ratio of 3:1 and Understanding WCAG 2.1 : Target Size.

Examples

Styling scrollbars using <code>-webkit-scrollbar</code>

CSS

```
.visible-scrollbar,
.invisible-scrollbar,
.mostly-customized-scrollbar {
  display: block;
  width: 10em;
  overflow: auto;
  height: 2em;
  padding: 1em;
  margin: 1em auto;
  outline: 2px dashed cornflowerblue;
}

.invisible-scrollbar::-webkit-scrollbar {
  display: none;
}

/* Demonstrate a "mostly customized" scrollbar
 * (won't be visible otherwise if width/height is specified) */
.mostly-customized-scrollbar::-webkit-scrollbar {
  width: 5px;
  height: 8px;
  background-color: #aaaaaa; /* or add it to the track */
}

/* Add a thumb */
.mostly-customized-scrollbar::-webkit-scrollbar-thumb {
  background: black;
}
```

HTML

```
<div class="visible-scrollbar">
  <h3>Visible scrollbar</h3>
  <p>
    Etiam sagittis sem sed lacus laoreet, eu fermentum eros auctor. Proin at
    nulla elementum, consectetur ex eget, commodo ante. Sed eros mi, bibendum ut
    dignissim et, maximus eget nibh. Phasellus blandit quam turpis, at mollis
    velit pretium ut. Nunc consequat efficitur ultrices. Nullam hendrerit
    posuere est. Nulla libero sapien, egestas ac felis porta, cursus ultricies
    quam. Vestibulum tincidunt accumsan sapien, a fringilla dui semper in.
    Vivamus consectetur ipsum a ornare blandit. Aenean tempus at lorem sit amet
    faucibus. Curabitur nibh justo, faucibus sed velit cursus, mattis cursus
    dolor. Pellentesque id pretium est. Quisque convallis nisi a diam malesuada
    mollis. Aliquam at enim ligula.
  </p>
```

```
</div>

<div class="invisible-scrollbar">
  <h3>Invisible scrollbar</h3>
  <p>
    Thisisaveeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeerylongword
  </p>
</div>

<div class="mostly-customized-scrollbar">
  <h3>Custom scrollbar</h3>
  <p>
    Thisisaveeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeeerylongword<br />
    And pretty tall<br />
    thing with weird scrollbars.<br />
    Who thought scrollbars could be made weird?
  </p>
</div>
```

Result

Adding a fallback for scrollbar styles

You can use a `@supports` at-rule to detect if a browser supports the standard `scrollbar-color` and `scrollbar-width` properties, and otherwise use a fallback with `::-webkit-scrollbar-*` pseudo-elements. The following example shows how to apply colors to scrollbars using `scrollbar-color` if supported and `::-webkit-scrollbar-*` pseudo-elements if not.

HTML

```
<div class="scroll-box">
  <h1>Yoshi</h1>
  <p>
    Yoshi is a fictional dinosaur who appears in video games published by
    Nintendo. Yoshi debuted in Super Mario World (1990) on the SNES as Mario and
    Luigi's sidekick.
  </p>
  <p>
    Throughout the mainline Super Mario series, Yoshi typically serves as
    Mario's trusted steed.
  </p>
  <p>
    With a gluttonous appetite, Yoshi can gobble enemies with his long tongue,
    and lay eggs that doubly function as projectiles.
  </p>
</div>
```

CSS

```
.scroll-box {
  overflow: auto;
  width: 20rem;
  height: 5rem;
  border: 2px solid cornflowerblue;
  margin: 2rem auto;
  font-family: monospace;
}
```

```
/* For browsers that support `scrollbar-*` properties */
@supports (scrollbar-color: auto) {
  .scroll-box {
    scrollbar-color: aquamarine cornflowerblue;
  }
}

/* Otherwise, use `::-webkit-scrollbar-*` pseudo-elements */
@supports selector(::-webkit-scrollbar) {
  .scroll-box::-webkit-scrollbar {
    background: aquamarine;
  }
  .scroll-box::-webkit-scrollbar-thumb {
    background: cornflowerblue;
  }
}
```

Result

In the example below, you can scroll the bordered box vertically to see the effect of styling the scrollbar.

::-webkit-search-cancel-button CSS pseudo-element

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`::-webkit-search-cancel-button`** CSS pseudo-element represents a button (the "cancel button") at the edge of an `<input>` of `type="search"` which clears away the current value of the `<input>` element. This button and pseudo-element are non-standard, supported only in WebKit and Blink, hence the vendor prefix. The clear button is only shown on non-empty search `<input>` elements.

Syntax

```
selector::-webkit-search-cancel-button {
  /* ... */
}
```

Specifications

Not part of any standard.

- Couple of Gotchas to Watch-out For

::after CSS pseudo-element

In CSS, **`::after`** creates a pseudo-element that is the last child of the selected element. It is often used to add cosmetic content to an element with the `content` property. It is inline by default.

Try it

```
a::after {
  content: " (" attr(href) ")";
}

.dead-link {
  text-decoration: line-through;
}

.dead-link::after {
  content: url("/shared-assets/images/examples/warning.svg");
  display: inline-block;
  width: 12px;
  height: 12px;
}
```

```
<p>
  The sailfish is named for its sail-like dorsal fin and is widely considered
  the fastest fish in the ocean.
  <a href="https://en.wikipedia.org/wiki/Sailfish"
    >You can read more about it here</a
  >.
</p>

<p>
  The red lionfish is a predatory scorpionfish that lives on coral reefs of the
  Indo-Pacific Ocean and more recently in the western Atlantic.
  <a href="" class="dead-link">You can read more about it here</a>.
</p>
```

Syntax

```
::after {
  content: /* value */;
  /* properties */
}
```

Description

The `::after` pseudo-element is an inline box generated as an immediate child of the element it is associated with, or the "originating element". It is often used to add cosmetic content to an element via the `content` property, such as icons, quote marks, or other decoration.

`::after` pseudo-elements can't be applied to *replaced elements* such as `<img>`, whose contents are determined by external resources and not affected by the current document's styles.

An `::after` pseudo-element with a `display` value of `list-item` behaves like a list item, and can therefore generate a `::marker` pseudo-element just like an `<li>` element.

If the `content` property is not specified, has an invalid value, or has `normal` or `none` as a value, then the `::after` pseudo-element is not rendered. It behaves as if `display: none` is set.

> **Note:** The Selectors Level 3 specification introduced the double-colon notation `::after` to distinguish pseudo-classes from pseudo-elements. Browsers also accept single-colon notation `:after`, introduced in CSS2.

By default, the `::before` and `::after` pseudo-elements share the same stacking context as their parent. If no `z-index` is explicitly set, the `::after` pseudo-element's generated content will appear above the `::before` pseudo-element's generated content because `::after` is rendered later in the DOM flow.

Accessibility

Using an `::after` pseudo-element to add content is discouraged, as it is not reliably accessible to screen readers.

Examples

Basic usage

Let's create two classes: one for boring paragraphs and one for exciting ones. We can use these classes to add pseudo-elements to the end of paragraphs.

HTML

```
<p class="boring-text">Here is some plain old boring text.</p>
<p>Here is some normal text that is neither boring nor exciting.</p>
<p class="exciting-text">Contributing to MDN is fun.</p>
```

CSS

```
.exciting-text::after {
  content: " <- EXCITING!";
  color: darkgreen;
  font-weight: bolder;
}

.boring-text::after {
  content: " <- BORING";
  color: darkviolet;
  font-weight: bolder;
}
```

Result

Decorative example

We can style text or images in the `content` property almost any way we want.

HTML

```
<span class="ribbon">Look at the orange box after this text. </span>
```

CSS

```
.ribbon {
  background-color: #5bc8f7;
}

.ribbon::after {
  content: "This is a fancy orange box.";
  background-color: #ffba10;
  border-color: black;
  border-style: dotted;
}
```

Result

Tooltips

This example uses `::after`, in conjunction with the `attr()` CSS expression and a `data-description` custom data attribute, to create tooltips. No JavaScript is required!

We can also support keyboard users with this technique, by adding a `tabindex` of `0` to make each `span` keyboard focusable, and using a CSS `:focus` selector. This shows how flexible `::before` and `::after` can be, though for the most accessible experience a semantic disclosure widget created in some other way (such as with details and summary elements) is likely to be more appropriate.

HTML

```
<p>
  Here we have some
  <span tabindex="0" data-description="collection of words and punctuation">
    text
  </span>
  with a few
  <span tabindex="0" data-description="small popups that appear when hovering">
    tooltips</span
  >.
</p>
```

CSS

```
span[data-description] {
  position: relative;
  text-decoration: underline;
  color: blue;
  cursor: help;
}

span[data-description]:hover::after,
span[data-description]:focus::after {
  content: attr(data-description);
  position: absolute;
  left: 0;
  top: 24px;
  min-width: 200px;
  border: 1px #aaaaaa solid;
  border-radius: 10px;
  background-color: #ffffcc;
  padding: 12px;
  color: black;
  font-size: 14px;
  z-index: 1;
}
```

Result

<code>::after::marker</code> nested pseudo-elements

The `::after::marker` nested pseudo-element selects the list `::marker` of an `::after` pseudo-element that is itself a list item, that is, it has its `display` property set to `list-item`.

In this demo, we generate extra list items before and after a list navigation menu using `::before` and `::after` (setting them to `display: list-item` so they behave like list items). We then use `ul::before::marker` and `ul::after::marker` to give their list markers a different color.

HTML

```
<ul>
  <li><a href="#">Introduction</a></li>
  <li><a href="#">Getting started</a></li>
  <li><a href="#">Understanding the basics</a></li>
</ul>
```

CSS

```
ul {
  font-size: 1.5rem;
  font-family: "Helvetica", "Arial", sans-serif;
}

ul::before,
ul::after {
  display: list-item;
  color: orange;
}

ul::before {
  content: "Start";
}

ul::after {
  content: "End";
}
```

```
ul::before::marker,
ul::after::marker {
  color: red;
}
```

Result

While the list bullets of the three navigation items are generated because they are `<li>` elements, "Start" and "End" have been inserted via pseudo-elements and `::marker` is used to style their bullets.

- `::before`
- `content`

::backdrop CSS pseudo-element

The **`::backdrop`** CSS pseudo-element is a box the size of the viewport, which is rendered immediately beneath any element being presented in the top layer.

Try it

```
button {
  font-size: 1.2rem;
  padding: 5px 15px;
}

dialog::backdrop {
  background-color: salmon;
}
```

```
<button id="showDialogBtn">Show a dialog</button>

<dialog id="favDialog">
  <form method="dialog">
    <p>The background shown outside of this dialog is a backdrop.</p>
    <button id="confirmBtn">Close the dialog</button>
  </form>
</dialog>
```

```
const showDialogBtn = document.getElementById("showDialogBtn");
const favDialog = document.getElementById("favDialog");

showDialogBtn.addEventListener("click", () => favDialog.showModal());
```

Syntax

```
::backdrop {
  /* ... */
}
```

Description

Backdrops appear in the following instances:

- Elements which have been placed in fullscreen mode using the Fullscreen API `Element.requestFullscreen()` method.
- `<dialog>` elements that have been shown in the top layer via a `HTMLDialogElement.showModal()` call.
- Popover elements that have been shown in the top layer via a `HTMLElement.showPopover()` call.

When multiple elements have been placed into the top layer, each one has its own `::backdrop` pseudo-element.

```
/* Backdrop is only displayed when dialog is opened with dialog.showModal() */
dialog::backdrop {
  background: rgb(255 0 0 / 25%);
}
```

Elements are placed in a last-in/first out (LIFO) stack in the top layer. The `::backdrop` pseudo-element makes it possible to obscure, style, or completely hide everything located below a top layer element.

`::backdrop` neither inherits from nor is inherited by any other elements. No restrictions are made on what properties apply to this pseudo-element.

Examples

Styling a modal dialog's backdrop

In this example, we use the `::backdrop` pseudo-element to style the backdrop that is used when a modal `<dialog>` is open.

HTML

We include a `<button>` that, when clicked, will open the included `<dialog>`. When the `<dialog>` is opened, we give focus to the button that closes the dialog:

```
<dialog>
  <button autofocus>Close</button>
  <p>This modal dialog has a beautiful backdrop!</p>
</dialog>
<button>Show the dialog</button>
```

CSS

We add a background to the backdrop, creating a colorful donut using CSS gradients:

```
::backdrop {
  background-image:
    radial-gradient(
      circle,
      white 0 5vw,
      transparent 5vw 20vw,
      white 20vw 22.5vw,
      #eeeeee 22.5vw
    ),
```

```
    conic-gradient(
      #272b66 0 50grad,
      #2d559f 50grad 100grad,
      #9ac147 100grad 150grad,
      #639b47 150grad 200grad,
      #e1e23b 200grad 250grad,
      #f7941e 250grad 300grad,
      #662a6c 300grad 350grad,
      #9a1d34 350grad 400grad,
      #43a1cd 100grad 150grad,
      #ba3e2e
    );
}
```

JavaScript

The dialog is opened modally using the `.showModal()` method and closed using the `.close()` method.

```
const dialog = document.querySelector("dialog");
const showButton = document.querySelector("dialog + button");
const closeButton = document.querySelector("dialog button");

// "Show the dialog" button opens the dialog modally
showButton.addEventListener("click", () => {
  dialog.showModal();
});

// "Close" button closes the dialog
closeButton.addEventListener("click", () => {
  dialog.close();
});
```

::before CSS pseudo-element

In CSS, **`::before`** creates a pseudo-element that is the first child of the selected element. It is often used to add cosmetic content to an element with the `content` property. It is inline by default.

Try it

```
a {
  color: blue;
  text-decoration: none;
}

a::before {
  content: "🔗";
}

.local-link::before {
  content: url("/shared-assets/images/examples/firefox-logo.svg");
  display: inline-block;
  width: 15px;
  height: 15px;
  margin-right: 5px;
}
```

```
<p>
  Learning resources for web developers can be found all over the internet. Try
  out
  <a href="https://web.dev/">web.dev</a>,
  <a href="https://www.w3schools.com/">w3schools.com</a> or our
  <a href="https://developer.mozilla.org/" class="local-link">MDN web docs</a>.
</p>
```

Syntax

```
::before {
  content: /* value */;
  /* properties */
}
```

Description

The `::before` pseudo-element is an inline box generated as an immediate child of the element it is associated with, or the "originating element". It is often used to add cosmetic content to an element via the `content` property, such as icons, quote marks, or other decoration.

`::before` pseudo-elements can't be applied to *replaced elements* such as `<img>`, whose contents are determined by external resources and not affected by the current document's styles.

A `::before` pseudo-element with a `display` value of `list-item` behaves like a list item, and can therefore generate a `::marker` pseudo-element just like an `<li>` element.

If the `content` property is not specified, has an invalid value, or has `normal` or `none` as a value, then the `::before` pseudo-element is not rendered. It behaves as if `display: none` is set.

> **Note:** The Selectors Level 3 specification introduced the double-colon notation `::before` to distinguish pseudo-classes from pseudo-elements. Browsers also accept single-colon notation `:before`, introduced in CSS2.

By default, the `::before` and `::after` pseudo-elements share the same stacking context as their parent. If no `z-index` is explicitly set, the `::after` pseudo-element's generated content will appear above the `::before` pseudo-element's generated content because `::after` is rendered later in the DOM flow.

Accessibility

Using a `::before` pseudo-element to add content is discouraged, as it is not reliably accessible to screen readers.

Examples

Quotation marks

One example of using `::before` pseudo-elements is to provide quotation marks. Here we use both `::before` and `::after` to insert quotation characters.

HTML

```
<q>Some quotes</q>, he said, <q>are better than none.</q>
```

CSS

```
q::before {
  content: "«";
  color: blue;
}

q::after {
  content: "»";
  color: red;
}
```

Result

Decorative example

We can style text or images in the `content` property almost any way we want.

HTML

```
<span class="ribbon">Notice where the orange box is.</span>
```

CSS

```
.ribbon {
  background-color: #5bc8f7;
}

.ribbon::before {
  content: "Look at this orange box.";
  background-color: #ffba10;
  border-color: black;
  border-style: dotted;
}
```

Result

To-do list

In this example we will create a to-do list using pseudo-elements. This method can often be used to add small touches to the UI and improve user experience.

HTML

```
<ul>
  <li>Buy milk</li>
  <li>Take the dog for a walk</li>
  <li>Exercise</li>
  <li>Write code</li>
  <li>Play music</li>
  <li>Relax</li>
</ul>
```

CSS

```
li {
  list-style-type: none;
  position: relative;
  margin: 2px;
  padding: 0.5em 0.5em 0.5em 2em;
  background: lightgrey;
  font-family: sans-serif;
}

li.done {
  background: #ccff99;
}

li.done::before {
  content: "";
  position: absolute;
  border-color: #009933;
  border-style: solid;
  border-width: 0 0.3em 0.25em 0;
  height: 1em;
  top: 1.3em;
  left: 0.6em;
  margin-top: -1em;
  transform: rotate(45deg);
  width: 0.5em;
}
```

JavaScript

```
const list = document.querySelector("ul");
list.addEventListener("click", (ev) => {
  if (ev.target.tagName === "LI") {
    ev.target.classList.toggle("done");
  }
});
```

Here is the above code example running live. Note that there are no icons used, and the check-mark is actually the `::before` that has been styled in CSS. Go ahead and get some stuff done.

Result

Unicode escape sequences

As generated content is CSS, not HTML, you **can't** use markup entities in content values. If you need to use a special character, and can't enter it literally into your CSS content string, use a unicode escape sequence. This consists of a backslash followed by the character's hexadecimal unicode value.

HTML

```
<ol>
  <li>Crack Eggs into bowl</li>
  <li>Add Milk</li>
  <li>Add Flour</li>
  <li aria-current="step">Mix thoroughly into a smooth batter</li>
  <li>Pour a ladleful of batter onto a hot, greased, flat frying pan</li>
  <li>Fry until the top of the pancake loses its gloss</li>
  <li>Flip it over and fry for a couple more minutes</li>
  <li>serve with your favorite topping</li>
</ol>
```

CSS

```
li {
  padding: 0.5em;
}

li[aria-current="step"] {
  font-weight: bold;
}

li[aria-current="step"]::before {
  content: "\21E8 "; /* Unicode escape sequence for "Rightwards White Arrow" */
  display: inline;
}
```

Result

<code>::before::marker</code> nested pseudo-elements

The `::before::marker` nested pseudo-element selects the list `::marker` of a `::before` pseudo-element that is itself a list item, that is, it has its `display` property set to `list-item`.

In this demo, we generate extra list items before and after a list navigation menu using `::before` and `::after` (setting them to `display: list-item` so they behave like list items). We then use `ul::before::marker` and `ul::after::marker` to give their list markers a different color.

HTML

```
<ul>
  <li><a href="#">Introduction</a></li>
  <li><a href="#">Getting started</a></li>
  <li><a href="#">Understanding the basics</a></li>
</ul>
```

CSS

```
ul {
  font-size: 1.5rem;
  font-family: "Helvetica", "Arial", sans-serif;
}

ul::before,
ul::after {
  display: list-item;
  color: orange;
}

ul::before {
  content: "Start";
}

ul::after {
  content: "End";
}

ul::before::marker,
ul::after::marker {
  color: red;
}
```

Result

While the list bullets of the three navigation items are generated because they are `<li>` elements, "Start" and "End" have been inserted via pseudo-elements and `::marker` is used to style their bullets.

- `content`

::checkmark CSS pseudo-element

The **`::checkmark`** CSS pseudo-element targets the checkmark placed inside the currently-selected `<option>` element of a customizable select element. It can be used to provide a visual indication of which option is selected.

Try it

```
<label for="pet-select">
  Select pet:
</label>
<br />
<select id="pet-select">
  <option value="cat">Cat</option>
  <option value="dog">Dog</option>
  <option value="chicken">
    Chicken
  </option>
</select>
```

```
option::checkmark {
  color: orange;
  font-size: 1.5rem;
}

select,
::picker(select) {
  appearance: base-select;
  width: 200px;
}

select {
  border: 2px solid #dddddd;
  background: #eeeeee;
  padding: 10px;
}

::picker(select) {
  border: none;
}

option {
  border: 2px solid #dddddd;
  background: #eeeeee;
  padding: 10px;
}

option:first-of-type {
  border-radius: 8px 8px 0 0;
}

option:last-of-type {
  border-radius: 0 0 8px 8px;
}

option:nth-of-type(odd) {
  background: white;
}

option:not(option:last-of-type) {
  border-bottom: none;
}
```

Syntax

```
::checkmark {
  /* ... */
}
```

Description

The `::checkmark` pseudo-element targets the checkmark placed inside a customizable select element's currently-selected `<option>`.

It is only available to target when the originating element has a picker and has base appearance set on it via the `appearance` property `base-select` value. Its generated box appears before any boxes generated by the `::before` pseudo-element. The icon can be customized using the `content` property.

The `::checkmark` selector is useful for example if you want to hide the checkmark, use a custom icon, or adjust the checkmark's rendering position inside `<option>` elements.

> **Note:** The `::checkmark` pseudo-element is not included in the accessibility tree, so any generated `content` set on it will not be announced by assistive technologies. You should still make sure that any new icon you set visually makes sense for its intended purpose.

Examples

Customizing the checkmark

To opt-in to customizable select functionality, the `<select>` element and its picker both need to have an `appearance` value of `base-select` set on them:

```
select,
::picker(select) {
  appearance: base-select;
}
```

Assuming flexbox is being used to lay out the `<option>` elements (which is true in **current implementations** of customizable selects), you could then move the checkmark from the start of the row to the end by setting an `order` value on it greater than `0`, and aligning it to the end of the row using an `auto` `margin-left` value (see Alignment and auto margins).

The value of the `content` property could also be set to a different emoji to change the displayed icon.

```
option::checkmark {
  order: 1;
```

```
  margin-left: auto;
  content: "☑";
}
```

See Styling the current selection checkmark for a full example that uses this code, along with a live example rendering.

::column CSS pseudo-element

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`::column`** CSS pseudo-element represents the individual columns generated when a container is set to display its content in multiple columns via CSS multi-column layout. The `::column` pseudo-element enables applying styles that do not affect the layout to these generated fragments.

Syntax

```
::column {
  /* ... */
}
```

Description

When CSS multi-column layout is used to lay out a container's content in multiple columns (for example, using the `column-count` property), `::column` pseudo-elements are generated to contain each individual column.

The `::column` pseudo-element only accepts scroll snap properties that apply to elements inside a scroll container, including `scroll-margin`, `scroll-snap-align`, and `scroll-snap-stop`.

The `::column` pseudo-element can have a `::scroll-marker` pseudo-element. Other pseudo-elements like `::before` and `::after` are not generated on `::column`. Applying `::column::scroll-marker` creates a marker for every column of the originating scroll container, with the `::scroll-marker` pseudo-elements inheriting from the `::column` pseudo-element's originating element rather than the `::column` itself.

This is useful for CSS carousels — `::column` can be used to generate `::scroll-marker` pseudo-elements for each column, and set them as snap targets using CSS scroll snap.

While the styling that can be applied to `::column` is very limited, it may be expanded in the future. Any properties and values supported in the future will be limited to ones that do not affect layout.

Examples

Scrolling column layout

This demo creates a responsive container that snaps each "page" of content into place. It uses the `columns` property and the `::column` pseudo-element to create content columns that span the full width of their parent scroll container, which can be scrolled horizontally. Each column contains one or more list items, which vary in number depending on the viewport width.

HTML

The HTML consists of an unordered list, with each list item containing some sample content:

```
<ul>
...
  <li>
    <h2>Item 1</h2>
  </li>
...
</ul>
```

```
<ul>
  <li>
    <h2>Item 1</h2>
  </li>
  <li>
    <h2>Item 2</h2>
  </li>
  <li>
    <h2>Item 3</h2>
  </li>
  <li>
    <h2>Item 4</h2>
  </li>
  <li>
    <h2>Item 5</h2>
  </li>
  <li>
    <h2>Item 6</h2>
  </li>
  <li>
    <h2>Item 7</h2>
  </li>
  <li>
    <h2>Item 8</h2>
  </li>
  <li>
    <h2>Item 9</h2>
  </li>
  <li>
    <h2>Item 10</h2>
  </li>
  <li>
    <h2>Item 11</h2>
  </li>
  <li>
    <h2>Item 12</h2>
  </li>
```

```
  <li>
    <h2>Item 13</h2>
  </li>
  <li>
    <h2>Item 14</h2>
  </li>
  <li>
    <h2>Item 15</h2>
  </li>
</ul>
```

CSS

The list is given a fixed `height` and a `width` of `100vw` to make it span the full width of the viewport. An `overflow-x` value of `scroll` is then set so that the content will scroll horizontally, and CSS scroll snap is used to snap to each item or "page" — a `scroll-snap-type` value of `x mandatory` is used to make the list into a scroll snap container. Finally, a `columns` value of `1` is set to force the list contents to display as a single column. A `text-align` value of `center` is also applied, to align the content with the center of the list.

```
* {
  box-sizing: border-box;
}

body {
  margin: 0;
  font-family: "Helvetica", "Arial", sans-serif;
}
```

```
ul {
  width: 100vw;
  height: 300px;
  padding: 10px;

  overflow-x: scroll;
  scroll-snap-type: x mandatory;

  columns: 1;
  text-align: center;
}
```

The list items are then styled:

- A `display` value of `inline-block` is set to make the list items sit alongside one another and make the list scroll horizontally.
- A fixed `width` and `height` has been set on them.
- A `text-align` value of `left` is set on them to override the `text-align: center` set on the parent container, so the item content will be left-aligned.
- Every even-numbered list item is given a different background-color via `:nth-child()`, so that it is easier to see the scrolling effect.

```
li {
  list-style-type: none;

  display: inline-block;
  height: 100%;
  width: 200px;
  text-align: left;

  background-color: #eeeeee;
  outline: 1px solid #dddddd;
  padding: 0 20px;
  margin: 0 10px;
}

li:nth-child(even) {
  background-color: cyan;
}
```

The `scroll-snap-align` property is set on the `::column` pseudo-elements — which represent the content columns generated by the `columns` property — so that when scrolled, a column is snapped to be centered within the scroll container.

```
ul::column {
  scroll-snap-align: center;
}
```

Result

Column-based carousel with scroll markers

Expanding on the previous example, we will create scroll markers to enable direct navigation to different columns by applying a `scroll-marker-group` to the container and a `::scroll-marker` to each `::column` pseudo-element. The HTML remains unchanged.

CSS

We create a scroll marker group with the `scroll-marker-group` property, placing the group after all the content:

```
ul {
  scroll-marker-group: after;
}
```

We then apply styles to the `::scroll-marker-group` pseudo-element to lay out the scroll markers in the center of the row with a `0.4em` gap between each one:

```
::scroll-marker-group {
  display: flex;
  gap: 0.4em;
  place-content: center;
}
```

Finally, we use the `::scroll-marker` pseudo-element to create a round, transparent marker for each list item with a black border, then style the marker of the currently-scrolled element differently from the others, targeting the marker with the `:target-current` pseudo-class:

```
ul::column::scroll-marker {
  content: "";
  width: 16px;
  height: 16px;
  background-color: transparent;
  border: 2px solid black;
  border-radius: 10px;
}

ul::column::scroll-marker:target-current {
  background-color: black;
}
```

Result

Try pressing the scroll markers to jump straight to each page. Note how the current marker is highlighted so you can see where you are in the pagination. Also try tabbing to the scroll marker group, then use the cursor keys to cycle through each page.

See Creating CSS carousels for more carousel examples.

::cue CSS pseudo-element

The **`::cue`** CSS pseudo-element matches WebVTT cues within a selected element. This can be used to style captions and other cues in media with VTT tracks.

Try it

```
video {
  width: 100%;
}

video::cue {
  font-size: 1rem;
  color: yellow;
}

::cue(u) {
  color: red;
}
```

```
<video controls src="/shared-assets/videos/friday.mp4">
  <track
    default
    kind="captions"
    srclang="en"
    src="/shared-assets/misc/friday.vtt" />
  Sorry, your browser doesn't support embedded videos.
</video>
```

The properties are applied to the entire set of cues as if they were a single unit. The only exception is that `background` and its longhand properties apply to each cue individually, to avoid creating boxes and obscuring unexpectedly large areas of the media.

In the example above, the `::cue(u)` selector selects all the `<u>` elements inside the cue text.

Syntax

```
::cue | ::cue(<selector>) {
  /* ... */
}
```

Permitted properties

Rules whose selectors include this element may only use the following CSS properties:

- `background`
- `background-attachment`
- `background-clip`
- `background-color`
- `background-image`
- `background-origin`
- `background-position`
- `background-repeat`
- `background-size`
- `color`
- `font`
- `font-family`
- `font-size`
- `font-stretch`
- `font-style`
- `font-variant`
- `font-weight`
- `line-height`
- `opacity`
- `outline`
- `outline-color`

- `outline-style`
- `outline-width`
- `ruby-position`
- `text-combine-upright`
- `text-decoration`
- `text-decoration-color`
- `text-decoration-line`
- `text-decoration-style`
- `text-decoration-thickness`
- `text-shadow`
- `visibility`
- `white-space`

Examples

Styling WebVTT cues as white-on-black

The following CSS sets the cue style so that the text is white and the background is a translucent black box.

```
::cue {
  color: white;
  background-color: rgb(0 0 0 / 60%);
}
```

Styling WebVTT internal node objects

Cue text can include *internal node objects* as the tags (similar to HTML elements) `<c>`, `<i>`, `<b>`, `<u>`, `<ruby>`, `<rt>`, `<v>`, and `<lang>`. The `::cue()` selector can be used to apply styles to content inside these tags to customize how the WebVTT track is displayed. Consider the following cue text that uses the `<u>` tag to underline some text:

```
00:00:01.500 --> 00:00:02.999 line:80%
Tell me, is the <u>lord of the universe</u> in?
```

The following CSS rule customizes the text inside the `<u>` tag with a color and a text-decoration:

```
::cue(u) {
  color: red;
  text-decoration: wavy overline lime;
}
```

- `<track>`, `<video>`

::details-content CSS pseudo-element

The **`::details-content`** CSS pseudo-element represents the expandable/collapsible contents of a `<details>` element.

Try it

```
details[open]::details-content {
  color: dodgerblue;
  padding: 0.5em;
  border: thin solid grey;
}
```

```
<details open>
  <summary>Example summary</summary>
  <p>Lorem ipsum dolor sit amet consectetur adipisicing elit.</p>
  <p>
    Architecto cupiditate ea optio modi quas sequi, esse libero asperiores
    debitis eveniet commodi hic ad.
  </p>
</details>
```

Syntax

```
selector::details-content
```

Examples

Basic example

This example demonstrates basic usage of the `::details-content` pseudo-element to style the content of a `<details>` element.

HTML

Our `<details>` element includes a `<summary>` element, whose contents will always be visible. The details content includes a `<p>` element.

```
<details>
  <summary>Click me</summary>
  <p>Here is some content</p>
</details>
```

CSS

We set a `background-color` on the `::details-content` pseudo-element:

```
details::details-content {
  background-color: #a29bfe;
}
```

Result

Click on the summary to view the detail contents.

Transition example

In this example the `::details-content` pseudo-element is used to set a transition on the content of the `<details>` element so that it smoothly fades into view when expanded, and fades out again when collapsed.

HTML

The HTML is the same as in the previous example.

```
<details>
  <summary>Click me</summary>
  <p>Here is some content</p>
</details>
```

CSS

To achieve our transition, we specify two separate transitions inside the `transition` shorthand property:

- The `opacity` property is given a basic transition over `600ms` to create the fade-in/fade-out effect.
- The `content-visibility` property (which is toggled between `hidden` and `visible` when the `<details>` content is expanded/collapsed) is given a `600ms` transition with the `transition-behavior` value `allow-discrete` specified. This opts the browser into having a transition started on `content-visibility`, the animation behavior of which is discrete. The effect is that the content is visible for the entire duration of the transition, allowing other transitions to be seen. If this transition was not included, the content would immediately disappear when the `<details>` content was collapsed — you wouldn't see the smooth fade-out.

```
details::details-content {
  opacity: 0;
  transition:
    opacity 600ms,
    content-visibility 600ms allow-discrete;
}

details[open]::details-content {
  opacity: 1;
}
```

Result

To see the animation, toggle the visibility of the detail contents by clicking on the summary.

- `<details>`
- `<summary>`

::file-selector-button CSS pseudo-element

The **`::file-selector-button`** CSS pseudo-element represents the button of an `<input>` of `type="file"`.

Try it

```
input {
  margin-top: 1rem;
}

input::file-selector-button {
  font-weight: bold;
  color: dodgerblue;
  padding: 0.5em;
  border: thin solid grey;
  border-radius: 3px;
}
```

```
<label for="avatar">Choose a profile picture:</label><br />

<input id="avatar" type="file" name="avatar" accept="image/png, image/jpeg" />
```

Syntax

```
::file-selector-button {
  /* ... */
}
```

Examples

Basic example

HTML

```
<form>
  <label for="fileUpload">Upload file</label>
  <input type="file" id="fileUpload" />
</form>
```

CSS

```
form {
  display: flex;
  gap: 1em;
  align-items: center;
}
```

```
input[type="file"]::file-selector-button {
  border: 2px solid #6c5ce7;
  padding: 0.2em 0.4em;
  border-radius: 0.2em;
  background-color: #a29bfe;
  transition: 1s;
}
```

```
input[type="file"]::file-selector-button:hover {
  background-color: #81ecec;
  border: 2px solid #00cec9;
}
```

Result

Note that `::file-selector-button` is a whole element, and as such matches the rules from the UA stylesheet. In particular, fonts and colors won't necessarily inherit from the `input` element.

Fallback example

HTML

```
<form>
  <label for="fileUpload">Upload file</label>
  <input type="file" id="fileUpload" />
</form>
```

CSS

```
form {
  display: flex;
  gap: 1em;
  align-items: center;
}
```

```
input[type="file"]::file-selector-button {
  border: 2px solid #6c5ce7;
  padding: 0.2em 0.4em;
  border-radius: 0.2em;
  background-color: #a29bfe;
  transition: 1s;
}

input[type="file"]::-ms-browse:hover {
  background-color: #81ecec;
  border: 2px solid #00cec9;
}

input[type="file"]::-webkit-file-upload-button:hover {
  background-color: #81ecec;
  border: 2px solid #00cec9;
}

input[type="file"]::file-selector-button:hover {
  background-color: #81ecec;
  border: 2px solid #00cec9;
}
```

Result

- `<input type="file">`

::first-letter CSS pseudo-element

The **`::first-letter`** CSS pseudo-element applies styles to the first letter of the first line of a block container, but only when not preceded by other content (such as images or inline tables).

Try it

```
p::first-letter {
  font-size: 1.5rem;
  font-weight: bold;
  color: brown;
}
```

```
<p>
  Scientists exploring the depths of Monterey Bay unexpectedly encountered a
  rare and unique species of dragonfish. This species is the rarest of its
  species.
</p>

<p>
  When Robison and a team of researchers discovered this fish, they were aboard
  a week-long expedition.
</p>
```

The first letter of an element is not always trivial to identify:

- Punctuation that precedes or immediately follows the first letter is included in the match. Punctuation includes any Unicode character defined in the *open* (Ps), *close* (Pe), *initial quote* (Pi), *final quote* (Pf), and *other punctuation* (Po) classes.
- Some languages have digraphs that are always capitalized together, like the `IJ` in Dutch. In these cases, both letters of the digraph should be matched by the `::first-letter` pseudo-element.
- A combination of the `::before` pseudo-element and the `content` property may inject some text at the beginning of the element. In that case, `::first-letter` will match the first letter of this generated content.

> **Note:** CSS introduced the `::first-letter` notation (with two colons) to distinguish pseudo-classes from pseudo-elements. For backward compatibility, browsers also accept `:first-letter`, introduced earlier.
>
> Browser support for digraphs such as `IJ` in Dutch is poor. Check the compatibility table below to see the current state of support.

Allowable properties

Only a small subset of CSS properties can be used with the `::first-letter` pseudo-element:

- All font properties: `font`, `font-style`, `font-feature-settings`, `font-kerning`, `font-language-override`, `font-stretch`, `font-synthesis`, `font-variant`, `font-variant-alternates`, `font-variant-caps`, `font-variant-east-asian`, `font-variant-ligatures`, `font-variant-numeric`, `font-variant-position`, `font-weight`, `font-size`, `font-size-adjust`, `line-height` and `font-family`
- All background properties: `background`, `background-color`, `background-image`, `background-clip`, `background-origin`, `background-position`, `background-repeat`, `background-size`, `background-attachment`, and `background-blend-mode`
- All margin properties: `margin`, `margin-top`, `margin-right`, `margin-bottom`, `margin-left`
- All padding properties: `padding`, `padding-top`, `padding-right`, `padding-bottom`, `padding-left`
- All border properties: the shorthands `border`, `border-style`, `border-color`, `border-width`, `border-radius`, `border-image`, and the longhands properties
- The `color` property
- The `text-decoration`, `text-shadow`, `text-transform`, `letter-spacing`, `word-spacing` (when appropriate), `line-height`, `text-decoration-color`, `text-decoration-line`, `text-decoration-style`, `box-shadow`, `float`, `vertical-align` (only if `float` is `none`) CSS properties

Syntax

```
::first-letter {
  /* ... */
}
```

Examples

Basic drop cap

In this example we will use the `::first-letter` pseudo-element to create a drop cap effect on the first letter of the paragraph coming right after the `<h2>`.

HTML

```
<h2>My heading</h2>
<p>
  Lorem ipsum dolor sit amet, consetetur sadipscing elitr, sed diam nonumy
  eirmod tempor invidunt ut labore et dolore magna aliquyam erat, sed diam
  voluptua. At vero eos et accusam et justo duo dolores et ea rebum. Stet clita
  kasd gubergren, no sea takimata sanctus est.
</p>
<p>
  Duis autem vel eum iriure dolor in hendrerit in vulputate velit esse molestie
  consequat.
</p>
```

CSS

```
p {
  width: 500px;
  line-height: 1.5;
}

h2 + p::first-letter {
  color: white;
  background-color: black;
  border-radius: 2px;
  box-shadow: 3px 3px 0 red;
  font-size: 250%;
  padding: 6px 3px;
  margin-right: 6px;
  float: left;
}
```

Result

Effect on special punctuation and non-Latin characters

This example illustrates the effect of `::first-letter` on special punctuation and non-Latin characters.

HTML

```
<p>
  Duis autem vel eum iriure dolor in hendrerit in vulputate velit esse molestie
  consequat.
</p>
<p>-The beginning of a special punctuation mark.</p>
<p>_The beginning of a special punctuation mark.</p>
<p>"The beginning of a special punctuation mark.</p>
<p>'The beginning of a special punctuation mark.</p>
<p>*The beginning of a special punctuation mark.</p>
<p>#The beginning of a special punctuation mark.</p>
<p>「特殊的汉字标点符号开头。</p>
<p>《特殊的汉字标点符号开头。</p>
<p>"特殊的汉字标点符号开头。</p>
```

CSS

```
p::first-letter {
  color: red;
  font-size: 150%;
}
```

Result

Styling first letter in SVG text element

In this example, we use the `::first-letter` pseudo-element to style the first letter of an SVG `<text>` element.

> **Note:** At time of writing this feature has limited support.

HTML

```
<svg viewBox="0 0 300 40">
  <text y="30">First letter in &lt;text&gt; SVG</text>
</svg>
```

CSS

```
text {
  font-family: sans-serif;
}

text::first-letter {
  font-family: serif;
  font-size: 2rem;
  font-weight: 600;
  fill: tomato;
  stroke: indigo;
}
```

Result

See also

- `::first-line`

::first-line CSS pseudo-element

The **`::first-line`** CSS pseudo-element applies styles to the first line of a block container.

Try it

```
p::first-line {
  font-size: 1.2rem;
  font-weight: bold;
  text-decoration: underline;
}
```

```
<p>
  In warm ocean waters around the world, you may see a strange sight: A fish
  leaping from the water and soaring dozens of meters before returning to the
  ocean's depths. Early Mediterranean sailors thought these flying fish returned
  to the shore at night to sleep, and therefore called this family of marine
  fish Exocoetidae.
</p>
```

The effects of `::first-line` are limited by the length and content of the first line of text in the element. The length of the first line depends on many factors, including the width of the element, the width of the document, and the font size of the text. `::first-line` has no effect when the first child of the element, which would be the first part of the first line, is an inline block-level element, such as an inline table.

> **Note:** Selectors Level 3 introduced the double-colon notation (`::`) to distinguish pseudo-elements from the single-colon (`:`) pseudo-classes. Browsers accept both `::first-line` and `:first-line`, which was introduced in CSS2.

For the purposes of CSS `background`, the `::first-line` pseudo-element is like an inline-level element meaning that in a left-justified first line, the background may not extend all the way to the right margin.

Allowable properties

Only a small subset of CSS properties can be used with the `::first-line` pseudo-element:

- All font-related properties: `font`, `font-kerning`, `font-style`, `font-variant`, `font-variant-numeric`, `font-variant-position`, `font-variant-east-asian`, `font-variant-caps`, `font-variant-alternates`, `font-variant-ligatures`, `font-synthesis`, `font-feature-settings`, `font-language-override`, `font-weight`, `font-size`, `font-size-adjust`, `font-stretch`, and `font-family`
- All background-related properties: `background-color`, `background-clip`, `background-image`, `background-origin`, `background-position`, `background-repeat`, `background-size`, `background-attachment`, and `background-blend-mode`
- The `color` property
- `word-spacing`, `letter-spacing`, `text-decoration`, `text-transform`, and `line-height`
- `text-shadow`, `text-decoration`, `text-decoration-color`, `text-decoration-line`, `text-decoration-style`, and `vertical-align`.

Syntax

```
::first-line {
  /* ... */
}
```

Examples

Styling first line of a paragraph

HTML

```
<p>
  Styles will only be applied to the first line of this paragraph. After that,
  all text will be styled like normal. See what I mean?
</p>

<span>
  The first line of this text will not receive special styling because it is not
  a block-level element.
</span>
```

CSS

```
* {
  font-size: 20px;
  font-family: sans-serif;
}
```

```
::first-line {
  color: blue;
  font-weight: bold;

  /* WARNING: DO NOT USE THESE */
  /* Many properties are invalid in ::first-line pseudo-elements */
  margin-left: 20px;
```

```
  text-indent: 20px;
}
```

Result

Styling the first line of an SVG text element

In this example, we style the first line of an SVG `<text>` element using the `::first-line` pseudo-element.

> **Note:** At time of writing this feature has limited support.

HTML

```
<svg viewBox="0 0 320 150">
  <text y="20">Here is an English paragraph
that is broken into multiple lines
in the source code so that it can
be more easily read and edited
in a text editor.
  </text>
</svg>
```

CSS

In order to make the SVG `<text>` element wrap to multiple lines, we use the `white-space` CSS property. We then select the first line using the `::first-line` pseudo-element.

```
text {
  font-size: 20px;
  font-family: sans-serif;
}
```

```
text {
  white-space: break-spaces;
}

text::first-line {
  fill: blue;
  font-weight: bold;
}
```

Result

See also

- `::first-letter`
- `white-space`

::grammar-error CSS pseudo-element

The **`::grammar-error`** CSS pseudo-element represents a text segment which the user agent has flagged as grammatically incorrect.

The `::grammar-error` pseudo-element follows a special inheritance model common to all highlight pseudo-elements. For more details on how this inheritance works, see the Highlight pseudo-elements inheritance section.

Allowable properties

Only a small subset of CSS properties can be used in a rule with `::grammar-error` in its selector:

- `color`
- `background-color`
- `cursor`
- `caret-color`
- `outline` and its longhands
- `text-decoration` and its associated properties
- `text-emphasis-color`
- `text-shadow`

Syntax

```
::grammar-error {
  /* ... */
}
```

Examples

Basic document grammar check

In this example, eventual supporting browsers should highlight any flagged grammatical errors with the styles shown.

HTML

```
<p contenteditable spellcheck="true">
  My friends is coming to the party tonight.
</p>
```

CSS

```
::grammar-error {
  text-decoration: underline red;
  color: red;
}
```

Result

See also

- `::spelling-error`
- `text-decoration-line`

::highlight() CSS pseudo-element

The **`::highlight()`** CSS pseudo-element applies styles to a custom highlight.

A custom highlight is a collection of `AbstractRange` objects and is registered on a webpage using the `HighlightRegistry`.

The `::highlight()` pseudo-element follows a special inheritance model common to all highlight pseudo-elements. For more details on how this inheritance works, see the Highlight pseudo-elements inheritance section.

Allowable properties

Only certain CSS properties can be used with `::highlight()`:

- `color`
- `background-color`
- `text-decoration` and its associated properties
- `text-shadow`
- `-webkit-text-stroke-color`, `-webkit-text-fill-color` and `-webkit-text-stroke-width`

In particular, `background-image` is ignored.

Syntax

```
::highlight(custom-highlight-name)
```

Examples

Highlighting characters

HTML

```
<p id="rainbow-text">CSS Custom Highlight API rainbow</p>
```

CSS

```
#rainbow-text {
  font-family: monospace;
  font-size: 1.5rem;
}

::highlight(rainbow-color-1) {
  color: violet;
  text-decoration: underline;
}
::highlight(rainbow-color-2) {
  color: purple;
  text-decoration: underline;
}
::highlight(rainbow-color-3) {
  color: blue;
  text-decoration: underline;
}
::highlight(rainbow-color-4) {
  color: green;
  text-decoration: underline;
}
::highlight(rainbow-color-5) {
  color: yellow;
  text-decoration: underline;
}
::highlight(rainbow-color-6) {
  color: orange;
  text-decoration: underline;
}
::highlight(rainbow-color-7) {
  color: red;
  text-decoration: underline;
}
```

JavaScript

```
const textNode = document.getElementById("rainbow-text").firstChild;

if (!CSS.highlights) {
  textNode.textContent =
    "The CSS Custom Highlight API is not supported in this browser!";
}

// Create and register highlights for each color in the rainbow.
const highlights = [];
for (let i = 0; i < 7; i++) {
  // Create a new highlight for this color.
  const colorHighlight = new Highlight();
  highlights.push(colorHighlight);

  // Register this highlight under a custom name.
  CSS.highlights.set(`rainbow-color-${i + 1}`, colorHighlight);
}

// Iterate over the text, character by character.
for (let i = 0; i < textNode.textContent.length; i++) {
  // Create a new range just for this character.
  const range = new Range();
  range.setStart(textNode, i);
  range.setEnd(textNode, i + 1);
```

```
  // Add the range to the next available highlight,
  // looping back to the first one once we've reached the 7th.
  highlights[i % 7].add(range);
}
```

::marker CSS pseudo-element

The **`::marker`** CSS pseudo-element selects the marker box of a list item, which typically contains a bullet or number. It works on any element or pseudo-element set to `display: list-item`, such as the `<li>` and `<summary>` elements.

Try it

```
li::marker {
  content: "† ";
  font-size: 1.2em;
}
```

```
<p>Group known as Mercury Seven:</p>
<ul>
  <li>Malcolm Scott Carpenter</li>
  <li>Leroy Gordon (Gordo) Cooper Jr.</li>
  <li>John Herschel Glenn Jr.</li>
  <li>Virgil Ivan (Gus) Grissom</li>
  <li>Walter Marty (Wally) Schirra Jr.</li>
  <li>Alan Bartlett Shepard Jr.</li>
  <li>Donald Kent (Deke) Slayton</li>
</ul>
```

Allowable properties

The `::marker` pseudo-element supports a limited number of CSS properties, including:

- All animation and transition properties
- All font properties
- `color`
- `content`
- `counter-increment`, `counter-reset`, and `counter-set`
- `quotes`
- `text-combine-upright`, `unicode-bidi`, and `direction`
- `white-space`

> **Note:** The specification states that additional CSS properties may be supported in the future.

Syntax

```
::marker {
  /* ... */
}
```

Examples

HTML

```
<ul>
  <li>Peaches</li>
  <li>Apples</li>
  <li>Plums</li>
</ul>
```

CSS

```
ul li::marker {
  color: red;
  font-size: 1.5em;
}
```

::part() CSS pseudo-element

The **`::part`** CSS pseudo-element represents any element within a shadow tree that has a matching `part` attribute.

```
custom-element::part(foo) {
  /* Styles to apply to the `foo` part */
}
```

Description

The global `part` attribute makes a shadow tree element visible to its parent DOM. The part names declared using the `part` attribute are used as the parameter of the `::part()` pseudo-element. In this way, you can apply CSS styles to elements in the shadow tree from outside of it.

Part names are similar to CSS classes: multiple elements can have the same part name, and a single element can have multiple part names. All part names used in `::part()` pseudo-element must be present in the `part` value declared on the shadow tree element but the order of the part names doesn't matter, i.e., the selectors `::part(tab active)` and `::part(active tab)` are the same.

The `::part()` pseudo-element is only visible to the parent DOM. This means that when a shadow tree is nested, the parts are not visible to any ancestors other than the direct parent. The `exportparts` attribute solves this limitation by explicitly exporting already defined `part` names, making them globally stylable.

Pseudo-classes (such as `::part(label):hover`) can be appended to the `::part()` selector, but structural pseudo-classes that match based on tree information, such as `:empty` and `:last-child`, cannot be appended.

Additional pseudo-elements, such as `::before`, can be appended to the `::part()` selector, but additional `::part()` element can't be appended. For example, `::part(confirm-button)::part(active)` never matches anything, i.e, it is not the same as `::part(confirm-button active)`. This is because doing so would expose more structural information than is intended.

Syntax

```
::part(<ident>+) {
  /* ... */
}
```

Examples

HTML

```
<template id="tabbed-custom-element">
  <style>
    *,
    ::before,
    ::after {
      box-sizing: border-box;
      padding: 1rem;
    }
    :host {
      display: flex;
    }
  </style>
  <div part="tab active">Tab A</div>
  <div part="tab">Tab B</div>
  <div part="tab">Tab C</div>
</template>

<tabbed-custom-element></tabbed-custom-element>
```

CSS

```
tabbed-custom-element::part(tab) {
  color: blue;
  border-bottom: transparent solid 4px;
}

tabbed-custom-element::part(tab):hover {
  background-color: black;
  color: white;
}

tabbed-custom-element::part(tab active) {
  border-color: blue !important;
}
```

JavaScript

```
const template = document.querySelector("#tabbed-custom-element");
globalThis.customElements.define(
  template.id,
  class extends HTMLElement {
    constructor() {
      super().attachShadow({ mode: "open" }).append(template.content);
    }
  },
);
```

Result

::picker() CSS pseudo-element

The **`::picker()`** CSS pseudo-element targets the picker part of an element, for example the drop-down picker of a customizable select element.

Syntax

```
::picker(<ident>) {
  /* ... */
}
```

Parameters

`<ident>`

A string representing the element whose picker you want to target. The following values are available:

`select`

The drop-down picker of customizable select elements.

Description

The `::picker()` pseudo-element targets the picker part of a form control, that is, the pop-up part that appears to allow you to make a selection when you press the control button. It is only available to target when the originating element has a picker and has base appearance set on it via the `appearance` property `base-select` value.

The `::picker(select)` selector targets all descendants of customizable `<select>` element except for the first `<button>` child; these descendants are grouped together by the browser and rendered as the picker. The first `<button>` child represents the control button that opens the picker when pressed.

This allows you to target all of the picker contents as a single entity, for example if you want to customize its border, animate it when it appears and disappears, or position it somewhere different to the default position. Our customizable select elements guide shows many examples of `::picker(select)` usage.

Picker popover behavior

The `<select>` element and the picker have an implicit invoker/popover relationship assigned to them automatically, as specified by the Popover API. See Using the Popover API for more details of popover behavior, and see Animating the picker drop-down using popover states for a typical use case allowed by the implicit popover association.

Picker anchor positioning

A further side-effect of the implicit invoker/popover relationship mentioned above is that the `<select>` element and the picker also have an implicit anchor reference, meaning that the picker is automatically associated with the select via CSS anchor positioning. This has several advantages, most notably:

- The browser default styles position the picker relative to the button (the anchor) and you can customize this position as explained in Positioning elements relative to their anchor. For reference, the related default styles are as follows:

  ```
  inset: auto;
  margin: 0;
  min-inline-size: anchor-size(self-inline);
  min-block-size: 1lh;
  /* Go to the edge of the viewport, and add scrollbars if needed. */
  max-block-size: stretch;
  overflow: auto;
  /* Below and span-right, by default. */
  position-area: block-end span-inline-end;
  ```

- The browser default styles also define some position-try fallbacks that reposition the picker if it is in danger of overflowing the viewport. Position-try fallbacks are explained in the Fallback options and conditional hiding for overflow guide. For reference, the related default fallback styles are as follows:

  ```
  position-try-order: most-block-size;
  position-try-fallbacks:
    /* First try above and span-right, */
    /* then below but span-left, */
    /* then above and span-left. */
    block-start span-inline-end,
    block-end span-inline-start,
    block-start span-inline-start;
  ```

> **Note:** If you want to remove the implicit anchor reference to stop the picker from being anchored to the `<select>` element, you can do so by setting the `position-anchor` property of the picker to an anchor name that doesn't exist in the current document, such as `--not-an-anchor-name`. See also removing an anchor association.

Examples

Basic custom select usage

To opt-in to the custom select functionality and minimal browser base styles (and remove the OS-provided styling), the `<select>` element and its picker both need to have an `appearance` value of `base-select` set on them:

```
select,
::picker(select) {
  appearance: base-select;
}
```

You could then, for example, remove the picker's default black `border`:

```
::picker(select) {
  border: none;
}
```

::picker-icon CSS pseudo-element

The **`::picker-icon`** CSS pseudo-element targets the picker icon inside form controls that have an icon associated with them. In the case of a customizable select element, it selects the arrow icon shown on the `<select>` element that points down when it is closed.

Syntax

```
::picker-icon {
  /* ... */
}
```

Description

The `::picker-icon` pseudo-element targets the picker icon of form controls, that is, the icon shown on the control button. It is only available to target when the originating element has a picker and has base appearance set on it via the `appearance` property `base-select` value. Its generated box appears after any boxes generated by the `::after` pseudo-element, with the icon specified in default browser stylesheet; you

can customize it using the `content` property.

The `::picker-icon` selector can be used to select the down-facing arrow on the inline-end side of a customizable select element. This is useful for example if you want to customize the color or size of the icon, use a different icon (using `content` or SVG), or animate it when the picker is opened and closed.

Selecting customizable `<select>` picker icons is the only current use case for `::picker-icon`, but more may be added in the future.

> **Note:** The `::picker-icon` pseudo-element is not included in the accessibility tree, so any generated `content` set on it will not be announced by assistive technologies. You should still make sure that any new icon you set visually makes sense for its intended purpose.

Examples

Animating the picker icon

To opt-in to customizable select functionality, the `<select>` element and its picker both need to have an `appearance` value of `base-select` set on them:

```
select,
::picker(select) {
  appearance: base-select;
}
```

You could then, for example, target the `::picker-icon` and give it a custom `color` and a `transition` so that changes to its `rotate` property are smoothly animated:

```
select::picker-icon {
  color: #999999;
  transition: 0.4s rotate;
}
```

In the next rule, `::picker-icon` is combined with the `:open` pseudo-class — which targets the icon only when the picker is open — transitioning it to a `rotate` value of `180deg` when the `<select>` is opened.

```
select:open::picker-icon {
  rotate: 180deg;
}
```

See Styling the picker icon for a full example that uses this code, along with a live example rendering.

::placeholder CSS pseudo-element

The **`::placeholder`** CSS pseudo-element represents the placeholder text in an `<input>` or `<textarea>` element.

Try it

```
input {
  margin-top: 0.5rem;
}

input::placeholder {
  font-weight: bold;
  opacity: 0.5;
  color: red;
}
```

```
<label for="first-name">Your phone number:</label><br />

<input
  id="first-name"
  type="tel"
  name="phone"
  minlength="9"
  maxlength="9"
  placeholder="It must be 9 digits" />
```

Only the subset of CSS properties that apply to the `::first-line` pseudo-element can be used in a rule using `::placeholder` in its selector.

> **Note:** In most browsers, the appearance of placeholder text is a translucent or light gray color by default.

Syntax

```
::placeholder {
  /* ... */
}
```

Accessibility

Color contrast

Contrast Ratio

Placeholder text typically has a lighter color treatment to indicate that it is a suggestion for what kind of input will be valid, and is not actual input of any kind.

It is important to ensure that the contrast ratio between the color of the placeholder text and the background of the input is high enough that people experiencing low vision conditions will be able to read it while also making sure there is enough of a difference between the placeholder text and input text color that users do not mistake the placeholder for inputted data.

Color contrast ratio is determined by comparing the luminosity of the placeholder text and the input background color values. In order to meet current Web Content Accessibility Guidelines (WCAG), a ratio of 4.5:1 is required for text content and 3:1 for larger text such as headings. Large text is defined as 18.66px and bold or larger, or 24px or larger.

- WebAIM: Color Contrast Checker
- MDN Understanding WCAG, Guideline 1.4 explanations
- Understanding Success Criterion 1.4.3 | W3C Understanding WCAG 2.0

Usability

Placeholder text with sufficient color contrast may be interpreted as entered input. Placeholder text will also disappear when a person enters content into an `<input>` element. Both of these circumstances can interfere with successful form completion, especially for people with cognitive concerns.

An alternate approach to providing placeholder information is to include it outside of the input in close visual proximity, then use `aria-describedby` to programmatically associate the `<input>` with its hint.

With this implementation, the hint content is available even if information is entered into the input field, and the input appears free of preexisting input when the page is loaded. Most screen reading technology will use `aria-describedby` to read the hint after the input's label text is announced, and the person using the screen reader can mute it if they find the extra information unnecessary.

```
<label for="user-email">Your email address</label>
<span id="user-email-hint" class="input-hint">Example: jane@sample.com</span>
<input
  id="user-email"
  aria-describedby="user-email-hint"
  name="email"
  type="email" />
```

- Placeholders in Form Fields Are Harmful — Nielsen Norman Group

Windows High Contrast Mode

Placeholder text will appear with the same styling as user-entered text content when rendered in Windows High Contrast Mode. This will make it difficult for some people to determine which content has been entered, and which content is placeholder text.

Labels

Placeholders are not a replacement for the `<label>` element. Without a label that has been programmatically associated with an input using a combination of the `for` and `id` attributes, assistive technology such as screen readers cannot parse `<input>` elements.

- Placeholders in Form Fields Are Harmful — Nielsen Norman Group

Examples

Change placeholder appearance

This example shows some of the adjustments that you can make to the styles of placeholder text.

HTML

```
<input placeholder="Type here" />
```

CSS

```
input::placeholder {
  color: red;
  font-size: 1.2em;
  font-style: italic;
  opacity: 0.5;
}
```

Result

Opaque text

Some browsers make placeholder text less opaque. If you want fully opaque text, then set the `color` property value explicitly. The `currentColor` value can be used to have the same color as the corresponding input element.

HTML

```
<input placeholder="Color set by browser" />
<input placeholder="Same color as input" class="explicit-color" />
<input placeholder="Semi-opaque text color" class="opacity-change" />
```

CSS

```
input {
  font-weight: bold;
  color: green;
}

.explicit-color::placeholder {
  /* use the same color as input element to avoid the browser set default color */
  color: currentColor;
}

.opacity-change::placeholder {
  /* less opaque text */
  color: color-mix(in srgb, currentColor 70%, transparent);
}
```

Result

> **Note:** Note that browsers use different default colors for placeholder text. For example, Firefox uses the input element's color with 54% opacity, and Chrome uses `darkgray` color. If you want consistent placeholder text color across the browsers, then set the `color` explicitly.

::scroll-button() CSS pseudo-element

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`::scroll-button()`** CSS pseudo-element represents a button for controlling the scrolling of a scroll container. They are generated on scroll containers when their `content` value is not `none`. The direction of the scrolling is determined by the parameter value.

Syntax

```
::scroll-button(<scroll-button-direction>) {
  /* ... */
}
```

Parameters

`<scroll-button-direction>`

A value representing which direction of scroll button you want to select. The following values are available:

`*`

Selects all the originating element's scroll buttons, allowing styles to be applied to each of them in a single rule.

`down`

Selects the button that will scroll the content downward.

`left`

Selects the button that will scroll the content left.

`right`

Selects the button that will scroll the content right.

`up`

Selects the button that will scroll the content upward.

`block-end`

Selects the button that will scroll the content in the block-end direction.

`block-start`

Selects the button that will scroll the content in the block-start direction.

`inline-end`

Selects the button that will scroll the content in the inline-end direction.

`inline-start`

Selects the button that will scroll the content in the inline-start direction.

The specification also defines two other values — `next` and `prev` — but these are not currently supported in any browser.

Description

The `::scroll-button()` pseudo-elements are generated inside a scroll container only when their `content` properties are set to a value other than `none`. They are generated as siblings of the scroll container's child DOM elements, immediately preceding them and any `::scroll-marker-group` generated on the container.

You can generate up to four scroll buttons per scroll container, which will scroll the content towards the start and end of the block and inline axes. The selector's argument specifies which scrolling direction is selected. You can also specify a value of `*` to target all of the `::scroll-button()` pseudo-elements, providing styles to all the buttons in a single rule.

The generated buttons behave just like regular `<button>` elements, including sharing their default browser styles. They are focusable, accessible, and can be activated like regular buttons. When a scroll button is pressed, the scroll container's content is scrolled in the specified direction by one "page," or approximately the dimension of the scroll container, similar to pressing `PgUp` and `PgDn` keys.

The recommendation is to set up CSS scroll snapping on the scroll container and set each separate item of content you want to scroll to as a snap target. This being the case, activating a scroll button will scroll the content to the snap target that is one "page" away. While the scroll buttons will work without scroll snapping, you might not get the desired effect.

When it is not possible to scroll any further in a particular scroll button's scrolling direction, the button is automatically disabled, otherwise it is enabled. You can style the scroll buttons in their enabled and disabled states using the `:enabled` and `:disabled` pseudo-classes.

Examples

See Creating CSS carousels for more carousel examples.

Creating scroll buttons

In this example, we demonstrate how to create scroll buttons on a CSS carousel.

HTML

We have a basic HTML `<ul>` list with several `<li>` list items.

```
<ul>
  <li>Item 1</li>
  <li>Item 2</li>
  <li>Item 3</li>
  <li>Item 4</li>
  <li>Item 5</li>
  <li>Item 6</li>
  <li>Item 7</li>
  <li>Item 8</li>
</ul>
```

CSS

Styling the carousel

We convert our `<ul>` into a carousel by setting the `display` to `flex`, creating a single, non-wrapping row of `<li>` elements. The `overflow-x` property is set to `auto`, meaning if the items overflow their container on the x-axis, the content will scroll horizontally. We then convert the `<ul>` into a scroll-snap container, ensuring that items always snap into place when the container is scrolled with a `scroll-snap-type` value of `mandatory`.

```
ul {
  display: flex;
  gap: 4vw;
  padding-left: 0;
  overflow-x: auto;
  overscroll-behavior-x: contain;
  scroll-snap-type: x mandatory;
}
```

Next, we style the `<li>` elements, using the `flex` property to make them 100% of the width of the container. The `scroll-snap-align` value of `start` causes the left-hand side of the left-most visible item to snap to the left edge of the container when the content is scrolled.

```
li {
  list-style-type: none;
  background-color: #eeeeee;
  flex: 0 0 100%;
  height: 100px;
  padding-top: 20px;
  scroll-snap-align: start;
  text-align: center;
}
```

Creating the scroll buttons

First, all scroll buttons are targeted with some rudimentary styles, as well as styling based on different states. It is important to set `:focus` styles for keyboard users. Also, as scroll buttons are automatically set to `disabled` when no more scrolling can occur in that direction, we use the `:disabled` pseudo-class to target this state.

```
ul::scroll-button(*) {
  border: 0;
  font-size: 2rem;
  background: none;
  color: black;
  opacity: 0.7;
  cursor: pointer;
}

ul::scroll-button(*):hover,
ul::scroll-button(*):focus {
  opacity: 1;
}

ul::scroll-button(*):active {
  translate: 1px 1px;
}

ul::scroll-button(*):disabled {
  opacity: 0.2;
  cursor: unset;
}
```

> **Note:** We also set a `cursor` value of `pointer` on the scroll buttons to make it more obvious that they can be interacted with (an improvement for both general UX and cognitive accessibility), unsetting it when the scroll buttons are `:disabled`.

Next, an appropriate icon is set on the left and right scroll buttons via the `content` property, which is also what causes the scroll buttons to be generated:

```
ul::scroll-button(left) {
  content: "◄";
}

ul::scroll-button(right) {
  content: "►";
}
```

We don't need to set alternative text for the icons on the `content` as the browser takes care of providing appropriate accessible names automatically.

Result

Note how the scroll buttons are created at the bottom left on the carousel. Try pressing them to see how they cause the content to be scrolled.

Positioning the scroll buttons

The previous example works, but the buttons are not ideally placed. In this section, we will add some CSS to position them using anchor positioning.

CSS

First of all, a reference `anchor-name` is set on the `<ul>` to define it as a named anchor. Next, each scroll button has its `position` set to `absolute` and its `position-anchor` property set to the list's `anchor-name`, to associate the two together.

```
ul {
  anchor-name: --my-carousel;
}

ul::scroll-button(*) {
  position: absolute;
  position-anchor: --my-carousel;
}
```

To actually position each scroll button, we first set an `align-self` value of `anchor-center` on both of them, to center them vertically on the carousel:

```
ul::scroll-button(*) {
  align-self: anchor-center;
}
```

We then set values on their inset properties to handle the horizontal positioning. We use `anchor()` functions to position the specified sides of the buttons relative to the sides of the carousel. In each case, the `calc()` function is used to add some space between the button edge and the carousel edge. For example, the right-hand edge of the left scroll button is positioned 45 pixels to the right of the carousel's left-hand edge.

```
ul::scroll-button(left) {
  right: calc(anchor(left) - 45px);
}

ul::scroll-button(right) {
  left: calc(anchor(right) - 45px);
}
```

::scroll-marker CSS pseudo-element

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`::scroll-marker`** CSS pseudo-element can be generated inside any element and represents its scroll marker. All elements can have a `::scroll-marker` pseudo-element, which is placed into the `::scroll-marker-group` of the nearest scroll container ancestor. A scroll marker behaves like an anchor (`<a>` element) whose scroll target is the marker's originating element — and scrolls the scroll container to that element when activated.

Syntax

```
::scroll-marker {
  /* ... */
}
```

Description

A `::scroll-marker` is generated on an element when the `::scroll-marker`'s `content` property is set to a non-`none` value, and its has an ancestor scroll container with a non-`none` `scroll-marker-group` property value (meaning that it will generate a `::scroll-marker-group` pseudo-element).

The scroll container's `::scroll-marker-group` pseudo-element automatically contains any `::scroll-marker` pseudo-elements generated on the scroll container or its descendants. This allows them to be positioned and laid out as a group and is typically used when creating a CSS carousel to create a scroll position indicator. The individual scroll markers can be used to navigate to their associated content items.

> **Note:** Alternatively, a scroll marker group container can be created from an existing element container using `scroll-target-group`; any contained `<a>` elements with fragment identifiers linking to sections of the page automatically behave like scroll markers.

When a scroll marker group container is created on a scroll container using the `scroll-marker-group` property, the scroll container is rendered with `tablist`/`tab` semantics. You can `Tab` to it with the keyboard, then move between the different "pages" using the left and right (or up and down) cursor keys, which also changes the state of the associated scroll markers and scroll buttons as expected. The scroll markers can also be tabbed between normally, as expected.

Examples

See Creating CSS carousels for other examples that use the `::scroll-marker` pseudo-element.

Creating carousel scroll markers

In this example, we demonstrate how to create scroll markers on a CSS carousel.

HTML

We have a basic HTML `<ul>` list with several `<li>` list items.

```
<ul>
  <li>Item 1</li>
  <li>Item 2</li>
  <li>Item 3</li>
  <li>Item 4</li>
  <li>Item 5</li>
  <li>Item 6</li>
  <li>Item 7</li>
  <li>Item 8</li>
</ul>
```

CSS

We convert our `<ul>` into a scroll snapping overflow container by setting the `display` to `flex`, creating a single, non-wrapping row of `<li>` elements. The `overflow-x` property is set to `auto`, meaning if the items overflow their container on the x-axis, the content will scroll horizontally. We then convert the `<ul>` into a scroll-snap container, ensuring that items always snap into place when the container is scrolled with a `scroll-snap-type` value of `mandatory`.

We create a scroll marker group container with the `scroll-marker-group` property, placing it after all the content.

```
ul {
  display: flex;
  gap: 4vw;
  padding-left: 0;
  overflow-x: auto;
  overscroll-behavior-x: contain;
  scroll-snap-type: x mandatory;
  scroll-marker-group: after;
}
```

Next, we style the `<li>` elements, using the `flex` property to make them `33%` of the width of the container. The `scroll-snap-align` value of `start` causes the left-hand side of the left-most visible item to snap to the left edge of the container when the content is scrolled.

```
li {
  list-style-type: none;
  background-color: #eeeeee;
  flex: 0 0 33%;
  height: 100px;
  padding-top: 20px;
  scroll-snap-align: start;
  text-align: center;
}
```

We then use the `::scroll-marker` pseudo-element to create a square marker for each list item with a red border:

```
li::scroll-marker {
  content: "";
  border: 1px solid red;
  height: 1em;
  width: 1em;
}
```

We also apply styles to the `::scroll-marker-group` pseudo-element to lay out the scroll markers in the center of the row with a `0.4em` gap between each one:

```
::scroll-marker-group {
  display: flex;
  gap: 0.4em;
  place-content: center;
}
```

Finally, we style the marker of the currently-scrolled element differently from the others, targeting the marker with the `:target-current` pseudo-class.

```
::scroll-marker:target-current {
  background: red;
}
```

Result

Custom scroll marker numbering and style

This example is the same as the previous one, except that we have applied some different styling to the scroll markers, and used CSS counters to increment the number shown on each marker. The CSS differences are explained in the next section.

CSS

In this example, we set a name of a counter we want to increment on each `<li>` — `markers` — using the `counter-increment` property:

```
li {
  counter-increment: markers;
}
```

We then set the `::scroll-marker` pseudo-element's `content` property to the `counter()` function, passing it the `markers` counter name as an argument. This has the effect of inserting a number into each marker, which increments automatically. The rest of the styling is rudimentary, but it illustrates how the markers can be fully-styled.

```
li::scroll-marker {
  content: counter(markers);
  font-family: sans-serif;
  width: fit-content;
  height: 1em;
  padding: 5px;
  color: black;
  text-decoration: none;
  border: 2px solid rgb(0 0 0 / 0.15);
  border-radius: 0.5em;
  background-color: #eeeeee;
}
```

For another interesting customization, we include two rules to select the marker of the first and last list items by inserting `:first-child` and `:last-child` into the selector chain, respectively. We give the first marker text content of "First", and the last marker text content of "Last".

```
li:first-child::scroll-marker {
  content: "First";
}

li:last-child::scroll-marker {
  content: "Last";
}
```

To improve user experience, we set a different color on the markers on `:hover` and use the `:target-current` pseudo-class to set a different `color` and `background-color` on the currently-scrolled element's marker so users know which item is currently in view:

```
::scroll-marker:hover {
  background-color: #ddcccc;
}

::scroll-marker:target-current {
```

```
  background-color: purple;
  color: white;
}
```

::scroll-marker-group CSS pseudo-element

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`::scroll-marker-group`** CSS pseudo-element is generated inside a scroll container and contains any `::scroll-marker` pseudo-elements generated on descendants of the scroll container.

Syntax

```
::scroll-marker-group {
  /* ... */
}
```

Description

A scroll container's **`::scroll-marker-group`** pseudo-element represents a **scroll marker group container**. This is a container that automatically contains any `::scroll-marker` pseudo-elements generated on itself or its descendants. This allows them to be positioned and styled as a group. This pseudo-element is typically used when creating a CSS carousel to provide a scroll position indicator. The individual scroll markers can be used to navigate to their associated content items.

The scroll container must have its `scroll-marker-group` property set to a non-`none` value for the `::scroll-marker-group` pseudo-element to be generated. The `scroll-marker-group` value determines where the scroll marker group container appears in the carousel's tab order and layout box order (but not DOM structure) — `before` puts it at the start, while `after` puts it at the end.

> **Note:** Alternatively, a scroll marker group container can be created from an existing element containing a set of `<a>` elements using `scroll-target-group`.

As an accessibility best practice, match the visual rendering position of the scroll marker group container with the tab order. When positioning the group at the start of the content, put it at the beginning of the tab order using `before`. When positioning the group at the end of the content, put it at the end of the tab order using `after`.

When a scroll marker group container is created on a scroll container using the `scroll-marker-group` property, the scroll container is rendered with `tablist`/`tab` semantics. You can `Tab` to it with the keyboard, then move between the different "pages" using the left and right (or up and down) cursor keys, which also changes the state of the associated scroll markers and scroll buttons as expected. The scroll markers can also be tabbed between normally, as expected.

Examples

See Creating CSS carousels for other examples that use the `::scroll-marker` pseudo-element.

Creating carousel scroll markers

This demo is a carousel of single pages, with each item taking up the full page. We have included scroll markers to enable the user to navigate to any page with the click of a marker.

HTML

The HTML consists of an unordered list, with each list item containing some sample content:

```
<ul>
  <li>
    <h2>Page 1</h2>
  </li>
  <li>
    <h2>Page 2</h2>
  </li>
  <li>
    <h2>Page 3</h2>
  </li>
  <li>
    <h2>Page 4</h2>
  </li>
</ul>
```

CSS

We first convert our `<ul>` into a carousel by setting the `display` to `flex`, creating a single, non-wrapping row of `<li>` elements. The `overflow-x` property is set to `auto`, meaning if the items overflow their container on the x-axis, the content will scroll horizontally. We then convert the `<ul>` into a scroll-snap container, ensuring that items always snap into place when the container is scrolled with a `scroll-snap-type` value of `mandatory`.

```
* {
  box-sizing: border-box;
}

body {
  margin: 0;
  font-family: "Helvetica", "Arial", sans-serif;
}
```

```
ul {
  display: flex;
  gap: 4vw;
  padding-left: 0;
  overflow-x: auto;
  overscroll-behavior-x: contain;
  scroll-snap-type: x mandatory;
}
```

Next, we style the `<li>` elements, using the `flex` property to make them `100%` of the width of the container. The `scroll-snap-align` value of `start` causes the left-hand side of the left-most visible item to snap to the left edge of the container when the content is scrolled.

```
li {
  list-style-type: none;
  background-color: #eeeeee;
  flex: 0 0 100%;
  height: 200px;
  padding-top: 20px;
  scroll-snap-align: start;
  text-align: center;
}
```

Next, the list's `scroll-marker-group` property is set to `after`, so the `::scroll-marker-group` pseudo-element is placed after the list's DOM content in the tabbing order and layout box order; this means it comes after the scroll buttons:

```
ul {
  scroll-marker-group: after;
}
```

Next, the list's `::scroll-marker-group` pseudo-element is laid out using flexbox, with a `justify-content` value of `center` and a `gap` of `20px` so that its children (the `::scroll-marker` pseudo-elements) are centered inside the `::scroll-marker-group` with a gap between each one.

```
ul::scroll-marker-group {
  display: flex;
  justify-content: center;
  gap: 20px;
}
```

Next, the scroll markers themselves are styled. The look of each one is handled by setting `width`, `height`, `background-color`, `border`, and `border-radius`, but we also need to set a non-`none` value for the `content`, property so they are actually generated.

```
li::scroll-marker {
  width: 16px;
  height: 16px;
  background-color: transparent;
  border: 2px solid black;
  border-radius: 50%;
  content: "";
}
```

> **Note:** Generated content is inline by default; we can apply `width` and `height` to our scroll markers because they are being laid out as flex items.

Finally, the `:target-current` pseudo-class is used to select whichever scroll marker corresponds to the currently visible "page", highlighting how far the user has scrolled through the content. In this case, we set the `background-color` to `black` so it is styled as a filled-in circle.

```
li::scroll-marker:target-current {
  background-color: black;
}
```

Result

Positioning the scroll marker group container with anchor positioning

This example extends the previous one, demonstrating the use of CSS anchor positioning to position the scroll marker group container relative to the carousel.

CSS

The list's `::scroll-marker-group` pseudo-element is positioned relative to the carousel using CSS anchor positioning by giving the group a value for `position-anchor` that matches the `anchor-name` of the `<ul>`. We then position the group relative to the scroll container in the block direction by setting a `top` value that includes an `anchor()` function. We also add a `justify-self` value of `anchor-center`, which aligns the group to the center of the scroll container in the inline direction.

```
ul {
  anchor-name: --my-carousel;
}

ul::scroll-marker-group {
  /* From the previous example */
  display: flex;
  gap: 20px;

  position: absolute;
  position-anchor: --my-carousel;
  top: calc(anchor(bottom) - 70px);
  justify-self: anchor-center;
}
```

::search-text CSS pseudo-element

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`::search-text`** CSS pseudo-element applies styles to search results identified by the user agent's "Find" or "Find in page" text search feature.

Try it

```
p::search-text {
  color: crimson;
  background-color: wheat;
}
```

```
<p>
  Using your browser's "Find in page" functionality, find a word or phrase that
  appears in this sentence, and note how, in supporting browsers, each result is
  highlighted using the specified custom styles.
</p>
```

Syntax

```
::search-text {
  /* ... */
}
```

Description

Most browsers include some kind of in-page text search functionality, usually labeled "Find" or "Find in page". The `::search-text` pseudo-element, one of the highlight pseudo-elements, allows you to apply a limited set of styles to the text results highlighted by the browser search functionality.

Not all browsers and browser versions highlight search results using in-page highlights that are stylable with CSS. In such cases, `::search-text` may be unimplemented or just ignored.

Using `::search-text` as a selector on its own will style browser search results appearing *anywhere* on a page. If you want to only style browser search results appearing inside certain elements, you can combine `::search-text` with other selectors, for example `section::search-text`.

Additionally, `::search-text` can be combined with the `:current` pseudo-class to provide specific styles to the currently-focused search result, for example:

```
p::search-text {
  color: white;
  background-color: purple;
}

p::search-text:current {
  background-color: crimson;
}
```

Inheritance model

The `::search-text` pseudo-element follows a special inheritance model common to all highlight pseudo-elements, wherein styles are inherited from both their parent elements and the pseudo-elements of their parents. For more details on how this inheritance works, see the Highlight pseudo-elements inheritance section.

Allowable properties

A limited subset of CSS properties can be used with `::search-text`:

- `color`
- `background-color`
- The `text-decoration` shorthand and associated longhand properties:
  - `text-decoration-line`: the `grammar-error`, `spelling-error`, `line-through`, `none`, and `underline` values only.
  - `text-decoration-color`
  - `text-decoration-style`
  - `text-decoration-thickness`
  - `text-decoration-skip-ink`
- `text-underline-offset`
- `text-shadow`

Accessibility

Override text search result styles sparingly, especially when doing so for purely aesthetic reasons. For people experiencing cognitive concerns or who are less technologically literate, unexpected changes to these styles may hurt their understanding of the functionality.

A primary use case of `::search-text` is to increase color contrast compared to the default browser styling. When customizing highlighted text, it is important to ensure that the contrast ratio between the foreground and background colors is great enough for people to be able to perceive the content of the highlighted text.

Examples

Custom styles for text search results

This example shows how to use `::search-text` and `:current` to create custom styles for your browser's "Find in page" search results.

HTML

The HTML consists of a basic paragraph of text. We won't show the HTML source, both for brevity, and so that it is easier to navigate the search results in the rendered example.

```
<p>
  Lorem ipsum dolor sit amet, consectetur adipiscing elit. Donec finibus est
  eget eros congue pellentesque. Etiam a augue accumsan, scelerisque nisl sit
  amet, lobortis nulla. Aliquam condimentum eu orci eu elementum. Donec
  porttitor quam et posuere commodo. Mauris rhoncus diam a scelerisque molestie.
  Integer sollicitudin risus dui, ut sagittis lorem laoreet eget. Duis eget
  pretium enim. Morbi tristique, diam sit amet gravida finibus, metus ex
  tincidunt nibh, ac volutpat urna purus et arcu. Donec risus risus, semper vel
  purus sit amet, gravida vestibulum est. Sed et tristique urna. Nam vel mi eget
  nisi consectetur elementum. Aenean faucibus aliquam cursus. Morbi posuere
  tincidunt velit, et sagittis quam sagittis in. Nam eget ante ultrices, auctor
  dui vel, euismod lacus. Vivamus tincidunt, sem ac sodales aliquet, tortor
  tortor consequat diam, nec tempor mi dui vel eros. Aliquam ac erat et metus
  egestas scelerisque.
</p>
```

CSS

In our CSS, we start by styling the `::search-text` pseudo-element. We give it custom `background-color`, `color`, and `text-shadow` styles.

```
html {
  font-family: "Helvetica", "Arial";
}

p {
  font-size: 1.5rem;
  line-height: 1.5;
  width: 90%;
  margin: 0 auto;
}
@layer no-support {
  body::before {
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1em 0;
  }
  @supports not selector(:current) {
    body::before {
      content: "Your browser doesn't support the :current pseudo-class.";
    }
  }
  @supports not selector(::search-text) {
    body::before {
      content: "Your browser doesn't support the ::search-text pseudo-element.";
    }
  }
}
```

```
::search-text {
  background-color: purple;
  color: white;
  text-shadow: 1px 1px 1px black;
}
```

Finally, we style the currently-focused search result via `::search-text:current`, providing it with a different `background-color` and some `text-decoration` styles so that it is distinguishable from the rest of the results.

```
::search-text:current {
  background-color: crimson;
  text-decoration-line: underline;
  text-decoration-color: yellow;
  text-decoration-thickness: 3px;
}
```

Result

The example renders as follows:

Try using the browser's find in page interface to find a word that appears multiple times in the example text, such as "aliquam", "amet", or "tortor". Move between the previous and next results to check out the `:current` styling.

See also

- `:current`
- Highlight pseudo-elements
- CSS pseudo-elements module

::selection CSS pseudo-element

The **`::selection`** CSS pseudo-element applies styles to the part of a document that has been highlighted by the user (such as clicking and dragging the mouse across text).

The `::selection` pseudo-element follows a special inheritance model common to all highlight pseudo-elements. For more details on how this inheritance works, see the Highlight pseudo-elements inheritance section.

Try it

```
p::selection {
  color: red;
  background-color: yellow;
}
```

```
<p>
  Select a fragment of this paragraph, to see how its appearance is affected.
</p>
```

Allowable properties

Only certain CSS properties can be used with `::selection`:

- `color`
- `background-color`
- `text-decoration` and its associated properties
- `text-shadow`
- `-webkit-text-stroke-color`, `-webkit-text-fill-color` and `-webkit-text-stroke-width`

In particular, `background-image` is ignored.

Syntax

```
::selection {
  /* ... */
}
```

Accessibility

Don't override selected text styles for purely aesthetic reasons — users can customize them to suit their needs. For people experiencing cognitive concerns or who are less technologically literate, unexpected changes to selection styles may hurt their understanding of the functionality.

If overridden, it is important to ensure that the **contrast ratio** between the text and background colors of the selection is high enough that people experiencing low vision conditions can read it.

Color contrast ratio is found by comparing the luminosity of the selected text and the selected text background colors. To meet current Web Content Accessibility Guidelines (WCAG), text content must have a contrast ratio of **4.5:1**, or 3:1 for larger text such as headings. (WCAG defines large text as between `18.66px` and `24px` and bold, or `24px` or larger.)

- WebAIM: Color Contrast Checker
- MDN Understanding WCAG, Guideline 1.4 explanations
- Understanding Success Criterion 1.4.3 | W3C Understanding WCAG 2.0

Examples

HTML

```
This text has special styles when you highlight it.
<p>Also try selecting text in this paragraph.</p>
```

CSS

```
::-moz-selection {
  color: gold;
  background-color: red;
}

p::-moz-selection {
  color: white;
  background-color: blue;
}
```

```
/* Make selected text gold on a red background */
::selection {
  color: gold;
  background-color: red;
}

/* Make selected text in a paragraph white on a blue background */
p::selection {
  color: white;
  background-color: blue;
}
```

Result

::slotted() CSS pseudo-element

The **`::slotted()`** CSS pseudo-element represents any element that has been placed into a slot inside an HTML template (see Using templates and slots for more information).

This only works when used inside CSS placed within a shadow DOM. Note that this selector won't select a text node placed into a slot; it only targets actual elements.

Try it

```
/* This CSS is being applied inside the shadow DOM. */

::slotted(.content) {
  background-color: aqua;
}

h2 ::slotted(span) {
  background: silver;
}
```

```
<template id="card-template">
  <div>
    <h2><slot name="caption">title goes here</slot></h2>
    <slot name="content">content goes here</slot>
  </div>
</template>

<my-card>
  <span slot="caption">Error</span>
  <p class="content" slot="content">Build failed!</p>
</my-card>
```

```
customElements.define(
  "my-card",
  class extends HTMLElement {
    constructor() {
      super();

      const template = document.getElementById("card-template");
      const shadow = this.attachShadow({ mode: "open" });
      shadow.appendChild(document.importNode(template.content, true));

      const elementStyle = document.createElement("style");
      elementStyle.textContent = `
        div {
          width: 200px;
          border: 2px dotted red;
          border-radius: 4px;
        }`;
      shadow.appendChild(elementStyle);

      const cssTab = document.querySelector("#css-output");
      const editorStyle = document.createElement("style");
      editorStyle.textContent = cssTab.textContent;
      shadow.appendChild(editorStyle);
      cssTab.addEventListener("change", () => {
        editorStyle.textContent = cssTab.textContent;
      });
    }
  },
);
```

```
/* Selects any element placed inside a slot */
::slotted(*) {
  font-weight: bold;
}

/* Selects any <span> placed inside a slot */
::slotted(span) {
  font-weight: bold;
}
```

Syntax

```
::slotted(<compound-selector>) {
  /* ... */
}
```

Examples

Highlighting slotted elements

In this example, we use a template with three slots:

```
<template id="person-template">
  <div>
    <h2>Personal ID Card</h2>
    <slot name="person-name">NAME MISSING</slot>
    <ul>
      <li><slot name="person-age">AGE MISSING</slot></li>
      <li><slot name="person-occupation">OCCUPATION MISSING</slot></li>
    </ul>
  </div>
</template>
```

We define the `<person-details>` custom element. In this case, we add styles with JavaScript, though we could have added them in a `<style>` block within the `<template>` with the same effect:

```
customElements.define(
  "person-details",
  class extends HTMLElement {
    constructor() {
      super();
      const template = document.getElementById("person-template");

      const shadowRoot = this.attachShadow({ mode: "open" });

      const style = document.createElement("style");
      style.textContent =
        "div { padding: 10px; border: 1px solid gray; width: 200px; margin: 10px; }" +
        "h2 { margin: 0 0 10px; }" +
        "ul { margin: 0; }" +
        "p { margin: 10px 0; }" +
        "::slotted(*) { color: gray; font-family: sans-serif; } " +
        "::slotted(span) {text-decoration: underline;} ";

      shadowRoot.appendChild(style);
      shadowRoot.appendChild(document.importNode(template.content, true));
    }
  },
);
```

When filling the `style` element with content, you'll see that we select all slotted elements (`::slotted(*)`) and give them a different font and color. This differentiates them from the slots that haven't been filled. We styled all the slotted `<span>`s (`::slotted(span)`) to differentiate the `<span>`s from the `<p>`s.

Our markup includes three custom elements, including a custom element with an invalid slot name in a source order that differs from the `<template>`:

```
<person-details>
  <p slot="person-name">Wonder Woman</p>
  <span slot="person-age">Immortal</span>
  <span slot="person-occupation">Superhero</span>
</person-details>
```

```
<person-details>
  <p slot="person-name">Malala Yousafzai</p>
  <span slot="person-age">17</span>
  <span slot="person-occupation">Activist</span>
</person-details>

<person-details>
  <span slot="person-age">44</span>
  <span slot="not-a-slot-name">Time traveler</span>
  <p slot="person-name">Dr. Who</p>
</person-details>
```

Result

::spelling-error CSS pseudo-element

The **`::spelling-error`** CSS pseudo-element represents a text segment which the user agent has flagged as incorrectly spelled.

The `::spelling-error` pseudo-element follows a special inheritance model common to all highlight pseudo-elements. For more details on how this inheritance works, see the Highlight pseudo-elements inheritance section.

Allowable properties

Only a small subset of CSS properties can be used in a rule with `::spelling-error` in its selector:

- `color`
- `background-color`
- `cursor`
- `caret-color`
- `outline` and its longhands
- `text-decoration` and its associated properties
- `text-emphasis-color`
- `text-shadow`

Syntax

```
::spelling-error {
  /* ... */
}
```

Examples

Basic document spell check

In this example, eventual supporting browsers should highlight any flagged spelling errors with the styles shown.

HTML

```
<p contenteditable spellcheck="true">
  My friends are coegdfgfddffbgning to the party tonight.
</p>
```

CSS

```
::spelling-error {
  text-decoration: wavy red underline;
}
```

Result

See also

- `::grammar-error`
- `text-decoration-line`

::target-text CSS pseudo-element

The **`::target-text`** CSS pseudo-element represents the text that has been scrolled to if the browser supports text fragments. It allows authors to choose how to highlight that section of text.

The `::target-text` pseudo-element follows a special inheritance model common to all highlight pseudo-elements. For more details on how this inheritance works, see the Highlight pseudo-elements inheritance section.

Syntax

```
::target-text {
  /* ... */
}
```

Examples

Highlighting text fragments

```
::target-text {
  background-color: rebeccapurple;
```

```
  color: white;
}
```

To see this CSS in action follow the link to scroll-to-text demo.

See also

- Text fragments
- `:target` (for highlighting target elements)

::view-transition CSS pseudo-element

The **`::view-transition`** CSS pseudo-element represents the root of the view transitions overlay, which contains all view transition snapshot groups and sits over the top of all other page content.

During a view transition, `::view-transition` is included in the associated pseudo-element tree as explained in The view transition pseudo-element tree. It is the top-level node of this tree, and has one or more `::view-transition-group()`s as children.

`::view-transition` is given the following default styling in the UA stylesheet:

```
:root::view-transition {
  position: fixed;
  inset: 0;
}
```

All `::view-transition-group()` pseudo-elements are positioned relative to the view transition root.

Syntax

```
::view-transition {
  /* ... */
}
```

Examples

```
::view-transition {
  background-color: rgb(0 0 0 / 25%);
}
```

::view-transition-group() CSS pseudo-element

The **`::view-transition-group()`** CSS pseudo-element represents a single view transition snapshot group.

During a view transition, `::view-transition-group()` is included in the associated pseudo-element tree as explained in The view transition pseudo-element tree. It is only ever a child of `::view-transition`, and has a `::view-transition-image-pair()` as a child.

`::view-transition-group()` is given the following default styling in the UA stylesheet:

```
:root::view-transition-group(*) {
  position: absolute;
  top: 0;
  left: 0;

  animation-duration: 0.25s;
  animation-fill-mode: both;
}
```

By default, selected elements initially mirror the size and position of the `::view-transition-old()` pseudo-element representing the "old" view state, or the `::view-transition-new()` pseudo-element representing the "new" view state if there isn't an "old" view state.

If there's both an "old" and "new" view state, styles in the view transition style sheet animate this pseudo-element's `width` and `height` from the size of the "old" view state's border box to that of the "new" view state's border box.

> **Note:** View transition styles are dynamically generated during the view transition; see the specification setup transition pseudo-elements and update pseudo-element styles sections for more details.

In addition, the element's transform is animated from the "old" view state's screen space transform to the new view state's screen space transform. This style is generated dynamically since the values of animated properties are determined at the time that the transition begins.

Syntax

```
::view-transition-group([ <pt-name-selector> <pt-class-selector>? ] | <pt-class-selector>) {
  /* ... */
}
```

Parameters

`*`

The universal selector (`*`); selects all view transition groups on a page.

`root`

The `view-transition-name` applied to `:root` causes the pseudo-element to match the default `root` view transition group. This is the snapshot group created by the user agent to contain the view transition for the overall page. This group includes any element not assigned to its own specific view transition snapshot group via the `view-transition-name` property.

`<pt-name-selector>`

The `<custom-ident>` set as the value of the `view-transition-name` property.

`<pt-class-selector>`

The `<custom-ident>` set as the value of the `view-transition-class` property, preceded by a period (`.`).

The specificity of the named view transition pseudo-element is equal to the specificity of the type selector, unless the parameter used is the universal selector is used, in which case the specificity is zero.

Examples

```
::view-transition-group(embed-container) {
  animation-duration: 0.3s;
  animation-timing-function: ease;
  z-index: 1;
}

::view-transition-group(.card) {
  animation-duration: 1s;
}
```

::view-transition-image-pair() CSS pseudo-element

The **`::view-transition-image-pair()`** CSS pseudo-element represents a container for a view transition's "old" and "new" view states — before and after the transition.

During a view transition, `::view-transition-image-pair()` is included in the associated pseudo-element tree as explained in The view transition pseudo-element tree. It is only ever a child of a `::view-transition-group()`. In terms of children, it can have a `::view-transition-new()` or a `::view-transition-old()`, or both.

`::view-transition-image-pair()` is given the following default styling in the UA stylesheet:

```
:root::view-transition-image-pair(*) {
  position: absolute;
  inset: 0;

  animation-duration: inherit;
  animation-fill-mode: inherit;
  animation-delay: inherit;
}
```

During a view transition, `::view-transition-image-pair()` has `isolation: isolate` set on it in the view transition style sheet so that its children can be blended with non-normal blend modes without affecting other visual outputs.

Syntax

```
::view-transition-image-pair([ <pt-name-selector> <pt-class-selector>? ] | <pt-class-selector>) {
  /* ... */
}
```

Parameters

`*`

The universal selector (`*`); selects all view transition groups on a page.

`root`

Causes the pseudo-element to match the default `root` view transition snapshot group created by the user agent to contain the view transition for the overall page. This group includes any element not assigned to its own specific view transition snapshot group via the `view-transition-name` property.

`<pt-name-selector>`

The `<custom-ident>` set as the value of the `view-transition-name` property.

`<pt-class-selector>`

The `<custom-ident>` set as the value of the `view-transition-class` property preceded by a period (`.`).

Examples

```
::view-transition-image-pair(root) {
  isolation: auto;
}

::view-transition-image-pair(.card) {
  isolation: isolate;
}
```

- View Transition API
- Smooth transitions with the View Transition API

::view-transition-new() CSS pseudo-element

The **`::view-transition-new()`** CSS pseudo-element represents the "new" view state of a view transition — a snapshot live representation of the state after the transition.

During a view transition, `::view-transition-new()` is included in the associated pseudo-element tree as explained in The view transition pseudo-element tree. It is only ever a child of a `::view-transition-image-pair()`, and never has any children.

It is a replaced element and therefore can be manipulated with properties such as `object-fit` and `object-position`. It has natural dimensions equal to the content's size.

The following default styling is included in the UA stylesheet:

```
:root::view-transition-old(*),
:root::view-transition-new(*) {
  position: absolute;
  inset-block-start: 0;
  inline-size: 100%;
  block-size: auto;

  animation-duration: inherit;
```

```
  animation-fill-mode: inherit;
  animation-delay: inherit;
}

/* Keyframes for blending when there are 2 images */
@keyframes -ua-mix-blend-mode-plus-lighter {
  from {
    mix-blend-mode: plus-lighter;
  }
  to {
    mix-blend-mode: plus-lighter;
  }
}

@keyframes -ua-view-transition-fade-in {
  from {
    opacity: 0;
  }
}
```

> **Note:** Additional view transition styles are also setup to animate `::view-transition-new()`. These are dynamically generated during the view transition; see the specification setup transition pseudo-elements and update pseudo-element styles sections for more details.

Syntax

```
::view-transition-new([ <pt-name-selector> <pt-class-selector>? ] | <pt-class-selector>) {
  /* ... */
}
```

Parameters

`*`

The universal selector (`*`); selects all view transition groups on a page.

`root`

Causes the pseudo-element to match the default `root` view transition snapshot group created by the user agent to contain the view transition for the overall page. This group includes any element not assigned to its own specific view transition snapshot group via the `view-transition-name` property.

`<pt-name-selector>`

The `<custom-ident>` set as the value of the `view-transition-name` property.

`<pt-class-selector>`

The `<custom-ident>` set as the value of the `view-transition-class` property preceded by a period (`.`).

Examples

```
figcaption {
  view-transition-name: figure-caption;
}

@keyframes grow-x {
  from {
    transform: scaleX(0);
  }
  to {
    transform: scaleX(1);
  }
}

@keyframes shrink-x {
  from {
    transform: scaleX(1);
  }
  to {
    transform: scaleX(0);
  }
}

::view-transition-old(figure-caption),
::view-transition-new(figure-caption) {
  height: auto;
  right: 0;
  left: auto;
  transform-origin: right center;
}

::view-transition-old(figure-caption) {
  animation: 0.25s linear both shrink-x;
}

::view-transition-new(figure-caption) {
  animation: 0.25s 0.25s linear both grow-x;
}
```

::view-transition-old() CSS pseudo-element

The **`::view-transition-old()`** CSS pseudo-element represents the "old" view state of a view transition — a static snapshot of the old view, before the transition.

During a view transition, `::view-transition-old()` is included in the associated pseudo-element tree as explained in The view transition pseudo-element tree, provided there's an "old" view state to represent. It is only ever a child of a `::view-transition-image-pair()`, and never has any children.

It is a replaced element and therefore can be manipulated with properties such as `object-fit` and `object-position`. It has natural dimensions equal to the content's size.

The following default styling is included in the UA stylesheet:

```
:root::view-transition-old(*),
:root::view-transition-new(*) {
  position: absolute;
  inset-block-start: 0;
  inline-size: 100%;
  block-size: auto;

  animation-duration: inherit;
  animation-fill-mode: inherit;
  animation-delay: inherit;
}

/* Keyframes for blending when there are 2 images */
@keyframes -ua-mix-blend-mode-plus-lighter {
  from {
    mix-blend-mode: plus-lighter;
  }
  to {
    mix-blend-mode: plus-lighter;
  }
}

@keyframes -ua-view-transition-fade-out {
  to {
    opacity: 0;
  }
}
```

> **Note:** Additional view transition styles are also setup to animate `::view-transition-old()`. These are dynamically generated during the view transition; see the specification setup transition pseudo-elements and update pseudo-element styles sections for more details.

Syntax

```
::view-transition-old([ <pt-name-selector> <pt-class-selector>? ] | <pt-class-selector>) {
  /* ... */
}
```

Parameters

`*`

The universal selector (`*`) selects all view transition groups on a page.

`root`

Causes the pseudo-element to match the default `root` view transition snapshot group created by the user agent to contain the view transition for the overall page. This group includes any element not assigned to its own specific view transition snapshot group via the `view-transition-name` property.

`<pt-name-selector>`

The `<custom-ident>` set as the value of the `view-transition-name` property.

`<pt-class-selector>`

The `<custom-ident>` set as the value of the `view-transition-class` property preceded by a period (`.`).

Examples

```
figcaption {
  view-transition-name: figure-caption;
}

@keyframes grow-x {
  from {
    transform: scaleX(0);
  }
  to {
    transform: scaleX(1);
  }
}

@keyframes shrink-x {
  from {
    transform: scaleX(1);
  }
  to {
    transform: scaleX(0);
  }
}

::view-transition-old(figure-caption),
::view-transition-new(figure-caption) {
  height: auto;
  right: 0;
  left: auto;
  transform-origin: right center;
}

::view-transition-old(figure-caption) {
  animation: 0.25s linear both shrink-x;
}

::view-transition-new(figure-caption) {
  animation: 0.25s 0.25s linear both grow-x;
}
```

:active CSS pseudo-class

The **`:active`** CSS pseudo-class represents an element (such as a button) that is being activated by the user. When using a mouse, "activation" typically starts when the user presses down the primary mouse button.

Try it

```
.joinBtn {
  width: 10em;
  height: 5ex;
  background-image: linear-gradient(135deg, #f34079 40%, #fc894d);
  border: none;
  border-radius: 5px;
  font-weight: bold;
  color: white;
  cursor: pointer;
}

.joinBtn:active {
  box-shadow: 2px 2px 5px #fc894d;
}
```

```
<p>Would you like to subscribe to our channel?</p>
<button class="joinBtn">Subscribe</button>
```

The `:active` pseudo-class is commonly used on `<a>` and `<button>` elements. Other common targets of this pseudo-class include elements that are *contained in* an activated element, and form elements that are being activated through their associated `<label>`.

Styles defined by the `:active` pseudo-class will be overridden by any subsequent link-related pseudo-class (`:link`, `:hover`, or `:visited`) that has at least equal specificity. To style links appropriately, put the `:active` rule after all other link-related rules, as defined by the *LVHA-order*: `:link` — `:visited` — `:hover` — `:active`.

> **Note:** On systems with multi-button mice, CSS specifies that the `:active` pseudo-class must only apply to the primary button; on right-handed mice, this is typically the leftmost button.

Syntax

```
:active {
  /* ... */
}
```

Examples

Active links

HTML

```
<p>
  This paragraph contains a link:
  <a href="#">This link will turn red while you click on it.</a>
  The paragraph will get a gray background while you click on it or the link.
</p>
```

CSS

```
/* Unvisited links */
a:link {
  color: blue;
}
/* Visited links */
a:visited {
  color: purple;
}
/* Hovered links */
a:hover {
  background: yellow;
}
/* Active links */
a:active {
  color: red;
}

/* Active paragraphs */
p:active {
  background: #eeeeee;
}
```

Result

Active form elements

HTML

```
<form>
  <label for="my-button">My button: </label>
  <button id="my-button" type="button">Try Clicking Me or My Label!</button>
</form>
```

CSS

```
form :active {
  color: red;
}
```

```
form button {
  background: white;
}
```

Result

:active-view-transition CSS pseudo-class

The **`:active-view-transition`** CSS pseudo-class matches the root element of a document when a view transition is in progress (*active*) and stops matching once the transition has completed.

Syntax

```
:root:active-view-transition ... {
  /* ... */
}
```

Examples

Styling an active view transition

This example extends the Basic view transition example on the `startViewTransition` page.

```
<main>
  <section class="color">
    <h2>Color is changing!</h2>
  </section>
  <button id="change-color">Change Color</button>
</main>
```

A `<h2>` element initially has a `display: none` style, and this is overwritten using the `:active-view-transition` pseudo-class setting the `<h2>` style to `display: block`. The button is hidden using `visibility: hidden`, when the view transition is in progress:

```
html {
  --bg: indigo;
}
main {
  display: flex;
  flex-direction: column;
  gap: 5px;
}
section {
  background-color: var(--bg);
  height: 60px;
  border-radius: 5px;
  display: flex;
  justify-content: center;
  align-items: center;
}
::view-transition-group(root) {
  animation-duration: 2s;
}
```

```
h2 {
  display: none;
  color: white;
}
:root:active-view-transition h2 {
  display: block;
}
:root:active-view-transition button {
  visibility: hidden;
}
```

```
const colors = ["darkred", "darkslateblue", "darkgreen"];
const colBlock = document.querySelector(".color");
let count = 0;
const updateColor = () => {
  colBlock.style = `--bg: ${colors[count]}`;
  count = count !== colors.length - 1 ? ++count : 0;
};
const changeColor = () => {
  if (!document.startViewTransition) {
    updateColor();
    return;
  }
  const transition = document.startViewTransition(() => {
    updateColor();
  });
};
const changeColorButton = document.querySelector("#change-color");
changeColorButton.addEventListener("click", changeColor);
changeColorButton.addEventListener("keypress", changeColor);
```

:active-view-transition-type() CSS pseudo-class

The functional **`:active-view-transition-type()`** CSS pseudo-class matches elements when a view transition with one or more specific types is in progress (is *active*) and stops matching once the view transition has completed.

```
html:active-view-transition-type(forwards, backwards) {
  /* ... */
}
```

Syntax

```
:active-view-transition-type(<custom-ident>#) {
  /* ... */
}
```

Parameters

`<custom-ident>#`

One or more comma-separated `<custom-ident>` values representing the choice of types that can be applied to the active view transition for this selector to match.

Description

View transition types provide a mechanism by which different **types** can be specified for active view transitions. Types can be set on view transitions in multiple ways:

- For same-document (SPA) view transitions, specify types in the `types` option of the `startViewTransition()` method.
- For cross-document view transitions, specify types in the `types` descriptor of the `@view-transition` at-rule.
- You can also modify the active view transition's types on-the-fly via the `types` property of the corresponding `ViewTransition` object:
  - For same-document view transitions, this is the `ViewTransition` object returned by the `startViewTransition()` method.
  - For cross-document view transitions, the `ViewTransition` object is available in the `viewTransition` property of the `pageswap` event object in the case of the outgoing page, and the `viewTransition` property of the `pagereveal` event object in the case of the incoming page.
  - You can also access the active `ViewTransition` via the `Document.activeViewTransition` property. This provides a consistent way to access the active view transition in any context.

Once the active view transition has one or more types set on it, the `:active-view-transition-type()` pseudo-class can be applied to the document root element to set custom styles for each type. The pseudo-class takes a comma-separated list of types as its argument to specify the types that can be set on the active view transition for the selector to be matched.

For example, you might want to apply different transition animations to an `<img>` element in an image gallery app as the displayed image changes, depending on whether you are moving forward or backward in the sequence, deleting an image, or adding an image into the sequence.

OR versus AND behavior

It is important to note that the comma-separated list of types specified inside the `:active-view-transition-type()` pseudo-class provides OR behavior — if one or more of these types are set on the active view transition, the selector will match.

For example, in this case, the selector will match if the active view transition has a type of `forwards`, `backwards`, or both:

```
html:active-view-transition-type(forwards, backwards) {
  /* ... */
}
```

If you want to specify AND behavior — that is, all the types must be set for the selector to match — you can do so by chaining multiple `:active-view-transition-type()` pseudo-classes together. In the following case, the selector will only match if the active view transition has types of `slide` *and* `forwards`:

```
html:active-view-transition-type(slide):active-view-transition-type(forwards) {
  /* ... */
}
```

Examples

See also Using view transition types for multiple complete examples.

Basic <code>:active-view-transition-type()</code> usage

This example includes a basic document that transitions between two different pieces of content via two different buttons, "Backwards" and "Forwards". We demonstrate how view transition types can be used to animate the transition differently depending on which button was pressed.

HTML

The markup includes a single `<p>` element to contain the content and two `<button>` elements to trigger the view transitions.

```
<p>This is my first piece of content. I hope you like it!</p>
<div>
  <button id="backwards">Backwards</button>
  <button id="forwards">Forwards</button>
</div>
```

JavaScript

In our script, we create references to both buttons and the content paragraph, and then store our two different pieces of content in two constants.

```
const backBtn = document.getElementById("backwards");
const fwdBtn = document.getElementById("forwards");
const content = document.querySelector("p");

const first = "This is my first piece of content. I hope you like it!";
const second =
  "This is my second piece of content. Is it better than the first?";
```

Next, we add `click` event listeners to the backwards and forwards buttons; when they are clicked, the `changeContent()` function is run.

```
backBtn.addEventListener("click", changeContent);
fwdBtn.addEventListener("click", changeContent);
```

Finally, we define the `changeContent()` function. We start by declaring a `type` value that will hold our view transition type value. If the event target is the "Backwards" button, we set `type` to `backwards`. If not, we set `type` to `forwards`. We then invoke the `startViewTransition()` method to update the content and start the transition:

- The `update` callback checks whether the paragraph `textContent` is equal to the `first` string. If so, we set it to the `second` string. If not, we set it to the `first` string.
- The `types` array is given one element: the `type` value we declared earlier.

```
function changeContent(e) {
  const type = e.target === backBtn ? "backwards" : "forwards";
  document.startViewTransition({
    update() {
      content.textContent === first
        ? (content.textContent = second)
        : (content.textContent = first);
    },
    types: [type],
  });
}
```

CSS

In our styles, we start off by creating a set of nested rules using the `:active-view-transition` pseudo-class. These styles will be applied whenever a view transition is active, regardless of the their types. We apply a `view-transition-name` of `none` to the `:root`, as we don't want any elements captured and animated on transition except for the `<p>` element, which is given a `view-transition-name` of `slide`.

```
html,
body {
  height: 100%;
}

body {
  display: flex;
  flex-direction: column;
  justify-content: center;
  align-items: center;
}

div {
  display: flex;
  width: 60%;
  justify-content: space-between;
}

p {
  font-size: 1.7em;
  width: 60%;
  color: blue;
  margin-top: 0;
}
```

```
html:active-view-transition {
  :root {
    view-transition-name: none;
  }
  p {
    view-transition-name: slide;
  }
}
```

Next, we use the `:active-view-transition-type()` pseudo-class to create two blocks of nested styles, the first of which is only applied when the active view transition has a type of `forwards`, and the second of which is only applied when the active view transition has a type of `backwards`. In each block, we use the `::view-transition-old()` and `::view-transition-new()` pseudo-elements to apply custom `animation-name` values to the `slide` capture group's outgoing and incoming views.

As a result:

- When the transition type is `forwards`, the old content view slides out to the left, and the new content view slides in from the right.
- When the transition type is `backwards`, the old content view slides out to the right, and the new content view slides in from the left.

```
html:active-view-transition-type(forwards) {
  &::view-transition-old(slide) {
    animation-name: slide-out-to-left;
  }
  &::view-transition-new(slide) {
    animation-name: slide-in-from-right;
  }
}

html:active-view-transition-type(backwards) {
  &::view-transition-old(slide) {
    animation-name: slide-out-to-right;
  }
  &::view-transition-new(slide) {
    animation-name: slide-in-from-left;
  }
}
```

Finally, we use `@keyframes` animation blocks to define the animations referenced previously.

```
@keyframes slide-in-from-left {
  from {
    translate: -100vw 0;
  }
}
@keyframes slide-in-from-right {
  from {
    translate: 100vw 0;
  }
}
@keyframes slide-out-to-left {
  to {
    translate: -100vw 0;
  }
}
@keyframes slide-out-to-right {
```

```
  to {
    translate: 100vw 0;
  }
}
```

Result

The example is rendered like so:

Try clicking the "Backwards" and "Forwards" buttons, and note how, even though the same code is used to trigger the content update and view transition in each case, a different animation is used for the transition. This is because a different transition type is set depending on which button is pressed.

- Using view transition types

:any-link CSS pseudo-class

The **`:any-link`** CSS pseudo-class selector represents an element that acts as the source anchor of a hyperlink, independent of whether it has been visited. In other words, it matches every `<a>` or `<area>` element that has an `href` attribute. Thus, it matches all elements that match `:link` or `:visited`.

Try it

```
p {
  font-weight: bold;
}

a:any-link {
  color: forestgreen;
  text-decoration-color: hotpink;
}
```

```
<p>Pages that you might have visited:</p>
<ul>
  <li>
    <a href="https://developer.mozilla.org">MDN Web Docs</a>
  </li>
  <li>
    <a href="https://www.youtube.com/YouTube">Google</a>
  </li>
</ul>
<p>Pages unlikely to be in your history:</p>
<ul>
  <li>
    <a href="https://developer.mozilla.org/missing-3">Random MDN page</a>
  </li>
  <li>
    <a href="https://example.com/missing-3">Random Example page</a>
  </li>
</ul>
```

Syntax

```
:any-link {
  /* ... */
}
```

Examples

HTML

```
<a href="https://example.com">External link</a><br />
<a href="#">Internal target link</a><br />
<a>Placeholder link (won't get styled)</a>
```

CSS

```
a:any-link {
  border: 1px solid blue;
  color: orange;
}

/* WebKit browsers */
a:-webkit-any-link {
  border: 1px solid blue;
  color: orange;
}
```

Result

- Matches HTML elements: `<a>` and `<area>` with an `href` attribute
- Related CSS selectors:
  - `:visited`
  - `:link`

:autofill CSS pseudo-class

The **`:autofill`** CSS pseudo-class matches when an `<input>` element has its value autofilled by the browser. The class stops matching if the user edits the field.

Try it

```
input {
  border: 3px solid black;
}
input:autofill {
  outline: 5px solid magenta;
  border: 3px dashed yellow;
}
```

```
<form>
  <p>Click on the text box and choose any option suggested by your browser.</p>
  <p>
    <label for="name">Name</label>
    <input id="name" name="name" type="text" autocomplete="given-name" />
  </p>
  <p>
    <label for="email">Email Address</label>
    <input id="email" name="email" type="email" autocomplete="email" />
  </p>
  <p>
    <label for="country">Country</label>
    <input
      id="country"
      name="country"
      type="text"
      autocomplete="country-name" />
  </p>
</form>
```

Description

The `:autofill` pseudo-class selects `<input>` elements containing un-edited content that was auto-filled by the user-agent. Autocompletion may occur when browser settings are set to enable autocompletion or the `autocomplete` attribute is set on the element itself.

When the user uses the browser's autocompletion feature to autofill a form control, all the form controls that can be autofilled based on the selection get populated. These will all match the `:autofill` UI state. If the user edits a control, that control will no longer match `:autofill`, even if the value is the same as the autofilled value.

The specification includes the vendor-prefixed `:-webkit-autofill` pseudo-class as an alias. This also matches input elements autofilled by the user agent, and no longer matches if the user edits the autofilled field.

Note that the user agent style sheets of many browsers use `!important` in their style declarations, making some styles non-overridable. For example, Chrome has the following in its internal stylesheet:

```
input:-internal-autofill-selected {
  appearance: menulist-button;
  background-image: none !important;
  background-color:
    light-dark(rgb(232 240 254), rgb(70 90 126 / 0.4)) !important;
  color: fieldtext !important;
}
```

This means that you cannot override the default `background-color`, `background-image`, or `color` values on selected autofilled input elements in your own rules, but you can override the `appearance`, and you can override these properties for the autofilled elements that aren't currently focused.

Syntax

```
:autofill {
  /* ... */
}
```

Examples

The following example demonstrates the use of the `:autofill` pseudo-class to change the border of a text field that has been autocompleted by the browser.

HTML

We include three HTML `<input>` elements, each with an associated `<label>`. The `name` and `email` will likely autocomplete and match `:autofill`, while the `pet` value is unlikely to.

```
<form method="post" action="">
  <p>
    <label for="name">Name: </label>
    <input name="n" id="name" autocomplete="given-name" />
  </p>
  <p>
    <label for="email">Email: </label>
    <input type="email" name="email" id="email" autocomplete="email" />
  </p>
  <p>
    <label for="pet">Your pet's name: </label>
    <input name="pet" id="pet" />
  </p>
</form>
```

CSS

We apply a `border-radius`, `outline`, and `border-color` to the `<input>` elements when they match the `:autofill` state.

```
input {
  border-radius: 0px;
}

input:autofill {
  border-radius: 0.5lh;
  outline: 5px dashed magenta;
  border-color: yellow;
}
```

```
@supports not selector(:autofill) {
  body::before {
```

```
    content: "Your browser doesn't support the :autofill selector.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

Results

If you allow the `name` to autocomplete, the `name` and `email` will both have a rounded border and a magenta outline, though likely the border will not change due to the `!important` flag set in the user agent style sheet. Try editing one of the fields: note how once you edit the value, even if you reset it to it's autocompletion value, the `:autofill` styles are no longer applied.

:blank CSS pseudo-class

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

> **Note:** The `:blank` selector is considered at risk, as the CSSWG keeps changing it.
>
> See CSSWG issue #1967.

The **`:blank`** CSS pseudo-class selects empty user input elements (e.g., `<input>` or `<textarea>`).

Syntax

```
:blank {
  /* ... */
}
```

Examples

Basic :blank example

In eventual supporting browsers, the `:blank` pseudo-class will enable developers to highlight in some way input controls that are not required, but still have no content filled in, perhaps as a reminder to users.

HTML

```
<textarea></textarea>
```

CSS

```
textarea:blank {
  border: 3px solid red;
}
```

Result

Browser compatibility

Currently, no browsers support this feature.

- `:empty`
- CSS selectors module

:buffering CSS pseudo-class

The **`:buffering`** CSS pseudo-class selector represents an element that is playable, such as `<audio>` or `<video>`, when the playable element is buffering a media resource.

An element is considered as buffering when that element cannot continue playing because it is trying to load media data but does not yet have enough data to begin or continue playback. For more information, see the Media buffering, seeking, and time ranges guide.

> **Note:** An element is still considered to be `:playing` when it is "buffering". If `:buffering` matches an element, `:playing` will also match that element.

Syntax

```
:buffering {
  /* ... */
}
```

Examples

CSS

```
:buffering {
  outline: 5px solid red;
}

video:buffering {
  outline: 5px solid blue;
}
```

:checked CSS pseudo-class

The **`:checked`** CSS pseudo-class selector represents any **radio** (`<input type="radio">`), **checkbox** (`<input type="checkbox">`), or **option** (`<option>` in a `<select>` element) that is checked or toggled to an `on` state.

Try it

```
label {
  display: block;
  margin-top: 0.5em;
}

fieldset {
  margin-top: 0.5em;
}

input:checked {
  border: none;
  outline: 2px solid deeppink;
}
```

```
<label for="name">Name (required):</label>
<input id="name" name="name" type="text" required />

<label for="birth">Date of birth:</label>
<input id="birth" name="birth" type="date" />

<label for="origin">How did you find out about us? (required)</label>
<select id="origin" name="origin" required>
  <option value="">Choose an option</option>
  <option value="google">Google</option>
  <option value="facebook">Facebook</option>
  <option value="advertisement">Advertisement</option>
</select>

<fieldset>
  <legend>Preferred contact method:</legend>
  <label>
    <input name="contact" type="radio" value="email" checked /> Email
  </label>
  <label><input name="contact" type="radio" value="phone" /> Phone</label>
</fieldset>

<label>
  <input name="newsletter" type="checkbox" checked /> I want to subscribe to a
  personalized newsletter.
</label>
<label>
  <input name="privacy" type="checkbox" required /> I have read and I agree to
  the Privacy Policy (required).
</label>
```

The user can engage this state by checking/selecting an element, or disengage it by unchecking/deselecting the element.

> **Note:** Because browsers often treat `<option>`s as replaced elements, the extent to which they can be styled with the `:checked` pseudo-class varies from browser to browser. Customizable select element functionality can be used to enable full customization of `<option>` elements just like any regular DOM element, in supporting browsers.

Syntax

```
:checked {
  /* ... */
}
```

Examples

Basic example

HTML

```
<div>
  <input type="radio" name="my-input" id="yes" value="yes" />
  <label for="yes">Yes</label>

  <input type="radio" name="my-input" id="no" value="no" />
  <label for="no">No</label>
</div>

<div>
  <input type="checkbox" name="my-checkbox" id="opt-in" />
  <label for="opt-in">Check me!</label>
</div>

<select name="my-select" id="fruit">
  <option value="opt1">Apples</option>
  <option value="opt2">Grapes</option>
  <option value="opt3">Pears</option>
</select>
```

CSS

```
div,
select {
  margin: 8px;
```

```
}

/* Labels for checked inputs */
input:checked + label {
  color: red;
}

/* Radio element, when checked */
input[type="radio"]:checked {
  box-shadow: 0 0 0 3px orange;
}

/* Checkbox element, when checked */
input[type="checkbox"]:checked {
  box-shadow: 0 0 0 3px hotpink;
}

/* Option elements, when selected */
option:checked {
  box-shadow: 0 0 0 3px lime;
  color: red;
}
```

Result

Toggling elements with a hidden checkbox

This example utilizes the `:checked` pseudo-class to let the user toggle content based on the state of a checkbox, all without using JavaScript.

HTML

```
<input type="checkbox" id="expand-toggle" />

<table>
  <thead>
    <tr>
      <th>Column #1</th>
      <th>Column #2</th>
      <th>Column #3</th>
    </tr>
  </thead>
  <tbody>
    <tr class="expandable">
      <td>[more text]</td>
      <td>[more text]</td>
      <td>[more text]</td>
    </tr>
    <tr>
      <td>[cell text]</td>
      <td>[cell text]</td>
      <td>[cell text]</td>
    </tr>
    <tr>
      <td>[cell text]</td>
      <td>[cell text]</td>
      <td>[cell text]</td>
    </tr>
    <tr class="expandable">
      <td>[more text]</td>
      <td>[more text]</td>
      <td>[more text]</td>
    </tr>
    <tr class="expandable">
      <td>[more text]</td>
      <td>[more text]</td>
      <td>[more text]</td>
    </tr>
  </tbody>
</table>

<label for="expand-toggle" id="expand-btn">Toggle hidden rows</label>
```

CSS

```
/* Hide the toggle checkbox */
#expand-toggle {
  display: none;
}

/* Hide expandable content by default */
.expandable {
  visibility: collapse;
  background: #dddddd;
}

/* Style the button */
#expand-btn {
  display: inline-block;
  margin-top: 12px;
  padding: 5px 11px;
  background-color: #ffff77;
  border: 1px solid;
  border-radius: 3px;
}

/* Show hidden content when the checkbox is checked */
#expand-toggle:checked ~ * .expandable {
  visibility: visible;
}

/* Style the button when the checkbox is checked */
#expand-toggle:checked ~ #expand-btn {
```

```
  background-color: #cccccc;
}
```

:current CSS pseudo-class

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`:current`** CSS pseudo-class selector represents an element or the ancestor of an element that is currently being displayed or highlighted.

Syntax

```
:current {
  /* ... */
}

:current(<compound-selector-list>) {
  /* ... */
}
```

Description

The `:current` pseudo-class is used to represent the "currently displayed" element out of a series of elements.

This can mean "current" in terms of time: `:current` can be used to target the currently displayed captions or subtitles (represented using WebVTT) that are associated with a playing video.

It can also refer to the currently highlighted element in a series. For example, `:current` can be combined with the `::search-text` pseudo-element to provide specific styles to the currently-focused search result from the browser's "Find in page" text search feature.

For example:

```
p::search-text {
  color: white;
  background-color: purple;
}

p::search-text:current {
  background-color: crimson;
}
```

Examples

Custom styles for text search results

This example shows how to use `::search-text` and `:current` to create custom styles for your browser's "Find in page" search results.

HTML

The HTML consists of a basic paragraph of text. We won't show the HTML source, both for brevity, and so that it is easier to navigate the search results in the rendered example.

```
<p>
  Lorem ipsum dolor sit amet, consectetur adipiscing elit. Donec finibus est
  eget eros congue pellentesque. Etiam a augue accumsan, scelerisque nisl sit
  amet, lobortis nulla. Aliquam condimentum eu orci eu elementum. Donec
  porttitor quam et posuere commodo. Mauris rhoncus diam a scelerisque molestie.
  Integer sollicitudin risus dui, ut sagittis lorem laoreet eget. Duis eget
  pretium enim. Morbi tristique, diam sit amet gravida finibus, metus ex
  tincidunt nibh, ac volutpat urna purus et arcu. Donec risus risus, semper vel
  purus sit amet, gravida vestibulum est. Sed et tristique urna. Nam vel mi eget
  nisi consectetur elementum. Aenean faucibus aliquam cursus. Morbi posuere
  tincidunt velit, et sagittis quam sagittis in. Nam eget ante ultrices, auctor
  dui vel, euismod lacus. Vivamus tincidunt, sem ac sodales aliquet, tortor
  tortor consequat diam, nec tempor mi dui vel eros. Aliquam ac erat et metus
  egestas scelerisque.
</p>
```

CSS

In our CSS, we start by styling the `::search-text` pseudo-element. We give it custom `background-color`, `color`, and `text-shadow` styles.

```
html {
  font-family: "Helvetica", "Arial";
}

p {
  font-size: 1.5rem;
  line-height: 1.5;
  width: 90%;
  margin: 0 auto;
}

@layer no-support {
  body::before {
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1em 0;
  }
  @supports not selector(::search-text) {
```

```
    body::before {
      content: "Your browser doesn't support the ::search-text pseudo-element.";
    }
  }
  @supports not selector(:current) {
    body::before {
      content: "Your browser doesn't support the :current pseudo-class.";
    }
  }
}
```

```
::search-text {
  background-color: purple;
  color: white;
  text-shadow: 1px 1px 1px black;
}
```

Finally, we style the currently-focused search result via `::search-text:current`, providing it with a different `background-color` and some `text-decoration` styles so that it is distinguishable from the rest of the results.

```
::search-text:current {
  background-color: crimson;
  text-decoration-line: underline;
  text-decoration-color: yellow;
  text-decoration-thickness: 3px;
}
```

Result

The example renders as follows:

Try using the browser's find in page interface to find a word that appears multiple times in the example text, such as "aliquam", "amet", or "tortor". Move between the previous and next results to check out the `:current` styling.

Styling currently-shown WebVTT subtitles

CSS

```
:current(p, span) {
  background-color: yellow;
}
```

HTML

```
<video controls preload="metadata">
  <source src="video.mp4" type="video/mp4" />
  <source src="video.webm" type="video/webm" />
  <track
    label="English"
    kind="subtitles"
    srclang="en"
    src="subtitles.vtt"
    default />
</video>
```

WebVTT

```
WEBVTT FILE

1
00:00:03.500 --> 00:00:05.000
This is the first caption

2
00:00:06.000 --> 00:00:09.000
This is the second caption

3
00:00:11.000 --> 00:00:19.000
This is the third caption
```

:default CSS pseudo-class

The **`:default`** CSS pseudo-class selects form elements that are the default in a group of related elements.

Try it

```
label {
  display: block;
  margin-top: 0.5em;
}

fieldset {
  margin-top: 0.5em;
}

input:default {
  border: none;
  outline: 2px solid deeppink;
}
```

```
<label for="name">Name (required):</label>
<input id="name" name="name" type="text" required />

<label for="birth">Date of birth:</label>
<input id="birth" name="birth" type="date" />

<label for="origin">How did you find out about us? (required)</label>
<select id="origin" name="origin" required>
  <option value="">Choose an option</option>
  <option value="google">Google</option>
  <option value="facebook">Facebook</option>
  <option value="advertisement">Advertisement</option>
</select>

<fieldset>
  <legend>Preferred contact method:</legend>
  <label>
    <input name="contact" type="radio" value="email" checked /> Email
  </label>
  <label><input name="contact" type="radio" value="phone" /> Phone</label>
</fieldset>

<label>
  <input name="newsletter" type="checkbox" checked /> I want to subscribe to a
  personalized newsletter.
</label>
<label>
  <input name="privacy" type="checkbox" required /> I have read and I agree to
  the Privacy Policy (required).
</label>
```

What this selector matches is defined in HTML Standard §4.16.3 Pseudo-classes — it may match the `<button>`, `<input type="checkbox">`, `<input type="radio">`, and `<option>` elements:

- A default option element is the first one with the `selected` attribute, or the first enabled option in DOM order. `multiple` `<select>`s can have more than one `selected` option, so all will match `:default`.
- `<input type="checkbox">` and `<input type="radio">` match if they have the `checked` attribute.
- `<button>` matches if it is a `<form>`'s default submission button: the first `<button>` in DOM order that belongs to the form. This also applies to `<input>` types that submit forms, like `image` or `submit`.

Syntax

```
:default {
  /* ... */
}
```

Examples

HTML

```
<fieldset>
  <legend>Favorite season</legend>

  <input type="radio" name="season" id="spring" value="spring" />
  <label for="spring">Spring</label>

  <input type="radio" name="season" id="summer" value="summer" checked />
  <label for="summer">Summer</label>

  <input type="radio" name="season" id="fall" value="fall" />
  <label for="fall">Fall</label>

  <input type="radio" name="season" id="winter" value="winter" />
  <label for="winter">Winter</label>
</fieldset>
```

CSS

```
input:default {
  box-shadow: 0 0 2px 1px coral;
}

input:default + label {
  color: coral;
}
```

Result

:defined CSS pseudo-class

The **`:defined`** CSS pseudo-class represents any element that has been defined. This includes any standard element built into the browser and custom elements that have been successfully defined (i.e., with the `CustomElementRegistry.define()` method).

```
/* Selects any defined element */
:defined {
  font-style: italic;
}

/* Selects any instance of a specific custom element */
custom-element:defined {
  display: block;
}
```

Syntax

```
:defined {
  /* ... */
}
```

Examples

Hiding elements until they are defined

In this demo, we define a basic custom element named `<custom-element>` and use the `:not(:defined)` and `:defined` selectors to style the element before and after it is defined. This is useful if you have a complex custom element that takes a while to load into the page — you might want to hide instances of the element until the definition is complete so that you don't end up with flashes of ugly unstyled elements on the page.

HTML

The following HTML code uses the custom element but the element hasn't been defined yet. We also include a `<button>` that will define the custom element when clicked, allowing you to see its state before and after definition.

```
<custom-element>
  <p>
    Loaded content: Lorem ipsum tel sed tellus eiusmod tellus. Aenean. Semper
    dolor sit nisi. Elit porttitor nisi sit vivamus.
  </p>
</custom-element>

<button id="btn">define the <code>&amp;lt;custom-element&amp;gt;</code></button>
```

CSS

```
custom-element {
  display: block;
  border: 5px dashed grey;
  border-radius: 1rem;
  height: 100px;
  width: 400px;
  padding: 1rem;
  position: relative;
  user-select: none;
}

code {
  background: #cccccc;
}

#btn {
  margin-top: 1rem;
  cursor: pointer;
}
```

In the following CSS, we use the `custom-element:not(:defined)` selector to select the element and color it gray while it is not defined and the `custom-element:defined` selector to select the element and color it black after it is defined.

```
custom-element:not(:defined) {
  border-color: grey;
  color: grey;
}

custom-element:defined {
  background-color: wheat;
  border-color: black;
  color: black;
}

/* show loading message */
custom-element:not(:defined)::before {
  content: "Loading...";
  position: absolute;
  inset: 0;
  align-content: center;
  text-align: center;
  font-size: 2rem;
  background-color: white;
  border-radius: 1rem;
}

/* remove the loading message */
custom-element:defined::before {
  content: "";
}
```

We have also used the `::before` pseudo-element to show a "Loading..." overlay message until the element is defined. After definition, it is removed by setting the `content` to an empty string.

The following JavaScript has been used to define the custom element. To allow you to see the state of the custom element before and after definition we run the `define()` method when the button is clicked.

```
const btn = document.querySelector("#btn");

btn.addEventListener("click", () => {
  customElements.define("custom-element", class extends HTMLElement {});
  btn.remove();
});
```

:dir() CSS pseudo-class

The **`:dir()`** CSS pseudo-class matches elements based on the directionality of the text contained in them.

```
/* Selects any element with right-to-left text */
:dir(rtl) {
  background-color: red;
}
```

The `:dir()` pseudo-class uses only the *semantic* value of the directionality, i.e., the one defined in the document itself. It doesn't account for *styling* directionality, i.e., the directionality set by CSS properties such as `direction`.

> **Note:** Be aware that the behavior of the `:dir()` pseudo-class is not equivalent to the `[dir=…]` attribute selectors. The latter match the HTML `dir` attribute, and ignore elements that lack it — even if they inherit a direction from their parent. (Similarly, `[dir=rtl]` and `[dir=ltr]` won't match the `auto` value.) In contrast, `:dir()` will match the value calculated by the user agent, even if inherited.

> **Note:** In HTML, the direction is determined by the `dir` attribute. Other document types may have different methods.

Syntax

```
:dir([ltr | rtl]) {
  /* ... */
}
```

Parameters

The `:dir()` pseudo-class requires one parameter, representing the text directionality you want to target.

`ltr`

Target left-to-right elements.

`rtl`

Target right-to-left elements.

Examples

HTML

```
<div dir="rtl">
  <span>test1</span>
  <div dir="ltr">
    test2
    <div dir="auto">עִבְרִית</div>
  </div>
</div>
```

CSS

```
:dir(ltr) {
  background-color: yellow;
}

:dir(rtl) {
  background-color: powderblue;
}
```

Result

- Language-related pseudo-classes: `:lang`
- HTML `lang` attribute
- HTML `translate` attribute

:disabled CSS pseudo-class

The **`:disabled`** CSS pseudo-class represents any disabled element. An element is disabled if it can't be activated (selected, clicked on, typed into, etc.) or accept focus. The element also has an enabled state, in which it can be activated or accept focus.

Try it

```
label {
  display: block;
  margin-top: 1em;
}

*:disabled {
  background-color: dimgrey;
  color: linen;
  opacity: 1;
}
```

```
<form>
  <label for="name">Name:</label>
  <input id="name" name="name" type="text" />

  <label for="emp">Employed:</label>
  <select id="emp" name="emp" disabled>
    <option>No</option>
    <option>Yes</option>
  </select>

  <label for="empDate">Employment Date:</label>
  <input id="empDate" name="empDate" type="date" disabled />
```

```
  <label for="resume">Resume:</label>
  <input id="resume" name="resume" type="file" />
</form>
```

Syntax

```
:disabled {
  /* ... */
}
```

Examples

This example shows a basic shipping form. It uses the JavaScript `change` event to let the user enable/disable the billing fields.

HTML

```
<form action="#">
  <fieldset id="shipping">
    <legend>Shipping address</legend>
    <input type="text" placeholder="Name" />
    <input type="text" placeholder="Address" />
    <input type="text" placeholder="Zip Code" />
  </fieldset>
  <br />
  <fieldset id="billing">
    <legend>Billing address</legend>
    <label for="billing-checkbox">Same as shipping address:</label>
    <input type="checkbox" id="billing-checkbox" checked />
    <br />
    <input type="text" placeholder="Name" disabled />
    <input type="text" placeholder="Address" disabled />
    <input type="text" placeholder="Zip Code" disabled />
  </fieldset>
</form>
```

CSS

```
input[type="text"]:disabled {
  background: #cccccc;
}
```

JavaScript

Toggle the disabled input fields when the checkbox is clicked

```
const checkbox = document.querySelector("#billing-checkbox");
const billingItems = document.querySelectorAll('#billing input[type="text"]');

checkbox.addEventListener("change", () => {
  billingItems.forEach((item) => {
    item.disabled = !item.disabled;
  });
});
```

Result

Check/un-check the checkbox to change the styling on the billing fields.

- `:enabled`

:empty CSS pseudo-class

The **`:empty`** CSS pseudo-class represents any element that has no children. Children can be either element nodes or text (including whitespace). Comments, processing instructions, and CSS `content` do not affect whether an element is considered empty.

Try it

```
div:empty {
  outline: 2px solid deeppink;
  height: 1em;
}
```

```
<p>Element with no content:</p>
<div></div>

<p>Element with comment:</p>
<div><!-- A comment --></div>

<p>Element with nested empty element:</p>
<div><p></p></div>
```

> **Note:** In Selectors Level 4, the `:empty` pseudo-class was changed to act like `:-moz-only-whitespace`, but no browser currently supports this yet.

Syntax

```
:empty {
  /* ... */
}
```

Accessibility

Assistive technology such as screen readers cannot parse interactive content that is empty. All interactive content must have an accessible name, which is created by providing a text value for the interactive control's parent element (anchors, buttons, etc.). Accessible names expose the interactive control to the accessibility tree, an API that communicates information useful for assistive technologies.

The text that provides the interactive control's accessible name can be hidden using a combination of properties that remove it visually from the screen but keep it parsable by assistive technology. This is commonly used for buttons that rely solely on an icon to convey purpose.

- What is an accessible name? | Vispero
- Hidden content for better a11y | Go Make Things
- MDN Understanding WCAG, Guideline 2.4 explanations
- Understanding Success Criterion 2.4.4 | W3C Understanding WCAG 2.0

Examples

HTML

```
<div class="box"><!-- I will be lime. --></div>
<div class="box">I will be pink.</div>
<div class="box">
  <!-- I will be pink in older browsers because of the whitespace around this comment. -->
</div>
<div class="box">
  <p>
    <!-- I will be pink in all browsers because of the non-collapsible whitespace and elements around this comment. -->
  </p>
</div>
```

CSS

```
body {
  display: flex;
  justify-content: space-around;
}
```

```
.box {
  background: pink;
  height: 80px;
  width: 80px;
}

.box:empty {
  background: lime;
}
```

Result

- `:-moz-only-whitespace` – The prefixed implementation of the changes in Selectors Level 4
- `:blank`

:enabled CSS pseudo-class

The **`:enabled`** CSS pseudo-class represents any enabled element. An element is enabled if it can be activated (selected, clicked on, typed into, etc.) or accept focus. The element also has a disabled state, in which it can't be activated or accept focus.

Try it

```
label {
  display: block;
  margin-top: 1em;
}

*:enabled {
  background-color: gold;
}
```

```
<form>
  <label for="name">Name:</label>
  <input id="name" name="name" type="text" />

  <label for="emp">Employed:</label>
  <select id="emp" name="emp" disabled>
    <option>No</option>
    <option>Yes</option>
  </select>

  <label for="empDate">Employment Date:</label>
  <input id="empDate" name="empDate" type="date" disabled />

  <label for="resume">Resume:</label>
  <input id="resume" name="resume" type="file" />
</form>
```

Syntax

```
:enabled {
  /* ... */
}
```

Examples

The following example makes the color of text and button `<input>`s green when enabled, and gray when disabled. This helps the user understand which elements can be interacted with.

HTML

```
<form action="url_of_form">
  <label for="FirstField">First field (enabled):</label>
  <input type="text" id="FirstField" value="Lorem" /><br />

  <label for="SecondField">Second field (disabled):</label>
  <input type="text" id="SecondField" value="Ipsum" disabled /><br />
```

```
  <input type="button" value="Submit" />
</form>
```

CSS

```
input:enabled {
  color: #22bb22;
}

input:disabled {
  color: #aaaaaa;
}
```

Result

See also

- `:disabled`

:first CSS pseudo-class

The **`:first`** CSS pseudo-class, used with the `@page` at-rule, represents the first page of a printed document. (See `:first-child` for general first element of a node.)

```
/* Selects the first page when printing */
@page :first {
  margin-left: 50%;
  margin-top: 50%;
}
```

> **Note:** You can't change all CSS properties with this pseudo-class. You can only change the margins, `orphans`, `widows`, and page breaks of the document. Furthermore, you may only use absolute-length units when defining the margins. All other properties will be ignored.

Syntax

```
:first {
  /* ... */
}
```

Examples

Using <code>:first</code> for page print styles

Press the "Print!" button to print the example. The words on the first page should be somewhere around the center, while other pages will have their contents at the default position:

```
<p>First Page.</p>
<p>Second Page.</p>
<button>Print!</button>
```

```
@page :first {
  size: 8.5in 11in;
  margin-left: 3in;
  margin-top: 5in;
}

p {
  page-break-after: always;
  font: 1.2em sans-serif;
}
```

```
document.querySelector("button").addEventListener("click", () => {
  window.print();
});
```

See also

- `@page`
- Other page-related pseudo-classes: `:left`, `:right`

:first-child CSS pseudo-class

The **`:first-child`** CSS pseudo-class represents the first element among a group of sibling elements.

Try it

```
p {
  font-weight: bold;
}

li:first-child {
  border: 2px solid orange;
}
```

```
<p>Track &amp;amp; field champions:</p>
<ul>
  <li>Adhemar da Silva</li>
  <li>Wang Junxia</li>
  <li>Wilma Rudolph</li>
  <li>Babe Didrikson-Zaharias</li>
  <li>Betty Cuthbert</li>
  <li>Fanny Blankers-Koen</li>
  <li>Florence Griffith-Joyner</li>
  <li>Irena Szewinska</li>
  <li>Jackie Joyner-Kersee</li>
  <li>Shirley Strickland</li>
  <li>Carl Lewis</li>
  <li>Emil Zatopek</li>
```

```
  <li>Haile Gebrselassie</li>
  <li>Jesse Owens</li>
  <li>Jim Thorpe</li>
  <li>Paavo Nurmi</li>
  <li>Sergei Bubka</li>
  <li>Usain Bolt</li>
</ul>
```

Syntax

```
:first-child {
  /* ... */
}
```

Examples

Basic example

HTML

```
<div>
  <p>This text is selected!</p>
  <p>This text isn't selected.</p>
</div>

<div>
  <h2>This text isn't selected: it's not a `p`.</h2>
  <p>This text isn't selected.</p>
</div>
```

CSS

```
p:first-child {
  color: lime;
  background-color: black;
  padding: 5px;
}
```

Result

Styling a list

HTML

```
<ul>
  <li>Item 1</li>
  <li>Item 2</li>
  <li>
    Item 3
    <ul>
      <li>Item 3.1</li>
      <li>Item 3.2</li>
      <li>Item 3.3</li>
    </ul>
  </li>
</ul>
```

CSS

```
ul li {
  color: blue;
}

ul li:first-child {
  color: red;
  font-weight: bold;
}
```

Result

- `:nth-child()`

:first-of-type CSS pseudo-class

The **`:first-of-type`** CSS pseudo-class represents the first element of its type (tag name) among a group of sibling elements.

Try it

```
dt {
  font-weight: bold;
}

dd {
  margin: 3px;
}

dd:first-of-type {
  border: 2px solid orange;
}
```

```
<dl>
  <dt>Vegetables:</dt>
  <dd>1. Tomatoes</dd>
  <dd>2. Cucumbers</dd>
```

```
  <dd>3. Mushrooms</dd>
  <dt>Fruits:</dt>
  <dd>4. Apples</dd>
  <dd>5. Mangos</dd>
  <dd>6. Pears</dd>
  <dd>7. Oranges</dd>
</dl>
```

Syntax

```
:first-of-type {
  /* ... */
}
```

Examples

Styling the first paragraph

HTML

```
<h2>Heading</h2>
<p>Paragraph 1</p>
<p>Paragraph 2</p>
```

CSS

```
p:first-of-type {
  color: red;
  font-style: italic;
}
```

Result

Nested elements

This example shows how nested elements can also be targeted. Note that the universal selector (*) is implied when no type selector is written.

HTML

```
<article>
  <div>This `div` is first!</div>
  <div>This <span>nested `span` is first</span>!</div>
  <div>
    This <em>nested `em` is first</em>, but this <em>nested `em` is last</em>!
  </div>
  <div>This <span>nested `span` gets styled</span>!</div>
  <p>This `p` qualifies!</p>
  <div>This is the final `div`.</div>
</article>
```

CSS

```
article :first-of-type {
  background-color: pink;
}
```

Result

- `:first-child`, `:last-of-type`, `:nth-of-type`

:focus CSS pseudo-class

The **`:focus`** CSS pseudo-class represents an element (such as a form input) that has received focus. It is generally triggered when the user clicks or taps on an element or selects it with the keyboard's `Tab` key.

Try it

```
label {
  display: block;
  margin-top: 1em;
}

input:focus {
  background-color: lightblue;
}

select:focus {
  background-color: ivory;
}
```

```
<p>Which flavor would you like to order?</p>
<label>Full Name: <input name="firstName" type="text" /></label>
<label
  >Flavor:
  <select name="flavor">
    <option>Cherry</option>
    <option>Green Tea</option>
    <option>Moose Tracks</option>
    <option>Mint Chip</option>
  </select>
</label>
```

> **Note:** This pseudo-class applies only to the focused element itself. Use `:focus-within` if you want to select an element that *contains* a focused element.

Syntax

```
:focus {
  /* ... */
}
```

Accessibility

Make sure the visual focus indicator can be seen by people with low vision. This will also benefit anyone use a screen in a brightly lit space (like outside in the sun). WCAG 2.1 SC 1.4.11 Non-Text Contrast requires that the visual focus indicator be at least 3 to 1.

- Accessible Visual Focus Indicators: Give Your Site Some Focus! Tips for Designing Useful and Usable Focus Indicators

<code>:focus { outline: none; }</code>

Never just remove the focus outline (visible focus indicator) without replacing it with a focus outline that will pass WCAG 2.1 SC 1.4.11 Non-Text Contrast.

- Quick Tip: Never remove CSS outlines

Examples

HTML

```
<div><input class="red-input" value="I'll be red when focused." /></div>
<div><input class="blue-input" value="I'll be blue when focused." /></div>
```

CSS

```
.red-input:focus {
  background: yellow;
  color: red;
}

.blue-input:focus {
  background: yellow;
  color: blue;
}
```

Result

See also

- `:focus-visible`
- `:focus-within`

:focus-visible CSS pseudo-class

The **`:focus-visible`** pseudo-class applies while an element matches the `:focus` pseudo-class and the UA (User Agent) determines via heuristics that the focus should be made evident on the element. (Many browsers show a "focus ring" by default in this case.)

This selector is useful to provide a different focus indicator based on the user's input modality (mouse vs. keyboard).

Try it

```
label {
  display: block;
  margin-top: 1em;
}

input:focus-visible {
  outline: 2px solid crimson;
  border-radius: 3px;
}

select:focus-visible {
  border: 2px dashed crimson;
  border-radius: 3px;
  outline: none;
}
```

```
<p>Which flavor would you like to order?</p>
<label>Full Name: <input name="firstName" type="text" /></label>
<label
  >Flavor:
  <select name="flavor">
    <option>Cherry</option>
    <option>Green Tea</option>
    <option>Moose Tracks</option>
    <option>Mint Chip</option>
  </select>
</label>
```

Syntax

```
:focus-visible {
  /* ... */
}
```

:focus vs :focus-visible

Originally, user-agent CSS set focus styles based only on the `:focus` pseudo-class, styling most focused elements with a focus ring outline. This meant all elements, including all links and buttons, had a focus ring applied when focused, which many found ugly. Because of the appearance, some authors removed the user-agent outline focus styles. Changing focus style can decrease usability, while removing focus styles makes keyboard navigation inaccessible for sighted users.

Browsers no longer visibly indicate focus (such as by drawing a "focus ring"), around each element when it has focus. Instead, they use a variety of heuristics to provide focus indicators only when it would be most helpful to the user. For instance, when a button is clicked using a pointing device, the focus is generally not visually indicated, but when a text box needing user input has focus, focus is indicated. While focus styles are always required when users are navigating the page with the keyboard or when focus is managed via scripts, focus styles are not required when the user knows where they are putting focus, such as when they use a pointing device such as a mouse or finger to physically set focus on an element, unless that element continues to need user attention.

The `:focus` pseudo-class always matches the currently-focused element. The `:focus-visible` pseudo-class also matches the focused element, but only if the user needs to be informed where the focus currently is. Because the `:focus-visible` pseudo-class matches the focused element when needed, using the `:focus-visible` (instead of the `:focus` pseudo-class) allows authors to change the appearance of the focus indicator without changing when the focus indicator appears.

When the `:focus` pseudo-class is used, it always targets the currently focused element. This means that when a user employs a pointing device, a visible focus ring appears around the focused element, which some consider obtrusive. The `:focus-visible` pseudo-class respects user agents' selective focus indication behavior while still allowing focus indicator customization.

Accessibility

Low vision

Make sure the visual focus indicator can be seen by people with low vision. This will also benefit anyone use a screen in a brightly lit space (like outside in the sun). WCAG 2.1 SC 1.4.11 Non-Text Contrast requires that the visual focus indicator be at least 3 to 1.

- Accessible Visual Focus Indicators: Give Your Site Some Focus! Tips for Designing Useful and Usable Focus Indicators

Cognition

It may not be obvious as to why the focus indicator is appearing and disappearing if a person is using mixed forms of input. For users with cognitive concerns, or who are less technologically literate, this lack of consistent behavior for interactive elements may be confusing.

Examples

Comparing :focus and :focus-visible

This example presents three pairs of controls. Each pair consists of a `text` input and a button.

- The first pair does not add any custom styles for focus states, and shows the default case.
- The second pair adds styles using the `:focus` pseudo-class.
- The third pair adds styles using the `:focus-visible` pseudo-class.

```
<input type="text" value="Default styles" /><br />
<button>Default styles</button><br />

<input class="focus-only" type="text" value=":focus" /><br />
<button class="focus-only">:focus</button><br />

<input class="focus-visible-only" type="text" value=":focus-visible" /><br />
<button class="focus-visible-only">:focus-visible</button>
```

```
input,
button {
  margin: 10px;
}

.focus-only:focus {
  outline: 2px solid black;
}

.focus-visible-only:focus-visible {
  outline: 4px dashed darkorange;
}
```

If you click each element in turn, you will see that when `:focus` is used to style the focus ring, the UA draws the focus ring when the user clicks the button. However, when `:focus-visible` is used to style the focus ring, the UA does not draw the focus ring when the user clicks the button, just like in the default case.

If you then tab through each element, you will see that in all three cases — default, `:focus`, and `:focus-visible` — the UA draws the focus ring around the button when the user navigates to it with the keyboard.

This shows how `:focus-visible` enables a designer to follow the browser's logic in determining when a focus ring should be shown.

See also

- `:focus`
- `:focus-within`

:focus-within CSS pseudo-class

The **`:focus-within`** CSS pseudo-class matches an element if the element or any of its descendants are focused. In other words, it represents an element that is itself matched by the `:focus` pseudo-class or has a descendant that is matched by `:focus`. (This includes descendants in shadow trees.)

This selector is useful, to take a common example, for highlighting an entire `<form>` container when the user focuses on one of its `<input>` fields.

Try it

```
label {
  display: block;
  margin-top: 1em;
}

label:focus-within {
  font-weight: bold;
}
```

```
<p>Which flavor would you like to order?</p>
<label>Full Name: <input name="firstName" type="text" /></label>
<label
  >Flavor:
  <select name="flavor">
    <option>Cherry</option>
    <option>Green Tea</option>
    <option>Moose Tracks</option>
    <option>Mint Chip</option>
  </select>
</label>
```

Syntax

```
:focus-within {
  /* ... */
```

```
}
```

Examples

In this example, the container will receive special coloring styles when either text input receives focus.

HTML

```
<ul class="group">
  <li>
    <label for="given-name">Given Name:</label>
    <input id="given-name" type="text" />
  </li>
  <li>
    <label for="family-name">Family Name:</label>
    <input id="family-name" type="text" />
  </li>
</ul>
```

CSS

```
.group {
  list-style: none;
  border: 1px solid;
  color: gray;
  padding: 4px;
}

.group:focus-within {
  background: #ffff88;
  color: black;
}

input {
  margin: 4px;
}
```

Result

Try typing in the text fields.

See also

- `:focus`
- `:focus-visible`
- Grab your user's attention with the focus-within selector

:fullscreen CSS pseudo-class

The **`:fullscreen`** CSS pseudo-class matches every element that is currently in fullscreen mode. If multiple elements have been put into fullscreen mode, this selects them all.

Syntax

```
:fullscreen {
  /* ... */
}
```

Usage notes

The `:fullscreen` pseudo-class lets you configure your stylesheets to automatically adjust the size, style, or layout of content when elements switch back and forth between fullscreen and traditional presentations.

Examples

Styling a fullscreen element

This example applies a different background color to a `<div>` element, depending on whether or not it is in fullscreen mode. It includes a `<button>` to toggle fullscreen on and off.

```
<div class="element">
  <h1><code>:fullscreen</code> pseudo-class demo</h1>

  <p>
    This demo uses the <code>:fullscreen</code> pseudo-class to automatically
    change the background color of the <code>.element</code> div.
  </p>

  <p>
    Normally, the background is light yellow. In fullscreen mode, the background
    is light pink.
  </p>

  <button class="toggle">Toggle Fullscreen</button>
</div>
```

The `:fullscreen` pseudo-class is used to override the `background-color` of the `<div>` when it is in fullscreen mode.

```
.element {
  background-color: lightyellow;
}

.element:fullscreen {
  background-color: lightpink;
}
```

The following JavaScript provides an event handler function that toggles fullscreen when the `<button>` is clicked.

```
document.querySelector(".toggle").addEventListener("click", (event) => {
  if (document.fullscreenElement) {
    // If there is a fullscreen element, exit full screen.
    document.exitFullscreen();
```

```
    return;
  }
  // Make the .element div fullscreen.
  document.querySelector(".element").requestFullscreen();
});
```

```
.element {
  display: flex;
  flex-direction: column;
  align-items: center;
  justify-content: center;
  font-family: sans-serif;
  padding: 1.2em;
}
```

- `allowfullscreen` attribute

:future CSS pseudo-class

The **`:future`** CSS pseudo-class selector is a time-dimensional pseudo-class that will match for any element which appears entirely after an element that matches `:current`. For example in a video with captions which are being displayed by WebVTT.

```
:future(p, span) {
  display: none;
}
```

Syntax

```
:future {
  /* ... */
}
```

Examples

CSS

```
:future(p, span) {
  display: none;
}
```

HTML

```
<video controls preload="metadata">
  <source src="video.mp4" type="video/mp4" />
  <source src="video.webm" type="video/webm" />
  <track
    label="English"
    kind="subtitles"
    srclang="en"
    src="subtitles.vtt"
    default />
</video>
```

WebVTT

```
WEBVTT FILE

1
00:00:03.500 --> 00:00:05.000
This is the first caption

2
00:00:06.000 --> 00:00:09.000
This is the second caption

3
00:00:11.000 --> 00:00:19.000
This is the third caption
```

- `:past`

:has() CSS pseudo-class

The functional **`:has()`** CSS pseudo-class represents an element if any of the relative selectors that are passed as an argument match at least one element when anchored against this element. This pseudo-class presents a way of selecting a parent element or a previous sibling element with respect to a reference element by taking a relative selector list as an argument.

```
/* Selects an h1 heading with a
paragraph element that immediately follows
the h1 and applies the style to h1 */
h1:has(+ p) {
  margin-bottom: 0;
}
```

The `:has()` pseudo-class takes on the specificity of the most specific selector in its arguments the same way as `:is()` and `:not()` do.

Syntax

```
:has(<relative-selector-list>) {
  /* ... */
}
```

If the `:has()` pseudo-class itself is not supported in a browser, the entire selector block will fail unless `:has()` is in a forgiving selector list, such as in `:is()` and `:where()`.

The `:has()` pseudo-class cannot be nested within another `:has()`.

Pseudo-elements are also not valid selectors within `:has()` and pseudo-elements are not valid anchors for `:has()`. This is because many pseudo-elements exist conditionally based on the styling of their ancestors and allowing these to be queried by `:has()` can introduce cyclic querying.

Examples

Selecting a parent element

You may be looking for a "parent combinator", which allows you to go up the DOM tree and select the parent of a specific element. The `:has()` pseudo-class does that by using `parent:has(child)` (for any parent) or `parent:has(> child)` (for direct parent). This example shows how to style a `<section>` element when it contains a child with the `featured` class.

```
<section>
  <article class="featured">Featured content</article>
  <article>Regular content</article>
</section>
<section>
  <article>Regular content</article>
</section>
```

```
section:has(.featured) {
  border: 2px solid blue;
}
```

Result

With the sibling combinator

The `:has()` style declaration in the following example adjusts the spacing after `<h1>` headings if they are immediately followed by an `<h2>` heading.

HTML

```
<section>
  <article>
    <h1>Morning Times</h1>
    <p>
      Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod
      tempor incididunt ut labore et dolore magna aliqua.
    </p>
  </article>
  <article>
    <h1>Morning Times</h1>
    <h2>Delivering you news every morning</h2>
    <p>
      Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod
      tempor incididunt ut labore et dolore magna aliqua.
    </p>
  </article>
</section>
```

CSS

```
section {
  display: flex;
  align-items: start;
  justify-content: space-around;
}

article {
  display: inline-block;
  width: 40%;
}

h1,
h2 {
  font-size: 1.2em;
}

h2 {
  font-size: 1em;
  color: rgb(150 149 149);
}
```

```
h1,
h2 {
  margin: 0 0 1rem 0;
}

h1:has(+ h2) {
  margin: 0 0 0.25rem 0;
}
```

Result

This example shows two similar texts side-by-side for comparison – the left one with an `H1` heading followed by a paragraph and the right one with an `H1` heading followed by an `H2` heading and then a paragraph. In the example on the right, `:has()` helps to select the `H1` element that is immediately followed by an `H2` element (indicated by the next-sibling combinator `+`) and the CSS rule reduces the spacing after such an `H1` element. Without the `:has()` pseudo-class, you cannot use CSS selectors to select a preceding sibling of a different type or a parent element.

This usage of `:has()` is analogous to a lookahead assertion in regular expressions because they both allow you to select elements (or strings in regular expressions) based on what *follows* it, which is only possible if the processor is able to "rewind". In the regular expression `abc(?=xyz)`, the string `abc` is matched only if it is immediately followed by the string `xyz`. As it is a lookahead operation, the `xyz` is not included in the match. The analogous construct in CSS would be `.abc:has(+ .xyz)`: it selects the element `.abc` only if there is a next sibling `.xyz`. The part `:has(+ .xyz)` looks ahead for the next element `.xyz`, but then selects the

previous element `.abc` instead. Similarly, you can implement negative lookahead like `abc(?!xyz)` by negating the `:has()`: `.abc:not(:has(+ .xyz))` only matches `.abc` elements that are not followed by `.xyz` (either because the next sibling does not match `.xyz` or because it's the last child node).

With the :is() pseudo-class

This example builds on the previous example to show how to select multiple elements with `:has()`.

HTML

```
<section>
  <article>
    <h1>Morning Times</h1>
    <h2>Delivering you news every morning</h2>
    <p>
      Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod
      tempor incididunt ut labore et dolore magna aliqua.
    </p>
  </article>
  <article>
    <h1>Morning Times</h1>
    <h2>Delivering you news every morning</h2>
    <h3>8:00 am</h3>
    <p>
      Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod
      tempor incididunt ut labore et dolore magna aliqua.
    </p>
  </article>
</section>
```

CSS

```
section {
  display: flex;
  align-items: start;
  justify-content: space-around;
}

article {
  display: inline-block;
  width: 40%;
}

h1 {
  font-size: 1.2em;
}

h2 {
  font-size: 1em;
  color: rgb(150 149 149);
}

h3 {
  font-size: 0.9em;
  color: darkgrey;
}
```

```
h1,
h2,
h3 {
  margin: 0 0 1rem 0;
}

:is(h1, h2, h3):has(+ :is(h2, h3, h4)) {
  margin: 0 0 0.25rem 0;
}
```

Result

Here, the first `:is()` pseudo-class is used to select any of the heading elements in the list. The second `:is()` pseudo-class is used to pass a list of next-sibling selectors as an argument to `:has()`. The `:has()` pseudo-class helps to select any `H1`, `H2`, or `H3` element that is immediately followed by (indicated by `+`) an `H2`, `H3`, or `H4` element and the CSS rule reduces the spacing after such `H1`, `H2`, or `H3` elements.

This selector could have also been written as:

```
:is(h1, h2, h3):has(+ h2, + h3, + h4) {
  margin: 0 0 0.25rem 0;
}
```

Logical operations

The `:has()` relational selector can be used to check if one of the multiple features is true or if all the features are true.

By using comma-separated values inside the `:has()` relational selector, you are checking to see if any of the parameters exist. `x:has(a, b)` will style `x` if descendant `a` OR `b` exists.

By chaining together multiple `:has()` relational selectors together, you are checking to see if all of the parameters exist. `x:has(a):has(b)` will style `x` if descendant `a` AND `b` exist.

```
body:has(video, audio) {
  /* styles to apply if the content contains audio OR video */
}
body:has(video):has(audio) {
  /* styles to apply if the content contains both audio AND video */
}
```

Performance considerations

Certain uses of the `:has()` pseudo-class can significantly impact page performance, particularly during dynamic updates (DOM mutations). Browser engines must re-evaluate `:has()` selectors when the DOM changes, and complex or poorly constrained selectors can lead to expensive computations.

Avoid broad anchoring

The anchor selector (the `A` in `A:has(B)`) should not be an element that has too many children, like `body`, `:root`, or `*`. Anchoring `:has()` to very general selectors can degrade performance because any DOM change within the entire subtree of a broadly selected element requires the browser to re-check the `:has()` condition.

```
/* Avoid anchoring :has() to broad elements */
body:has(.sidebar) {
  /* styles */
}
:root:has(.content) {
  /* styles */
}
*:has(.item) {
  /* styles */
}
```

Instead, anchor `:has()` to specific elements like `.container` or `.gallery` to reduce the scope and improve performance.

```
/* Use specific containers to limit scope */
.container:has(.sidebar-expanded) {
  /* styles */
}
.content-wrapper:has(> article[data-priority="high"]) {
  /* styles */
}
.gallery:has(> img[data-loaded="false"]) {
  /* styles */
}
```

Minimize subtree traversals

The inner selector (the `B` in `A:has(B)`) should use combinators like `>` or `+` to limit traversal. When the selector inside `:has()` is not tightly constrained, the browser might need to traverse the entire subtree of the anchor element on every DOM mutation to check if the condition still holds.

In this example, any change within `.ancestor` requires checking all descendants for `.foo`:

```
/* May trigger full subtree traversal */
.ancestor:has(.foo) {
  /* styles */
}
```

Using child or sibling combinators limits the scope of the inner selector, reducing the performance cost of DOM mutations. In this example, the browser only needs to check direct children or a specific sibling's descendants:

```
/* More constrained - limits traversal */
.ancestor:has(> .foo) {
  /* direct child */
}
.ancestor:has(+ .sibling .foo) {
  /* descendant of adjacent sibling */
}
```

Certain inner selectors can force the browser to traverse up the ancestor chain for every DOM mutation, looking for potential anchors that might need updating. This happens when the structure implies a need to check ancestors of the mutated element.

In this example, any DOM change requires checking if the changed element is any element (`*`) that is a direct child of `.foo`, and if its parent (or further ancestors) is `.ancestor`.

```
/* Might trigger ancestor traversal */
.ancestor:has(.foo > *) {
  /* styles */
}
```

Constraining the inner selector with specific classes or direct child combinators (e.g., `.specific-child` in the next snippet) reduces expensive ancestor traversals by limiting the browser's check to a well-defined element, improving performance.

```
/* Constrain the inner selector to avoid ancestor traversals */
.ancestor:has(.foo > .specific-child) {
  /* styles */
}
```

> **Note:** These performance characteristics may improve as browsers optimize `:has()` implementations, but the fundamental constraints remain: `:has()` needs to traverse a whole subtree, so you need to minimize the subtree's size. In a selector like `A:has(B)`, make sure your `A` does not have too many children, and make sure your `B` is tightly constrained to avoid unnecessary traversal.

:has-slotted CSS pseudo-class

The **`:has-slotted`** CSS pseudo-class matches when the content of a `<slot>` element is not empty or not using the default value (see Using templates and slots for more information).

> **Note:** Even a single whitespace text node is sufficient to make `:has-slotted` apply.

This only works when used inside CSS placed within a shadow DOM.

```
/* Selects the content of a <slot> element that has content that is not default  */
:has-slotted {
```

```
  color: green;
}

/* Selects the content of a <slot> element that has no content or default  */
:not(:has-slotted) {
  color: red;
}
```

Syntax

```
:has-slotted {
  /* ... */
}
```

Examples

This example has two `<slot>` elements, one of which has been assigned some content and the other has not.

HTML

```
<p>
  <template shadowrootmode="open">
    <style>
      :has-slotted {
        color: rebeccapurple;
      }
    </style>
    <slot name="one">Placeholder 1</slot>
    <slot name="two">Placeholder 2</slot>
  </template>
  <span slot="one">Slotted content</span>
</p>
```

Result

The `<slot>` element that has been assigned content matched the `:has-slotted` pseudo-class and has the `color` value of `rebeccapurple` applied.

:heading CSS pseudo-class

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`:heading`** CSS pseudo-class matches all heading elements in a document.

Syntax

```
:heading {
  /* ... */
}
```

Description

The `:heading` pseudo-class allows you to style all headings at once, rather than matching and styling them individually.

This pseudo-class matches only elements that by default are semantically recognized as headings (`<h1>` through `<h6>`). Elements with `role="heading"` are not matched; you can select those by using the `[role="heading"]` attribute selector.

The `:heading` pseudo-class has the same specificity as a class selector, that is, `0-1-0`. So `:heading` has a specificity of `0-1-0`, whereas `h1, h2, h3, h4, h5, h6` would have a specificity of `0-0-1` and `section:heading` would have a specificity of `0-1-1`.

Examples

Styling all headings

In this example, we use the `:heading` pseudo-class to style multiple levels of headings.

HTML

The document contains headings at three different levels, along with `<p>` paragraph elements.

```
<h1>Mastering CSS</h1>
<h2>Chapter 1: Selectors</h2>
<p>
  A CSS selector is the part of a CSS rule that describes what elements in a
  document the rule will match.
</p>
<h3>1.1 Pseudo-classes</h3>
<p>
  CSS pseudo-classes enable selecting elements based on information that lies
  outside of the document tree.
</p>
```

CSS

We set the heading elements to be italic and tomato red.

```
:heading {
  color: tomato;
  font-style: italic;
}
```

Results

The `:heading` pseudo-class applies the `color` and `font-style` to all the headings in the document, but not the paragraphs:

- `:heading()`

:heading() CSS pseudo-class

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`:heading()`** CSS pseudo-class function represents all heading elements whose levels match a comma-separated list of integers. This allows you to style elements at specific heading levels at once, rather than matching and styling them individually.

> **Note:** The `:heading()` functional pseudo-class has the same specificity as a class selector, that is, `0-1-0`. For example, `section:heading()` has a specificity of `0-1-1`.

Syntax

```
:heading( <integer># ) {
  /* ... */
}
```

Parameters

The `:heading()` pseudo-class function takes a comma-separated list of `<integer>`s that represent the heading levels to be styled.

Usage notes

The `:heading()` functional pseudo-class matches only elements that are semantically recognized as headings. It does not match elements that use `role="heading"` or 'aria-level' attributes.

The heading level used by `:heading()` may be different from an element's type selector in cases where the browser computes a different exposed heading level. For example, `h1:heading(3)` will match any `<h1>` element that is exposed as a level 3 heading.

Examples

Selecting specific heading levels

In this example, a comma-separated list of values is used to target headings at odd-numbered levels (`<h1>` and `<h3>`) and even-numbered levels (`<h2>` and `<h4>`).

```
<h1>Heading 1</h1>
<h2>Heading 2</h2>
<h3>Heading 3</h3>
<h4>Heading 4</h4>
```

```
:heading(1, 3) {
  color: tomato;
}
:heading(2, 4) {
  color: slateblue;
}
```

- `:heading`

:host CSS pseudo-class

The **`:host`** CSS pseudo-class selects the shadow host of the shadow DOM containing the CSS it is used inside — in other words, this allows you to select a custom element from inside its shadow DOM.

> **Note:** This has no effect when used outside a shadow DOM.

Try it

```
/* This CSS is being applied inside the shadow DOM. */

:host {
  background-color: aqua;
}
```

```
<h1 id="shadow-dom-host"></h1>
```

```
const shadowDom = init();

// add a <span> element in the shadow DOM
const span = document.createElement("span");
span.textContent = "Inside shadow DOM";
shadowDom.appendChild(span);

// attach shadow DOM to the #shadow-dom-host element
function init() {
  const host = document.getElementById("shadow-dom-host");
  const shadowDom = host.attachShadow({ mode: "open" });

  const cssTab = document.querySelector("#css-output");
  const shadowStyle = document.createElement("style");
  shadowStyle.textContent = cssTab.textContent;
  shadowDom.appendChild(shadowStyle);

  cssTab.addEventListener("change", () => {
    shadowStyle.textContent = cssTab.textContent;
  });
```

```
  return shadowDom;
}
```

```
/* Selects a shadow root host */
:host {
  font-weight: bold;
}
```

Syntax

```
:host {
  /* ... */
}
```

Examples

Styling the shadow host

The following snippets are taken from our host-selectors example (see it live also).

In this example we have a basic custom element — `<context-span>` — that you can wrap around text:

```
<h1>
  Host selectors <a href="#"><context-span>example</context-span></a>
</h1>
```

Inside the element's constructor, we create `style` and `span` elements, fill the `span` with the content of the custom element, and fill the `style` element with some CSS rules:

```
const style = document.createElement("style");
const span = document.createElement("span");
span.textContent = this.textContent;

const shadowRoot = this.attachShadow({ mode: "open" });
shadowRoot.appendChild(style);
shadowRoot.appendChild(span);

style.textContent =
  "span:hover { text-decoration: underline; }" +
  ":host-context(h1) { font-style: italic; }" +
  ':host-context(h1)::after { content: " - no links in headers!" }' +
  ":host-context(article, aside) { color: gray; }" +
  ":host(.footer) { color : red; }" +
  ":host { background: rgb(0 0 0 / 10%); padding: 2px 5px; }";
```

The `:host { background: rgb(0 0 0 / 10%); padding: 2px 5px; }` rule styles all instances of the `<context-span>` element (the shadow host in this instance) in the document.

:host() CSS pseudo-class

The **`:host()`** CSS pseudo-class function selects the shadow host of the shadow DOM containing the CSS it is used inside (so you can select a custom element from inside its shadow DOM) — but only if the selector given as the function's parameter matches the shadow host. **`:host()`** has no effect when used outside a shadow DOM.

The most obvious use of this is to put a class name only on certain custom element instances, and then include the relevant class selector as the function argument. You can't use this with a descendant selector expression to select only instances of the custom element that are inside a particular ancestor. That's the job of `:host-context()`.

> **Note:** While other functional pseudo-classes such as `:is()` and `:not()` accept a list of selectors as their parameters, `:host()` takes a single compound selector as its parameter. In addition, while `:is()` and `:not()` only take into account the specificity of their argument, the specificity of `:host()` is both the specificity of the pseudo-class **and** the specificity of its argument.

Try it

```
/* Following CSS is being applied inside the shadow DOM. */

:host(h1) {
  color: red;
}

:host(#shadow-dom-host) {
  border: 2px dashed blue;
}
```

```
<!-- elements outside shadow dom -->
<div id="container">
  <h1 id="shadow-dom-host"></h1>
</div>
```

```
const shadowDom = init();

// add a <span> element in the shadow DOM
const span = document.createElement("span");
span.textContent = "Inside shadow DOM";
shadowDom.appendChild(span);

// attach shadow DOM to the #shadow-dom-host element
function init() {
  const host = document.getElementById("shadow-dom-host");
  const shadowDom = host.attachShadow({ mode: "open" });
```

```
  const cssTab = document.querySelector("#css-output");
  const shadowStyle = document.createElement("style");
  shadowStyle.textContent = cssTab.textContent;
  shadowDom.appendChild(shadowStyle);

  cssTab.addEventListener("change", () => {
    shadowStyle.textContent = cssTab.textContent;
  });
  return shadowDom;
}
```

```
/* Selects a shadow root host, only if it is
   matched by the selector argument */
:host(.special-custom-element) {
  font-weight: bold;
}
```

Syntax

```
:host(<compound-selector>) {
  /* ... */
}
```

Examples

Selectively styling shadow hosts

The following snippets are taken from our host-selectors example (see it live also).

In this example we have a custom element — `<context-span>` — that you can wrap around text:

```
<h1>
  Host selectors <a href="#"><context-span>example</context-span></a>
</h1>
```

Inside the element's constructor, we create `style` and `span` elements, fill the `span` with the content of the custom element, and fill the `style` element with some CSS rules:

```
const style = document.createElement("style");
const span = document.createElement("span");
span.textContent = this.textContent;

const shadowRoot = this.attachShadow({ mode: "open" });
shadowRoot.appendChild(style);
shadowRoot.appendChild(span);

style.textContent =
  "span:hover { text-decoration: underline; }" +
  ":host-context(h1) { font-style: italic; }" +
  ':host-context(h1)::after { content: " - no links in headers!" }' +
  ":host-context(article, aside) { color: gray; }" +
  ":host(.footer) { color : red; }" +
  ":host { background: rgb(0 0 0 / 10%); padding: 2px 5px; }";
```

The `:host(.footer) { color : red; }` rule styles all instances of the `<context-span>` element (the shadow host in this instance) in the document that have the `footer` class set on them — we've used it to give instances of the element inside the `<footer>` a special color.

- `:host-context()`
- `:state()`

:host-context() CSS pseudo-class

The **`:host-context()`** CSS pseudo-class allows you to style elements within a shadow DOM differently based on the selector of the shadow host (the element that has the shadow root) and its DOM ancestors.

Normally, elements within a shadow DOM are isolated from the DOM outside of it. The `:host-context()` allows you to "peek outside" of this Shadow DOM and check if any of the element's ancestor elements match a certain CSS selector. For example, applying a different text color to elements within a shadow root when a `.dark-theme` class is applied to `<body>`.

Think of it like this: Imagine you have a `<greenhouse>` custom element, that has a `<chameleon>` living inside. Here, the `<greenhouse>` is the Shadow DOM host and the `<chameleon>` element is within the Shadow DOM. The `:host-context()` lets the `<chameleon>` change its appearance based on the `<greenhouse>`'s environment. If the `<greenhouse>` is in a sunny location (has a "sunny-theme" class), the `<chameleon>` turns yellow. If the `<greenhouse>` is in a shady spot (a "shady-theme" class applied instead), the `<chameleon>` turns blue.

This selector pierces through all shadow boundaries. It will look for the sunny or shady theme applied directly to the `<greenhouse>` or on any of the host's ancestors and ancestor DOMs all the way up until it reaches the document root.

To limit the selector to only the `<greenhouse>` host directly or limit the selection to host's DOM, use the `:host` or `:host()` pseudo-class instead.

> **Note:** This has no effect when used outside a shadow DOM.

The specificity of `:host-context()` is that of a pseudo-class, plus the specificity of the selector passed as the function's argument.

Try it

```
/* Following CSS is being applied inside the shadow DOM. */

:host-context(.container) {
  border: 5px dashed green;
}

:host-context(h1) {
  color: red;
}
```

```
<!-- elements outside shadow dom -->
<div class="container">
  <h1 id="shadow-dom-host"></h1>
</div>
```

```
const shadowDom = init();

// add a <span> element in the shadow DOM
const span = document.createElement("span");
span.textContent = "Inside shadow DOM";
shadowDom.appendChild(span);

// attach shadow DOM to the #shadow-dom-host element
function init() {
  const host = document.getElementById("shadow-dom-host");
  const shadowDom = host.attachShadow({ mode: "open" });

  const cssTab = document.querySelector("#css-output");
  const shadowStyle = document.createElement("style");
  shadowStyle.textContent = cssTab.textContent;
  shadowDom.appendChild(shadowStyle);

  cssTab.addEventListener("change", () => {
    shadowStyle.textContent = cssTab.textContent;
  });
  return shadowDom;
}
```

```
/* Selects a shadow root host, only if it is
   a descendant of the selector argument given */
:host-context(h1) {
  font-weight: bold;
}

/* Changes paragraph text color from black to white when
   a .dark-theme class is applied to the document body */
p {
  color: black;
}

:host-context(body.dark-theme) p {
  color: white;
}
```

Syntax

```
:host-context(<compound-selector>) {
  /* ... */
}
```

Examples

Selectively styling shadow hosts

The following snippets are taken from our host-selectors example (see it live also).

In this example we have a basic custom element — `<context-span>` — that you can wrap around text:

```
<h1>
  Host selectors <a href="#"><context-span>example</context-span></a>
</h1>
```

Inside the element's constructor, we create `style` and `span` elements, fill the `span` with the content of the custom element, and fill the `style` element with some CSS rules:

```
const style = document.createElement("style");
const span = document.createElement("span");
span.textContent = this.textContent;

const shadowRoot = this.attachShadow({ mode: "open" });
shadowRoot.appendChild(style);
shadowRoot.appendChild(span);

style.textContent =
  "span:hover { text-decoration: underline; }" +
  ":host-context(h1) { font-style: italic; }" +
  ':host-context(h1)::after { content: " - no links in headers!" }' +
  ":host(.footer) { color : red; }" +
  ":host { background: rgb(0 0 0 / 10%); padding: 2px 5px; }";
```

The `:host-context(h1) { font-style: italic; }` and `:host-context(h1)::after { content: " - no links in headers!" }` rules style the instance of the `<context-span>` element (the shadow host in this instance) inside the `<h1>`. We've used it to make it clear that the custom element shouldn't appear inside the `<h1>` in our design.

- CSS `:state()` pseudo-class
- CSS `::slotted` pseudo-element
- HTML `<template>` element
- CSS scoping module

:hover CSS pseudo-class

The **`:hover`** CSS pseudo-class matches an element when a user interacts with it using a pointing device. The pseudo-class is generally triggered when the user moves the cursor (mouse pointer) over an element without pressing the mouse button.

Try it

```
.joinBtn {
  width: 10em;
  height: 5ex;
  background-color: gold;
  border: 2px solid firebrick;
  border-radius: 10px;
  font-weight: bold;
  color: black;
  cursor: pointer;
}

.joinBtn:hover {
  background-color: bisque;
}
```

```
<p>Would you like to join our quest?</p>
<button class="joinBtn">Confirm</button>
```

Styles defined by the `:hover` pseudo-class will be overridden by any subsequent link-related pseudo-class (`:link`, `:visited`, or `:active`) that has at least equal specificity. To style links appropriately, put the `:hover` rule after the `:link` and `:visited` rules but before the `:active` one, as defined by the *LVHA-order*: `:link` — `:visited` — `:hover` — `:active`.

> **Note:** The `:hover` pseudo-class is problematic on touchscreens. Depending on the browser, the `:hover` pseudo-class might never match, match only for a moment after touching an element, or continue to match even after the user has stopped touching and until the user touches another element. Web developers should make sure that content is accessible on devices with limited or non-existent hovering capabilities.

Syntax

```
:hover {
  /* ... */
}
```

Examples

Basic example

HTML

```
<a href="#">Try hovering over this link.</a>
```

CSS

```
a {
  background-color: powderblue;
  transition: background-color 0.5s;
}

a:hover {
  background-color: gold;
}
```

Result

See also

- Chromium bug #370155: Don't make `:hover` sticky on tap on sites that set a mobile viewport
- Chromium bug #306581: Immediately show hover and active states on touch when page isn't scrollable.

:in-range CSS pseudo-class

The **`:in-range`** CSS pseudo-class represents an `<input>` element whose current value is within the range limits specified by the `min` and `max` attributes.

Try it

```
label {
  display: block;
  margin-top: 1em;
}

input:in-range {
  background-color: palegreen;
}
```

```
<label for="amount">How many tickets? (You can buy 2-6 tickets)</label>
<input id="amount" name="amount" type="number" min="2" max="6" value="4" />

<label for="dep">Departure Date: (Whole year 2022 is acceptable)</label>
<input
  id="dep"
  name="dep"
  type="date"
  min="2022-01-01"
  max="2022-12-31"
  value="2025-05-05" />

<label for="ret">Return Date: (Whole year 2022 is acceptable)</label>
<input id="ret" name="ret" type="date" min="2022-01-01" max="2022-12-31" />
```

This pseudo-class is useful for giving the user a visual indication that a field's current value is within the permitted limits.

> **Note:** This pseudo-class only applies to elements that have (and can take) a range limitation. In the absence of such a limitation, the element can neither be "in-range" nor "out-of-range."

Syntax

```
:in-range {
  /* ... */
}
```

Examples

HTML

```
<p>
  <label for="value1">How many toes? Values between 1 and 10 are valid.</label>
  <input
    id="value1"
    name="value1"
    type="number"
    placeholder="1 to 10"
    min="1"
    max="10"
    value="12"
    required />
  <span></span>
</p>
```

CSS

```
input {
  border: 1px solid black;
}

input:in-range {
  background-color: rgb(0 255 0 / 25%);
}

input:out-of-range {
  background-color: rgb(255 0 0 / 25%);
  border: 2px solid red;
}

input:in-range + span::after {
  content: "Your value is okay.";
}

input:out-of-range + span::after {
  content: "Your value is out of range!";
}
```

Result

> **Note:** An empty `<input>` does not count as out of range, and will not be selected using the `:out-of-range` pseudo-class selector. The `:blank` pseudo-class exists to select blank inputs, although at the time of writing this is experimental and not well-supported. You could also use the `required` attribute and the `:invalid` pseudo-class to provide more general logic and styling for making inputs mandatory (`:invalid` will style blank *and* out-of-range inputs).

See also

- `:out-of-range`
- Form data validation

:indeterminate CSS pseudo-class

The **`:indeterminate`** CSS pseudo-class represents any form element whose state is indeterminate, such as checkboxes that have been set to an `indeterminate` state with JavaScript, radio buttons which are members of a group in which all radio buttons are unchecked, and `<progress>` elements with no `value` attribute.

```
/* Selects any <input> whose state is indeterminate */
input:indeterminate {
  background: lime;
}
```

Elements targeted by this selector are:

- `<input type="checkbox">` elements with the `indeterminate` property set to `true`.
- `<input type="radio">` elements with the same `name` value and none of them `checked`.
- `<progress>` elements with no `value`, placing them in an indeterminate state.

Syntax

```
:indeterminate {
  /* ... */
}
```

Examples

Checkbox & radio button

This example applies special styles to the labels associated with indeterminate form fields.

HTML

```
<fieldset>
  <legend>Checkbox</legend>
  <div>
    <input type="checkbox" id="checkbox" />
    <label for="checkbox">This checkbox label starts out lime.</label>
  </div>
</fieldset>

<fieldset>
```

```
  <legend>Radio</legend>
  <div>
    <input type="radio" id="radio1" name="radioButton" value="val1" />
    <label for="radio1">First radio label starts out lime.</label>
  </div>
  <div>
    <input type="radio" id="radio2" name="radioButton" value="val2" />
    <label for="radio2">Second radio label also starts out lime.</label>
  </div>
</fieldset>
```

CSS

```
input:indeterminate + label {
  background: lime;
}
```

```
fieldset {
  padding: 1em 0.75em;
}

fieldset:first-of-type {
  margin-bottom: 1.5rem;
}

fieldset:not(:first-of-type) > div:not(:last-child) {
  margin-bottom: 0.5rem;
}
```

JavaScript

```
const inputs = document.getElementsByTagName("input");

for (const input of inputs) {
  input.indeterminate = true;
}
```

Result

Progress bar

HTML

```
<progress></progress>
```

CSS

```
progress {
  margin: 4px;
}

progress:indeterminate {
  width: 80vw;
  height: 20px;
}
```

Result

:interest-source CSS pseudo-class

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`:interest-source`** CSS pseudo-class represents an interest invoker element when interest is shown on it.

Syntax

```
:interest-source {
  /* ... */
}
```

Examples

Selecting an interest invoker element

In this example, we demonstrate how `:interest-source` can be used to apply styles to an interest invoker element when interest is shown on it.

HTML

The markup includes a `<button>` and a `<p>`. We specify the `<button>` as an interest invoker by giving it the `interestfor` attribute whose value matches the `id` of the `<p>` element, making the paragraph the target element. The paragraph is turned into a popover by giving it the `popover` attribute, which hides it initially.

```
<button interestfor="mypopover">Button</button>
<p id="mypopover" popover>A hover tooltip</p>
```

CSS

In the CSS, we specify a rule with an `:interest-source` selector to apply a specific combination of `background-color` and `color` to the `<button>` when interest is shown on it. We also apply some other styles to the `<button>`, which are hidden for brevity.

```
button {
  margin: 10px;
  padding: 5px 10px;
  border: 1px solid #dddddd;
  border-radius: 5px;
  font-size: 1.5em;
  background-color: #eeeeee;

  cursor: pointer;
}
```

```
button:interest-source {
  background-color: hotpink;
  color: purple;
}
```

Result

This renders as follows:

Try showing interest in the button (for example, by hovering or focusing it), and note how the `hotpink` and `purple` color combination is applied only when interest is shown.

:interest-target CSS pseudo-class

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`:interest-target`** CSS pseudo-class represents the target element associated with an interest invoker when interest is shown on that invoker.

Syntax

```
:interest-target {
  /* ... */
}
```

Examples

Selecting the target element associated with an interest invoker

In this example, we demonstrate how `:interest-target` can be used to apply styles to an interest invoker element's target element when interest is shown on the invoker.

HTML

The markup includes a `<button>` and a `<p>`. We specify the `<button>` as an interest invoker by giving it the `interestfor` attribute whose value matches the `id` of the `<p>` element, making the paragraph the target element.

```
<button interestfor="mytarget">Button</button>
<p id="mytarget">A paragraph</p>
```

CSS

In the CSS, we specify a rule with an `:interest-target` selector, which will apply a specific set of styles to the `<p>` element when interest is shown in the `<button>`. We also apply some other styles to the `<button>`, which we've hidden for brevity.

```
body {
  margin: 10px;
}

button {
  padding: 5px 10px;
  border: 1px solid #dddddd;
  border-radius: 5px;
  background-color: #eeeeee;

  cursor: pointer;
}
```

```
p:interest-target {
  font-size: 1.5em;
  font-family: sans-serif;
  padding: 10px;
  background-color: hotpink;
  color: purple;
}
```

Result

This renders as follows:

Try showing interest in the button (for example, by hovering or focusing it), and note how this results in the styles shown earlier being applied to the paragraph.

:invalid CSS pseudo-class

The **`:invalid`** CSS pseudo-class represents any `<form>`, `<fieldset>`, `<input>` or other `<form>` element whose contents fail to validate.

This pseudo-class is useful for highlighting field errors for the user.

Try it

```
label {
  display: block;
  margin-top: 1em;
}

input:invalid {
  background-color: ivory;
  border: none;
  outline: 2px solid red;
  border-radius: 5px;
}
```

```
<label for="email">Email Address:</label>
<input id="email" name="email" type="email" value="na@me@example.com" />

<label for="secret">Secret Code: (lower case letters)</label>
<input id="secret" name="secret" type="text" value="test" pattern="[a-z]+" />

<label for="age">Your age: (18+)</label>
<input id="age" name="age" type="number" value="5" min="18" />

<label
  ><input name="tos" type="checkbox" required checked /> - Do you agree to
  ToS?</label
>
```

Syntax

```
:invalid {
  /* ... */
}
```

Accessibility

The color red is commonly used to indicate invalid input. People who have certain types of color blindness will be unable to determine the input's state unless it is accompanied by an additional indicator that does not rely on color to convey meaning. Typically, descriptive text and/or an icon are used.

- MDN Understanding WCAG, Guideline 1.4 explanations
- Understanding Success Criterion 1.4.1 | W3C Understanding WCAG 2.0

Examples

Coloring elements to show validation

HTML

```
<form>
  <div class="field">
    <label for="url_input">Enter a URL:</label>
    <input type="url" id="url_input" />
  </div>

  <div class="field">
    <label for="email_input">Enter an email address:</label>
    <input type="email" id="email_input" required />
  </div>
</form>
```

CSS

```
label {
  display: block;
  margin: 1px;
  padding: 1px;
}

.field {
  margin: 1px;
  padding: 1px;
}

input:invalid {
  background-color: #ffdddd;
}

form:invalid {
  border: 5px solid #ffdddd;
}

input:valid {
  background-color: #ddffdd;
}

form:valid {
  border: 5px solid #ddffdd;
}

input:required {
```

```
  border-color: maroon;
  border-width: 3px;
}

input:required:invalid {
  border-color: #c00000;
}
```

Result

Showing sections in stages

In this example we use `:invalid` along with ~, the subsequent-sibling combinator, to make a form appear in stages, so the form initially shows the first item to complete, and when the user completes each item the form displays the next one. When the whole form is complete the user can submit it.

HTML

```
<form>
  <fieldset>
    <legend>Personal Information</legend>
    <label for="form-name">Name</label><br />
    <input type="text" name="name" id="form-name" required />
  </fieldset>

  <fieldset>
    <legend>Contact Information</legend>
    <label for="form-email">Email Address</label><br />
    <input type="email" name="email" id="form-email" required />
  </fieldset>

  <fieldset>
    <legend>Message</legend>
    <label for="form-message">Message</label><br />
    <textarea name="message" id="form-message" required></textarea>
  </fieldset>

  <button type="submit" name="send">Submit</button>
</form>
```

```
document.querySelector("form").addEventListener("submit", (event) => {
  event.preventDefault();
});
```

CSS

```
/* Hide the fieldset after an invalid fieldset */
fieldset:invalid ~ fieldset {
  display: none;
}

/* Dim and disable the button while the form is invalid */
form:invalid button {
  opacity: 0.3;
  pointer-events: none;
}

input,
textarea {
  box-sizing: border-box;
  width: 100%;
  font-family: monospace;
  padding: 0.25em 0.5em;
}

button {
  width: 100%;
  border: thin solid darkgrey;
  font-size: 1.25em;
  background-color: darkgrey;
  color: white;
}
```

Result

Notes

Radio buttons

If any one of the radio buttons in a group is `required`, the `:invalid` pseudo-class is applied to all of them if none of the buttons in the group is selected. (Grouped radio buttons share the same value for their `name` attribute.)

Gecko defaults

By default, Gecko does not apply a style to the `:invalid` pseudo-class. However, it does apply a style (a red "glow" using the `box-shadow` property) to the `:user-invalid` pseudo-class, which applies in a subset of cases for `:invalid`.

See also

- Other validation-related pseudo-classes: `:required`, `:optional`, `:valid`

- Accessing the validity state from JavaScript

:is() CSS pseudo-class

The **`:is()`** CSS pseudo-class function takes a selector list as its argument, and selects any element that can be selected by one of the selectors in that list. This is useful for writing large selectors in a more compact form.

> **Note:** Originally named `:matches()` (and `:any()`), this selector was renamed to `:is()` in CSSWG issue #3258.

Try it

```
ol {
  list-style-type: upper-alpha;
  color: darkblue;
}

:is(ol, ul, menu:unsupported) :is(ol, ul) {
  color: green;
}

:is(ol, ul) :is(ol, ul) ol {
  list-style-type: lower-greek;
  color: chocolate;
}
```

```
<ol>
  <li>Saturn</li>
  <li>
    <ul>
      <li>Mimas</li>
      <li>Enceladus</li>
      <li>
        <ol>
          <li>Voyager</li>
          <li>Cassini</li>
        </ol>
      </li>
      <li>Tethys</li>
    </ul>
  </li>
  <li>Uranus</li>
  <li>
    <ol>
      <li>Titania</li>
      <li>Oberon</li>
    </ol>
  </li>
</ol>
```

Syntax

```
:is(<forgiving-selector-list>) {
  /* ... */
}
```

Parameters

The `:is()` pseudo-class requires a selector list, a comma-separated list of one or more selectors as its argument. The list must not contain a pseudo-element, but any other simple, compound, and complex selectors are allowed.

Difference between :is() and :where()

The difference between the two is that `:is()` counts towards the specificity of the overall selector (it takes the specificity of its most specific argument), whereas `:where()` has a specificity value of 0. This is demonstrated by the example on the `:where()` reference page.

Forgiving Selector Parsing

The specification defines `:is()` and `:where()` as accepting a forgiving selector list.

In CSS when using a selector list, if any of the selectors are invalid then the whole list is deemed invalid. When using `:is()` or `:where()` instead of the whole list of selectors being deemed invalid if one fails to parse, the incorrect or unsupported selector will be ignored and the others used.

```
:is(:valid, :unsupported) {
  /* … */
}
```

Will still parse correctly and match `:valid` even in browsers which don't support `:unsupported`, whereas:

```
:valid,
:unsupported {
  /* … */
}
```

Will be ignored in browsers which don't support `:unsupported` even if they support `:valid`.

Examples

Simplifying list selectors

The `:is()` pseudo-class can greatly simplify your CSS selectors. For example, take the following CSS:

```
/* 3-deep (or more) unordered lists use a square */
ol ol ul,
ol ul ul,
ol menu ul,
ol ol menu,
ol ul menu,
ol menu menu,
ul ol ul,
ul ul ul,
ul menu ul,
ul ol menu,
ul ul menu,
ul menu menu,
```

```
menu ol ul,
menu ul ul,
menu menu ul,
menu ol menu,
menu ul menu,
menu menu menu {
  list-style-type: square;
}
```

You can replace it with:

```
/* 3-deep (or more) unordered lists use a square */
:is(ol, ul, menu) :is(ol, ul, menu) :is(ul, menu) {
  list-style-type: square;
}
```

Simplifying section selectors

The `:is()` pseudo-class is particularly useful when dealing with HTML sections and headings. Since `<section>`, `<article>`, `<aside>`, and `<nav>` are commonly nested together, without `:is()`, styling them to match one another can be tricky.

For example, without `:is()`, styling all the h1 elements at different depths could be very complicated:

```
/* Level 0 */
h1 {
  font-size: 30px;
}

/* Level 1 */
section h1,
article h1,
aside h1,
nav h1 {
  font-size: 25px;
}

/* Level 2 */
section section h1,
section article h1,
section aside h1,
section nav h1,
article section h1,
article article h1,
article aside h1,
article nav h1,
aside section h1,
aside article h1,
aside aside h1,
aside nav h1,
nav section h1,
nav article h1,
nav aside h1,
nav nav h1 {
  font-size: 20px;
}

/* Level 3 */
/* don't even think about it! */
```

Using `:is()`, though, it's much easier:

```
/* Level 0 */
h1 {
  font-size: 30px;
}
/* Level 1 */
:is(section, article, aside, nav) h1 {
  font-size: 25px;
}
/* Level 2 */
:is(section, article, aside, nav) :is(section, article, aside, nav) h1 {
  font-size: 20px;
}
/* Level 3 */
:is(section, article, aside, nav)
  :is(section, article, aside, nav)
  :is(section, article, aside, nav)
  h1 {
  font-size: 15px;
}
```

:is() does not select pseudo-elements

The `:is()` pseudo-class does not match pseudo-elements. So rather than this:

```
some-element:is(::before, ::after) {
  display: block;
}
```

or this:

```
:is(some-element::before, some-element::after) {
  display: block;
}
```

instead do:

```
some-element::before,
some-element::after {
```

```
  display: block;
}
```

- `:where()` - Like `:is()`, but with 0 specificity.
- Selector list
- Web components

:lang() CSS pseudo-class

The **`:lang()`** CSS pseudo-class matches elements based on the language they are determined to be in.

Try it

```
*:lang(en-US) {
  outline: 2px solid deeppink;
}
```

```
<p lang="en-US">
  Music during road trips and long commutes aren't a problem, but using
  headphones isn't the best thing to do while driving in your car.
</p>

<p lang="pl-PL">
  Gdy widzimy znak z narysowaną czaszką i napisem
  <strong lang="en-US">DANGER</strong> to lepiej nie wchodzić do środka.
</p>
```

> **Note:** In HTML, the language is determined by a combination of the `lang` attribute, the `<meta>` element, and possibly by information from the protocol (such as HTTP headers). For other document types there may be other document methods for determining the language.

Syntax

```
:lang(<language-code> [,<language-code> ]*) {
  /* ... */
}
```

Parameters

`<language-code>`

A comma-separated list of one or more `<string>`s that target elements based on the BCP 47 language tags set in their `lang` attributes. Matching by language range is case-insensitive.

Description

When selecting languages, there is implicit wildcard matching, so `:lang(de-DE)` will match `de-DE`, `de-DE-1996`, `de-Latn-DE`, `de-Latf-DE`, and `de-Latn-DE-1996`. Explicitly using wildcards must include a full match of a language subtag, so `:lang("*-F*")` is invalid but `:lang("*-Fr")` is valid.

Examples

Matching children of a given language

In this example, the `:lang()` pseudo-class is used to match the parents of quote elements (`<q>`) using child combinators. Note that this doesn't illustrate the only way to do this, and that the best method to use depends on the type of document. Also note that Unicode values are used to specify some of the special quote characters.

HTML

```
<div lang="en">
  <q>This English quote has a <q>nested</q> quote inside.</q>
</div>
<div lang="fr">
  <q>This French quote has a <q>nested</q> quote inside.</q>
</div>
<div lang="de">
  <q>This German quote has a <q>nested</q> quote inside.</q>
</div>
```

CSS

```
:lang(en) > q {
  quotes: "\201C" "\201D" "\2018" "\2019";
}
:lang(fr) > q {
  quotes: "« " " »";
}
:lang(de) > q {
  quotes: "»" "«" "\2039" "\203A";
}
```

Result

Matching multiple languages

The following example shows how to match multiple languages by providing a comma-separated list of language codes. It's also possible to use a wildcard to match languages in a given language range.

```
p {
  margin: 0;
}
```

CSS

```
/* Matches nl and de */
:lang("nl", "de") {
  color: green;
}
```

```
/* Omitting quotes & case-insensitive matching */
:lang(EN, FR) {
  color: blue;
}

/* Wildcard matching a language range */
:lang("*-Latn") {
  color: red;
}
```

HTML

```
<p lang="nl">Dit is een Nederlandse paragraaf.</p>
<p lang="de">Dies ist ein deutscher Satz.</p>
<p lang="en">This is an English sentence.</p>
<p lang="en-GB">Matching the language range of English.</p>
<p lang="fr">Ceci est un paragraphe français.</p>
<p lang="fr-Latn-FR">Ceci est un paragraphe français en latin.</p>
```

Result

:last-child CSS pseudo-class

The **`:last-child`** CSS pseudo-class represents the last element among a group of sibling elements.

Try it

```
p {
  font-weight: bold;
}

li:last-child {
  border: 2px solid orange;
}
```

```
<p>Track &amp;amp; field champions:</p>
<ul>
  <li>Adhemar da Silva</li>
  <li>Wang Junxia</li>
  <li>Wilma Rudolph</li>
  <li>Babe Didrikson-Zaharias</li>
  <li>Betty Cuthbert</li>
  <li>Fanny Blankers-Koen</li>
  <li>Florence Griffith-Joyner</li>
  <li>Irena Szewinska</li>
  <li>Jackie Joyner-Kersee</li>
  <li>Shirley Strickland</li>
  <li>Carl Lewis</li>
  <li>Emil Zatopek</li>
  <li>Haile Gebrselassie</li>
  <li>Jesse Owens</li>
  <li>Jim Thorpe</li>
  <li>Paavo Nurmi</li>
  <li>Sergei Bubka</li>
  <li>Usain Bolt</li>
</ul>
```

Syntax

```
:last-child {
  /* ... */
}
```

Examples

Basic example

HTML

```
<div>
  <p>This text isn't selected.</p>
  <p>This text is selected!</p>
</div>

<div>
  <p>This text isn't selected.</p>
  <h2>This text isn't selected: it's not a `p`.</h2>
</div>
```

CSS

```
p:last-child {
  color: lime;
  background-color: black;
  padding: 5px;
}
```

Result

Styling a list

HTML

```
<ul>
  <li>Item 1</li>
  <li>Item 2</li>
  <li>
    Item 3
    <ul>
      <li>Item 3.1</li>
      <li>Item 3.2</li>
      <li>Item 3.3</li>
    </ul>
  </li>
</ul>
```

CSS

```
ul li {
  color: blue;
}

ul li:last-child {
  border: 1px solid red;
  color: red;
}
```

Result

See also

- `:-moz-last-node`
- `:last-of-type`
- `:first-child`
- `:nth-child`

:last-of-type CSS pseudo-class

The **`:last-of-type`** CSS pseudo-class represents the last element of its type (tag name) among a group of sibling elements.

Try it

```
dt {
  font-weight: bold;
}

dd {
  margin: 3px;
}

dd:last-of-type {
  border: 2px solid orange;
}
```

```
<dl>
  <dt>Vegetables:</dt>
  <dd>1. Tomatoes</dd>
  <dd>2. Cucumbers</dd>
  <dd>3. Mushrooms</dd>
  <dt>Fruits:</dt>
  <dd>4. Apples</dd>
  <dd>5. Mangos</dd>
  <dd>6. Pears</dd>
  <dd>7. Oranges</dd>
</dl>
```

Syntax

```
:last-of-type {
  /* ... */
}
```

Examples

Styling the last paragraph

HTML

```
<h2>Heading</h2>
<p>Paragraph 1</p>
<p>Paragraph 2</p>
```

CSS

```
p:last-of-type {
  color: red;
  font-style: italic;
}
```

Result

Nested elements

This example shows how nested elements can also be targeted. Note that the universal selector (*) is implied when no simple selector is written.

HTML

```
<article>
  <div>This `div` is first.</div>
  <div>This <span>nested `span` is last</span>!</div>
  <div>
    This <em>nested `em` is first</em>, but this <em>nested `em` is last</em>!
  </div>
  <p>This `p` qualifies!</p>
  <div>This is the final `div`!</div>
</article>
```

CSS

```
article :last-of-type {
  background-color: pink;
}
```

Result

Multiple selectors elements

This HTML example contains nested elements of different types. The CSS contains both type selectors and class selectors.

HTML

```
<p>This `p` is not selected.</p>
<p>This `p` is not selected either.</p>
<p>
  This `p` is last `p` element of its parent e.g. `body` selected by `p` type
  selector.
</p>
<div class="container">
  <div class="item">This `div` is not selected.</div>
  <div class="item">This `div` is not selected either.</div>
  <div class="item">
    This `div` is last `div` element of its parent `div` selected by `.container
    .item` class selector.
  </div>
  <p class="item">
    This `p` is last `p` element of its parent `div` selected by `.container
    .item` class selector.
  </p>
</div>
```

CSS

```
p:last-of-type {
  background: skyblue;
}

.container .item:last-of-type {
  color: red;
  font-weight: bold;
}
```

Result

The last `<div>` and the last `<p>` are both red and bold as the `.item:last-of-type` selects the last of every type if that last element also has the `item` class.

See also

- `:last-child`, `:nth-last-of-type`

:left CSS pseudo-class

The **`:left`** CSS pseudo-class, used with the `@page` at-rule, represents all left-hand pages of a printed document.

```
/* Selects any left-hand pages when printing */
@page :left {
  margin: 2in 3in;
}
```

Whether a given page is "left" or "right" is determined by the major writing direction of the document. For example, if the first page has a major writing direction of left-to-right then it will be a `:right` page; if it has a major writing direction of right-to-left then it will be a `:left` page.

> **Note:** This pseudo-class can be used to change only the `margin`, `padding`, `border`, and `background` properties of the *page box*. All other properties will be ignored, and only the page box, not the document content on the page, will be affected.

Syntax

```
:left {
  /* ... */
}
```

Examples

Setting a margin for left-hand pages

```
@page :left {
  margin: 2in 3in;
}
```

See also

- `@page`
- Other page-related pseudo-classes: `:first`, `:right`

:link CSS pseudo-class

The **`:link`** CSS pseudo-class represents an element that has not yet been visited. It matches every unvisited `<a>` or `<area>` element that has an `href` attribute.

Try it

```
p {
  font-weight: bold;
}

a:link {
  color: forestgreen;
  text-decoration-color: hotpink;
}
```

```
<p>Pages that you might have visited:</p>
<ul>
  <li>
    <a href="https://developer.mozilla.org">MDN Web Docs</a>
  </li>
  <li>
    <a href="https://www.youtube.com/">YouTube</a>
  </li>
</ul>
<p>Pages unlikely to be in your history:</p>
<ul>
  <li>
    <a href="https://developer.mozilla.org/missing-2">Random MDN page</a>
  </li>
  <li>
    <a href="https://example.com/missing-2">Random Example page</a>
  </li>
</ul>
```

Styles defined by the `:link` and `:visited` pseudo-classes can be overridden by any subsequent user-action pseudo-classes (`:hover` or `:active`) that have at least equal specificity. To style links appropriately, put the `:link` rule before all other link-related rules, as defined by the *LVHA-order*: `:link` — `:visited` — `:hover` — `:active`. The `:visited` pseudo-class and `:link` pseudo-class are mutually exclusive.

> **Note:** Use `:any-link` to select an element independent of whether it has been visited or not.

Syntax

```
:link {
  /* ... */
}
```

Examples

By default, most browsers apply a special `color` value to visited links. Thus, the links in this example will probably have special font colors only before you visit them. (After that, you'll need to clear your browser history to see them again.) However, the `background-color` values are likely to remain, as most browsers do not set that property on visited links by default.

HTML

```
<a href="#ordinary-target">This is an ordinary link.</a><br />
<a href="">You've already visited this link.</a><br />
<a>Placeholder link (won't get styled)</a>
```

CSS

```
a:link {
  background-color: gold;
  color: green;
}
```

:local-link CSS pseudo-class

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`:local-link`** CSS pseudo-class represents a link to the same document. Therefore an element that is the source anchor of a hyperlink whose target's absolute URL matches the element's own document URL.

```
/* Selects any <a> that links to the current document */
a:local-link {
  color: green;
}
```

Syntax

```
:local-link {
  /* ... */
}
```

Examples

HTML

```
<a href="#target">This is a link on the current page.</a><br />
<a href="https://example.com">This is an external link</a><br />
```

CSS

```
a:local-link {
  color: green;
}
```

Result

Browser compatibility

Currently, no browsers support this feature.

:modal CSS pseudo-class

The **`:modal`** CSS pseudo-class matches an element that is in a state in which it excludes all interaction with elements outside it until the interaction has been dismissed. Multiple elements can be selected by the `:modal` pseudo-class at the same time, but only one of them will be active and able to receive input.

Try it

```
button {
  display: block;
  margin: auto;
  width: 10rem;
  height: 2rem;
}

:modal {
  background-color: beige;
  border: 2px solid burlywood;
  border-radius: 5px;
}

p {
  color: black;
}
```

```
<p>Would you like to see a new random number?</p>
<button id="showNumber">Show me</button>

<dialog id="favDialog">
  <form method="dialog">
    <p>Lucky number is: <strong id="number"></strong></p>
    <button>Close dialog</button>
  </form>
</dialog>
```

```
const showNumber = document.getElementById("showNumber");
const favDialog = document.getElementById("favDialog");
const number = document.getElementById("number");

showNumber.addEventListener("click", () => {
  number.innerText = Math.floor(Math.random() * 1000);
  favDialog.showModal();
});
```

Syntax

```
:modal {
  /* ... */
}
```

Usage notes

Examples of elements that will prevent user interaction with the rest of the page and will be selected by the `:modal` pseudo-class include:

- The `dialog` element opened with the `showModal()` API.
- The element selected by the `:fullscreen` pseudo-class when opened with the `requestFullscreen()` API.

Examples

Styling a modal dialog

This example styles a modal dialog that opens when the "Show the dialog" button is activated. This example is adapted from the `<dialog>` element example.

```
<!-- A modal dialog containing a form -->
<dialog id="favDialog">
  <form method="dialog">
    <p>
      <label>
        Favorite animal:
        <select>
          <option>Choose…</option>
          <option>Brine shrimp</option>
          <option>Red panda</option>
          <option>Spider monkey</option>
        </select>
      </label>
    </p>
    <div>
      <button>Cancel</button>
      <button>Confirm</button>
    </div>
  </form>
</dialog>
```

```
<p>
  <button id="showDialog">Show the dialog</button>
</p>
```

CSS

The `:modal` pseudo-class selects the dialog opened with `showModal()`, giving it a red border, a yellow background, and a box shadow.

```
:modal {
  border: 5px solid red;
  background-color: yellow;
  box-shadow: 3px 3px 10px rgb(0 0 0 / 50%);
}
```

```
const showButton = document.getElementById("showDialog");
const favDialog = document.getElementById("favDialog");

showButton.addEventListener("click", () => {
  favDialog.showModal();
});
```

Result

- `dialog` element
- Other element display state pseudo-classes: `:fullscreen` and `:picture-in-picture`
- Complete list of pseudo-classes

:muted CSS pseudo-class

The **`:muted`** CSS pseudo-class selector represents an element that is capable of making sound, such as `<audio>` or `<video>`, but is muted (forced silent).

Muted is different from `:volume-locked` in that the page author has control over whether a media element can be muted or un-muted. User agents may set media `muted` value according to use preferences (e.g., remembering the last set value across sessions, on a per-site basis, or otherwise). An element that is `:volume-locked` cannot be muted, un-muted, or have its volume changed via JavaScript because of an operating system or user agent preference.

Syntax

```
:muted {
  /* ... */
}
```

Examples

HTML

The `muted` attribute is added to the `<video>` element so that the sound is muted, this works the same for `<audio>` elements.

```
<!-- 'Big Buck Bunny' licensed under CC 3.0 by the Blender foundation. Hosted by archive.org -->
<!-- Poster from peach.blender.org -->
<video
  controls
  muted
  src="https://archive.org/download/BigBuckBunny_124/Content/big_buck_bunny_720p_surround.mp4"
  poster="https://peach.blender.org/wp-content/uploads/title_anouncement.jpg?x11217"
  width="620">
  Sorry, your browser doesn't support embedded videos, but don't worry, you can
  <a href="https://archive.org/details/BigBuckBunny_124">download it</a>
  and watch it with your favorite video player!
</video>
```

CSS

If the `<video>` element is `muted` then a red outline is drawn around it, when it is not muted then it has a green outline. Try toggling the mute icon in the controls to see the state change.

```
video {
  margin: 5px;
}
```

```
video:muted {
  outline: 5px solid red;
}

video:not(:muted) {
  outline: 5px solid green;
}
```

:not() CSS pseudo-class

The **`:not()`** CSS pseudo-class represents elements that do not match a list of selectors. Since it prevents specific items from being selected, it is known as the *negation pseudo-class*.

The `:not()` pseudo-class has a number of quirks, tricks, and unexpected results that you should be aware of before using it.

Try it

```
p:not(.irrelevant) {
  font-weight: bold;
}

p > strong,
p > b.important {
  color: crimson;
}

p > :not(strong, b.important) {
  color: darkmagenta;
}
```

```
<p>
  <b>Mars</b> is one of the most Earth-like planets. <b>Mars</b> day is almost
  the same as an Earth day, only <strong>37 minutes</strong> longer.
</p>

<p class="irrelevant">
  <b class="important">NASA</b>'s Jet <del>Momentum</del> Propulsion Laboratory
  is designing mission concepts to survive the <b>Venus</b> extreme temperatures
  and atmospheric pressure.
</p>
```

Syntax

```
:not(<complex-selector-list>) {
  /* ... */
}
```

Parameters

The `:not()` pseudo-class requires a selector list, a comma-separated list of one or more selectors, as its argument. The list must not contain a pseudo-element, but any other simple, compound, and complex selectors are allowed.

Description

There are several unusual effects and outcomes when using `:not()` that you should keep in mind when using it:

- Useless selectors can be written using this pseudo-class. For example, `:not(*)` matches any element which is not an element, which is obviously nonsense, so the accompanying rule will never be applied.
- This pseudo-class can increase the specificity of a rule. For example, `#foo:not(#bar)` will match the same element as the simpler `#foo`, but has the higher specificity of two `id` selectors.
- The specificity of the `:not()` pseudo-class is replaced by the specificity of the most specific selector in its comma-separated argument of selectors; providing the same specificity as if it had been written `:not(:is(argument))`.
- `:not(.foo)` will match anything that isn't `.foo`, *including* `<html>` *and* `<body>`.
- This selector will match everything that is "not an X". This may be surprising when used with descendant combinators, since there are multiple paths to select a target element. For instance, `body :not(table) a` will still apply to links inside a `<table>`, since `<tr>`, `<tbody>`, `<th>`, `<td>`, `<caption>`, etc. can all match the `:not(table)` part of the selector. To avoid this, you can use `body a:not(table a)` instead, which will only apply to links that are not descendants of a table.
- You can negate several selectors at the same time. Example: `:not(.foo, .bar)` is equivalent to `:not(.foo):not(.bar)`.
- If any selector passed to the `:not()` pseudo-class is invalid or not supported by the browser, the whole rule will be invalidated. The effective way to overcome this behavior is to use `:is()` pseudo-class, which accepts a forgiving selector list. For example `:not(.foo, :invalid-pseudo-class)` will invalidate a whole rule, but `:not(:is(.foo, :invalid-pseudo-class))` will match any (*including* `<html>` *and* `<body>`) element that isn't `.foo`.

Examples

Using :not() with valid selectors

This example shows a few ways of using `:not()`.

HTML

```
<p>I am a paragraph.</p>
<p class="fancy">I am so very fancy!</p>
<div>I am NOT a paragraph.</div>
<h2>
  <span class="foo">foo inside h2</span>
  <span class="bar">bar inside h2</span>
</h2>
```

CSS

```
.fancy {
  text-shadow: 2px 2px 3px gold;
}

/* <p> elements that don't have a class `.fancy` */
p:not(.fancy) {
  color: green;
}

/* Elements that are not <p> elements */
body :not(p) {
  text-decoration: underline;
}

/* Elements that are not <div>s or `.fancy` */
body :not(div):not(.fancy) {
  font-weight: bold;
}

/* Elements that are not <div>s or `.fancy` */
body :not(div, .fancy) {
  text-decoration: overline underline;
}

/* Elements inside an <h2> that aren't a <span> with a class of `.foo` */
h2 :not(span.foo) {
```

```
  color: red;
}
```

Result

Using :not() with invalid selectors

This example shows the use of `:not()` with invalid selectors and how to prevent invalidation.

HTML

```
<p class="foo">I am a paragraph with .foo</p>
<p class="bar">I am a paragraph with .bar</p>
<div>I am a div without a class</div>
<div class="foo">I am a div with .foo</div>
<div class="bar">I am a div with .bar</div>
<div class="foo bar">I am a div with .foo and .bar</div>
```

CSS

```
/* Invalid rule, does nothing */
p:not(.foo, :invalid-pseudo-class) {
  color: red;
  font-style: italic;
}

/* Select all <p> elements without the `foo` class */
p:not(:is(.foo, :invalid-pseudo-class)) {
  color: green;
  border-top: dotted thin currentColor;
}

/* Select all <div> elements without the `foo` or the `bar` class */
div:not(.foo, .bar) {
  color: red;
  font-style: italic;
}

/* Select all <div> elements without the `foo` or the `bar` class */
div:not(:is(.foo, .bar)) {
  border-bottom: dotted thin currentColor;
}
```

Result

The `p:not(.foo, :invalid-pseudo-class)` rule is invalid because it contains an invalid selector. The `:is()` pseudo-class accepts a forgiving selector list, so the `:is(.foo, :invalid-pseudo-class)` rule is valid and equivalent to `:is(.foo)`. Thus, the `p:not(:is(.foo, :invalid-pseudo-class))` rule is valid and equivalent to `p:not(.foo)`.

If `:invalid-pseudo-class` was a valid selector, the first two rules above would still be equivalent (the last two rules showcase that). The use of `:is()` makes the rule more robust.

:nth-child() CSS pseudo-class

The **`:nth-child()`** CSS pseudo-class matches elements based on the indexes of the elements in the child list of their parents. In other words, the `:nth-child()` selector selects child elements according to their position among all the sibling elements within a parent element.

Try it

```
p {
  font-weight: bold;
}

li:nth-child(-n + 3) {
  border: 2px solid orange;
  margin-bottom: 1px;
}

li:nth-child(even) {
  background-color: lightyellow;
}
```

```
<p>Track &amp;amp; field champions:</p>
<ul>
  <li>Adhemar da Silva</li>
  <li>Wang Junxia</li>
  <li>Wilma Rudolph</li>
  <li>Babe Didrikson-Zaharias</li>
  <li>Betty Cuthbert</li>
  <li>Fanny Blankers-Koen</li>
  <li>Florence Griffith-Joyner</li>
  <li>Irena Szewinska</li>
  <li>Jackie Joyner-Kersee</li>
  <li>Shirley Strickland</li>
  <li>Carl Lewis</li>
  <li>Emil Zatopek</li>
  <li>Haile Gebrselassie</li>
  <li>Jesse Owens</li>
  <li>Jim Thorpe</li>
```

```
  <li>Paavo Nurmi</li>
  <li>Sergei Bubka</li>
  <li>Usain Bolt</li>
</ul>
```

> **Note:** In the `element:nth-child()` syntax, the child count includes sibling children of any element type; but it is considered a match only if the element *at that child position* matches the other components of the selector.

Syntax

```
:nth-child([ <An+B> | even | odd ] [of <complex-selector-list>]?) {
  /* ... */
}
```

Parameters

`:nth-child()` takes a single argument that describes a pattern for matching element indices in a list of siblings. Element indices are 1-based.

Keyword values

`odd`

Represents elements whose numeric position in a series of siblings is odd: 1, 3, 5, etc.

`even`

Represents elements whose numeric position in a series of siblings is even: 2, 4, 6, etc.

Functional notation

`<An+B>`

Represents elements whose numeric position in a series of siblings matches the pattern `An+B`, for every positive integer or zero value of `n`, where:

- `A` is an integer step size,
- `B` is an integer offset,
- `n` is all non-negative integers, starting from 0.

It can be read as the `An+B`-th element of a list. The `A` and `B` must both have `<integer>` values.

The `of <selector>` syntax

By passing a selector argument, we can select the **nth** element that matches that selector. For example, the following selector matches the first three list items which have a `class="important"` set.

```
:nth-child(-n + 3 of li.important) {
}
```

This is different from moving the selector outside of the function, like:

```
li.important:nth-child(-n + 3) {
}
```

This selector selects list items if they are among the first three children and match the selector `li.important`.

Examples

Example selectors

`tr:nth-child(odd)` or `tr:nth-child(2n+1)`

Represents the odd rows of an HTML table: 1, 3, 5, etc.

`tr:nth-child(even)` or `tr:nth-child(2n)`

Represents the even rows of an HTML table: 2, 4, 6, etc.

`:nth-child(7)`

Represents the seventh element.

`:nth-child(5n)`

Represents elements **5** [=5×1], **10** [=5×2], **15** [=5×3], **etc.** The first one to be returned as a result of the formula is **0** [=5x0], resulting in a no-match, since the elements are indexed from 1, whereas `n` starts from 0. This may seem weird at first, but it makes more sense when the `B` part of the formula is `>0`, like in the next example.

`:nth-child(n+7)`

Represents the seventh and all following elements: **7** [=0+7], **8** [=1+7], **9** [=2+7], **etc.**

`:nth-child(3n+4)`

Represents elements **4** [=(3×0)+4], **7** [=(3×1)+4], **10** [=(3×2)+4], **13** [=(3×3)+4], **etc.**

`:nth-child(-n+3)`

Represents the first three elements. [=-0+3, -1+3, -2+3]

`p:nth-child(n)`

Represents every `<p>` element in a group of siblings. This selects the same elements as a simple `p` selector (although with a higher specificity).

`p:nth-child(1)` or `p:nth-child(0n+1)`

Represents every `<p>` that is the first element in a group of siblings. This is the same as the `:first-child` selector (and has the same specificity).

`p:nth-child(n+8):nth-child(-n+15)`

Represents the eighth through the fifteenth `<p>` elements of a group of siblings.

Detailed example

HTML

```
<h3>
  <code>span:nth-child(2n+1)</code>, WITHOUT an <code>&lt;em&gt;</code> among
  the child elements.
</h3>
<p>Children 1, 3, 5, and 7 are selected.</p>
<div class="first">
  <span>Span 1!</span>
  <span>Span 2</span>
  <span>Span 3!</span>
  <span>Span 4</span>
  <span>Span 5!</span>
  <span>Span 6</span>
  <span>Span 7!</span>
</div>

<br />

<h3>
  <code>span:nth-child(2n+1)</code>, WITH an <code>&lt;em&gt;</code> among the
  child elements.
</h3>
<p>
  Children 1, 5, and 7 are selected.<br />
  3 is used in the counting because it is a child, but it isn't selected because
  it isn't a <code>&lt;span&gt;</code>.
</p>
<div class="second">
  <span>Span!</span>
  <span>Span</span>
  <em>This is an `em`.</em>
  <span>Span</span>
  <span>Span!</span>
  <span>Span</span>
  <span>Span!</span>
  <span>Span</span>
</div>

<br />

<h3>
  <code>span:nth-of-type(2n+1)</code>, WITH an <code>&lt;em&gt;</code> among the
  child elements.
</h3>
<p>
  Children 1, 4, 6, and 8 are selected.<br />
  3 isn't used in the counting or selected because it is an
  <code>&lt;em&gt;</code>, not a <code>&lt;span&gt;</code>, and
  <code>nth-of-type</code> only selects children of that type. The
  <code>&lt;em&gt;</code> is completely skipped over and ignored.
</p>
<div class="third">
  <span>Span!</span>
  <span>Span</span>
  <em>This is an `em`.</em>
  <span>Span!</span>
  <span>Span</span>
  <span>Span!</span>
  <span>Span</span>
  <span>Span!</span>
</div>
```

CSS

```
* {
  font-family: sans-serif;
}

span,
div em {
  padding: 5px;
  border: 1px solid tomato;
  display: inline-block;
  margin-bottom: 3px;
}
```

```
.first span:nth-child(2n + 1),
.second span:nth-child(2n + 1),
.third span:nth-of-type(2n + 1) {
  background-color: tomato;
}
```

Result

Using 'of <selector>'

In this example there is an unordered list of names, some of them have been marked as **noted** using `class="noted"`. These have been highlighted with a thick bottom border.

HTML

```
<ul>
  <li class="noted">Diego</li>
  <li>Shilpa</li>
  <li class="noted">Caterina</li>
  <li>Jayla</li>
  <li>Tyrone</li>
  <li>Ricardo</li>
  <li class="noted">Gila</li>
  <li>Sienna</li>
```

```
  <li>Titilayo</li>
  <li class="noted">Lexi</li>
  <li>Aylin</li>
  <li>Leo</li>
  <li>Leyla</li>
  <li class="noted">Bruce</li>
  <li>Aisha</li>
  <li>Veronica</li>
  <li class="noted">Kyouko</li>
  <li>Shireen</li>
  <li>Tanya</li>
  <li class="noted">Marlene</li>
</ul>
```

CSS

```
* {
  font-family: sans-serif;
}

ul {
  display: flex;
  flex-wrap: wrap;
  list-style: none;
  font-size: 1.2rem;
  padding-left: 0;
}

li {
  margin: 0.125rem;
  padding: 0.25rem;
}

li {
  border: 1px solid tomato;
}

.noted {
  border-bottom: 5px solid tomato;
}
```

In the following CSS we are targeting the **even** list items that are marked with `class="noted"`.

```
li:nth-child(even of .noted) {
  background-color: tomato;
  border-bottom-color: seagreen;
}
```

Result

Items with `class="noted"` have a thick bottom border and items 3, 10 and 17 have a solid background as they are the *even* list items with `class="noted"`.

of selector syntax vs selector nth-child

In this example, there are two unordered lists of names. The first list shows the effect of `li:nth-child(-n + 3 of .noted)` and the second list shows the effect of `li.noted:nth-child(-n + 3)`.

HTML

```
<ul class="one">
  <li class="noted">Diego</li>
  <li>Shilpa</li>
  <li class="noted">Caterina</li>
  <li>Jayla</li>
  <li>Tyrone</li>
  <li>Ricardo</li>
  <li class="noted">Gila</li>
  <li>Sienna</li>
  <li>Titilayo</li>
  <li class="noted">Lexi</li>
</ul>
<ul class="two">
  <li class="noted">Diego</li>
  <li>Shilpa</li>
  <li class="noted">Caterina</li>
  <li>Jayla</li>
  <li>Tyrone</li>
  <li>Ricardo</li>
  <li class="noted">Gila</li>
  <li>Sienna</li>
  <li>Titilayo</li>
  <li class="noted">Lexi</li>
</ul>
```

CSS

```
* {
  font-family: sans-serif;
}

ul {
  display: flex;
  flex-wrap: wrap;
  list-style: none;
  font-size: 1.2rem;
  padding-left: 0;
}

li {
  margin: 0.125rem;
  padding: 0.25rem;
}
```

```
li {
  border: 1px solid tomato;
}

.noted {
  border-bottom: 5px solid tomato;
}
```

```
ul.one > li:nth-child(-n + 3 of .noted) {
  background-color: tomato;
  border-bottom-color: seagreen;
}

ul.two > li.noted:nth-child(-n + 3) {
  background-color: tomato;
  border-bottom-color: seagreen;
}
```

Result

The first case applies a style to the first three list items with `class="noted"` whether or not they are the first three items in the list.

The second case applies a style to the items with `class="noted"` if they are within the first 3 items in the list.

Using of selector to fix striped tables

A common practice for tables is to use *zebra-stripes* which alternates between light and dark background colors for rows, making tables easier to read and more accessible. If a row is hidden, the stripes will appear merged and alter the desired effect. In this example, you can see two tables with a `hidden` row. The second table handles hidden rows using `of :not([hidden])`.

HTML

```
<table class="broken">
  <thead>
    <tr><th>Name</th><th>Age</th><th>Country</th></tr>
  </thead>
  <tbody>
    <tr><td>Mamitiana</td><td>23</td><td>Madagascar</td></tr>
    <tr><td>Yuki</td><td>48</td><td>Japan</td></tr>
    <tr hidden><td>Tlayolotl</td><td>36</td><td>Mexico</td></tr>
    <tr><td>Adilah</td><td>27</td><td>Morocco</td></tr>
    <tr><td>Vieno</td><td>55</td><td>Finland</td></tr>
    <tr><td>Ricardo</td><td>66</td><td>Brazil</td></tr>
  </tbody>
</table>
<table class="fixed">
  <thead>
    <tr><th>Name</th><th>Age</th><th>Country</th></tr>
  </thead>
  <tbody>
    <tr><td>Mamitiana</td><td>23</td><td>Madagascar</td></tr>
    <tr><td>Yuki</td><td>48</td><td>Japan</td></tr>
    <tr hidden><td>Tlayolotl</td><td>36</td><td>Mexico</td></tr>
    <tr><td>Adilah</td><td>27</td><td>Morocco</td></tr>
    <tr><td>Vieno</td><td>55</td><td>Finland</td></tr>
    <tr><td>Ricardo</td><td>66</td><td>Brazil</td></tr>
  </tbody>
</table>
```

CSS

```
body {
  display: flex;
  justify-content: space-around;
}
td {
  padding: 0.125rem 0.5rem;
}
```

```
.broken > tbody > tr:nth-child(even) {
  background-color: silver;
}
```

```
.fixed > tbody > tr:nth-child(even of :not([hidden])) {
  background-color: silver;
}
```

Result

In the first table this is just using `:nth-child(even)` the third row has the `hidden` attribute applied to it. So in this instance the 3rd row is not visible and the 2nd & 4th rows are counted as even, which technically they are but visually they are not.

In the second table the *of syntax* is used to target only the `tr`s that are **not** hidden using `:nth-child(even of :not([hidden]))`.

Styling a table column

To style a table column, you can't set the style on the `<col>` element as table cells are not children of it (as you can with the row element, `<tr>`). Pseudo-classes like `:nth-child()` are handy to select the column cells.

In this example, we set different styles for each of the column.

HTML

```
<table>
<caption>Student roster</caption>
<colgroup>
  <col/>
  <col/>
  <col/>
</colgroup>
  <thead>
```

```
    <tr><th>Name</th><th>Age</th><th>Country</th></tr>
  </thead>
  <tbody>
    <tr><td>Mamitiana</td><td>23</td><td>Madagascar</td></tr>
    <tr><td>Yuki</td><td>48</td><td>Japan</td></tr>
  </tbody>
</table>
```

CSS

```
td {
  padding: 0.125rem 0.5rem;
  height: 3rem;
  border: 1px solid black;
}

tr :nth-child(1) {
  text-align: left;
  vertical-align: bottom;
  background-color: silver;
}

tbody tr :nth-child(2) {
  text-align: center;
  vertical-align: middle;
}

tbody tr :nth-child(3) {
  text-align: right;
  vertical-align: top;
  background-color: tomato;
}
```

:nth-last-child() CSS pseudo-class

The **`:nth-last-child()`** CSS pseudo-class matches elements based on their position among a group of siblings, counting from the end.

Try it

```
p {
  font-weight: bold;
}

li:nth-last-child(-n + 3) {
  border: 2px solid orange;
  margin-top: 1px;
}

li:nth-last-child(even) {
  background-color: lightyellow;
}
```

```
<p>Eight deadliest wildfires:</p>
<ol reversed>
  <li>Matheson Fire</li>
  <li>Miramichi Fire</li>
  <li>1997 Indonesian fires</li>
  <li>Thumb Fire</li>
  <li>Great Hinckley Fire</li>
  <li>Cloquet Fire</li>
  <li>Kursha-2 Fire</li>
  <li>Peshtigo Fire</li>
</ol>
```

Syntax

```
:nth-last-child(<nth> [of <complex-selector-list>]?) {
  /* ... */
}
```

Parameters

The `:nth-last-child()` pseudo-class is specified with a single argument, which represents the pattern for matching elements, counting from the end.

Keyword values

`odd`

Represents elements whose numeric position in a series of siblings is odd: 1, 3, 5, etc., counting from the end.

`even`

Represents elements whose numeric position in a series of siblings is even: 2, 4, 6, etc., counting from the end.

Functional notation

`<An+B>`

Represents elements whose numeric position in a series of siblings matches the pattern `An+B`, for every positive integer or zero value of `n`, where:

- `A` is an integer step size,
- `B` is an integer offset,
- `n` is all non-negative integers, starting from 0.

It can be read as the `An+B`-th element of a list. The index of the first element, counting from the end, is `1`. The `A` and `B` must both have `<integer>` values.

The `of <selector>` syntax

By passing a selector argument, we can select the **nth-last** element that matches that selector. For example, the following selector matches the last three *important* list items, which are assigned with `class="important"`.

```
:nth-last-child(-n + 3 of li.important) {
}
```

> **Note:** This is different from moving the selector outside of the function, like:

```
li.important:nth-last-child(-n + 3) {
}
```

This selector applies a style to list items if they are also within the last three children.

Examples

Example selectors

`tr:nth-last-child(odd)` or `tr:nth-last-child(2n+1)`

Represents the odd rows of an HTML table: 1, 3, 5, etc., counting from the end.

`tr:nth-last-child(even)` or `tr:nth-last-child(2n)`

Represents the even rows of an HTML table: 2, 4, 6, etc., counting from the end.

`:nth-last-child(7)`

Represents the seventh element, counting from the end.

`:nth-last-child(5n)`

Represents elements 5, 10, 15, etc., counting from the end.

`:nth-last-child(3n+4)`

Represents elements 4, 7, 10, 13, etc., counting from the end.

`:nth-last-child(-n+3)`

Represents the last three elements among a group of siblings.

`p:nth-last-child(n)` or `p:nth-last-child(n+1)`

Represents every `<p>` element among a group of siblings. This is the same as a simple `p` selector. (Since `n` starts at zero, while the last element begins at one, `n` and `n+1` will both select the same elements.)

`p:nth-last-child(1)` or `p:nth-last-child(0n+1)`

Represents every `<p>` that is the first element among a group of siblings, counting from the end. This is the same as the `:last-child` selector.

Table example

HTML

```
<table>
  <tbody>
    <tr>
      <td>First line</td>
    </tr>
    <tr>
      <td>Second line</td>
    </tr>
    <tr>
      <td>Third line</td>
    </tr>
    <tr>
      <td>Fourth line</td>
    </tr>
    <tr>
      <td>Fifth line</td>
    </tr>
  </tbody>
</table>
```

CSS

```
table {
  border: 1px solid blue;
}

/* Selects the last three elements */
tr:nth-last-child(-n + 3) {
  background-color: pink;
}

/* Selects every element starting from the second to last item */
tr:nth-last-child(n + 2) {
  color: blue;
}

/* Select only the last second element */
tr:nth-last-child(2) {
```

```
  font-weight: 600;
}
```

Result

Quantity query

A *quantity query* styles elements depending on how many of them there are. In this example, list items turn red when there are at least three of them in a given list. This is accomplished by combining the capabilities of the `nth-last-child` pseudo-class and the subsequent-sibling combinator.

HTML

```
<h4>A list of four items (styled):</h4>
<ol>
  <li>One</li>
  <li>Two</li>
  <li>Three</li>
  <li>Four</li>
</ol>

<h4>A list of two items (unstyled):</h4>
<ol>
  <li>One</li>
  <li>Two</li>
</ol>
```

CSS

```
/* If there are at least three list items,
   style them all */
li:nth-last-child(n + 3),
li:nth-last-child(3) ~ li {
  color: red;
}
```

Result

<code>of <selector></code> syntax example

In this example, there is an unordered list of names. Some items have a `noted` class applied and are then highlighted with a thick bottom border.

HTML

```
<ul>
  <li class="noted">Diego</li>
  <li>Shilpa</li>
  <li class="noted">Caterina</li>
  <li>Jayla</li>
  <li>Tyrone</li>
  <li>Ricardo</li>
  <li class="noted">Gila</li>
  <li>Sienna</li>
  <li>Titilayo</li>
  <li class="noted">Lexi</li>
  <li>Aylin</li>
  <li>Leo</li>
  <li>Leyla</li>
  <li class="noted">Bruce</li>
  <li>Aisha</li>
  <li>Veronica</li>
  <li class="noted">Kyouko</li>
  <li>Shireen</li>
  <li>Tanya</li>
  <li class="noted">Marlene</li>
</ul>
```

CSS

```
* {
  font-family: sans-serif;
}

ul {
  display: flex;
  flex-wrap: wrap;
  list-style: none;
  font-size: 1.2rem;
  padding-left: 0;
}

li {
  margin: 0.125rem;
  padding: 0.25rem;
  border: 1px solid tomato;
}

.noted {
  border-bottom: 5px solid tomato;
}
```

In the following CSS we are targeting the **odd** list items that are marked with `class="noted"`.

```
li:nth-last-child(odd of .noted) {
  background-color: tomato;
  border-bottom-color: seagreen;
}
```

Result

Items with `class="noted"` have a thick bottom border and items 1, 7, 14, and 20 have a solid background as they are the *odd* list items with `class="noted"`.

:nth-last-of-type() CSS pseudo-class

The **`:nth-last-of-type()`** CSS pseudo-class matches elements based on their position among siblings of the same type (tag name), counting from the end.

Try it

```
dt {
  font-weight: bold;
}

dd {
  margin: 3px;
}

dd:nth-last-of-type(3n) {
  border: 2px solid orange;
}
```

```
<dl>
  <dt>Vegetables:</dt>
  <dd>1. Tomatoes</dd>
  <dd>2. Cucumbers</dd>
  <dd>3. Mushrooms</dd>
  <dt>Fruits:</dt>
  <dd>4. Apples</dd>
  <dd>5. Mangos</dd>
  <dd>6. Pears</dd>
  <dd>7. Oranges</dd>
</dl>
```

Syntax

```
:nth-last-of-type(<An+B> | even | odd) {
  /* ... */
}
```

Parameters

The `:nth-last-of-type()` pseudo-class is specified with a single argument, which represents the pattern for matching elements, counting from the end.

See `:nth-last-child` for a more detailed explanation of its syntax.

Examples

HTML

```
<div>
  <span>This is a span.</span>
  <span>This is another span.</span>
  <em>This is emphasized.</em>
  <span>Wow, this span gets limed!!!</span>
  <del>This is struck through.</del>
  <span>Here is one last span.</span>
</div>
```

CSS

```
span:nth-last-of-type(2) {
  background-color: lime;
}
```

Result

- `:nth-last-child`, `:nth-of-type`

:nth-of-type() CSS pseudo-class

The **`:nth-of-type()`** CSS pseudo-class matches elements based on their position among siblings of the same type (tag name).

Try it

```
dt {
  font-weight: bold;
}

dd {
  margin: 3px;
}

dd:nth-of-type(even) {
  border: 2px solid orange;
}
```

```
<dl>
  <dt>Vegetables:</dt>
  <dd>1. Tomatoes</dd>
  <dd>2. Cucumbers</dd>
  <dd>3. Mushrooms</dd>
  <dt>Fruits:</dt>
  <dd>4. Apples</dd>
  <dd>5. Mangos</dd>
```

```
  <dd>6. Pears</dd>
  <dd>7. Oranges</dd>
</dl>
```

Syntax

```
:nth-of-type(<An+B> | even | odd) {
  /* ... */
}
```

Parameters

The `:nth-of-type()` pseudo-class is specified with a single argument, which represents the pattern for matching elements.

See `:nth-child` for a more detailed explanation of its syntax.

Examples

Basic example

HTML

```
<div>
  <div>This element isn't counted.</div>
  <p>1st paragraph.</p>
  <p class="fancy">2nd paragraph.</p>
  <div>This element isn't counted.</div>
  <p class="fancy">3rd paragraph.</p>
  <p>4th paragraph.</p>
</div>
```

CSS

```
/* Odd paragraphs */
p:nth-of-type(2n + 1) {
  color: red;
}

/* Even paragraphs */
p:nth-of-type(2n) {
  color: blue;
}

/* First paragraph */
p:nth-of-type(1) {
  font-weight: bold;
}

/* This will match the 3rd paragraph as it will match elements which are 2n+1 AND have a class of fancy.
The second paragraph has a class of fancy but is not matched as it is not :nth-of-type(2n+1) */
p.fancy:nth-of-type(2n + 1) {
  text-decoration: underline;
}
```

Result

> **Note:** There is no way to select the "nth-of-class" using this selector. The `:nth-of-type` selector looks at the type only when creating the list of matches. You can however use the `:nth-of-child` selector `of` syntax to achieve an "nth-of-class" behavior. You can also apply CSS to an element based on `:nth-of-type` location **and** a class, as shown in the previous example.

:only-child CSS pseudo-class

The **`:only-child`** CSS pseudo-class represents an element without any siblings. This is the same as `:first-child:last-child` or `:nth-child(1):nth-last-child(1)`, but with a lower specificity.

Try it

```
li:only-child {
  color: fuchsia;
}

b:only-child {
  text-decoration: underline;
}
```

```
<p>Stars expected to attend:</p>
<ol>
  <li>Robert Downey, Jr.</li>
</ol>

<p>Stars yet to confirm:</p>
<ol>
  <li>Scarlett Johansson</li>
  <li>Samuel L. Jackson</li>
  <li>Chris Pratt</li>
</ol>

<p>The ceremony is going to be held in <b>The Dolby Theatre</b>.</p>
```

Syntax

```
:only-child {
  /* ... */
}
```

Examples

Basic example

HTML

```
<div>
  <div>I am an only child.</div>
</div>

<div>
  <div>I am the 1st sibling.</div>
  <div>I am the 2nd sibling.</div>
  <div>
    I am the 3rd sibling,
    <div>but this is an only child.</div>
  </div>
</div>
```

CSS

```
div:only-child {
  color: red;
}

div {
  display: inline-block;
  margin: 6px;
  outline: 1px solid;
}
```

Result

A list example

HTML

```
<ol>
  <li>
    First
    <ul>
      <li>This list has just one element.</li>
    </ul>
  </li>
  <li>
    Second
    <ul>
      <li>This list has three elements.</li>
      <li>This list has three elements.</li>
      <li>This list has three elements.</li>
    </ul>
  </li>
</ol>
```

CSS

```
li li {
  list-style-type: disc;
}

li:only-child {
  color: red;
  list-style-type: square;
}
```

Result

:open CSS pseudo-class

The **`:open`** CSS pseudo-class represents an element that has open and closed states, only when it is currently in the open state.

Syntax

```
:open {
  /* ... */
}
```

Description

The `:open` pseudo-class selects any element currently in the open state, which includes the following elements:

- `<details>` and `<dialog>` elements that are in an open state, that is, they have the `open` attribute set. This selection can also be done using an attribute selector: `details[open]`.
- `<input>` elements that display a picker interface for the user to choose a value from (for example `<input type="color">`), when the picker is displayed.
- `<select>` elements that display a drop-down picker for the user to choose a value from, when the picker is displayed. Note that when implementing customizable select elements, the picker itself can be selected using the `::picker(select)` pseudo-element.

Note that the open and closed states are semantic states, and don't necessary correlate with the visibility of the element in question. For example, a `<details>` element that is expanded to show its content is open, and will be selected by the `details:open` selector, even if it is hidden with a `visibility` value of `hidden`.

Popover elements (that is, elements with the `popover` attribute set on them) have distinct semantic states representing popovers that are showing or hidden, which can coexist alongside open and closed states. To target a popover element in a showing state, use the `:popover-open` pseudo-class instead.

Examples

Basic <code>:open</code> usage

This example demonstrates some of the HTML elements that have an open state.

CSS

```
details:open > summary {
  background-color: pink;
}

:is(select, input):open {
  background-color: pink;
}
```

```
@supports not selector(:open) {
  body::before {
    content: "Your browser doesn't support the :open selector.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

HTML

```
<details>
  <summary>Details</summary>
  Lorem ipsum dolor sit amet, consectetur adipiscing elit. In pulvinar dapibus
  lacus, sit amet finibus lectus mollis eu. Nullam quis orci dictum, porta lacus
  et, cursus nunc. Aenean pulvinar imperdiet neque fermentum facilisis. Nulla
  facilisi. Curabitur vitae sapien ut nunc pulvinar semper vitae vitae nisi.
</details>
<hr />

<label for="pet-select">Choose a pet:</label>
<select id="pet-select">
  <option value="dog">Dog</option>
  <option value="cat">Cat</option>
  <option value="hamster">Hamster</option>
</select>
<hr />

<label for="start">Start date:</label>
<input type="date" id="start" />
```

Result

Custom <code><select></code> styling with <code>:open</code>

In this example, we give a basic `<select>` element some custom styling. The `:open` pseudo-class is used to apply a styling enhancement to its open state — when the dropdown menu is displayed.

HTML

There is nothing special about our fruit selector.

```
<label>
  Choose your favorite fruit:
  <select name="fruit">
    <option>apple</option>
    <option>banana</option>
    <option>boysenberry</option>
    <option>cranberry</option>
    <option>fig</option>
    <option>grapefruit</option>
    <option>lemon</option>
    <option>orange</option>
    <option>papaya</option>
    <option>pomegranate</option>
    <option>tomato</option>
  </select>
</label>
```

> **Note:** We are not using a multi-line `<select>` (that is, one with the `multiple` attribute set) — those tend to render as a scrolling list box rather than a dropdown menu, so don't have an open state.

CSS

In the CSS, we set an `appearance` value of `none` on our `<select>` element to remove the default OS styling from the select box, and provide some basic styles of or own. Most notably, we set an SVG background image of a down arrow on the right-hand side — users tend to recognize `<select>` elements by the down arrow, so it is a good idea to include it.

We then set some `padding` on the surrounding `<label>` element, and a transparent border to keep the layout consistent when we later add a colored border to it.

```
select {
  appearance: none;
  width: 100%;
  display: block;
  font-family: inherit;
  font-size: 100%;
  padding: 5px;
  border: 1px solid black;
  background: url("data:image/svg+xml,%3Csvg width='20' height='20' viewBox='0 0 20 20' xmlns='http://www.w3.org/2000/svg'%3E%3Cpolygon points='5,5 15,5 10,15'/%3E%3C/svg%3E")
    no-repeat right 3px center / 1em 1em;
}

label {
  font-family: sans-serif;
  max-width: 20em;
  display: block;
  padding: 20px;
  border: 2px solid transparent;
}
```

When the `<select>` is opened, we use the `:open` pseudo-class to set a different background color and change the background image to an up arrow. We also set a different background color and border on the enclosing `<label>` element using a combination of the `:open` and `:has()` pseudo-classes to create a parent selector. We are literally saying "select the `<label>`, but only when its descendant `<select>` is open."

```
select:open {
  background-color: #f8f2dc;
  background-image: url("data:image/svg+xml,%3Csvg width='20' height='20' viewBox='0 0 20 20' xmlns='http://www.w3.org/2000/svg'%3E%3Cpolygon points='5,15 10,5 15,15'/%3E%3C/svg%3E");
}

label:has(select:open) {
  background-color: #81adc8;
  border-color: #cd4631;
}
```

Result

The result is as follows. Try opening the `<select>` dropdown to see the effect on the styling:

- `<details>`, `<dialog>`, `<select>`, and `<input>` elements

- `:popover-open` pseudo-class
- `:modal`

:optional CSS pseudo-class

The **`:optional`** CSS pseudo-class represents any `<input>`, `<select>`, or `<textarea>` element that does not have the `required` attribute set on it.

Try it

```
label {
  display: block;
  margin-top: 0.5em;
}

fieldset {
  margin-top: 0.5em;
}

*:optional {
  background-color: palegreen;
}
```

```
<label for="name">Name (required):</label>
<input id="name" name="name" type="text" required />

<label for="birth">Date of birth:</label>
<input id="birth" name="birth" type="date" />

<label for="origin">How did you find out about us? (required)</label>
<select id="origin" name="origin" required>
  <option value="">Choose an option</option>
  <option value="google">Google</option>
  <option value="facebook">Facebook</option>
  <option value="advertisement">Advertisement</option>
</select>

<fieldset>
  <legend>Preferred contact method:</legend>
  <label>
    <input name="contact" type="radio" value="email" checked /> Email
  </label>
  <label><input name="contact" type="radio" value="phone" /> Phone</label>
</fieldset>

<label>
  <input name="newsletter" type="checkbox" checked /> I want to subscribe to a
  personalized newsletter.
</label>
<label>
  <input name="privacy" type="checkbox" required /> I have read and I agree to
  the Privacy Policy (required).
</label>
```

This pseudo-class is useful for styling fields that are not required to submit a form.

> **Note:** The `:required` pseudo-class selects *required* form fields.

Syntax

```
:optional {
  /* ... */
}
```

Accessibility

If a form contains optional `<input>`s, required inputs should be indicated using the `required` attribute. This will ensure that people navigating with the aid of assistive technology such as a screen reader will be able to understand which inputs need valid content to ensure a successful form submission.

Required inputs should also be indicated visually, using a treatment that does not rely solely on color to convey meaning. Typically, descriptive text and/or an icon are used.

- MDN Understanding WCAG, Guideline 3.3 explanations
- Understanding Success Criterion 3.3.2 | W3C Understanding WCAG 2.0

Examples

The optional field has a purple border

HTML

```
<form>
  <div class="field">
    <label for="url_input">Enter a URL:</label>
    <input type="url" id="url_input" />
  </div>

  <div class="field">
    <label for="email_input">Enter an email address:</label>
    <input type="email" id="email_input" required />
  </div>
</form>
```

CSS

```
label {
  display: block;
  margin: 1px;
  padding: 1px;
}
```

```
.field {
  margin: 1px;
  padding: 1px;
}

input:optional {
  border-color: rebeccapurple;
  border-width: 3px;
}
```

Result

See also

- Other validation-related pseudo-classes: `:required`, `:invalid`, `:valid`
- Form data validation

:out-of-range CSS pseudo-class

The **`:out-of-range`** CSS pseudo-class represents an `<input>` element whose current value is outside the range limits specified by the `min` and `max` attributes.

Try it

```
label {
  display: block;
  margin-top: 1em;
}

input:out-of-range {
  background-color: orangered;
}
```

```
<label for="amount">How many tickets? (You can buy 2-6 tickets)</label>
<input id="amount" name="amount" type="number" min="2" max="6" value="4" />

<label for="dep">Departure Date: (Whole year 2022 is acceptable)</label>
<input
  id="dep"
  name="dep"
  type="date"
  min="2022-01-01"
  max="2022-12-31"
  value="2025-05-05" />

<label for="ret">Return Date: (Whole year 2022 is acceptable)</label>
<input id="ret" name="ret" type="date" min="2022-01-01" max="2022-12-31" />
```

This pseudo-class is useful for giving the user a visual indication that a field's current value is outside the permitted limits.

> **Note:** This pseudo-class only applies to elements that have (and can take) a range limitation. In the absence of such a limitation, the element can neither be "in-range" nor "out-of-range."

Syntax

```
:out-of-range {
  /* ... */
}
```

Examples

HTML

```
<p>Values between 1 and 10 are valid.</p>
<ul>
  <li>
    <input
      id="value1"
      name="value1"
      type="number"
      placeholder="1 to 10"
      min="1"
      max="10"
      value="12" />
    <label for="value1">Your value is </label>
  </li>
</ul>
```

CSS

```
li {
  list-style: none;
  margin-bottom: 1em;
}

input {
  border: 1px solid black;
}

input:in-range {
  background-color: rgb(0 255 0 / 25%);
}

input:out-of-range {
  background-color: rgb(255 0 0 / 25%);
  border: 2px solid red;
}

input:in-range + label::after {
```

```
  content: "okay.";
}

input:out-of-range + label::after {
  content: "out of range!";
}
```

Result

See also

- `:in-range`
- Form data validation

:past CSS pseudo-class

The **`:past`** CSS pseudo-class selector is a time-dimensional pseudo-class that will match for any element which appears entirely before an element that matches `:current`. For example in a video with captions which are being displayed by WebVTT.

```
:past(p, span) {
  display: none;
}
```

Syntax

```
:past {
  /* ... */
}
```

Examples

CSS

```
:past(p, span) {
  display: none;
}
```

HTML

```
<video controls preload="metadata">
  <source src="video.mp4" type="video/mp4" />
  <source src="video.webm" type="video/webm" />
  <track
    label="English"
    kind="subtitles"
    srclang="en"
    src="subtitles.vtt"
    default />
</video>
```

WebVTT

```
WEBVTT FILE

1
00:00:03.500 --> 00:00:05.000
This is the first caption

2
00:00:06.000 --> 00:00:09.000
This is the second caption

3
00:00:11.000 --> 00:00:19.000
This is the third caption
```

See also

- Web Video Text Tracks Format (WebVTT)
- `:current`
- `:future`

:paused CSS pseudo-class

The **`:paused`** CSS pseudo-class selector represents an element that is playable, such as `<audio>` or `<video>`, when that element is "paused" (i.e., not "playing").

A resource is paused if the user explicitly paused it, or if it is in a non-activated or other non-playing state, like "loaded, hasn't been activated yet". This is different from `:buffering` or `:stalled`, which are states that occur while the resource is considered "playing".

Syntax

```
:paused {
  /* ... */
}
```

Examples

CSS

```
:paused {
  border: 5px solid orange;
}
```

See also

- `:buffering`
- `:muted`

- `:playing`
- `:seeking`
- `:stalled`
- `:volume-locked`
- CSS selectors

:picture-in-picture CSS pseudo-class

The **`:picture-in-picture`** CSS pseudo-class matches the element which is currently in picture-in-picture mode.

Syntax

```
:picture-in-picture {
  /* ... */
}
```

Usage notes

The `:picture-in-picture` pseudo-class lets you configure your stylesheets to automatically adjust the size, style, or layout of content when a video switches back and forth between picture-in-picture and traditional presentation modes.

Examples

In this example, a video has a box shadow when it is displayed in the floating window.

HTML

The page's HTML looks like this:

```
<h1>MDN Web Docs Demo: :picture-in-picture pseudo-class</h1>

<p>
  This demo uses the <code>:picture-in-picture</code> pseudo-class to
  automatically change the style of a video entirely using CSS.
</p>

<video id="pip-video"></video>
```

The `<video>` with the ID `"pip-video"` will change between having a red box shadow or not, depending on whether or not it is displayed in the picture-in-picture floating window.

CSS

The magic happens in the CSS.

```
:picture-in-picture {
  box-shadow: 0 0 0 5px red;
}
```

See also

- Picture-in-picture API
- `HTMLVideoElement.requestPictureInPicture()`
- `HTMLVideoElement.disablePictureInPicture`
- `Document.pictureInPictureEnabled`
- `Document.exitPictureInPicture()`
- `Document.pictureInPictureElement`

:placeholder-shown CSS pseudo-class

The **`:placeholder-shown`** CSS pseudo-class represents any `<input>` or `<textarea>` element that is currently displaying placeholder text.

Try it

```
label {
  display: block;
  margin-top: 1em;
}

input:placeholder-shown {
  background-color: ivory;
  border: 2px solid darkorange;
  border-radius: 5px;
}
```

```
<label for="name">Full Name:</label>
<input id="name" name="name" type="text" />

<label for="email">Email Address:</label>
<input id="email" name="email" type="email" placeholder="name@example.com" />

<label for="age">Your age:</label>
<input
  id="age"
  name="age"
  type="number"
  value="18"
  placeholder="You must be 18+" />
```

Syntax

```
:placeholder-shown {
  /* ... */
}
```

Examples

Basic example

This example applies special font and border styles when the placeholder is shown.

HTML

```
<input placeholder="Type something here!" />
```

CSS

```
input {
  border: 1px solid black;
  padding: 3px;
}

input:placeholder-shown {
  border-color: teal;
  color: purple;
  font-style: italic;
}
```

Result

Overflowing text

When form fields are too small, placeholder text can get cropped in an undesirable way. You can use the `text-overflow` property to alter the way overflowing text is displayed.

HTML

```
<input id="input1" placeholder="Name, Rank, and Serial Number" /> <br /><br />
<input id="input2" placeholder="Name, Rank, and Serial Number" />
```

CSS

```
#input2:placeholder-shown {
  text-overflow: ellipsis;
}
```

Result

Customized input field

The following example highlights the Student ID field with a custom style.

HTML

```
<p>
  <label for="name">Student Name:</label>
  <input id="name" placeholder="Student Name" />
</p>
<p>
  <label for="branch">Student Branch:</label>
  <input id="branch" placeholder="Student Branch" />
</p>
<p>
  <label for="sid">8-Digit Student ID:</label>
  <input
    pattern="[0-9]{8}"
    id="sid"
    class="student-id"
    placeholder="8 digit id" />
</p>
```

CSS

```
input {
  background-color: #e8e8e8;
  color: black;
}

input.student-id:placeholder-shown {
  background-color: yellow;
  color: red;
  font-style: italic;
}
```

Result

See also

- The `::placeholder` pseudo-element styles the placeholder *itself*.

:playing CSS pseudo-class

The **`:playing`** CSS pseudo-class selector represents the playback state of an element that is playable, such as `<audio>` or `<video>`, when that element is "playing". An element is considered to be playing if it is currently playing the media resource, or if it has temporarily stopped for reasons other than user intent (such as `:buffering` or `:stalled`).

Syntax

```
:playing {
  /* ... */
}
```

Examples

CSS

```
:playing {
  border: 5px solid green;
}
```

See also

- `:buffering`

- `:paused`
- `:seeking`
- `:stalled`
- `:volume-locked`
- CSS selectors

:popover-open CSS pseudo-class

The **`:popover-open`** CSS pseudo-class represents a popover element (i.e., one with a `popover` attribute) that is in the showing state. You can use this to apply style to popover elements only when they are shown.

Syntax

```
:popover-open {
  /* ... */
}
```

Examples

By default, popovers appear in the middle of the viewport. The default styling is achieved like this in the UA stylesheet:

```
[popover] {
  position: fixed;
  inset: 0;
  width: fit-content;
  height: fit-content;
  margin: auto;
  border: solid;
  padding: 0.25em;
  overflow: auto;
  color: CanvasText;
  background-color: Canvas;
}
```

To override the default styles and get the popover to appear somewhere else on your viewport, you could override the above styles with something like this:

```
:popover-open {
  width: 200px;
  height: 100px;
  position: absolute;
  inset: unset;
  bottom: 5px;
  right: 5px;
  margin: 0;
}
```

See also

- Popover API
- `popover` HTML global attribute

:read-only CSS pseudo-class

The **`:read-only`** CSS pseudo-class selects elements (such as certain `<input>` types and `<textarea>`) that are not editable by the user. Elements on which the HTML attribute `readonly` doesn't have an effect (such as `<input type="radio">`, `<input type="checkbox">`, and all other non-form elements) are also selected by the `:read-only` pseudo-class. In fact, `:read-only` matches anything that `:read-write` doesn't match, making it equivalent to `:not(:read-write)`.

Try it

```
label {
  display: block;
  margin-top: 1em;
}

*:read-only {
  font-weight: bold;
  color: indigo;
}
```

```
<p>Please enter your details:</p>

<label for="email">Email Address:</label>
<input id="email" name="email" type="email" value="test@example.com" readonly />

<label for="note">Short note about yourself:</label>
<textarea id="note" name="note">Don't be shy</textarea>

<label for="pic">Your picture:</label>
<input id="pic" name="pic" type="file" />
```

Syntax

```
:read-only {
  /* ... */
}
```

Examples

Confirming form information using read-only or read-write controls

One use of read-only form controls is to allow the user to check and verify information that they may have entered in an earlier form (for example, shipping details), while still being able to submit the information along with the rest of the form. This example shows how to style these controls.

The `:read-only` pseudo-class is used to remove all the styling that makes the inputs look like clickable fields, making them look more like read-only paragraphs. The `:read-write` pseudo-class on the other hand is used to provide some nicer styling to the editable `<textarea>`.

```
<fieldset>
  <legend>Check shipping details</legend>
  <div>
    <label for="name">Name: </label>
    <input id="name" name="name" type="text" value="Mr Soft" readonly />
  </div>
  <div>
    <label for="address">Address: </label>
    <textarea id="address" name="address" readonly>
23 Elastic Way,
Viscous,
Bright Ridge,
CA
</textarea>
  </div>
  <div>
    <label for="postal-code">Zip/postal code: </label>
    <input
      id="postal-code"
      name="postal-code"
      type="text"
      value="94708"
      readonly />
  </div>
</fieldset>

<fieldset>
  <legend>Final instructions</legend>
  <div>
    <label for="sms-confirm">Send confirmation by SMS?</label>
    <input id="sms-confirm" name="sms-confirm" type="checkbox" />
  </div>
  <div>
    <label for="instructions">Any special instructions?</label>
    <textarea id="instructions" name="instructions"></textarea>
  </div>
</fieldset>
```

```
body {
  font-family: "Josefin Sans", sans-serif;
  margin: 20px auto;
  max-width: 460px;
}

fieldset {
  padding: 10px 30px 0;
  margin-bottom: 20px;
}

legend {
  color: white;
  background: black;
  padding: 5px 10px;
}

fieldset > div {
  margin-bottom: 20px;
  display: flex;
  justify-content: space-between;
}

label,
input[type="text"],
textarea {
  display: block;
  font-family: inherit;
  font-size: 100%;
  margin: 0;
  box-sizing: border-box;
  padding: 5px;
  height: 30px;
}

input[type="text"],
textarea {
  width: 50%;
}

textarea {
  height: 110px;
  resize: none;
}

label {
  width: 40%;
}

input:hover,
input:focus,
textarea:hover,
textarea:focus {
```

```
  background-color: #eeeeee;
}
```

```
input:read-only,
textarea:read-only {
  border: 0;
  box-shadow: none;
  background-color: #dddddd;
}

textarea:read-write {
  outline: 1px dashed red;
  outline-offset: 2px;
  border-radius: 5px;
}
```

Styling read-only non-form controls

This selector doesn't just select `<input>`/`<textarea>` elements — it will select *any* element that cannot be edited by the user.

```
<p contenteditable>This paragraph is editable; it is read-write.</p>

<p>This paragraph is not editable; it is read-only.</p>
```

```
p {
  font-size: 150%;
  padding: 5px;
  border-radius: 5px;
}

p:read-only {
  background-color: red;
  color: white;
}

p:read-write {
  background-color: lime;
}
```

See also

- `:read-write`
- HTML `contenteditable` attribute

:read-write CSS pseudo-class

The **`:read-write`** CSS pseudo-class represents an element (such as `input` or `textarea`) that is editable by the user.

Try it

```
label {
  display: block;
  margin-top: 1em;
}

*:read-write {
  background-color: ivory;
  border: 2px solid darkorange;
  border-radius: 5px;
}
```

```
<p>Please fill in your details:</p>

<label for="email">Email Address:</label>
<input id="email" name="email" type="email" value="test@example.com" />

<label for="note">Short note about yourself:</label>
<textarea id="note" name="note">Don't be shy</textarea>

<label for="pic">Your picture:</label>
<input id="pic" name="pic" type="file" />
```

Syntax

```
:read-write {
  /* ... */
}
```

Examples

Confirming form details using read-only controls

You can use `readonly` form controls when you want a user to verify information they entered earlier, which you want to submit with new data in read-write controls. In the example below, the `:read-only` pseudo-class is used to make the `<textarea>` (a user's address) look like a regular paragraph. The `:read-write` pseudo-class provides a way to highlight the editable `<textarea>` (the delivery instructions):

```
body {
  font-family: "Josefin Sans", sans-serif;
  margin: 10px auto;
}

legend {
  color: white;
  background: black;
  padding: 5px 10px;
}

fieldset > div {
  margin-bottom: 10px;
```

```
  display: flex;
  justify-content: space-between;
}

label,
textarea {
  display: block;
  font-family: inherit;
  font-size: 100%;
  margin: 0;
  box-sizing: border-box;
  padding: 5px;
  height: 30px;
}

textarea {
  width: 50%;
}

textarea {
  height: 70px;
  resize: none;
}

label {
  width: 40%;
}
```

```
textarea:read-only {
  border: 0;
}

textarea:read-write {
  box-shadow: inset 1px 1px 3px #cccccc;
  border-radius: 5px;
}
```

```
<fieldset>
  <legend>Confirm details</legend>
  <div>
    <label for="address">Address:</label>
    <textarea id="address" name="address" readonly>
123 Choco Mountain,
Awesome Ridge,
CA</textarea>
  </div>
  <div>
    <label for="instructions">Delivery instructions</label>
    <textarea id="instructions" name="instructions"></textarea>
  </div>
</fieldset>
```

Styling read-write non-form controls

This selector doesn't just select `<input>`/`<textarea>` elements — it will select *any* element that can be edited by the user, such as a `<p>` element with `contenteditable` set on it.

```
<p contenteditable>This paragraph is editable; it is read-write.</p>

<p>This paragraph is not editable; it is read-only.</p>
```

```
body {
  font-family: sans-serif;
}

p {
  font-size: 150%;
  padding: 5px;
  border-radius: 5px;
}

p:read-only {
  background-color: red;
  color: white;
}

p:read-write {
  background-color: lime;
}
```

See also

- `:read-only`
- HTML `contenteditable` attribute

:required CSS pseudo-class

The **`:required`** CSS pseudo-class represents any `<input>`, `<select>`, or `<textarea>` element that has the `required` attribute set on it.

Try it

```
label {
  display: block;
  margin-top: 0.5em;
}

fieldset {
  margin-top: 0.5em;
}

*:required {
```

```
  background-color: gold;
}
```

```
<label for="name">Name (required):</label>
<input id="name" name="name" type="text" required />

<label for="birth">Date of birth:</label>
<input id="birth" name="birth" type="date" />

<label for="origin">How did you find out about us? (required)</label>
<select id="origin" name="origin" required>
  <option value="">Choose an option</option>
  <option value="google">Google</option>
  <option value="facebook">Facebook</option>
  <option value="advertisement">Advertisement</option>
</select>

<fieldset>
  <legend>Preferred contact method:</legend>
  <label>
    <input name="contact" type="radio" value="email" checked /> Email
  </label>
  <label><input name="contact" type="radio" value="phone" /> Phone</label>
</fieldset>

<label>
  <input name="newsletter" type="checkbox" checked /> I want to subscribe to a
  personalized newsletter.
</label>
<label>
  <input name="privacy" type="checkbox" required /> I have read and I agree to
  the Privacy Policy (required).
</label>
```

This pseudo-class is useful for highlighting fields that must have valid data before a form can be submitted.

> **Note:** The `:optional` pseudo-class selects *optional* form fields.

Syntax

```
:required {
  /* ... */
}
```

Accessibility

Mandatory `<input>`s should have the `required` attribute applied to them. This will ensure that people navigating with the aid of assistive technology such as a screen reader will be able to understand which inputs need valid content to ensure a successful submission.

If the form also contains optional inputs, required inputs should be indicated visually using a treatment that does not rely solely on color to convey meaning. Typically, descriptive text and/or an icon are used.

- MDN Understanding WCAG, Guideline 3.3 explanations
- Understanding Success Criterion 3.3.2 | W3C Understanding WCAG 2.0

Examples

The required field has a red border

HTML

```
<form>
  <div class="field">
    <label for="url_input">Enter a URL:</label>
    <input type="url" id="url_input" />
  </div>

  <div class="field">
    <label for="email_input">Enter an email address:</label>
    <input type="email" id="email_input" required />
  </div>
</form>
```

CSS

```
label {
  display: block;
  margin: 1px;
  padding: 1px;
}

.field {
  margin: 1px;
  padding: 1px;
}

input:required {
  border-color: maroon;
  border-width: 3px;
}

input:required:invalid {
  border-color: #c00000;
}
```

Result

See also

- Other validation-related pseudo-classes: `:optional`, `:invalid`, `:valid`

- Form data validation

:right CSS pseudo-class

The **`:right`** CSS pseudo-class, used with the `@page` at-rule, represents all right-hand pages of a printed document.

```
/* Selects any right-hand pages when printing */
@page :right {
  margin: 2in 3in;
}
```

Whether a given page is "left" or "right" is determined by the major writing direction of the document. For example, if the first page has a major writing direction of left-to-right then it will be a `:right` page; if it has a major writing direction of right-to-left then it will be a `:left` page.

> **Note:** This pseudo-class can be used to change only the `margin`, `padding`, `border`, and `background` properties of the *page box*. All other properties will be ignored, and only the page box, not the document content on the page, will be affected.

Syntax

```
:right {
  /* ... */
}
```

Examples

Setting margins for right-hand pages

```
@page :right {
  margin: 2in 3in;
}
```

See also

- `@page`
- Other page-related pseudo-classes: `:first`, `:left`

:root CSS pseudo-class

The **`:root`** CSS pseudo-class matches the root element of a tree representing the document. In HTML, `:root` represents the `<html>` element and is identical to the selector `html`, except that its specificity (0-1-0) is higher than html's (0-0-1).

```
/* Selects the root element of the document:
   <html> in the case of HTML */
:root {
  background: yellow;
}
```

Syntax

```
:root {
  /* ... */
}
```

Examples

Declaring global CSS variables

`:root` can be useful for declaring global CSS variables:

```
:root {
  --main-color: hotpink;
  --pane-padding: 5px 42px;
}
```

See also

- `<html>`
- `Document.rootElement`
- `Node.getRootNode()`
- `Element.shadowRoot`
- `ShadowRoot`

:scope CSS pseudo-class

The **`:scope`** CSS pseudo-class represents elements that are a reference point, or scope, for selectors to match against.

```
/* Selects a scoped element */
:scope {
  background-color: lime;
}
```

Which element(s) `:scope` matches depends on the context in which it is used:

- When used at the root level of a stylesheet, `:scope` is equivalent to `:root`, which in a regular HTML document matches the `<html>` element.
- When used inside a `@scope` block, `:scope` matches the block's defined scope root. It provides a way to apply styles to the root of the scope from inside the `@scope` block itself.
- When used within a DOM API call — such as `querySelector()`, `querySelectorAll()`, `matches()`, or `Element.closest()` — `:scope` matches the element on which the method was called.

Syntax

```
:scope {
  /* ... */
}
```

Examples

Using <code>:scope</code> as an alternative to <code>:root</code>

This example shows that `:scope` is equivalent to `:root` when used at the root level of a stylesheet. In this case, the provided CSS colors the background of the `<html>` element orange.

```
:scope {
  background-color: orange;
}
```

Using <code>:scope</code> to style the scope root in a <code>@scope</code> block

In this example, we use two separate `@scope` blocks to match links inside elements with a `.light-scheme` and `.dark-scheme` class respectively. Note how `:scope` is used to select and provide styling to the scope roots themselves. In this example, the scope roots are the `<div>` elements that have the classes applied to them.

HTML

```
<div class="light-scheme">
  <p>
    MDN contains lots of information about

    <a href="/en-US/docs/Web/CSS">CSS</a>, and
    <a href="/en-US/docs/Web/JavaScript">JavaScript</a>.
  </p>
</div>

<div class="dark-scheme">
  <p>
    MDN contains lots of information about
    <a href="/en-US/docs/Web/HTML">HTML</a>,
    <a href="/en-US/docs/Web/CSS">CSS</a>, and
    <a href="/en-US/docs/Web/JavaScript">JavaScript</a>.
  </p>
</div>
```

CSS

```
div {
  padding: 10px;
}
```

```
@scope (.light-scheme) {
  :scope {
    background-color: plum;
  }

  a {
    color: indigo;
  }
}

@scope (.dark-scheme) {
  :scope {
    background-color: indigo;
    color: antiquewhite;
  }

  a {
    color: plum;
  }
}
```

Result

Using <code>:scope</code> in JavaScript

This example demonstrates using the `:scope` pseudo-class in JavaScript. This can be useful if you need to get a direct descendant of an already retrieved `Element`.

HTML

```
<div id="context">
  <div id="element-1">
    <div id="element-1-1"></div>
    <div id="element-1-2"></div>
  </div>
  <div id="element-2">
    <div id="element-2-1"></div>
  </div>
</div>
<p>
  Selected element ids :
  <span id="results"></span>
</p>
```

JavaScript

```
const context = document.getElementById("context");
const selected = context.querySelectorAll(":scope > div");

document.getElementById("results").textContent = [...selected]
  .map((element) => `#${element.id}`)
  .join(", ");
```

Result

The scope of `context` is the element with the `id` of `context`. The selected elements are the `<div>` elements that are direct children of that context — `element-1` and `element-2` — but not their descendants.

Sibling combinators to the right of <code>:scope</code> never match

The relationship defined by `:scope` is always ancestor-to-descendant from the scope root. Because of that, putting a sibling combinator to the right of `:scope` creates a selector that can never match, because no element can both be within the selector scope and also be a sibling of `:scope`.

```
:scope + p {
  color: red;
}

:scope ~ * {
  color: red;
}
```

Selectors that never match may trigger a warning in browser DevTools.

:seeking CSS pseudo-class

The **`:seeking`** CSS pseudo-class selector represents an element that is playable, such as `<audio>` or `<video>`, when the playable element is seeking a playback position in the media resource. A resource is considered to be seeking if the user has requested playback of a specific position in the media resource, but the media element has not yet reached that position.

Seeking is different from `:buffering` in that the media element is not currently loading data, but is instead skipping to a new position in the media resource. For more information, see the Media buffering, seeking, and time ranges guide.

Syntax

```
:seeking {
  /* ... */
}
```

Examples

CSS

```
:seeking {
  outline: 5px solid red;
}

video:seeking {
  outline: 5px solid blue;
}
```

:stalled CSS pseudo-class

The **`:stalled`** CSS pseudo-class selector represents an element that is playable, such as `<audio>` or `<video>`, when playback is stalled. A resource is considered to be stalled if the user has requested playback of a specific position in the media resource, but it has failed to receive any data for some amount of time. This is different from `:buffering` in that the media element is unexpectedly not loading data when stalled (e.g., due to a network error) for around 3 seconds (the exact time is user agent dependent).

> **Note:** Like with the `:buffering` pseudo-class, the element is still considered to be "playing" when it is "stalled". If `:stalled` matches an element, `:playing` will also match that element.

Syntax

```
:stalled {
  /* ... */
}
```

Examples

CSS

```
:stalled {
  outline: 5px solid red;
}

audio:stalled {
  background-color: red;
}
```

:state() CSS pseudo-class

The **`:state()`** CSS pseudo-class matches custom elements that have the specified custom state.

Syntax

```
:state(<custom identifier>) {
  /* ... */
}
```

Parameters

The `:state()` pseudo-class takes as its argument a custom identifier that represents the state of the custom element to match.

Description

Elements can transition between states due to user interaction and other factors. For instance, an element can be in the "hover" state when a user hovers over the element, or a link can be in the "visited" state after a user clicks on it. Elements provided by browsers can be styled based on these states using CSS pseudo-classes such as `:hover` and `:visited`. Similarly, autonomous custom elements (custom elements that are not derived from built-in elements) can expose their states, allowing pages that use the elements to style them using the CSS `:state()` pseudo-class.

The states of a custom element are represented by string values. These values are added to or removed from a `CustomStateSet` object associated with the element. The CSS `:state()` pseudo-class matches an element when the identifier, passed as an argument, is present in the `CustomStateSet` of the element.

The `:state()` pseudo-class can also be used to match custom states within the implementation of a custom element. This is achieved by using `:state()` within the `:host()` pseudo-class function, which matches a state only within the shadow DOM of the current custom element.

Additionally, the `::part()` pseudo-element followed by the `:state()` pseudo-class allows matching on the shadow parts of a custom element that are in a particular state. (**Shadow parts** are parts of a custom element's shadow tree that are explicitly exposed to a containing page for styling purposes.)

Examples

Matching a custom state

This CSS shows how to change the border of the autonomous custom element `<labeled-checkbox>` to `red` when it is in the "checked" state.

```
labeled-checkbox {
  border: dashed red;
}
labeled-checkbox:state(checked) {
  border: solid;
}
```

For a live example of this code in action, see the Matching the custom state of a custom checkbox element example on the `CustomStateSet` page.

Matching a custom state in a custom element's shadow DOM

This example shows how the `:state()` pseudo-class can be used within the `:host()` pseudo-class function to match custom states within the implementation of a custom element.

The following CSS injects a gray `[x]` before the element when it is in the "checked" state.

```
:host(:state(checked))::before {
  content: "[x]";
}
```

For a live example of this code in action, see the Matching the custom state of a custom checkbox element example on the `CustomStateSet` page.

Matching a custom state in a shadow part

This example shows how the `:state()` pseudo-class can be used to target the shadow parts of a custom element.

Shadow parts are defined and named using the `part` attribute. For example, consider a custom element named `<question-box>` that uses a `<labeled-checkbox>` custom element as a shadow part named `checkbox`:

```
shadowRoot.innerHTML = `<labeled-checkbox part='checkbox'>Yes</labeled-checkbox>`;
```

The CSS below shows how the `::part()` pseudo-element can be used to match against the `'checkbox'` shadow part. It then shows how the `::part()` pseudo-element followed by the `:state()` pseudo-class can be used to match against the same part when it is in the `checked` state.

```
question-box::part(checkbox) {
  color: red;
}

question-box::part(checkbox):state(checked) {
  color: green;
  outline: dashed 1px green;
}
```

For a live example of this code in action, see the Matching a custom state in a shadow part of a custom element example on the `CustomStateSet` page.

:target CSS pseudo-class

The **`:target`** CSS pseudo-class selects the *target element of the document*. When the document is loaded, the target element is derived using the document's URL fragment identifier.

```
/* Selects document's target element */
:target {
```

```
  border: 2px solid black;
}
```

For example, the following URL has a fragment identifier (denoted by the # sign) that marks the element with the `id` of `setup` as the document's target element:

```
http://www.example.com/help/#setup
```

The following element would be selected by a `:target` selector when the current URL is equal to the above:

```
<section id="setup">Installation instructions</section>
```

Syntax

```
:target {
  /* ... */
}
```

Description

When an HTML document loads, the browser sets its target element. The element is identified using the URL fragment identifier. Without the URL fragment identifier, the document has no target element. The `:target` pseudo-class allows styling the document's target element. The element could be focused, highlighted, animated, etc.

The target element is set at document load and `history.back()`, `history.forward()`, and `history.go()` method calls. But it is *not* changed when `history.pushState()` and `history.replaceState()` methods are called.

> **Note:** Due to a possible bug in the CSS specification, `:target` doesn't work within a web component because the shadow root doesn't pass the target element down to the shadow tree.

Examples

A table of contents

The `:target` pseudo-class can be used to highlight the portion of a page that has been linked to from a table of contents.

HTML

```
<h3>Table of Contents</h3>
<ol>
  <li><a href="#p1">Jump to the first paragraph!</a></li>
  <li><a href="#p2">Jump to the second paragraph!</a></li>
  <li>
    <a href="#nowhere">
      This link goes nowhere, because the target doesn't exist.
    </a>
  </li>
</ol>

<h3>My Fun Article</h3>
<p id="p1">
  You can target <i>this paragraph</i> using a URL fragment. Click on the first
  link above to try out!
</p>
<p id="p2">
  This is <i>another paragraph</i>, also accessible from the second link above.
  Isn't that delightful?
</p>
```

CSS

```
p:target {
  background-color: gold;
}

/* Add a pseudo-element inside the target element */
p:target::before {
  font: 70% sans-serif;
  content: "►";
  color: limegreen;
  margin-right: 0.25em;
}

/* Style italic elements within the target element */
p:target i {
  color: red;
}
```

Result

:target-after CSS pseudo-class

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`:target-after`** CSS pseudo-class selects scroll markers that come *after* the active scroll marker (the one that currently matches `:target-current`) within a scroll marker group. You can use this selector to style navigation items that come after the current navigation position within a scroll marker group.

> **Note:** The `:target-after` pseudo-class is only valid on `::scroll-marker` pseudo-elements and elements that have been designated as scroll markers via the `scroll-target-group` property.

Syntax

```
:target-after {
  /* ... */
}
```

Examples

Styling navigation items before and after the active scroll marker

In this example, we use the `:target-before` and `:target-after` pseudo-classes to highlight the scroll markers before and after the active one, indicating items the user has already viewed and those that are still to come.

HTML

The markup contains a table of contents created using an ordered list (`<ol>`/`<li>`) and `<a>` elements. This is followed by a series of `<section>` elements containing content.

```
<nav id="toc">
  <ol>
    <li><a href="#intro">Introduction</a></li>

  </p>
</section>
```

CSS

We've set `scroll-target-group: auto` on the `<ol>` to turn it into a scroll marker group container and let the browser determine which `<a>` element is the active scroll marker at any given time (that is, which link's target is currently in view). We then style the `:target-current` pseudo-class with a `red` `color` so that it stands out clearly.

```
body {
  font: 1.2em / 1.5 system-ui;
  width: 50%;
  max-width: 700px;
  margin: 0 auto;
}

nav {
  position: fixed;
  top: 0;
  left: 0;
  right: 0;
  display: flex;
  justify-content: center;
}

section {
  padding-top: 60px;
}

a {
  color: black;
  text-decoration: none;
}

a:hover,
a:focus {
  text-decoration: underline;
}

ol {
  display: flex;
  width: 100%;
  justify-content: space-around;
  list-style-type: none;
  padding: 20px 0;
  margin: 0;
  background: white;
}

@supports not selector(:target-after) {
  body::before {
    content: "Your browser does not support the :target-before and :target-after pseudo-classes.";
    color: black;
    background-color: #ffcd33;
    text-align: center;
    padding: 1rem;
    position: fixed;
    bottom: 0;
    left: 0;
    right: 0;
    z-index: 1;
  }
}
```

```
ol {
  scroll-target-group: auto;
}

:target-current {
  color: red;
}
```

Finally, we use the `:target-before` pseudo-class to style all `<a>` elements before the active scroll marker with a gray color and strike-through, to make them look completed/finished, and we use the `:target-after` pseudo-class to style all `<a>` elements after the active scroll marker with a bright underline.

```
a:target-before {
  color: gray;
  text-decoration: line-through;
}

a:target-after {
  text-decoration: underline orange 2px;
}
```

Result

Try navigating either by clicking the links or by scrolling. In both cases, you'll see that the red text color moves between the links to match the section currently in view. The links before and after the current red link also update to use the styles defined in the `a:target-before` and `a:target-after` rules.

:target-before CSS pseudo-class

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`:target-before`** CSS pseudo-class selects scroll markers that come *before* the active scroll marker (the one that currently matches `:target-current`) within a scroll marker group. You can use this selector to style navigation items that come before the current navigation position within a scroll marker group.

> **Note:** The `:target-before` pseudo-class is only valid on `::scroll-marker` pseudo-elements and elements that have been designated as scroll markers via the `scroll-target-group` property.

Syntax

```
:target-before {
  /* ... */
}
```

Examples

Styling navigation items before and after the active scroll marker

In this example, we use the `:target-before` and `:target-after` pseudo-classes to highlight the scroll markers before and after the active one, indicating items the user has already viewed and those that are still to come.

HTML

```

CSS

We've set `scroll-target-group: auto` on the `<ol>` to turn it into a scroll marker group container and let the browser determine which `<a>` element is the active scroll marker at any given time (that is, which link's target is currently in view). We then style the `:target-current` pseudo-class with a `red` `color` so that it stands out clearly.

```
body {
  font: 1.2em / 1.5 system-ui;
  width: 50%;
  max-width: 700px;
  margin: 0 auto;
}

nav {
  position: fixed;
  top: 0;
  left: 0;
  right: 0;
  display: flex;
  justify-content: center;
}

section {
  padding-top: 60px;
}

a {
  color: black;
  text-decoration: none;
}

a:hover,
a:focus {
  text-decoration: underline;
}

ol {
  display: flex;
  width: 100%;
  justify-content: space-around;
  list-style-type: none;
  padding: 20px 0;
  margin: 0;
  background: white;
}

@supports not selector(:target-before) {
  body::before {
    content: "Your browser does not support the :target-before and :target-after pseudo-classes.";
    color: black;
    background-color: #ffcd33;
    text-align: center;
    padding: 1rem;
    position: fixed;
    bottom: 0;
    left: 0;
    right: 0;
    z-index: 1;
  }
}
```

```
ol {
  scroll-target-group: auto;
}

:target-current {
  color: red;
}
```

Finally, we use the `:target-before` pseudo-class to style all `<a>` elements before the active scroll marker with a gray color and strike-through, to make them look completed/finished, and we use the `:target-after` pseudo-class to style all `<a>` elements after the active scroll marker with a bright underline.

```
a:target-before {
  color: gray;
  text-decoration: line-through;
}

a:target-after {
  text-decoration: underline orange 2px;
}
```

Result

Try navigating either by clicking the links or by scrolling. In both cases, you'll see that the red text color moves between the links to match the section currently in view. The links before and after the current red link also update to use the styles defined in the `a:target-before` and `a:target-after` rules.

:target-current CSS pseudo-class

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`:target-current`** CSS pseudo-class selects the **active** scroll marker — the scroll marker of a `scroll-marker-group` that is currently scrolled to. This selector can be used to style the active navigation position within a scroll marker group.

> **Note:** The `:target-current` pseudo-class is only valid on `::scroll-marker` pseudo-elements and elements that have been designated as scroll markers using the `scroll-target-group` property.

Syntax

```
:target-current {
  /* ... */
}
```

Examples

See Creating CSS carousels and `::scroll-marker` for complete examples that use the `:target-current` pseudo-class.

Basic usage

```
::scroll-marker {
  background-color: white;
}

::scroll-marker:target-current {
  background-color: black;
}
```

:user-invalid CSS pseudo-class

The **`:user-invalid`** CSS pseudo-class represents any validated form element whose value isn't valid based on their validation constraints, after the user has interacted with it.

The `:user-invalid` pseudo-class must match an `:invalid`, `:out-of-range`, or blank-but `:required` element between the time the user has attempted to submit the form and before the user has interacted again with the form element.

Syntax

```
:user-invalid {
  /* ... */
}
```

Examples

Setting a color and symbol on :user-invalid

In the following example, the red border and ❌ only display once the user has interacted with the field. Try typing something other than an email address to see it in action.

```
<label for="email">Email *: </label>
<input id="email" name="email" type="email" required />
<span></span>
```

```
input:user-invalid {
  border: 2px solid red;
}

input:user-invalid + span::before {
  content: "✖";
  color: red;
}
```

See also

- `:valid`
- `:invalid`
- `:required`
- `:optional`
- `:user-valid`

:user-valid CSS pseudo-class

The **`:user-valid`** CSS pseudo-class represents any validated form element whose value validates correctly based on its validation constraints. However, unlike `:valid` it only matches once the user has interacted with it.

This pseudo-class is applied if the form control is valid and any of the following has occurred:

- The user made a change to the form control and committed the change such as by moving focus elsewhere.
- The user has attempted to submit the form, even if no change was made to the control.
- The value was invalid when it gained focus, and the user made a change making it valid, even if focus is still in the control.

Once this pseudo-class has been applied, the user-agent re-validates whether the control is valid at every keystroke when the control has focus.

- If the control has focus, and the value was invalid when it gained focus, re-validate on every keystroke.

The result is that if the control was valid when the user started interacting with it, the validity styling is changed only when the user shifts focus to another control. However, if the user is trying to correct a previously-flagged value, the control shows immediately when the value becomes valid. Required items are flagged as invalid only if the user changes them or attempts to submit an unchanged invalid value.

Syntax

```
:user-valid {
  /* ... */
}
```

Examples

Setting a color and symbol on :user-valid

In the following example, the green border and ✅ only display once the user has interacted with the field. Try changing the email address to another valid email to see it in action.

```
<label for="email">Email *: </label>
<input id="email" name="email" type="email" value="test@example.com" required />
<span></span>
```

```
input:user-valid {
  border: 2px solid green;
}

input:user-valid + span::before {
  content: "✓";
  color: green;
}
```

See also

- `:optional`
- `:user-invalid`

:valid CSS pseudo-class

The **`:valid`** CSS pseudo-class represents any `<input>` or other `<form>` element whose contents validate successfully. This allows you to easily make valid fields adopt an appearance that helps the user confirm that their data is formatted properly.

Try it

```
label {
  display: block;
  margin-top: 1em;
}

input:valid {
  background-color: ivory;
  border: none;
  outline: 2px solid deepskyblue;
  border-radius: 5px;
  accent-color: gold;
}
```

```
<label for="email">Email Address:</label>
<input id="email" name="email" type="email" value="na@me@example.com" />

<label for="secret">Secret Code: (lower case letters)</label>
<input id="secret" name="secret" type="text" value="test" pattern="[a-z]+" />

<label for="age">Your age: (18+)</label>
<input id="age" name="age" type="number" value="5" min="18" />

<label
  ><input name="tos" type="checkbox" required checked /> - Do you agree to
  ToS?</label
>
```

Syntax

```
:valid {
  /* ... */
}
```

Accessibility

The color green is commonly used to indicate valid input. People who have certain types of color blindness will be unable to determine the input's state unless it is accompanied by an additional indicator that does not rely on color to convey meaning. Typically, descriptive text and/or an icon are used.

- MDN Understanding WCAG, Guideline 1.4 explanations
- Understanding Success Criterion 1.4.1 | W3C Understanding WCAG 2.0

Examples

Indicating valid and invalid form fields

In this example, we include extra `<span>` elements to generate content that indicates valid or invalid data:

```
<fieldset>
  <legend>Contact information</legend>
  <p>Required fields are labeled with "required".</p>
  <div>
    <label for="fname">First name: </label>
    <input id="fname" name="fname" type="text" required />
    <span></span>
  </div>
  <div>
    <label for="lname">Last name: </label>
    <input id="lname" name="lname" type="text" required />
```

```
    <span></span>
  </div>
  <div>
    <label for="email"> Email address (include if you want a response): </label>
    <input id="email" name="email" type="email" />
    <span></span>
  </div>
</fieldset>
```

To provide these indicators, we use the following CSS:

```
body {
  font-family: sans-serif;
  margin: 20px auto;
  max-width: 460px;
}

fieldset {
  padding: 10px 30px 0;
}

legend {
  color: white;
  background: black;
  padding: 5px 10px;
}

fieldset > div {
  margin-bottom: 20px;
  display: flex;
  flex-flow: row wrap;
}

label,
input {
  display: block;
  font-family: inherit;
  margin: 0;
  box-sizing: border-box;
  width: 100%;
  padding: 5px;
  height: 30px;
}

input {
  box-shadow: inset 1px 1px 3px #cccccc;
  border-radius: 5px;
}

input:hover,
input:focus {
  background-color: #eeeeee;
}

input:required + span::after {
  font-size: 0.7rem;
  position: absolute;
  content: "required";
  color: white;
  background-color: black;
  padding: 5px 10px;
  top: -26px;
  left: -70px;
}
```

```
input + span {
  position: relative;
}

input + span::before {
  position: absolute;
  right: -20px;
  top: 5px;
}

input:invalid {
  border: 2px solid red;
}

input:invalid + span::before {
  content: "✖";
  color: red;
}

input:valid + span::before {
  content: "✓";
  color: green;
}
```

We set the `<span>`s to `position: relative` so that we can position the generated content relative to them. We then absolutely position different generated content depending on whether the form's data is valid or invalid — a green check or a red cross, respectively. To add a bit of extra urgency to the invalid data, we've also given the inputs a thick red border when invalid.

> **Note:** We've used `::before` to add these labels, as we were already using `::after` for the "required" labels.

You can try it below:

Notice how the required text inputs are invalid when empty, but valid when they have something filled in. The email input on the other hand is valid when empty, as it is not required, but invalid when it contains something that is not a proper email address.

:visited CSS pseudo-class

The **`:visited`** CSS pseudo-class applies once the link has been visited by the user. For privacy reasons, the styles that can be modified using this selector are very limited. The `:visited` pseudo-class applies only to `<a>` and `<area>` elements that have an `href` attribute.

Styles defined by the `:visited` and unvisited `:link` pseudo-classes can be overridden by any subsequent user-action pseudo-classes (`:hover` or `:active`) that have at least equal specificity. To style links appropriately, put the `:visited` rule after the `:link` rule but before the `:hover` and `:active` rules, as defined by the *LVHA-order*: `:link` — `:visited` — `:hover` — `:active`. The `:visited` pseudo-class and `:link` pseudo-class are mutually exclusive.

Try it

```
p {
  font-weight: bold;
}

a:visited {
  color: forestgreen;
  text-decoration-color: hotpink;
}
```

```
<p>Pages that you might have visited:</p>
<ul>
  <li>
    <a href="https://developer.mozilla.org">MDN Web Docs</a>
  </li>
  <li>
    <a href="https://www.youtube.com/">YouTube</a>
  </li>
</ul>
<p>Pages unlikely to be in your history:</p>
<ul>
  <li>
    <a href="https://developer.mozilla.org/missing-1">Random MDN page</a>
  </li>
  <li>
    <a href="https://example.com/missing-1">Random Example page</a>
  </li>
</ul>
```

Privacy restrictions

For privacy reasons, browsers strictly limit which styles you can apply using this pseudo-class, and how they can be used:

- Allowable CSS properties are `color`, `background-color`, `border-color`, `border-bottom-color`, `border-left-color`, `border-right-color`, `border-top-color`, `column-rule-color`, `outline-color`, `text-decoration-color`, and `text-emphasis-color`.
- Allowable SVG attributes are `fill` and `stroke`.
- The alpha component of the allowed styles will be ignored. The alpha component of the element's non-`:visited` state will be used instead. In Firefox when the alpha component is `0`, the style set in `:visited` will be ignored entirely.
- Although these styles can change the appearance of colors to the end user, the `window.getComputedStyle` method will lie and always return the value of the non-`:visited` color.
- The `<link>` element is never matched by `:visited`.
- DOM methods that match elements via CSS selectors — such as `querySelector()` and `querySelectorAll()` — will always return an "empty" result even if there are visited links in a document. For the aforementioned methods, this will be `null` or an empty `NodeList`, respectively.

> **Note:** For more information on these limitations and the reasons behind them, see Privacy and the :visited selector.

Syntax

```
:visited {
  /* ... */
}
```

Examples

Properties that would otherwise have no color or be transparent cannot be modified with `:visited`. Of the properties that can be set with this pseudo-class, your browser probably has a default value for `color` and `column-rule-color` only. Thus, if you want to modify the other properties, you'll need to give them a base value outside the `:visited` selector.

HTML

```
<a href="#test-visited-link">Have you visited this link yet?</a><br />
<a href="">You've already visited this link.</a>
```

CSS

```
a {
  /* Specify non-transparent defaults to certain properties,
     allowing them to be styled with the :visited state */
  background-color: white;
  border: 1px solid white;
}

a:visited {
  background-color: yellow;
  border-color: hotpink;
  color: hotpink;
}
```

Result

See also

- Privacy and the :visited selector
- Link-related pseudo-classes: `:link`, `:active`, `:hover`

:volume-locked CSS pseudo-class

The **`:volume-locked`** CSS pseudo-class selector represents an element that is capable of making sound, such as `<audio>` or `<video>`, but the audio volume of the media element is currently "locked" by the user.

User agents may set media `muted` or `volume` values according to user preferences (e.g., remembering the last set value across sessions, on a per-site basis, or otherwise). An element that is `:volume-locked` cannot be muted, un-muted, or have its volume changed via JavaScript. The locked status is an operating system or user agent preference.

Syntax

```
:volume-locked {
  /* ... */
}
```

Examples

CSS

```
:volume-locked {
  border: 5px solid green;
}

video:volume-locked {
  border: 5px solid aqua;
}
```

See also

- `:buffering`

- `:seeking`
- `:stalled`
- CSS selectors
- `volume` property of `HTMLMediaElement` objects

:where() CSS pseudo-class

The **`:where()`** CSS pseudo-class function takes a selector list as its argument, and selects any element that can be selected by one of the selectors in that list.

The difference between `:where()` and `:is()` is that `:where()` always has 0 specificity, whereas `:is()` takes on the specificity of the most specific selector in its arguments.

Try it

```
ol {
  list-style-type: upper-alpha;
  color: darkblue;
}

/* Not applied to ol, because of lower specificity */
:where(ol, ul, menu:unsupported) :where(ol, ul) {
  color: green;
}

:where(ol, ul) :where(ol, ul) ol {
  list-style-type: lower-greek;
  color: chocolate;
}
```

```
<ol>
  <li>Saturn</li>
  <li>
    <ul>
      <li>Mimas</li>
      <li>Enceladus</li>
      <li>
        <ol>
          <li>Voyager</li>
          <li>Cassini</li>
        </ol>
      </li>
      <li>Tethys</li>
    </ul>
  </li>
  <li>Uranus</li>
  <li>
    <ol>
      <li>Titania</li>
      <li>Oberon</li>
    </ol>
  </li>
</ol>
```

Syntax

```
:where(<complex-selector-list>) {
  /* ... */
}
```

Parameters

The `:where()` pseudo-class requires a selector list, a comma-separated list of one or more selectors, as its argument. The list must not contain a pseudo-element, but any other simple, compound, and complex selectors are allowed.

Forgiving Selector Parsing

The specification defines `:is()` and `:where()` as accepting a forgiving selector list.

In CSS when using a selector list, if any of the selectors are invalid then the whole list is deemed invalid. When using `:is()` or `:where()` instead of the whole list of selectors being deemed invalid if one fails to parse, the incorrect or unsupported selector will be ignored and the others used.

```
:where(:valid, :unsupported) {
  /* … */
}
```

Will still parse correctly and match `:valid` even in browsers which don't support `:unsupported`, whereas:

```
:valid,
:unsupported {
  /* … */
}
```

Will be ignored in browsers which don't support `:unsupported` even if they support `:valid`.

Examples

Comparing :where() and :is()

This example shows how `:where()` works, and also illustrates the difference between `:where()` and `:is()`.

Take the following HTML:

```
<article>
  <h2>:is()-styled links</h2>
  <section class="is-styling">
    <p>
      Here is my main content. This
      <a href="https://mozilla.org">contains a link</a>.
    </p>
  </section>

  <aside class="is-styling">
    <p>
      Here is my aside content. This
      <a href="https://developer.mozilla.org">also contains a link</a>.
    </p>
  </aside>

  <footer class="is-styling">
    <p>
      This is my footer, also containing
      <a href="https://github.com/mdn">a link</a>.
    </p>
  </footer>
</article>

<article>
  <h2>:where()-styled links</h2>
  <section class="where-styling">
    <p>
      Here is my main content. This
      <a href="https://mozilla.org">contains a link</a>.
    </p>
  </section>

  <aside class="where-styling">
    <p>
      Here is my aside content. This
      <a href="https://developer.mozilla.org">also contains a link</a>.
    </p>
  </aside>

  <footer class="where-styling">
    <p>
      This is my footer, also containing
      <a href="https://github.com/mdn">a link</a>.
    </p>
  </footer>
</article>
```

In this somewhat-contrived example, we have two articles that each contain a section, an aside, and a footer. They differ by the classes used to mark the child elements.

To group the selection of links, while keeping the `is-styling` and `where-styling` styles distinct, we *could* use `:is()` or `:where()`, in the following manner:

```
html {
  font-family: sans-serif;
  font-size: 150%;
}

:is(section.is-styling, aside.is-styling, footer.is-styling) a {
  color: red;
}

:where(section.where-styling, aside.where-styling, footer.where-styling) a {
  color: orange;
}
```

However, what if we later want to override the color of links in the footers using a compound selector made up of low-specificity type selectors?

```
footer a {
  color: blue;
}
```

This won't work for the red links, because the selectors inside `:is()` count towards the specificity of the overall selector, and class selectors have a higher specificity than element selectors.

However, selectors inside `:where()` have specificity 0, so the orange footer link will be overridden by our type-only compound selector.

> **Note:** You can also find this example on GitHub; see is-where.

- Selector list
- Web components
- Forgiving selector list via csswg.org.

:xr-overlay CSS pseudo-class

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`:xr-overlay`** CSS pseudo-class, defined in the WebXR DOM overlays module, matches the DOM overlay element when a web page is being viewed in an immersive AR or VR environment.

Syntax

```
:xr-overlay {
  /* ... */
}
```

Description

The `:xr-overlay` pseudo-class matches the overlay element for the duration of an immersive session using a DOM overlay.

The overlay element is a backdrop root. Any `backdrop-filter` effects on the DOM overlay element or its descendants do not modify the AR camera image (if applicable) or the rendered content drawn to the immersive session's `XRWebGLLayer`.

The overlay element itself is a stacking context due to its fixed `position`. The stacking contexts for ancestors of the overlay element, if any, do not paint to the immersive session's display.

> **Note:** On a multi-display system, the stacking contexts for ancestors or sibling trees of the overlay element may be displayed on separate displays.

Examples

Basic usage

In this example, we define the overlay to be semi-transparent black, enabling content behind the overlay to be partially visible. To ensure enough contrast between content and its background, we set the `color` to `white`.

```
:xr-overlay {
  background-color: rgb(0 0 0 / 0.5);
  color: white;
}
```

Targeting an overlay's contents

In this example, we use the `:xr-overlay` selector to style the `<button>` elements within an XR DOM overlay.

```
:xr-overlay button {
  background-color: white;
  color: black;
}
```

Attribute selectors

The CSS **attribute selector** matches elements based on the element having a given attribute explicitly set, with options for defining an attribute value or substring value match.

Syntax

```
/* <a> elements with a title attribute */
a[title] {
  color: purple;
}

/* <a> elements with an href matching "https://example.org" */
a[href="https://example.org"] {
  color: green;
}

/* <a> elements with an href containing "example" */
a[href*="example"] {
  font-size: 2em;
}

/* <a> elements with an href ending ".org", case-insensitive */
a[href$=".org" i] {
  font-style: italic;
```

```
}

/* <a> elements whose class attribute contains the word "logo" */
a[class~="logo"] {
  padding: 2px;
}
```

`[attr]`

Represents elements with an attribute name of *attr*.

`[attr=value]`

Represents elements with an attribute name of *attr* whose value is exactly *value*.

`[attr~=value]`

Represents elements with an attribute name of *attr* whose value is a whitespace-separated list of words, one of which is exactly *value*.

`[attr|=value]`

Represents elements with an attribute name of *attr* whose value can be exactly *value* or can begin with *value* immediately followed by a hyphen, - (U+002D). It is often used for language subcode matches.

`[attr^=value]`

Represents elements with an attribute name of *attr* whose value is prefixed (preceded) by *value*.

`[attr$=value]`

Represents elements with an attribute name of *attr* whose value is suffixed (followed) by *value*.

`[attr*=value]`

Represents elements with an attribute name of *attr* whose value contains at least one occurrence of *value* within the string.

`[attr operator value i]`

Adding an `i` (or `I`) before the closing bracket causes the value to be compared case-insensitively (for characters within the ASCII range).

`[attr operator value s]`

Adding an `s` (or `S`) before the closing bracket causes the value to be compared case-sensitively (for characters within the ASCII range).

Values

`<attr>`

An `<ident>`, that is, the unquoted name of the attribute. This can be any valid language-specific attribute (SVG, HTML, XML, etc.), a `data-*` attribute, or an author-created attribute.

`<value>`

An `<ident>` or `<string>`, representing the attribute value. The value must be quoted if it contains spaces or special characters.

`s` or `i`

Case sensitivity or insensitivity flag. If included before the closing bracket (`]`), makes the value case sensitive or insensitive, irrespective of the markup language.

Description

The case sensitivity of attribute names and values depends on the document language. In HTML, attribute names are case-insensitive, as are spec-defined enumerated values. The case-insensitive HTML attribute values are listed in the HTML spec. For these attributes, the attribute value in the selector is case-insensitive, regardless of whether the value is invalid or the attribute for the element on which it is set is invalid.

If the attribute value is case-sensitive, like `class`, `id`, and `data-*` attributes, the attribute selector value match is case-sensitive. Attributes defined outside of the HTML specification, like `role` and `aria-*` attributes, are also case-sensitive. Case-sensitive attribute selectors can be made case-insensitive with the inclusion of the case-insensitive modifier (`i`).

Examples

Links

CSS

```
a {
  color: blue;
}

/* Internal links, beginning with "#" */
a[href^="#"] {
  background-color: gold;
}

/* Links with "example" anywhere in the URL */
a[href*="example"] {
  background-color: silver;
}

/* Links with "insensitive" anywhere in the URL,
   regardless of capitalization */
a[href*="insensitive" i] {
  color: cyan;
}

/* Links with "cAsE" anywhere in the URL,
with matching capitalization */
a[href*="cAsE" s] {
  color: pink;
}

/* Links that end in ".org" */
a[href$=".org"] {
  color: red;
}

/* Links that start with "https://" and end in ".org" */
```

```
a[href^="https://"][href$=".org"] {
  color: green;
}
```

HTML

```
<ul>
  <li><a href="#internal">Internal link</a></li>
  <li><a href="http://example.com">Example link</a></li>
  <li><a href="#InSensitive">Insensitive internal link</a></li>
  <li><a href="http://example.org">Example org link</a></li>
  <li><a href="https://example.org">Example https org link</a></li>
</ul>
```

Result

Languages

CSS

```
/* All divs with a `lang` attribute are bold. */
div[lang] {
  font-weight: bold;
}

/* All divs without a `lang` attribute are italicized. */
div:not([lang]) {
  font-style: italic;
}

/* All divs in US English are blue. */
div[lang~="en-us"] {
  color: blue;
}

/* All divs in Portuguese are green. */
div[lang="pt"] {
  color: green;
}

/* All divs in Chinese are red, whether
   simplified (zh-Hans-CN) or traditional (zh-Hant-TW). */
div[lang|="zh"] {
  color: red;
}

/* All divs with a Traditional Chinese
   `data-lang` are purple. */
/* Note: You could also use hyphenated attributes
   without double quotes */
div[data-lang="zh-Hant-TW"] {
  color: purple;
}
```

HTML

```
<div lang="en-us en-gb en-au en-nz">Hello World!</div>
<div lang="pt">Olá Mundo!</div>
<div lang="zh-Hans-CN">世界您好! </div>
<div lang="zh-Hant-TW">世界您好! </div>
<div data-lang="zh-Hant-TW">世界您好! </div>
```

Result

HTML ordered lists

The HTML specification requires the `type` attribute to be matched case-insensitively because it is primarily used in the `<input>` element. Note that if a modifier is not supported by the user agent, then the selector will not match.

CSS

```
/* Case-sensitivity depends on document language */
ol[type="a"]:first-child {
  list-style-type: lower-alpha;
  background: red;
}

ol[type="i" s] {
  list-style-type: lower-alpha;
  background: lime;
}

ol[type="I" s] {
  list-style-type: upper-alpha;
  background: grey;
}

ol[type="a" i] {
  list-style-type: upper-alpha;
  background: green;
}
```

HTML

```
<ol type="A">
  <li>
    Red background for case-insensitive matching (default for the type selector)
  </li>
</ol>
<ol type="i">
  <li>Lime background if `s` modifier is supported (case-sensitive match)</li>
```

```
</ol>
<ol type="I">
  <li>Grey background if `s` modifier is supported (case-sensitive match)</li>
</ol>
<ol type="A">
  <li>
    Green background if `i` modifier is supported (case-insensitive match)
  </li>
</ol>
```

Child combinator

The **child combinator** (`>`) is placed between two CSS selectors. It matches only those elements matched by the second selector that are the direct children of elements matched by the first.

```
/* List items that are children of the "my-things" list */
ul.my-things > li {
  margin: 2em;
}
```

Elements matched by the second selector must be the immediate children of the elements matched by the first selector. This is stricter than the descendant combinator, which matches all elements matched by the second selector for which there exists an ancestor element matched by the first selector, regardless of the number of "hops" up the DOM.

Syntax

```
/* The white space around the > combinator is optional but recommended. */
selector1 > selector2 { /* style properties */ }
```

Examples

CSS

```
span {
  background-color: aqua;
}

div > span {
  background-color: yellow;
}
```

HTML

```
<div>
  <span>
    Span #1, in the div.
    <span>Span #2, in the span that's in the div.</span>
  </span>
</div>
<span>Span #3, not in the div at all.</span>
```

Result

See also

- Descendant combinator

Class selectors

The CSS **class selector** matches elements based on the contents of their `class` attribute.

```
/* All elements with class="spacious" */
.spacious {
  margin: 2em;
}

/* All <li> elements with class="spacious" */
li.spacious {
  margin: 2em;
}

/* All <li> elements with a class list that includes both "spacious" and "elegant" */
/* For example, class="elegant retro spacious" */
li.spacious.elegant {
  margin: 2em;
}
```

Syntax

```
.class_name {
  /* … */
}
```

Note that this is equivalent to the following attribute selector:

```
[class~="class_name"] {
  /* … */
}
```

The `class_name` value must be a valid CSS identifier. HTML `class` attributes which are not valid CSS identifiers must be escaped before they can be used in class selectors.

Examples

Valid class selectors

HTML

```
<p class="red">This paragraph has red text.</p>
<p class="red yellow-bg">
  This paragraph has red text and a yellow background.
</p>
<p class="red fancy">This paragraph has red text and "fancy" styling.</p>
<p>This is just a regular paragraph.</p>
```

```
<!-- The next two paragraphs have class attributes
that contain characters which must be escaped in CSS -->

<p class="item?one">This paragraph has a pink background.</p>
<p class="123item">This paragraph has a yellow background.</p>
```

CSS

```
.red {
  color: #ff3333;
}

.yellow-bg {
  background: #ffffaa;
}

.fancy {
  font-weight: bold;
  text-shadow: 4px 4px 3px #7777ff;
}
```

```
/* In the next two rules, the class attributes must be escaped */

.item\?one {
  background-color: pink;
}

.\00003123item {
  background-color: yellow;
}
```

Result

Invalid class selectors

The class selectors in the following rules are not valid CSS identifiers, and will be ignored.

```
.item?one {
  background-color: green;
}

.123item {
  background-color: green;
}
```

Column combinator

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **column combinator** (||) is placed between two CSS selectors. It matches only those elements matched by the second selector that belong to the column elements matched by the first.

```
/* Table cells that belong to the "selected" column */
col.selected||td {
  background: gray;
}
```

Syntax

```
/* The white space around the || combinator is optional but recommended. */
column-selector || cell-selector {
  /* style properties */
}
```

Examples

HTML

```
<table border="1">
  <colgroup>
    <col span="2" />
    <col class="selected" />
  </colgroup>
  <tbody>
    <tr>
      <td>A</td>
      <td>B</td>
      <td>C</td>
    </tr>
```

```
    <tr>
      <td colspan="2">D</td>
      <td>E</td>
    </tr>
    <tr>
      <td>F</td>
      <td colspan="2">G</td>
    </tr>
  </tbody>
</table>
```

CSS

```
col.selected||td {
  background: gray;
  color: white;
  font-weight: bold;
}
```

Result

Browser compatibility

Currently, no browsers support this feature.

CSS combinators

CSS **combinators** define relationships between selectors. They allow you to select elements based on their relationship to other elements in the document tree.

For example, to style only paragraph elements that are direct children of a `<div>`, you can use the child combinator (`>`):

```
/* Set top margin on <p> elements that are direct children of <div> */
div > p {
  margin-top: 0;
}
```

Syntax

```
/* Combine selectors to express relationships */
selector1 combinator selector2 {
  property: value;
}
```

Index of combinators

- Child combinator (`>`)
- Column combinator (`||`)
- Descendant combinator (" ")
- Next-sibling combinator (`+`)
- Subsequent-sibling combinator (`~`)

See also

- CSS selectors module
- Selectors and combinators

Descendant combinator

The **descendant combinator** — typically represented by a single space (" ") character — combines two selectors such that elements matched by the second selector are selected if they have an ancestor (parent, parent's parent, parent's parent's parent, etc.) element matching the first selector. Selectors that utilize a descendant combinator are called *descendant selectors*.

```
/* List items that are descendants of the "my-things" list */
ul.my-things li {
  margin: 2em;
}
```

The descendant combinator is technically one or more CSS white space characters — the space character and/or one of four control characters: carriage return, form feed, new line, and tab characters — between two selectors in the absence of another combinator. Additionally, the white space characters of which the combinator is comprised may contain any number of CSS comments.

Syntax

```
selector1 selector2 {
  /* property declarations */
}
```

Examples

CSS

```
li {
  list-style-type: disc;
}

li li {
  list-style-type: circle;
}
```

HTML

```
<ul>
  <li>
    <div>Item 1</div>
    <ul>
      <li>Subitem A</li>
      <li>Subitem B</li>
    </ul>
  </li>
  <li>
    <div>Item 2</div>
    <ul>
      <li>Subitem A</li>
      <li>Subitem B</li>
    </ul>
  </li>
</ul>
```

Result

- Child combinator

ID selectors

The CSS **ID selector** matches an element based on the value of the element's `id` attribute. In order for the element to be selected, its `id` attribute must match exactly the value given in the selector.

```
/* The element with id="demo" */
#demo {
  border: red 2px solid;
}
```

Syntax

```
#id_value {
  /* … */
}
```

Note that syntactically (but not specificity-wise), this is equivalent to the following attribute selector:

```
[id="id_value"] {
  /* … */
}
```

The `id_value` value must be a valid CSS identifier. HTML `id` attributes which are not valid CSS identifiers must be escaped before they can be used in ID selectors.

Examples

Valid ID selectors

HTML

```
<p id="blue">This paragraph has a blue background.</p>
<p>This is just a regular paragraph.</p>
```

```
<!-- The next two paragraphs have id attributes
that contain characters which must be escaped in CSS -->

<p id="item?one">This paragraph has a pink background.</p>
<p id="123item">This paragraph has a yellow background.</p>
```

CSS

```
#blue {
  background-color: skyblue;
}
```

```
/* In the next two rules, the id attributes must be escaped */

#item\?one {
  background-color: pink;
}

#\00003123item {
  background-color: yellow;
}
```

Result

Invalid ID selectors

The ID selectors in the following rules are not valid CSS identifiers, and will be ignored.

```
#item?one {
  background-color: green;
}

#123item {
  background-color: green;
}
```

Keyframe selectors

CSS **keyframe selectors** identify specific points in an animation timeline where keyframe styles should be applied. These selectors are used exclusively within the `@keyframes` at-rule.

Syntax

```
/* Keywords */
from {
}
to {
}

/* <percentage> values */
0% {
}
50% {
}
100% {
}

/* With <timeline-range-name> */
entry 20% {
}
exit 80% {
}

/* Selector lists */
0%,
50%,
100% {
}
from,
to {
}
```

Values

`from`

Represents the start of the animation sequence. It is equivalent to `0%`.

`to`

Represents the end of the animation sequence. It is equivalent to `100%`.

`<percentage>`

A `<percentage>` between `0%` and `100%`, inclusive, representing the total progression through the animation sequence.

`<timeline-range-name> <percentage>`

A `<timeline-range-name>` preceding a `<percentage>` component represents a specific progress point within the named timeline range.

Description

A `<keyframe-selector>` can be the `to` or `from` keyword, a percentage between `0%` and `100%`, inclusive, or a comma-separated list of these keywords and/or percentages. When the percentage is preceded by a `<timeline-range-name>`, it defines a timeline range if the animation timeline is a view progress timeline; otherwise, the selector is ignored. When a comma-separated `<keyframe-selector>` list is used, the style block that follows applies to all the specified progression points.

Valid percentage values

Percentage values must include the percent sign (`%`). Unitless values (such as `0` and `20`) and values outside the range `0%` to `100%` (such as `-10%` or `110%`) are invalid and will cause the keyframe block to be ignored.

Cascade, order, precedence, and importance

Property values set by animation `@keyframes` are more important than all normal styles, meaning no matter the specificity, an animated value will override values that do not have an `!important` flag set. Only important property values and values currently being transitioned take precedence over animated property values.

All keyframe selectors have the same specificity. The order of keyframe selectors within the selector list does not matter. The source order only matters if a duplicate keyframe selector declares a different value for an already declared property on the same selector.

The `!important` flag is not valid within an `@keyframes` definition.

Omitted start and end selectors

If no `0%` (or `from`) or `100%` (or `to`) keyframe is specified, the browser will use the element's computed styles for those states, allowing the animation to transition smoothly from or to the element's non-animated property values. In other words, if a property is specified in a middle-of-the-timeline keyframe without being set within a starting or ending keyframe selector block, the property will animate from its original value to that value.

For example, if an element has a `red` background color, and the following animation is applied:

```
@keyframes changeToPurple {
  25%,
  75% {
    background-color: purple;
  }
}
```

The background color will be `red` at the start of the animation, transitioning to `purple` a quarter of the way through the animation, remaining `purple` for half the animation, and transitioning back to `red`, the original background color, starting `75%` of the way through the animation timeline. See the example that omits the `to` and `from`.

Omitted property declarations

When creating an `@keyframes` animation to animate multiple properties, you don't have to declare all the properties in all the keyframe selector blocks.

For example, in the basic usage example, the `opacity` is declared in all the keyframe selector blocks, but only start and end `transform` values are set. In that case, the element will be fully opaque `50%` of the way through the animation timeline, but the point at which the element is transformed `25vw` to the right depends on the `animation-timing-function` — it will be `50%` in the case of `linear`, but not if `ease-in` is used (which it is in this case).

Cascade order

If multiple keyframe blocks use the same `<keyframe-selector>`, they cascade. This means that if the same property is defined in multiple blocks with the same selector, the last declaration in the rule takes precedence. If they define different properties, they are merged.

This animation repeats non-changing values in multiple selector blocks, which is not necessary:

```
@keyframes uglyAnimation {
  0% {
    transform: translateX(0);
    opacity: 0;
    background-color: purple;
  }
  50% {
    transform: translateX(0);
    opacity: 1;
    background-color: purple;
  }
  75% {
    transform: translateX(0);
    opacity: 0;
    background-color: green;
  }
  100% {
    transform: translateX(50vw);
    opacity: 0;
    background-color: purple;
  }
}
```

We can use the cascade to group values in one selector block, then override them as necessary. The following is equivalent to the previous animation, but with fewer lines of CSS:

```
@keyframes uglyAnimation {
  0%,
  50%,
  75%,
  100% {
    transform: translateX(0);
    opacity: 0;
    background-color: purple;
  }
  50% {
    opacity: 1;
  }
  75% {
    background-color: green;
  }
  100% {
    transform: translateX(50vw);
  }
}
```

Order is important! We can't ignore the cascade. If we reorder the above incorrectly, we lose the transitions. The following makes the element purple, fully opaque, and resets all the transforms during the entire time the animation is applied. The property values are applied and remain static because the last declaration overrides the declarations made in the previous keyframe selector blocks.

```
@keyframes makeItPurpleOnly {
  0% {
    background-color: yellow;
  }
  50% {
    opacity: 0;
  }
  75% {
    background-color: green;
  }
  100% {
    transform: translateX(50vw);
  }
  0%,
  50%,
  75%,
  100% {
    transform: translateX(0);
    opacity: 1;
    background-color: purple;
  }
}
```

With named timeline ranges

Originally defined in the CSS animation module, the CSS scroll-driven animations module expanded the keyframe selector to enable view progress timeline range information to be included directly in the `@keyframes` animation definition. A `<timeline-range-name>` can precede the `<percentage>` component of the selector to attach keyframes to specific progress points within the named timeline range. The `<timeline-range-name>` represents the selected predefined named timeline range, and the `<percentage>` after it represents the percentage progress between the start and end of that named timeline range.

```
@keyframes in-and-out {
  entry 0% {
    opacity: 0;
    transform: translateX(100%);
  }
  entry 100% {
    opacity: 1;
    transform: translateX(0);
  }
  exit 0% {
    opacity: 1;
    transform: translateX(0);
  }
  exit 100% {
    opacity: 0;
    transform: translateX(-100%);
```

```
  }
}
```

If the element's animation timeline does not have a corresponding named view timeline range, then any keyframes attached to points on that named timeline range are ignored. These attachment points may be outside the active interval of the animation. When this occurs, the automatic `from` (`0%`) and `to` (`100%`) keyframes are only generated for properties that don't have keyframes at or earlier than `0%` or at or after `100%`, respectively. See the timeline range name guide for more information.

Examples

Basic usage

This example demonstrates using keywords and percentages by creating a keyframe animation that uses these keyframe selector types.

HTML

We include an element that we will animate.

```
<div>I am animated</div>
```

CSS

We provide some basic styling to our box:

```
div {
  background-color: rebeccapurple;
  color: white;
  width: min-content;
  padding: 10px;
  font: 2rem sans-serif;
}
```

We create an `@keyframes` animation, applying styles to the `from` and `to` keywords and a middle percentage. We animate the `opacity` and the `transform` properties.

```
@keyframes slide-and-fade {
  from {
    transform: translateX(0);
    opacity: 0;
  }
  50% {
    opacity: 1;
  }
  to {
    transform: translateX(50vw);
    opacity: 0;
  }
}
```

We apply our animation to the element using the `animation` shorthand property:

```
div {
  animation: slide-and-fade 4s ease-in infinite;
}
```

Results

Selector lists

Using the same HTML and basic styling as in the previous example, this example demonstrates the use of comma-separated selectors to group keyframes, applying the same styles at multiple points in an animation.

```
<div>I am animated</div>
```

CSS

We create a `pulse` animation that changes the size of our element.

```
div {
  animation: pulse 4s linear infinite;
}

@keyframes pulse {
  0%,
  75% {
    transform: scale(1);
  }
  50% {
    transform: scale(1.2);
  }
  25%,
  100% {
    transform: scale(0.8);
  }
}
```

```
div {
  background-color: rebeccapurple;
  color: white;
  width: min-content;
  padding: 10px;
  font: 2rem sans-serif;
}
```

Result

By using a selector list with multiple comma-separated keyframe selectors, the animation "pauses" from the `25%` keyframe until it reaches the `75%` keyframe.

Omitting <code>to</code> and <code>from</code>

This example demonstrates how, when the `to` or `from` keyframe selectors are not included in a `@keyframes` animation definition, the animated properties will animate to and from the original, non-animated property values.

HTML

We include a few elements. We will be animating all of them.

```
<div>I am animated</div>
<div>I am animated</div>
<div>I am animated</div>
```

CSS

We provide basic styles to our elements, and give each one a different `outline-width` and `background-color`. We will animate these two properties.

```
div {
  background-color: magenta;
  outline: 10px dashed black;
  color: white;
  width: min-content;
  padding: 10px;
  font: 2rem sans-serif;
  margin: 35px auto;

  animation: changes 5s linear infinite;
}
div:first-of-type {
  background-color: blue;
  outline-width: 0;
}
div:last-of-type {
  background-color: green;
  outline-width: 20px;
}
```

We create an animation that sets an element's `background-color` and `outline-width` at `30%` and `40%` keyframes.

```
@keyframes changes {
  30%, 40% {
    background-color: black;
    outline-width: 15px;
}
```

Result

The `background-color` and `outline-width` properties are set in `30%` and `40%` keyframes. As a result, the elements' `background-color` values animate from `green`, `magenta`, and `blue` to `black` while their `outline-width` values animate from `0px`, `10px`, and `20px` to `15px`. They remain in that state for one-tenth of the animation — between `30%` and `40%` duration. After `40%` duration, these properties animate back to their initial values again.

- CSS scroll-driven animations

Namespace separator

The **namespace separator** (`|`) separates the selector from the namespace, identifying the namespace, or lack thereof, for a type selector.

```
/* Links in the namespace named myNameSpace */
myNameSpace|a {
  font-weight: bold;
}
/* paragraphs in any namespace (including no namespace) */
*|p {
  color: darkblue;
}
/* heading level 2 not in a namespace */
|h2 {
  margin-bottom: 0;
}
```

Type selectors and the universal selector allow an optional namespace component. When a namespace has been previously declared via `@namespace`, these selectors can be namespaced by prepending the selector with the name of the namespace separated by the namespace separator (`|`). This is useful when dealing with documents containing multiple namespaces such as HTML with inline SVG or MathML, or XML that mixes multiple vocabularies.

- `ns|h1` - matches `<h1>` elements in namespace `ns`
- `*|h1` - matches all `<h1>` elements
- `|h1` - matches all `<h1>` elements outside of any declared or implied namespace

Syntax

```
namespace|element { style properties }
```

Examples

By default, all elements in an HTML or SVG element have a namespace as the `http://www.w3.org/1999/xhtml` and `http://www.w3.org/2000/svg` namespace are implied. The `document.createElementNS` method, with an empty string for the namespace parameter, can be used to create elements with no namespace.

Named namespace example

In this example, all elements are in a namespace.

HTML

No namespaces are explicitly declared in the HTML or within the SVG.

```
<p>This paragraph <a href="#">has a link</a>.</p>

<svg width="400" viewBox="0 0 400 20">
  <a href="#">
    <text x="0" y="15">Link created in SVG</text>
  </a>
</svg>
```

CSS

The CSS declares two namespaces, then assigns styles to links globally (`a`), to links in no namespace (`|a`), to links in any namespace or no namespace (`*|a`), and then to two different named namespaces (`svgNamespace|a` and `htmlNameSpace|a`).

```
@namespace svgNamespace url("http://www.w3.org/2000/svg");
@namespace htmlNameSpace url("http://www.w3.org/1999/xhtml");
/* All `<a>`s in the default namespace, in this case, all `<a>`s */
a {
  font-size: 1.4rem;
}
/* no namespace */
|a {
  text-decoration: wavy overline lime;
  font-weight: bold;
}
/* all namespaces (including no namespace) */
*|a {
  color: red;
  fill: red;
  font-style: italic;
}
/* only the svgNamespace namespace, which is <svg> content */
svgNamespace|a {
  color: green;
  fill: green;
}
/* The htmlNameSpace namespace, which is the HTML document */
htmlNameSpace|a {
  text-decoration-line: line-through;
}
```

Result

The selector `|a`, a link not in a namespace, doesn't match any links. In HTML, the `http://www.w3.org/1999/xhtml` is implied, meaning all HTML is in a namespace, even if none is explicitly declared. In SVG, even if not explicitly set, the `http://www.w3.org/2000/svg` namespace is also implied. This means all the content is within at least one namespace.

Default namespace and no namespace

In this example, we use JavaScript to create an element without a namespace and append it to the document. We set the SVG namespace to be the default namespace by defining the unnamed namespace with `@namespace`.

> **Note:** If a default, or unnamed, namespace is defined, universal and type selectors apply only to elements in that namespace.

HTML

No namespaces are explicitly declared in the HTML or within the SVG.

```
<p><a href="#">A link</a> in the implied HTML namespace.</p>

<svg width="400" viewBox="0 0 400 20">
  <a href="#">
    <text x="0" y="15">Link created in SVG namespace</text>
  </a>
</svg>
```

JavaScript

With JavaScript, with `document.createElementNS`, we create an anchor link without a namespace, then append the link.

```
// create 'no namespace' anchor
const a = document.createElementNS("", "a");
a.href = "#";
a.appendChild(document.createTextNode("Link created without a namespace"));

document.body.appendChild(a);
```

CSS

We declare a namespace with `@namespace`. By omitting the name for the namespace, the `@namespace` declaration creates a default namespace.

```
/* By omitting a name, this sets SVG as the default namespace */
@namespace url("http://www.w3.org/2000/svg");

/* `<a>` in the default (set to SVG) namespace */
a {
  font-size: 1.4rem;
}

/* `<svg>` and `<p>` in the default (set to SVG) namespace */
svg,
p {
```

```
  border: 5px solid gold;
}

/* links outside of any namespace */
|a {
  text-decoration: wavy underline purple;
  font-weight: bold;
}

/* links with any namespace or no namespace */
*|a {
  font-style: italic;
  color: magenta;
  fill: magenta;
}
```

Result

The selector with no namespace separator, the `a`, matched only the SVG `<a>` elements, as SVG was set as the default namespace.

The selector with no namespace, the `|a`, matched the JavaScript defined and appended `<a>`, as that node is the only node that doesn't have a default namespace.

& nesting selector

The CSS **`&` nesting selector** explicitly states the relationship between parent and child rules when using CSS nesting. It makes the nested child rule selectors *relative to the parent element*. Without the `&` nesting selector, the child rule selector selects child elements. The child rule selectors have the same specificity weight as if they were within `:is()`.

> **Note:** *Child rule* does not mean *child element selector*. A child rule can target parent element or child elements depending on use of the `&` nesting selector.

If not used in nested style rule, the `&` nesting selector represents the scoping root.

Syntax

```
/* Nested directly — adds whitespace (descendant) */
parentRule {
  & childRule { }
}

/* Attached to parent — no whitespace (e.g., pseudo-class, compound selector) */
parentRule {
  &:pseudo-class { }
}

/* Reversed context — & placed after another selector */
parentRule {
  otherRule & { }
}
```

Description

<code>&</code> nesting selector and whitespace

Consider the following code where nesting is done *without* the `&` nesting selector.

```
.parent-rule {
  /* parent rule properties */
  .child-rule {
    /* child rule properties */
  }
}
```

When the browser parses the nested selectors, it automatically adds whitespace between the selectors to create a new CSS selector rule. The following code shows the equivalent non-nested rules:

```
.parent-rule {
  /* parent rule style properties */
}

.parent-rule .child-rule {
  /* style properties for .child-rule descendants for .parent-rule ancestors */
}
```

When the nested rule needs to be attached (with no whitespace) to the parent rule, such as when using a `pseudo-class` or creating compound selectors, the `&` nesting selector must be immediately prepended to achieve the desired effect.

Consider an example where we want to style an element, providing styles to be applied at all times, and also nesting some styles to be applied only on hover. If the `&` nesting selector is not included, whitespace is added and we end up with a ruleset that applies the nested styles to any *hovered descendant of the parent rule selector*. This is, however, not what we want.

```
.parent-rule {
  /* parent rule properties */
  :hover {
    /* child rule properties */
  }
}

/* the browser parses the above nested rules as shown below */
.parent-rule {
  /* parent rule properties */
}
```

```
.parent-rule *:hover {
  /* child rule properties */
}
```

With the `&` nesting selector added with no whitespace, the elements matched by the parent rule will be styled when hovered.

```
.parent-rule {
  /* parent rule properties */
  &:hover {
    /* child rule properties */
  }
}

/* the browser parses the above nested rules as shown below */
.parent-rule {
  /* parent rule properties */
}

.parent-rule:hover {
  /* child rule properties */
}
```

Appending the <code>&</code> nesting selector

The `&` nesting selector can also be appended to reverse the context of the rules.

```
.card {
  /* .card styles */
  .featured & {
    /* .featured .card styles */
  }
}

/* the browser parses above nested rules as */

.card {
  /* .card styles */
}

.featured .card {
  /* .featured .card styles */
}
```

The `&` nesting selector can be placed multiple times:

```
.card {
  /* .card styles */
  .featured & & & {
    /* .featured .card .card .card styles */
  }
}

/* the browser parses above nested rules as */

.card {
  /* .card styles */
}

.featured .card .card .card {
  /* .featured .card .card .card styles */
}
```

Cannot represent pseudo-elements

The `&` selector is equivalent to the `:is()` selector, and has the same limitation that it cannot represent pseudo-elements.

For example, with the following style rule, no generated content will be styled red, even when nested in `<div class="important">`, because `.important :is(.foo::before)` cannot match anything.

```
.foo::before {
  content: "Hello";

  .important & {
    color: red;
  }
}
```

This limitation also applies to nested at-rules, whose properties are implicitly wrapped in an `&` selector. For example, with the following rule, no generated content will be styled red, even on a small screen, because the `color: red` property is implicitly wrapped in an `&` selector, which in this case is `:is(.foo::before)`.

```
.foo::before {
  content: "Hello";

  @media (width < 600px) {
    color: red;
  }
}
```

Examples

Both of the following examples produce the same output. The first one uses normal CSS styles and the second one uses the `&` nesting selector.

Using normal CSS styles

This example uses normal CSS styling.

HTML

```
<p class="example">
  This paragraph <a href="#">contains a link</a>, try hovering or focusing it.
</p>
```

CSS

```
.example {
  font-family: system-ui;
  font-size: 1.2rem;
}

.example > a {
  color: tomato;
}

.example > a:hover,
.example > a:focus {
  color: ivory;
  background-color: tomato;
}
```

Result

Using <code>&</code> in nested CSS styles

This example uses nested CSS styling.

HTML

```
<p class="example">
  This paragraph <a href="#">contains a link</a>, try hovering or focusing it.
</p>
```

CSS

```
.example {
  font-family: system-ui;
  font-size: 1.2rem;
  & > a {
    color: tomato;
    &:hover,
    &:focus {
      color: ivory;
      background-color: tomato;
    }
  }
}
```

Result

Using <code>&</code> outside nested rule

If not used in a nested style rule, `&` represents the scoping root. In this case, all styles apply to the document.

```
<p>Hover over the output box to change document's background color.</p>
```

```
& {
  color: blue;
  font-weight: bold;
}

&:hover {
  background-color: wheat;
}
```

Next-sibling combinator

The **next-sibling combinator** (`+`) separates two selectors and matches the second element only if it *immediately* follows the first element, and both are children of the same parent `element`.

```
/* Paragraphs that come immediately after any image */
img + p {
  font-weight: bold;
}
```

Syntax

```
/* The white space around the + combinator is optional but recommended. */
former_element + target_element { style properties }
```

Examples

Basic usage

This example demonstrates how to select the next sibling if that next sibling is of a specific type.

CSS

We only style the `<li>` that comes immediately after an `<li>` that is the first of its type:

```
li:first-of-type + li {
  color: red;
  font-weight: bold;
}
```

HTML

```
<ul>
  <li>One</li>
  <li>Two!</li>
  <li>Three</li>
</ul>
```

Result

Selecting a previous sibling

The next-sibling combinator can be included within the `:has()` functional selector to select the previous sibling.

CSS

We only style the `<li>` with a next sibling that is an `<li>` that is the last of its type:

```
li:has(+ li:last-of-type) {
  color: red;
  font-weight: bold;
}
```

HTML

```
<ul>
  <li>One</li>
  <li>Two</li>
  <li>Three!</li>
  <li>Four</li>
</ul>
```

Result

- Subsequent-sibling combinator

Pseudo-classes

A CSS ***pseudo-class*** is a keyword added to a selector that lets you select elements based on information that lies outside of the document tree, such as a specific state of the selected element(s). For example, the pseudo-class `:hover` can be used to style a button when a user's pointer hovers over it.

```
/* Any button over which the user's pointer is hovering */
button:hover {
  color: blue;
}
```

A pseudo-class consists of a colon (`:`) followed by the pseudo-class name (e.g., `:hover`). A functional pseudo-class also contains a pair of parentheses to define the arguments (e.g., `:dir()`). The element that a pseudo-class is attached to is defined as an *anchor element* (e.g., `button` in case `button:hover`).

Pseudo-classes let you apply a style to an element not only in relation to the content of the document tree, but also in relation to external factors like the history of the navigator (`:visited`, for example), the status of its content (like `:checked` on certain form elements), or the position of the mouse (like `:hover`, which lets you know if the mouse is over an element or not).

> **Note:** In contrast to pseudo-classes, pseudo-elements can be used to style a *specific part* of an element.

Elemental pseudo-classes

These pseudo-classes relate to the core identity of elements.

`:defined`

Matches any element that is defined.

`:heading`

Matches any heading element (`<h1>`-`<h6>`).

Element display state pseudo-classes

These pseudo-classes enable the selection of elements based on their display states.

`:open`

Matches an element that can either be open or closed that is currently open.

`:popover-open`

Matches a popover element that is currently in the showing state.

`:modal`

Matches an element that is in a state in which it excludes all interaction with elements outside it until the interaction has been dismissed.

`:fullscreen`

Matches an element that is currently in fullscreen mode.

`:picture-in-picture`

Matches an element that is currently in picture-in-picture mode.

`:xr-overlay`

Matches the DOM overlay element during an immersive AR or VR session.

Input pseudo-classes

These pseudo-classes relate to form elements, and enable selecting elements based on HTML attributes and the state that the field is in before and after interaction.

`:enabled`

Represents a user interface element that is in an enabled state.

`:disabled`

Represents a user interface element that is in a disabled state.

`:read-only`

Represents any element that cannot be changed by the user.

`:read-write`

Represents any element that is user-editable.

`:placeholder-shown`

Matches an input element that is displaying placeholder text. For example, it will match the `placeholder` attribute in the `<input>` and `<textarea>` elements.

`:autofill`

Matches when an `<input>` has been autofilled by the browser.

`:default`

Matches one or more UI elements that are the default among a set of elements.

`:checked`

Matches when elements such as checkboxes and radio buttons are toggled on.

`:indeterminate`

Matches UI elements when they are in an indeterminate state.

`:blank`

Matches a user-input element which is empty, containing an empty string or other null input.

`:valid`

Matches an element with valid contents. For example, an input element with the type 'email' that contains a validly formed email address or an empty value if the control is not required.

`:invalid`

Matches an element with invalid contents. For example, an input element with type 'email' with a name entered.

`:in-range`

Applies to elements with range limitations. For example, a slider control when the selected value is in the allowed range.

`:out-of-range`

Applies to elements with range limitations. For example, a slider control when the selected value is outside the allowed range.

`:required`

Matches when a form element is required.

`:optional`

Matches when a form element is optional.

`:user-valid`

Represents an element with correct input, but only when the user has interacted with it.

`:user-invalid`

Represents an element with incorrect input, but only when the user has interacted with it.

Linguistic pseudo-classes

These pseudo-classes reflect the document language and enable the selection of elements based on language or script direction.

`:dir()`

The directionality pseudo-class selects an element based on its directionality as determined by the document language.

`:lang()`

Select an element based on its content language.

Location pseudo-classes

These pseudo-classes relate to links, and to targeted elements within the current document.

`:any-link`

Matches an element if the element would match either `:link` or `:visited`.

`:link`

Matches links that have not yet been visited.

`:visited`

Matches links that have been visited.

`:local-link`

Matches links whose absolute URL is the same as the target URL. For example, anchor links to the same page.

`:target`

Matches the element which is the target of the document URL.

`:scope`

Represents elements that are a reference point for selectors to match against.

> **Note:** A `:target-within` pseudo-class, to match elements that are or have a descendant which is the target of the document URL, was defined but removed from the specification. Use `:has(:target)` for this purpose.

Resource state pseudo-classes

These pseudo-classes apply to media that is capable of being in a state where it would be described as playing, such as a video.

`:playing`

Represents a playable element that is playing.

`:paused`

Represents a playable element that is paused.

`:seeking`

Represents a playable element that is currently seeking a playback position in the media resource.

`:buffering`

Represents a playable element that is playing but is temporarily stalled because it is downloading the media resource.

`:stalled`

Represents a playable element that is playing but is stalled because it cannot download the media resource.

`:muted`

Represents a sound-producing element that is muted.

`:volume-locked`

Represents a sound-producing element that has its volume level locked by the browser.

Time-dimensional pseudo-classes

These pseudo-classes apply when viewing something which has timing, such as a WebVTT caption track.

`:current`

Represents the element or ancestor of the element that is being displayed.

`:past`

Represents an element that occurs entirely before the `:current` element.

`:future`

Represents an element that occurs entirely after the `:current` element.

Tree-structural pseudo-classes

These pseudo-classes relate to the location of an element within the document tree.

`:root`

Represents an element that is the root of the document. In HTML this is usually the `<html>` element.

`:empty`

Represents an element with no children other than white-space characters.

`:nth-child()`

Uses `An+B` notation to select elements from a list of sibling elements.

`:nth-last-child()`

Uses `An+B` notation to select elements from a list of sibling elements, counting backwards from the end of the list.

`:first-child`

Matches an element that is the first of its siblings.

`:last-child`

Matches an element that is the last of its siblings.

`:only-child`

Matches an element that has no siblings. For example, a list item with no other list items in that list.

`:heading()`

Uses `An+B` notation to select heading elements (`<h1>`-`<h6>`).

`:nth-of-type()`

Uses `An+B` notation to select elements from a list of sibling elements that match a certain type from a list of sibling elements.

`:nth-last-of-type()`

Uses `An+B` notation to select elements from a list of sibling elements that match a certain type from a list of sibling elements counting backwards from the end of the list.

`:first-of-type`

Matches an element that is the first of its siblings, and also matches a certain type selector.

`:last-of-type`

Matches an element that is the last of its siblings, and also matches a certain type selector.

`:only-of-type`

Matches an element that has no siblings of the chosen type selector.

Shadow-structural pseudo-classes

These pseudo-classes relate to the shadow DOM.

`:host`

Matches the shadow tree's shadow host.

`:host()`

Matches an element that matches `:host` and matches any of the selectors in the list provided.

`:host-context()`

Selects elements outside of the shadow tree in the context of the shadow host.

`:has-slotted`

Matches slot elements that have been assigned content.

User action pseudo-classes

These pseudo-classes require some interaction by the user in order for them to apply, such as holding a mouse pointer over an element.

`:hover`

Matches when a user designates an item with a pointing device, such as holding the mouse pointer over the item.

`:active`

Matches when an item is being activated by the user. For example, when the item is clicked on.

`:focus`

Matches when an element has focus.

`:focus-visible`

Matches when an element has focus and the user agent identifies that the element should be visibly focused.

`:focus-within`

Matches an element to which `:focus` applies, plus any element that has a descendant to which `:focus` applies.

`:target-current`

Matches the `::scroll-marker` pseudo-element of a `scroll-marker-group` that is currently scrolled to, in other words, the **active** scroll marker.

Top-layer ancestor matching boundary

When setting styles using a `:hover`, `:active`, or `:focus-within` pseudo-class selector, the selector matches a nested set of elements up the DOM tree. If the hierarchy includes an element in the top layer (for example, a popover or customizable `<select>` picker), the matching stops at that top-layer element.

For example, the following code features a customizable `<select>` element and a popover. We've set every element in the page to have a thick blue dashed `border` on hover.

```
<main>
  <select>
    <option>One</option>
    <option>Two</option>
    <option>Three</option>
  </select>

  <div>
    <button popovertarget="mypopover">Toggle popover</button>
    <section id="mypopover" popover>
      <p>I am a popover</p>
      <button>I am a popover button</button>
    </section>
  </div>
</main>
```

```
* {
  padding: 5px;
}
```

```
select,
::picker(select) {
  appearance: base-select;
}

:hover {
  border: 5px dashed blue;
}
```

Note that when you hover over the `<select>` element or the popover toggle button, all ancestors of those elements get the border. However, once the select picker or the popover is open, hovering over one of its descendants applies the border only up to the top-layer element itself (the select picker or the popover), that is, the matching stops at this element.

This behavior stops the pseudo-class matching from spilling out of a top-layer component into the surrounding page, which can otherwise cause a user interface to look broken.

Functional pseudo-classes

These pseudo-classes accept a selector list or forgiving selector list as a parameter.

`:is()`

The matches-any pseudo-class matches any element that matches any of the selectors in the list provided. The list is forgiving.

`:not()`

The negation, or matches-none, pseudo-class represents any element that is not represented by its argument.

`:where()`

The specificity-adjustment pseudo-class matches any element that matches any of the selectors in the list provided without adding any specificity weight. The list is forgiving.

`:has()`

The relational pseudo-class represents an element if any of the relative selectors match when anchored against the attached element.

Custom state pseudo-classes

These pseudo-classes apply to custom elements.

`:state()`

Matches custom elements that have the specified custom state.

Page pseudo-classes

These pseudo-classes relate to pages in a printed document and are used with the `@page` at-rule.

`:left`

Represents all left-hand pages of a printed document.

`:right`

Represents all right-hand pages of a printed document.

`:first`

Represents the first page of a printed document.

`:blank`

Represents a blank page in a printed document.

View transition pseudo-classes

These pseudo-classes relate to elements involved in a view transition.

`:active-view-transition`

Matches the root element of a document when a view transition is in progress (*active*) and stops matching once the transition has completed.

`:active-view-transition-type()`

Matches the root element of a document when a specified view transition is in progress (*active*) and stops matching once the transition has completed.

Syntax

```
selector:pseudo-class {
  property: value;
}
```

Like regular classes, you can chain together as many pseudo-classes as you want in a selector.

Alphabetical index

Pseudo-classes defined by a set of CSS specifications include the following:

A

- `:active`
- `:active-view-transition`
- `:active-view-transition-type()`
- `:any-link`
- `:autofill`

B

- `:blank` (input)
- `:blank` (page)
- `:buffering`

C

- `:checked`
- `:current`

D

- `:default`
- `:defined`
- `:dir()`
- `:disabled`

E

- :empty
- :enabled

F

- :first
- :first-child
- :first-of-type
- :focus
- :focus-visible
- :focus-within
- :fullscreen
- :future

H

- :has-slotted
- :has()
- :heading
- :heading()
- :host
- :host()
- :host-context()
- :hover

I

- :in-range
- :indeterminate
- :interest-source
- :interest-target
- :invalid
- :is()

L

- :lang()
- :last-child
- :last-of-type
- :left
- :link
- :local-link

M

- :modal
- :muted

N

- :not()
- :nth-child()
- :nth-last-child()
- :nth-last-of-type()
- :nth-of-type()

O

- :only-child
- :only-of-type
- :open
- :optional
- :out-of-range

P

- :past
- :paused
- :picture-in-picture
- :placeholder-shown
- :playing
- :popover-open

R

- :read-only
- :read-write
- :required
- :right
- :root

S

- :scope
- :seeking
- :stalled
- :state()

T

- :target
- :target-after
- :target-current

- `:target-before`

U

- `:user-invalid`
- `:user-valid`

V

- `:valid`
- `:visited`
- `:volume-locked`

W

- `:where()`

X

- `:xr-overlay`

Non-standard pseudo-classes

Non-standard vendor-prefixed pseudo-classes include:

`-moz-` prefix

- `:-moz-broken`
- `:-moz-drag-over`
- `:-moz-first-node`
- `:-moz-handler-blocked`
- `:-moz-handler-crashed`
- `:-moz-handler-disabled`
- `:-moz-last-node`
- `:-moz-loading`
- `:-moz-locale-dir(ltr)`
- `:-moz-locale-dir(rtl)`
- `:-moz-only-whitespace`
- `:-moz-submit-invalid`
- `:-moz-suppressed`
- `:-moz-user-disabled`
- `:-moz-window-inactive`

- CSS selectors module

Pseudo-elements

A CSS **pseudo-element** is a keyword added to a selector that lets you style a specific part of the selected element(s).

> **Note:** This page is an index of all pseudo-elements in CSS. The CSS pseudo-elements page introduces the module that defines some, but not all, of these pseudo-elements.

Syntax

```
selector::pseudo-element {
  property: value;
}
```

For example, `::first-line` can be used to change the font of the first line of a paragraph.

```
/* The first line of every <p> element. */
p::first-line {
  color: blue;
  text-transform: uppercase;
}
```

Double colons (`::`) are used for pseudo-elements. This distinguishes pseudo-elements from pseudo-classes that use a single colon (`:`) in their notation. Note, browsers support single colon syntax for the original four pseudo-elements: `::before`, `::after`, `::first-line`, and `::first-letter`.

Pseudo-elements do not exist independently. The element of which a pseudo-element is a part is called its *originating element*. A pseudo-element must appear after all the other components in the complex or compound selector. The last element in the selector is the originating element of the pseudo-element. For example, you can select a paragraph's first line using `p::first-line` but not the first-line's children. So `p::first-line > *` is invalid.

A pseudo-element can be selected based on the current state of the originating element. For example, `p:hover::first-line` selects the first line (pseudo-element) of a paragraph when the paragraph itself is being hovered (pseudo-class).

The specifications allow some pseudo-elements to be selected based on the current state of the originating element. In these cases, the pseudo-element is selected only when it is in the same state. For example, `::picker(select):hover` selects the currently hovered descendant of a customizable `<select>` element, excluding the first `<button>` child, which is not selected by the `::picker()` pseudo-element. Note, however, that when a selector list contains an invalid selector, the entire style block is ignored, so make sure the state you're including is supported on the pseudo-element to which it is attached.

Typographic pseudo-elements

`::first-line`

The first line-box of the originating element.

`::first-letter`

The first letter, number, or symbol character on the first line of its originating element.

`::cue`

The WebVTT cues within a selected element. This can be used to style captions and other cues in media with VTT tracks. The CSS pseudo-elements module also defines the `::postfix` and `::prefix` sub-pseudo elements. These are not yet supported by any browser.

Highlight pseudo-elements

Selects document sections based on content and document status, enabling those areas to be styled differently to indicate that status to the user.

`::grammar-error`

A portion of text that the browser thinks is grammatically incorrect.

`::highlight()`

The elements in the highlight registry. It is used to create custom highlights.

`::search-text`

Search results identified by the user agent's "Find" or "Find in page" text search feature.

`::selection`

The portion of a document that has been selected.

`::spelling-error`

A portion of text that the browser thinks is misspelled.

`::target-text`

The document's target element. The target element is identified using the URL's fragment identifier.

Tree-Abiding pseudo-elements

These pseudo-elements behave like regular elements, fitting seamlessly within the box model. They act as a child element that can be styled directly within the originating element hierarchy.

`::before`

Creates a pseudo-element that is the first child of the selected element.

`::after`

Creates a pseudo-element that is the last child of the selected element.

`::column`

Each column fragment of a multi-column layout.

`::marker`

The automatically generated marker box of a list item.

`::backdrop`

The backdrop of the originating element rendered in the top layer.

`::scroll-button()`

Creates a button that can control the scrolling of the scroll container to which it is applied.

`::scroll-marker`

Creates a pseudo-element that is a scroll marker — a scroll target button for its originating element nested in a scroll-marker group.

`::scroll-marker-group`

Generates a container before or after a scroll container to contain the `::scroll-marker` pseudo-elements generated on the element or its descendants.

Element-backed pseudo-elements

These pseudo-elements are real elements that are not otherwise selectable.

`::details-content`

The expandable/collapsible contents of a `<details>` element.

`::part()`

Any element within a shadow tree that has a matching `part` attribute.

`::slotted()`

Any element placed into a slot inside an HTML template.

Form-related pseudo-elements

The pseudo-elements are related to form controls.

`::checkmark`

Targets the checkmark placed inside the currently-selected `<option>` element of a customizable select element to provide a visual indication of which one is selected.

`::file-selector-button`

The button of an `<input>` of `type="file"`.

`::picker()`

The picker part of an element, for example the drop-down picker of a customizable select element.

`::picker-icon`

The picker icon inside form controls that have an icon associated with them. In the case of a customizable select element, it selects the arrow that points down when the select is closed.

`::placeholder`

The placeholder text in an input field.

Alphabetical index

Pseudo-elements defined by a set of CSS specifications include the following:

A

- `::after`

B

- `::backdrop`
- `::before`

C

- `::column`
- `::checkmark`
- `::cue` (and `::cue()`)

D

- `::details-content`

F

- `::file-selector-button`
- `::first-letter`
- `::first-line`

G

- `::grammar-error`

H

- `::highlight()`

M

- `::marker`

P

- `::part()`
- `::picker()`
- `::picker-icon`
- `::placeholder`

S

- `::scroll-button()`
- `::scroll-marker`
- `::scroll-marker-group`
- `::selection`
- `::slotted()`
- `::spelling-error`

T

- `::target-text`

V

- `::view-transition`
- `::view-transition-image-pair()`
- `::view-transition-group()`
- `::view-transition-new()`
- `::view-transition-old()`

Non-standard pseudo-elements

Non-standard vendor-prefixed pseudo-elements include:

`-moz-` prefix

- `::-moz-color-swatch`
- `::-moz-focus-inner`
- `::-moz-list-bullet`
- `::-moz-list-number`
- `::-moz-meter-bar`
- `::-moz-progress-bar`
- `::-moz-range-progress`
- `::-moz-range-thumb`
- `::-moz-range-track`

`-webkit-` prefix

- `::-webkit-inner-spin-button`
- `::-webkit-meter-bar`
- `::-webkit-meter-even-less-good-value`
- `::-webkit-meter-inner-element`
- `::-webkit-meter-optimum-value`
- `::-webkit-meter-suboptimum-value`
- `::-webkit-progress-bar`
- `::-webkit-progress-inner-element`

- `::-webkit-progress-value`
- `::-webkit-scrollbar`
- `::-webkit-search-cancel-button`
- `::-webkit-search-results-button`
- `::-webkit-slider-runnable-track`
- `::-webkit-slider-thumb`

Nesting pseudo-elements

You can chain some pseudo-element selectors together to style pseudo-elements nested inside other pseudo-elements. The following nested pseudo-element combinations are supported:

- `::after`
  - `::after::marker`: Selects the `::marker` pseudo-element of an `::after` pseudo-element, when `::after` is styled as a list item, with `display: list-item`.
- `::before`
  - `::before::marker`: Selects the `::marker` pseudo-element of a `::before` pseudo-element, when `::before` is styled as a list item, with `display: list-item`.

Check out the individual pseudo-element reference pages for examples and browser compatibility information.

Highlight pseudo-elements inheritance

Highlight pseudo-elements, such as `::selection`, `::target-text`, `::highlight()`, `::spelling-error`, and `::grammar-error`, follow a consistent inheritance model that differs from regular element inheritance.

When you apply styles to highlight pseudo-elements, they inherit from both:

1. Their parent elements (following normal inheritance).
2. The highlight pseudo-elements of their parent elements (following highlight inheritance).

This means that if you style both a parent element's highlight pseudo-element and a child element's highlight pseudo-element, the child's highlighted text will combine properties from both sources.

Here is a concrete example.

First, we have some HTML that includes two nested `<div>` elements. Some of the included text content is contained directly inside the parent `<div>`, and some is nested inside the child `<div>`.

```
<div class="parent">
  Parent text
  <div class="child">Child text</div>
</div>
```

Next we include some CSS, which selects the parent and child `<div>` elements separately and gives them different `color` values, and selects the parent and child's selected text (`::selection`). This gives each `<div>` a different `background-color` and sets a different text `color` on the parent selection.

```
/* Style for the parent element */
.parent {
  color: blue;
}

/* Style for the parent's selected text */
.parent::selection {
  background-color: yellow;
  color: red;
}

/* Style for the child element */
.child {
  color: green;
}

/* Style for the child's selected text */
.child::selection {
  background-color: orange;
}
```

The example renders as follows:

Try selecting the text in both the parent and child elements. Notice that:

1. When you select the parent text, it uses the yellow background and red text color defined in `.parent::selection`.
2. When you select the child text, it uses:
   - The orange background from `.child::selection`.
   - The red text color inherited from the parent's `::selection` pseudo-element.

This demonstrates how the child's highlight pseudo-element inherits from both its parent element and the parent's highlight pseudo-element.

CSS custom properties (variables) in highlight pseudo-elements inherit from their originating element (the element they're being applied to), not through the highlight inheritance chain. For example:

```
:root {
  --selection-color: lightgreen;
}

::selection {
  color: var(--selection-color);
}

.blue {
  --selection-color: blue;
}
```

When using the universal selector with highlight pseudo-elements, it prevents highlight inheritance. For example:

```
/* This prevents highlight inheritance */
*::selection {
  color: lightgreen;
}

/* Prefer this to allow inheritance */
:root::selection {
  color: lightgreen;
}
```

Selector list

The CSS **selector list** (`,`) selects all the matching nodes. A selector list is a comma-separated list of selectors.

Description

When multiple selectors share the same declarations, they can be grouped together into a comma-separated list. Selector lists can also be passed as parameters to some functional CSS pseudo-classes. White space may appear before and/or after the comma.

The following three declarations are equivalent:

```
span {
  border: red 2px solid;
}
div {
  border: red 2px solid;
}
```

```
span,
div {
  border: red 2px solid;
}
```

```
:is(span, div) {
  border: red 2px solid;
}
```

Examples

When applying the same styles to elements matching different criteria, grouping the selectors in a comma-separated list can improve consistency while reducing the size of style sheets.

Single line grouping

This example shows grouping selectors in a single line using a comma-separated list.

```
h1, h2, h3, h4, h5, h6 {
  font-family: "Helvetica", "Arial";
}
```

Multi line grouping

This example shows grouping selectors in multiple lines using a comma-separated list.

```
#main,
.content,
article,
h1 + p {
  font-size: 1.1em;
}
```

Valid and invalid selector lists

An invalid selector represents, and therefore matches, nothing. When a selector list contains an invalid selector, the entire style block is ignored, except for the `:is()` and `:where()` pseudo-classes that accept forgiving selector lists.

Invalid selector list

A downside to using a selector list is that a single unsupported selector in the selector list invalidates the entire rule.

Consider the following two CSS rule sets:

```
h1 {
  font-family: sans-serif;
}
h2:invalid-pseudo {
  font-family: sans-serif;
}
h3 {
  font-family: sans-serif;
}
```

```
h1,
h2:invalid-pseudo,
h3 {
  font-family: sans-serif;
}
```

They are not equivalent. In the first rule set, styles will be applied on the `h1` and `h3` elements, but the `h2:invalid-pseudo` rule will not be parsed. In the second rule set, because one selector in the list is invalid, the entire rule will not be parsed. Because of this, no style will be applied to the `h1` and `h3` elements as when any selector in a list of selectors in invalid, the entire style block will be ignored.

Forgiving selector list

A way to remedy the invalid selector list problem is to use the `:is()` or the `:where()` pseudo-class, which accept a forgiving selector list. Each selector in a forgiving selector list is parsed individually. So any invalid selectors in the list are ignored and the valid ones are used.

Carrying on from the previous example, the following two CSS rule sets are now equivalent:

```
h1 {
  font-family: sans-serif;
```

```
}
h2:maybe-unsupported {
  font-family: sans-serif;
}
h3 {
  font-family: sans-serif;
}
```

```
:is(h1, h2:maybe-unsupported, h3) {
  font-family: sans-serif;
}
```

The difference between the two is that the specificity of `:is()` is its most specific argument, whereas the `:where()` selector and the forgiving selector list parameter do not add any specificity weight.

Relative selector list

A relative selector list is a comma-separated selector list parsed as relative selectors, which begin with an explicit or implied combinator.

```
h2:has(+ p, + ul.red) {
  font-style: italic;
}
```

In the above example, the italic style will be applied to any `h2` heading that is immediately followed by `<p>` or `<ul class="red">`. Note that pseudo-elements and the `:has()` selector are not valid within the `:has()` relative selector list.

See also

- The `:is()` and `:where()` pseudo-classes accept forgiving selector lists.
- The `:not()` pseudo-class accepts a regular selector list
- The `:has()` pseudo-class accepts a relative selector list.
- CSS selectors module
- Selectors and combinators

Subsequent-sibling combinator

The **subsequent-sibling combinator** (~, a tilde) separates two selectors and matches *all instances* of the second element that follow the first element (not necessarily immediately) and share the same parent element.

In the following example, the subsequent-sibling combinator (~) helps to select and style paragraphs that are both siblings of an image and appear after any image.

```
img ~ p {
  color: red;
}
```

Syntax

```
/* The white space around the ~ combinator is optional but recommended. */
former_element ~ target_element { style properties }
```

Examples

Using the combinator with simple selectors

This example shows the use of the ~ combinator when both the selectors are simple selectors (`p` and `span`).

```
<article>
  <span>This is not red because it appears before any paragraph.</span>
  <p>Here is a paragraph.</p>
  <code>Here is some code.</code>
  <span>
    This span is red because it appears after the paragraph, even though there
    are other nodes in between.
  </span>
  <p>Whatever it may be, keep smiling.</p>
  <h1>Dream big</h1>
  <span>
    Doesn't matter how many or what kind of nodes are in between, all spans from
    the same parent after a paragraph are red.
  </span>
</article>
<span>
  This span is not red because it doesn't share a parent with a paragraph.
</span>
```

```
p ~ span {
  color: red;
}
```

Using the combinator with complex selectors

This example contains two complex selectors, both using the subsequent-sibling combinator: `.foo p ~ span` and `.foo p ~ .foo span`.

- The first complex selector, `.foo p ~ span`, matches all spans that come after a paragraph *if* the span and paragraph share the same parent **and** that parent or an ancestor of that parent has the class `.foo`.
- The second complex selector, `.foo p ~ .foo span`, matches all spans that are a descendant of the element with class `.foo` *if* that element is a sibling of the previously mentioned paragraph.

The example below shows that the target element in the complex selector must share the same parent as the initial element in the complex selector.

```
<h1>Dream big</h1>
<span>And yet again this is a red span!</span>
<div class="foo">
  <p>Here is another paragraph.</p>
  <span>A blue span</span>
  <div class="foo">
    <span>A green span</span>
  </div>
</div>
```

```
.foo p ~ span {
  color: blue;
}

.foo p ~ .foo span {
  color: green;
}
```

In the above HTML, the two siblings of `.foo p` are `span` and `.foo`. The green `span` is a descendant of the `.foo` class, which is a sibling of `p`.

- When the target selector is `span`, the `span` element that is a sibling of `p` is selected. The `p` element is a descendant of `.foo`, so are its `span` siblings.
- In `.foo p ~ .foo span`, the target selector is `span` that is a descendant of `.foo`. In this case, the `span` element that's a descendant of `.foo` is selected if that `.foo` is a sibling of `p`; essentially, both are nested in an ancestor of `.foo`.

- Next-sibling combinator

Type selectors

The CSS **type selector** matches elements by node name. In other words, it selects all elements of the given type within a document.

```
/* All <a> elements. */
a {
  color: red;
}
```

Type selectors can be namespaced when using `@namespace`. This is useful when dealing with documents containing multiple namespaces such as HTML with inline SVG or MathML, or XML that mixes multiple vocabularies.

- `ns|h1` - matches `<h1>` elements in namespace *ns*
- `*|h1` - matches all `<h1>` elements
- `|h1` - matches all `<h1>` elements without any declared namespace

Syntax

```
element { style properties }
```

Examples

CSS

```
span {
  background-color: skyblue;
}
```

HTML

```
<span>Here's a span with some text.</span>
<p>Here's a p with some text.</p>
<span>Here's a span with more text.</span>
```

Result

Namespaces

In this example the selector will only match `<h1>` elements in the example namespace.

```
@namespace example url("http://www.example.com/");
example|h1 {
  color: blue;
}
```

See also

- CSS Selectors
- Learn CSS: Basic selectors

Universal selectors

The CSS **universal selector** (`*`) matches elements of any type.

```
/* Selects all elements */
* {
  color: green;
}
```

The universal selector is a special type selector and can therefore be namespaced when using `@namespace`. This is useful when dealing with documents containing multiple namespaces such as HTML with inline SVG or MathML, or XML that mixes multiple vocabularies.

- `ns|*` - matches all elements in namespace *ns*
- `*|*` - matches all elements
- `|*` - matches all elements without any declared namespace

> **Note:** The universal selector (`*`) matches **elements only**. It does **not** directly match pseudo-elements by itself.
>
> To match all `::before` pseudo-elements on a page, for example, you would have to use a selector like `*::before`. This works because the `*` matches all elements, and the `::before` pseudo-element is available on all elements.

Syntax

```
* { style properties }
```

The asterisk is optional with simple selectors. For instance, `*.warning` and `.warning` are equivalent.

Examples

CSS

```
* [lang^="en"] {
  color: green;
}

*.warning {
  color: red;
}

*#maincontent {
  border: 1px solid blue;
}

.floating {
  float: left;
}

/* automatically clear the next sibling after a floating element */
.floating + * {
  clear: left;
}
```

HTML

```
<p class="warning">
  <span lang="en-us">A green span</span> in a red paragraph.
</p>
<p id="maincontent" lang="en-gb">
  <span class="warning">A red span</span> in a green paragraph.
</p>
```

Result

Namespaces

In this example the selector will only match elements in the example namespace.

```
@namespace example url("http://www.example.com/");
example|* {
  color: blue;
}
```

CSS values

CSS values are the values that can be assigned to CSS properties. These include keywords, data types, and functions.

> **Note:** This page is an index of all value features in CSS. The CSS values and units page introduces the module that defines some, but not all, of these values.

Index of keywords

- `!important`
- `fit-content`
- `inherit`
- `initial`
- `max-content`
- `min-content`
- `revert`
- `revert-layer`
- `unset`

See also

- CSS data types

- CSS syntax module

-moz-image-rect() CSS function

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`-moz-image-rect`** value for CSS `background-image` lets you use a portion of a larger image as a background.

Syntax

```
-moz-image-rect(url("my-url"), top, right, bottom, left);
```

Values

`<url>`

The URI of the image from which to take the sub-image.

`top`

The top edge, specified as an `<integer>` or `<percentage>`, of the sub-image within the specified image.

`right`

The right edge, specified as an `<integer>` or `<percentage>`, of the sub-image within the specified image.

`bottom`

The bottom edge, specified as an `<integer>` or `<percentage>`, of the sub-image within the specified image.

`left`

The left edge, specified as an `<integer>` or `<percentage>`, of the sub-image within the specified image.

Description

This property allows you to, for example, use different parts of one larger image as backgrounds in different parts of your content.

The syntax for the rectangle is similar to the `rect()` function generating a `<shape>` CSS type. All four values are relative to the upper left corner of the image.

Examples

This example loads an image and uses it in four segments to draw the Firefox logo in four `<div>` blocks. Clicking on their container causes the four segments to rotate around by swapping the `background-image` property values among the four `<div>` blocks.

CSS

The CSS defines one container style, then the styles for the four boxes that comprise the complete image.

The container looks like this:

```
#container {
  width: 267px;
  height: 272px;
  top: 100px;
  left: 100px;
  position: absolute;
  font-size: 16px;
  text-shadow: white 0px 0px 6px;
  text-align: center;
}
```

Then the four boxes defining the segments of the image are defined. Let's look at them one at a time.

```
#box1 {
  background-image: -moz-image-rect(url("firefox.png"), 0%, 50%, 50%, 0%);
  width: 133px;
  height: 136px;
  left: 0px;
  top: 0px;
  position: absolute;
}
```

This is the top-left corner of the image. It defines a rectangle containing the top-left quarter of the image in the file `firefox.jpg`.

```
#box2 {
  background-image: -moz-image-rect(url("firefox.png"), 0%, 100%, 50%, 50%);
  width: 133px;
  height: 136px;
  left: 133px;
  top: 0px;
  position: absolute;
}
```

This defines the top-right corner of the image.

The other corners follow a similar pattern:

```
#box3 {
  background-image: -moz-image-rect(url("firefox.png"), 50%, 50%, 100%, 0%);
  width: 133px;
  height: 136px;
  left: 0px;
  top: 136px;
  position: absolute;
}
#box4 {
  background-image: -moz-image-rect(url("firefox.png"), 50%, 100%, 100%, 50%);
  width: 133px;
  height: 136px;
  left: 133px;
  top: 136px;
  position: absolute;
}
```

HTML

We include a container with four boxes:

```
<div id="container">
  <div id="box1">Top left</div>
  <div id="box2">Top right</div>
  <div id="box3">Bottom left</div>
  <div id="box4">Bottom right</div>
</div>
```

This places the four segments of our image in a two-by-two box grid. These four segments are all contained within a larger `<div>` block whose primary purpose is to receive click events and dispatch them to our JavaScript code.

JavaScript

This code handles the click event when the container receives a mouse click.

```
function rotate() {
  let prevStyle = window
    .getComputedStyle(document.getElementById("box4"), null)
    .getPropertyValue("background-image");

  // Now that we've saved the last one, start rotating
  for (let i = 1; i <= 4; i++) {
    const curId = `box${i}`;

    // Shift the background images
    const curStyle = window
      .getComputedStyle(document.getElementById(curId), null)
      .getPropertyValue("background-image");
    document.getElementById(curId).style.backgroundImage = prevStyle;
    prevStyle = curStyle;
  }
}

document.getElementById("container").addEventListener("click", rotate);
```

This uses `window.getComputedStyle()` to fetch the style of each element, shifting it to the following element. Notice that before it begins doing so it saves a copy of the last box's style since it will be overwritten by the third element's style. By copying the values of the `background-image` property from one element to the next with each mouse click, we achieve the desired effect.

What it looks like

Specifications

Not part of any standard.

See also

- Mozilla CSS extensions
- CSS Backgrounds and Borders module

abs() CSS function

The **`abs()`** CSS function returns the absolute value of the argument, as the same type as the input.

Syntax

```
/* abs( <calc-sum> ) */
abs(20% - 100px)
abs(var(--gradientAngle))
```

Parameters

The `abs()` function accepts one parameter.

`<calc-sum>`

An expression or calculation that resolves to a `<number>`, a `<dimension>`, a `<percentage>` or a `<calc-keyword>`.

Return value

The absolute value of `<calc-sum>`.

- If `<calc-sum>`'s numeric value is positive or `0+`, the function returns `<calc-sum>`.
- Otherwise, it returns `-1 * <calc-sum>`.

Formal syntax

```
<abs()> =
  abs( <calc-sum> )

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Positive variables

The `abs()` function can be used to ensure that a value is always positive. In the following example a CSS custom property `--font-size` is used as the value of `font-size`. Wrapping this custom property in `abs()` will convert a negative value to a positive one.

```
h1 {
  font-size: abs(var(--font-size));
}
```

Control gradient angle of direction

You can also control the gradient direction using `abs()` function. In the following example, with an angle of -45deg the gradient would start red and transition to blue. By using `abs()` to make the value positive, the gradient will start blue and transition to red.

```
div {
  --deg: -45deg;
  background-image: linear-gradient(abs(var(--deg)), blue, red);
}
```

Backwards compatible fallback

In browsers that lack support for CSS `abs()` function, you can use the CSS `max()` function to achieve the same result:

```
p {
  line-height: max(var(--lh), -1 * var(--lh));
}
```

We use the `max()` function to return the largest (most positive) value from a list of two values: `var(--lh)` or `-1 * var(--lh)`. Irrespective of whether `--lh` is positive or negative, the calculated return value will always be positive, that is, an absolute number.

See also

- `sign()`

<absolute-size> CSS type

The **`<absolute-size>`** CSS data type describes the absolute size keywords. This data type is used in the `font` shorthand and `font-size` properties.

The font size keywords are mapped to the deprecated HTML `size` attribute. See the HTML size attribute section below.

Syntax

```
<absolute-size> = xx-small | x-small | small | medium | large | x-large | xx-large | xxx-large
```

Values

The `<absolute-size>` data type is defined using a keyword value chosen from the list below.

`xx-small`

An absolute size 60% the size of `medium`. Mapped to the deprecated `size="1"`.

`x-small`

An absolute size 75% the size of `medium`.

`small`

An absolute size 89% the size of `medium`. Mapped to the deprecated `size="2"`.

`medium`

A user's preferred font size. This value is used as the reference middle value. Mapped to `size="3"`.

`large`

An absolute size 20% larger than `medium`. Mapped to the deprecated `size="4"`.

`x-large`

An absolute size 50% larger than `medium`. Mapped to the deprecated `size="5"`.

`xx-large`

An absolute size twice the size of `medium`. Mapped to the deprecated `size="6"`.

`xxx-large`

An absolute size three times the size of `medium`. Mapped to the deprecated `size="7"`.

Description

Each `<absolute-size>` keyword value is sized relative to the `medium` size and the individual device's characteristics, such as device resolution. User agents maintain a table of font sizes for each font, with the `<absolute-size>` keywords being the index.

In CSS1 (1996), the scaling factor between adjacent keyword value indexes was 1.5, which was too large. In CSS2 (1998), the scaling factor between adjacent keyword value indexes was 1.2, which created issues for the small values. As a single fixed ratio between adjacent absolute-size keywords was found to be problematic, there is no longer a fixed ratio recommendation. The only recommendation to preserve readability is that the smallest font size should not be less than `9px`.

For each `<absolute-size>` keyword value, the following table lists the scaling factor, mapping to `<h1>` to `<h6>` headings, and mapping to the deprecated HTML `size` attribute.

`<absolute-size>`	xx-small	x-small	small	medium	large	x-large	xx-large	xxx-large
scaling factor	3/5	3/4	8/9	1	6/5	3/2	2/1	3/1
HTML headings	h6		h5	h4	h3	h2	h1	
HTML `size` attribute	1		2	3	4	5	6	7

HTML size attribute

The `size` attribute to set a font's size in HTML is deprecated. The attribute value was either an integer between `1` and `7` or a relative value. Relative values were an integer preceded by `+` or `-` to increase or decrease the font size, respectively. A value of `+1` meant increasing the `size` by one and `-2` meant decreasing the size by two, with the computed value clamped at a minimum of `1` and a maximum computed value of `7`.

Examples

Comparing the keyword values

```
<ul>
  <li class="xx-small">font-size: xx-small;</li>
  <li class="x-small">font-size: x-small;</li>
  <li class="small">font-size: small;</li>
  <li class="medium">font-size: medium;</li>
  <li class="large">font-size: large;</li>
  <li class="x-large">font-size: x-large;</li>
  <li class="xx-large">font-size: xx-large;</li>
  <li class="xxx-large">font-size: xxx-large;</li>
</ul>
```

```
li {
  margin-bottom: 0.3em;
}
.xx-small {
  font-size: xx-small;
}
.x-small {
  font-size: x-small;
}
.small {
  font-size: small;
}
.medium {
  font-size: medium;
}
.large {
  font-size: large;
}
.x-large {
  font-size: x-large;
}
.xx-large {
  font-size: xx-large;
}
.xxx-large {
  font-size: xxx-large;
}
```

acos() CSS function

The **`acos()`** CSS function is a trigonometric function that returns the inverse cosine of a number between `-1` and `1`. The function contains a single calculation that returns an `<angle>` between `0deg` and `180deg`.

Syntax

```
/* Single <number> values */
transform: rotate(acos(-0.2));
transform: rotate(acos(2 * 0.125));

/* Other values */
transform: rotate(acos(pi / 5));
transform: rotate(acos(e / 3));
```

Parameters

The `acos(number)` function accepts only one value as its parameter.

`number`

A calculation which resolves to a `<number>` between `-1` and `1`.

Return value

The inverse cosine of a `number` will always return an `<angle>` between `0deg` and `180deg`.

- If `number` is less than `-1` or greater than `1`, the result is `NaN`.
- If `number` is exactly `1`, the result is `0`.

Formal syntax

```
<acos()> =
  acos( <calc-sum> )

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
```

```
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Rotate elements

The `acos()` function can be used to `rotate` elements as it returns an `<angle>`.

HTML

```
<div class="box box-1"></div>
<div class="box box-2"></div>
<div class="box box-3"></div>
<div class="box box-4"></div>
<div class="box box-5"></div>
```

CSS

```
body {
  height: 100vh;
  display: flex;
  justify-content: center;
  align-items: center;
  gap: 50px;
}
```

```
div.box {
  width: 100px;
  height: 100px;
  background: linear-gradient(orange, red);
}
div.box-1 {
  transform: rotate(acos(1));
}
div.box-2 {
  transform: rotate(acos(0.5));
}
div.box-3 {
  transform: rotate(acos(0));
}
div.box-4 {
  transform: rotate(acos(-0.5));
}
div.box-5 {
  transform: rotate(acos(-1));
}
```

<alpha-value> CSS type

The **`<alpha-value>`** CSS data type represents a value that can be either a `<number>` or a `<percentage>`, specifying the **alpha channel** or **transparency** of a color.

Syntax

The value of an `<alpha-value>` is given as either a `<number>` or a `<percentage>`.

If given as a number, the useful range is 0 (fully transparent) to 1.0 (fully opaque), with decimal values in between; that is, 0.5 indicates that half of the foreground color is used and half of the background color is used. Values outside the range of 0 to 1 are permitted, but are clamped to lie within the range 0 to 1.

If the alpha value is given as a percentage, 0% corresponds to fully transparent while 100% indicates fully opaque.

Formal syntax

```
<alpha-value> =
  <number>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Color Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Interpolation

When animated, values of the `<alpha-value>` CSS data type are interpolated as real, floating-point numbers. The speed of the interpolation is determined by the easing function associated with the animation.

Examples

Setting text color opacity

The `rgb()` function accepts a fourth optional value to specify an alpha value. The following example shows how to apply a color with 60% opacity using the alpha value:

```
/* <rgb()> */
color: rgb(34 12 64 / 60%);
```

Setting shape image threshold

Here an alpha value is used to determine which parts of an image are considered part of a shape:

```
/* shape-image-threshold */
shape-image-threshold: 70%;
shape-image-threshold: 0.7;
```

anchor() CSS function

The **`anchor()`** CSS function can be used within an **anchor-positioned** element's inset property values, returning a length value relative to the position of the edges of its associated anchor element.

Syntax

```
/* side or percentage */
top: anchor(bottom);
top: anchor(50%);
top: calc(anchor(bottom) + 10px)
inset-block-end: anchor(start);

/* side of named anchor */
top: anchor(--my-anchor bottom);
inset-block-end: anchor(--my-anchor start);

/* side of named anchor with fallback */
top: anchor(--my-anchor bottom, 50%);
inset-block-end: anchor(--my-anchor start, 200px);
left: calc(anchor(--my-anchor right, 0%) + 10px);
```

Parameters

The `anchor()` function's syntax is as follows:

```
anchor(<anchor-name> <anchor-side>, <length-percentage>)
```

The parameters are:

`<anchor-name>` Optional

The `anchor-name` property value of an anchor element you want to position the element's side relative to. This is a `<dashed-ident>` value. If omitted, the element's **default anchor**, referenced in its `position-anchor` property, or associated with the element via the `anchor` HTML attribute, is used.

> **Note:** Specifying an `<anchor-name>` inside an `anchor()` function does not associate an element with an anchor; it only positions the element relative to that anchor. The `position-anchor` CSS property or the `anchor` HTML attribute is still needed to create the association.

`<anchor-side>`

Specifies the side of the anchor, or the relative distance from the `start` side, which the element is positioned relative to. If a physical or logical value is used that is not compatible with the inset property on which `anchor()` is set, the fallback value is used. Valid values include:

`top`

The top of the anchor element.

`right`

The right of the anchor element.

`bottom`

The bottom of the anchor element.

`left`

The left of the anchor element.

`inside`

The same side as the inset property.

`outside`

The opposite side of the inset property.

`start`

The logical start of the anchor element's containing block along the axis of the inset property on which the `anchor()` function is set.

`end`

The logical end of the anchor element's containing block along the axis of the inset property on which the `anchor()` function is set.

`self-start`

The logical start of the anchor element's content along the axis of the inset property on which the `anchor()` function is set.

`self-end`

The logical end of the anchor element's content along the axis of the inset property on which the `anchor()` function is set.

`center`

The center of the axis of the inset property on which the `anchor()` function is set.

`<percentage>`

Specifies the distance, as a percentage, from the start of the element's content along the axis of the inset property on which the `anchor()` function is set.

`<length-percentage>` Optional

Specifies a fallback value the function should resolve to if the `anchor()` function would otherwise not be valid.

Return value

Returns a `<length>` value.

Description

The `anchor()` function enables positioning an element relative to the edges of an anchor element. It is only valid within inset property values set on absolute or fixed position elements.

It returns a `<length>` value specifying the distance from the edge of the containing block corresponding to the inset property to the edge of the anchor element specified by the `<anchor-side>` value. As it returns a `<length>`, it can be used within other CSS functions that accept length values, including `calc()`, `clamp()`, etc.

If no anchor with the name specified by the `<anchor-name>` exists, or if the positioned element does not have an anchor associated with it (i.e., via the `position-anchor` property), the first parameter is considered invalid, and the fallback `<length-percentage>` value is used if one is available. For example, if `top: anchor(bottom, 50px)` were specified on the positioned element but no anchor was associated with it, the fallback value would be used, so `top` would get a computed value of `50px`.

For detailed information on anchor features and usage, see the CSS anchor positioning module and the Using CSS anchor positioning guide.

Properties that accept <code>anchor()</code> function values

The CSS inset properties that accept an `anchor()` function as a value component include:

- `top`
- `left`
- `bottom`
- `right`
- `inset` shorthand
- `inset-block-start`
- `inset-block-end`
- `inset-block` shorthand
- `inset-inline-start`
- `inset-inline-end`
- `inset-inline` shorthand

Compatibility of inset properties and <code><anchor-side></code> values

When using an `anchor()` function inside an inset property value, the `<anchor-side>` parameter specified inside the `anchor()` function has to be compatible with the axis on which the inset property resides.

This means that physical `<anchor-side>` values can be used within the values of physical inset properties if the property has the same axis direction as the `<anchor-side>`. In other words, the `top` and `bottom` sides are not valid within the `left` and `right` property values, and the `left` and `right` sides are not valid within `top` and `bottom` property values. For example, `top: anchor(bottom)` is fine, as they are both vertical values but `top: anchor(left)` is not valid, as `left` is a horizontal value. If `top: anchor(left, 50px)` were specified, the fallback value would be used, so `top` would get a computed value of `50px`. If no fallback is present, the inset property behaves as if it were set to `auto`.

You can use logical `<anchor-side>` values within both logical and physical inset properties as logical `<anchor-side>` values are relative to the inset property's relevant axis, whether the property is logical or relative. For example, `top: anchor(start)`, `top: anchor(self-end)`, `inset-block-start: anchor(end)` and `inset-inline-end: anchor(self-start)` all work fine.

The story gets more complicated when using physical `<anchor-side>` parameters within logical inset property values as the physical side has to match the axis the inset property is relevant to within the current writing mode. For example:

- In a horizontal writing mode, the block direction is top-to-bottom; therefore `inset-block-end: anchor(bottom)` will work, but `inset-block-end: anchor(left)` is incompatible. If `inset-block-end: anchor(left, 50px)` were set, the computed value would be `50px`, and the positioned element would be positioned `50px` from the block end (bottom) of its nearest positioned ancestor or the viewport, depending on the `position` value set.
- In a vertical writing mode, the block direction is right-to-left or left-to-right; therefore `inset-block-end: anchor(left)` will work, but `inset-block-end: anchor(top)` is incompatible. If `inset-block-end: anchor(top, 50px)` were set, the computed value would be `50px`, and the positioned element would be positioned `50px` from the block end (left or right depending on the writing mode) of its nearest positioned ancestor or the viewport, depending on the `position` value set.

To mitigate the potential for confusion with these values, you are advised to use logical inset properties with logical `<anchor-side>` values, and physical inset properties with physical `<anchor-side>` values. You should favor the use of logical values whenever possible because they are better for internationalization.

The `center` and `<percentage>` values are valid within the `anchor()` function within all logical and physical inset properties.

The below table lists the inset properties, and the `<anchor-side>` parameter values that are compatible with them. We have only listed the longhand inset properties; these comprise the shorthand inset property values.

Inset property	**Compatible `<anchor-side>` value**
All	`center`
All	`<percentage>`
`top` and `bottom`	`top`, `bottom`, `start`, `end`, `self-start`, `self-end`
`left` and `right`	`left`, `right`, `start`, `end`, `self-start`, `self-end`
`inset-block-start` and `inset-block-end`	`start`, `end`, `self-start`, and `self-end` `top` and `bottom` in horizontal writing modes `left` and `right` in vertical writing modes
`inset-inline-start` and `inset-inline-end`	`start`, `end`, `self-start`, and `self-end` `left` and `right` in horizontal writing modes `top` and `bottom` in vertical writing modes

Using <code>anchor()</code> to position popovers

When using `anchor()` to position popovers, be aware that the default styles for popovers may conflict with the position you're trying to achieve. The usual culprits are the default styles for `margin` and `inset`, so it's advisable to reset those:

```
.positionedPopover {
  margin: 0;
  inset: auto;
}
```

The CSS working group is looking at ways to avoid requiring this workaround.

Using <code>anchor()</code> inside <code>calc()</code>

When the `anchor()` function refers to a side of the default anchor, you can include a `margin` to create spacing between the edges of the anchor and the positioned element as needed. Alternatively, you can include the `anchor()` function within a `calc()` function to add spacing.

This example positions the right edge of the positioned element flush to the anchor element's left edge, then adds margin to make some space between the edges:

```
.positionedElement {
  right: anchor(left);
  margin-right: 10px;
}
```

This example positions the positioned element's logical block end edge `10px` from the anchor element's logical block start edge:

```
.positionedElement {
  inset-block-end: calc(anchor(start) + 10px);
}
```

Positioning an element relative to multiple anchors

You can position an element relative to multiple anchors by specifying different `<anchor-name>` values inside the `anchor()` function of different inset properties on the same element (see Element positioned relative to multiple anchors below). This can be used to create useful functionality such as drag handles at the corners of a positioned element that can be used to resize it.

While a positioned element can be positioned relative to more than one anchor element, it is only ever associated with the single anchor defined via its `position-anchor` property (or the `anchor` HTML attribute). This is the anchor the element will scroll with when the page scrolls; it can also be used to control when the element is conditionally hidden.

Formal syntax

```
<anchor()> =
  anchor( <anchor-name>?                 &&
  <anchor-side> , <length-percentage>? )

<anchor-name> =
  <dashed-ident>

<anchor-side> =
  inside        |
  outside       |
  top           |
  left          |
  right         |
  bottom        |
  start         |
  end           |
  self-start    |
  self-end      |
  <percentage>  |
  center

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Common usage

In this example, the `anchor()` function is used to set the height of an anchor-positioned element to the height of its anchor by setting the bottom and top edges to the bottom and top edges of the anchor. The `anchor()` function within a `calc()` function is then used to offset the anchor-positioned element from its anchor.

HTML

We include a `<div>` element, which we'll set as our anchor, and a `<p>` element that we will position relative to that anchor:

```
<div class="anchor">⚓</div>

<p class="positionedElement">This is a positioned element.</p>
```

CSS

We set the anchor element's `anchor-name` value as the value of the positioned element's `position-anchor` property to associate the elements, then set three inset properties on the anchor-positioned element. The first two position the element's top edge flush with the top edge of the anchor and the bottom edge flush with the bottom edge of the anchor. In the third inset property, the `anchor()` function is used within a `calc()` function to position the element's left edge `10px` to the right edge of the anchor.

```
.anchor {
  anchor-name: --infobox;
  background: palegoldenrod;
  font-size: 3em;
  width: fit-content;
  border: 1px solid goldenrod;
}

.positionedElement {
  position: absolute;
  position-anchor: --infobox;
  margin: 0;
  top: anchor(top);
  left: calc(anchor(right) + 10px);
  bottom: anchor(bottom);
  background-color: olive;
  border: 1px solid darkolivegreen;
}
```

Results

Comparison of different anchor-side values

This example shows an element positioned relative to an anchor via its `top` and `left` properties, which are defined using `anchor()` functions. It also includes two drop-down menus that allow you to vary the `<anchor-side>` values inside those `anchor()` functions, so you can see what effect they have.

HTML

We specify two `<div>` elements, one with a class of `anchor` and one with a class of `infobox`. These are intended to be the anchor element and the positioned element we will associate with it, respectively.

We also include some filler text around the two `<div>` elements to make the `<body>` taller so that it will scroll. This example also includes two `<select>` elements to create the drop-down menus enabling the selection of different `<anchor-side>` values to place the positioned element with. We've hidden the filler text and the `<select>` elements for brevity.

```
<p>Lorem ipsum dolor sit amet, consectetur adipiscing elit.</p>
```

```
<div class="anchor">⚓</div>

<div class="infobox">
  <p>This is an information box.</p>
</div>
```

```
<p>
  Nisi quis eleifend quam adipiscing vitae proin sagittis nisl rhoncus. In arcu
  cursus euismod quis viverra nibh cras pulvinar. Vulputate ut pharetra sit amet
  aliquam.
</p>

<p>
  Malesuada nunc vel risus commodo viverra maecenas accumsan lacus. Vel elit
  scelerisque mauris pellentesque pulvinar pellentesque habitant morbi
  tristique. Porta lorem mollis aliquam ut porttitor. Turpis cursus in hac
  habitasse platea dictumst quisque. Dolor sit amet consectetur adipiscing elit.
  Ornare lectus sit amet est placerat. Nulla aliquet porttitor lacus luctus
  accumsan.
</p>

<form>
  <div>
    <label for="top-anchor-side">
      Choose a vertical <code>anchor()</code> value:
    </label>
    <select id="top-anchor-side" name="top-anchor-side">
      <option value="top">top: anchor(top)</option>
      <option value="bottom" selected>top: anchor(bottom)</option>
      <option value="start">top: anchor(start)</option>
      <option value="end">top: anchor(end)</option>
      <option value="center">top: anchor(center)</option>
      <option value="0%">top: anchor(0%)</option>
      <option value="25%">top: anchor(25%)</option>
      <option value="50%">top: anchor(50%)</option>
      <option value="75%">top: anchor(75%)</option>
      <option value="100%">top: anchor(100%)</option>
    </select>
  </div>
  <div>
    <label for="left-anchor-side">
      Choose a horizontal <code>anchor()</code> value:
    </label>
    <select id="left-anchor-side" name="left-anchor-side">
      <option value="left">left: anchor(left)</option>
      <option value="right" selected>left: anchor(right)</option>
      <option value="self-start">left: anchor(self-start)</option>
      <option value="self-end">left: anchor(self-end)</option>
      <option value="center">left: anchor(center)</option>
      <option value="0%">left: anchor(0%)</option>
      <option value="25%">left: anchor(25%)</option>
      <option value="50%">left: anchor(50%)</option>
      <option value="75%">left: anchor(75%)</option>
      <option value="100%">left: anchor(100%)</option>
    </select>
  </div>
</form>
```

CSS

We declare the `anchor` `<div>` as an anchor element by setting an anchor name on it via the `anchor-name` property. We then associate it with the positioned element by setting the same value for its `position-anchor` property. `top: anchor(--my-anchor bottom)` positions the infobox's top edge flush to the bottom edge of its anchor, while `left: anchor(right)` positions the infobox's left edge flush to the right edge of its anchor. This provides an initial position that will be overwritten when different values are selected from the drop-down menus.

```
.anchor {
  font-size: 2rem;
  color: white;
  text-shadow: 1px 1px 1px black;
  background-color: hsl(240 100% 75%);
  width: 100px;
  height: 100px;
  text-align: center;
  line-height: 100px;
  border-radius: 10px;
  border: 1px solid black;
  padding: 3px;
}

body {
  width: 80%;
  margin: 0 auto;
}

form {
  background: white;
  border: 1px solid black;
```

```
  padding: 5px;
  position: fixed;
  top: 0;
  right: 2px;
}

select {
  display: block;
  margin-top: 5px;
}

form div:last-child {
  margin-top: 10px;
}

.infobox {
  color: darkblue;
  background-color: azure;
  border: 1px solid #dddddd;
  padding: 10px;
  border-radius: 10px;
  font-size: 1rem;
}
```

```
.anchor {
  anchor-name: --my-anchor;
}

.infobox {
  position: fixed;
  position-anchor: --my-anchor;
  top: anchor(--my-anchor bottom);
  left: anchor(right);
}
```

JavaScript

We listen for the `change` event that occurs when a new `<anchor-side>` value is selected, and set the selected value as the `<anchor-side>` in the `anchor()` function within the infobox's relevant inset property (`top` or `left`) value.

```
const infobox = document.querySelector(".infobox");
const topSelect = document.querySelector("#top-anchor-side");
const leftSelect = document.querySelector("#left-anchor-side");

topSelect.addEventListener("change", (e) => {
  const anchorSide = e.target.value;
  infobox.style.top = `anchor(--my-anchor ${anchorSide})`;
});

leftSelect.addEventListener("change", (e) => {
  const anchorSide = e.target.value;
  infobox.style.left = `anchor(${anchorSide})`;
});
```

Result

Select different values from the drop-down menus to see how they affect the positioning of the infobox.

Element positioned relative to multiple anchors

This example positions an element relative to two different anchors, which are used to set the position of the top-left and bottom-right corners of the anchor-positioned element. The anchors can be moved via keyboard controls or dragged, resizing the positioned element.

HTML

We specify three `<div>` elements in total. The first two have a class of `anchor` and will be defined as anchors; each one has an individual `id` that will be used to provide them with different positioning information. The last `<div>` has a class of `infobox` and will be defined as the positioned element. We include the `tabindex` attribute to enable them to receive keyboard focus.

```
<div id="anchor1" class="anchor" tabindex="0">1.1</div>

<div id="anchor2" class="anchor" tabindex="0">1.2</div>

<div class="infobox">
  <p>This is an information box.</p>
</div>
```

CSS

```
body {
  width: 150vw;
  height: 150vh;
}

.anchor {
  font-size: 1rem;
  color: white;
  text-shadow: 1px 1px 1px black;
  background-color: hsl(240 100% 75%);
  width: fit-content;
  border-radius: 10px;
  border: 1px solid black;
  padding: 3px;
  &:focus {
    background-color: hsl(60 100% 75%);
  }
}

.infobox {
  color: darkblue;
  background-color: azure;
  border: 1px solid #dddddd;
```

```
  padding: 10px;
  border-radius: 10px;
  font-size: 1rem;
}
```

The anchors are each given a different `anchor-name` value, a `position` value of `absolute`, and different inset values to position the anchors in a rectangular formation.

```
.anchor {
  position: absolute;
}

#anchor1 {
  anchor-name: --my-anchor1;
  top: 50px;
  left: 100px;
}

#anchor2 {
  anchor-name: --my-anchor2;
  top: 200px;
  left: 350px;
}
```

The anchor-positioned element, with its `position` set to `fixed`, is associated with one anchor via its `position-anchor` property. It is positioned relative to two anchors by including two different `<anchor-name>` values with the `anchor()` functions set on its inset properties. In this case, we used `<percentage>` values for the `<anchor-side>` parameter, specifying the distance from the start of the axis of the inset property on which the function is set.

```
.infobox {
  position-anchor: --my-anchor1;
  position: fixed;
  top: anchor(--my-anchor1 100%);
  left: anchor(--my-anchor1 100%);
  bottom: anchor(--my-anchor2 0%);
  right: anchor(--my-anchor2 0%);
}
```

```
// grab all the anchors and make each one draggable
const anchors = document.querySelectorAll(".anchor");
anchors.forEach((anchor) => makeDraggable(anchor));

function makeDraggable(elem) {
  let pos1, pos2, pos3, pos4;

  elem.onmousedown = dragMouseDown;
  elem.addEventListener("keyup", (e) => {
    switch (e.key) {
      case "d":
        elem.style.left = `${elem.offsetLeft + 5}px`;
        break;
      case "a":
        elem.style.left = `${elem.offsetLeft - 5}px`;
        break;
      case "w":
        elem.style.top = `${elem.offsetTop - 5}px`;
        break;
      case "s":
        elem.style.top = `${elem.offsetTop + 5}px`;
        break;
    }
    e.preventDefault();
  });

  function elementMove(e) {
    console.dir(e);
    // calculate the new cursor position:
    pos1 = pos3 - e.offsetLeft;
    pos2 = pos4 - e.offsetTop;
    pos3 = e.offsetLeft;
    pos4 = e.offsetTop;
    // set the element's new position:
    elem.style.top = `${elem.offsetTop - pos2}px`;
    elem.style.left = `${elem.offsetLeft - pos1}px`;
  }

  function dragMouseDown(e) {
    // get the mouse cursor position at startup:
    pos3 = e.clientX;
    pos4 = e.clientY;
    document.onmouseup = closeDragElement;
    // call a function whenever the mouse moves:
    document.onmousemove = elementDrag;
  }

  function elementDrag(e) {
    // calculate the new cursor position:
    pos1 = pos3 - e.clientX;
    pos2 = pos4 - e.clientY;
    pos3 = e.clientX;
    pos4 = e.clientY;
    // set the element's new position:
    elem.style.top = `${elem.offsetTop - pos2}px`;
    elem.style.left = `${elem.offsetLeft - pos1}px`;
  }

  function closeDragElement() {
    // stop moving when mouse button is released:
    document.onmouseup = null;
    document.onmousemove = null;
  }
}
```

Result

The positioned element is positioned relative to both anchor elements. Drag them with the mouse or tab to them and use the `W`, `A`, `S`, and `D` keys to move them up, down, left, and right. See how this changes their position, and as a consequence, the area of the positioned element. Scroll to see how the positions of all the elements are maintained.

> **Note:** This example is a proof-of-concept and not intended to be used in production code. Among its shortcomings, the example breaks if you try to move the anchors past each other horizontally or vertically.

anchor-size() CSS function

The **`anchor-size()`** CSS function enables setting anchor-positioned element's size, position, and margins relative to the dimensions of anchor elements. It returns the `<length>` of a specified side of the target anchor element. `anchor-size()` is only valid when used within the value of anchor-positioned elements' sizing, inset, and margin properties.

For detailed information on anchor features and usage, see the CSS anchor positioning module and the Using CSS anchor positioning guide.

Syntax

```
/* without parameters */
anchor-size()

/* anchor size parameter */
anchor-size(width);
anchor-size(block);
anchor-size(self-inline);

/* anchor-name and anchor-side */
width: anchor-size(--my-anchor width);
block-size: anchor-size(--my-anchor block);

/* sizing relative to named anchor's side with fallback */
width: anchor-size(--my-anchor width, 50%);
block-size: anchor-size(--my-anchor block, 200px);

/* positioning relative to anchor side */
left: anchor-size(width);
inset-inline-end: anchor-size(--my-anchor height, 100px);

/* setting margin relative to anchor side */
margin-left: calc(anchor-size(width) / 4);
margin-block-start: anchor-size(--my-anchor self-block, 20px);
```

Parameters

The `anchor-size()` function's syntax is as follows:

```
anchor-size(<anchor-name> <anchor-size>, <length-percentage>)
```

The parameters are:

`<anchor-name>` Optional

The `anchor-name` property value of an anchor element you want to set the element's size, position, or margins relative to. This is a `<dashed-ident>` value. If omitted, the element's default anchor is used.

> **Note:** Specifying an `<anchor-name>` inside an `anchor-size()` function neither associates nor tethers an element to an anchor; it only defines which anchor the element's property values should be set relative to.

`<anchor-size>` Optional

Specifies the dimension of the anchor element that the positioned element's property values will be set relative to. Valid values include:

`width`

The width of the anchor element.

`height`

The height of the anchor element.

`block`

The length of the anchor element's containing block in the block direction.

`inline`

The length of the anchor element's containing block in the inline direction.

`self-block`

The length of the anchor element in the block direction.

`self-inline`

The length of the anchor element in the inline direction.

> **Note:** If this parameter is omitted, the dimension defaults to the `<anchor-size>` keyterm that matches the axis of the property in which the function is included. For example, `width: anchor-size();` is equivalent to `width: anchor-size(width);`.

`<length-percentage>` Optional

Specifies the size to use as a fallback value if the element is not absolutely or fixed positioned, or the anchor element doesn't exist. If this parameter is omitted in a case when the fallback would otherwise be used, the declaration is invalid.

> **Note:** The anchor dimension you set the positioned element's property values relative to does not have to be along the same axis as the sizing value being set. For example, `width: anchor-size(height)` is valid.

Return value

Returns a `<length>` value.

Description

The `anchor-size()` function enables a positioned element's sizing, position, and margin values to be expressed in terms of an anchor element's dimensions; it returns a `<length>` value representing the dimension of a specific anchor element the positioned element's property values are set relative to. It is a valid value for sizing, inset, and margin properties set on anchor-positioned elements.

The length returned is the vertical or horizontal size of an anchor element or its containing block. The dimension used is defined by the `<anchor-size>` parameter. If that parameter is omitted, the dimension used will match the axis of the sizing, position, or margin property is it set on. So for example:

- `width: anchor-size()` is equivalent to `width: anchor-size(width)`.
- `top: anchor-size()` is equivalent to `top: anchor-size(height)`.
- `margin-inline-end: anchor-size()` is equivalent to `margin-inline-end: anchor-size(self-inline)`. `margin-inline-end: anchor-size()` is also equivalent to `margin-inline-end: anchor-size(width)` in horizontal writing modes, or `margin-inline-end: anchor-size(height)` in vertical writing modes.

The anchor element used as the basis for the dimension length is the element with the `anchor-name` specified in the `<anchor-name>` parameter. If more than one element has the same anchor name, the last element with that anchor name in the DOM order is used.

If no `<anchor-name>` parameter is included in the function call, the element's **default anchor**, referenced in its `position-anchor` property, or associated with the element via the `anchor` HTML attribute, is used.

If an `<anchor-name>` parameter is included and there are no elements matching that anchor name, the fallback value is used. If no fallback was included, the declaration is ignored. For example, if `width: anchor-size(--foo width, 50px); height: anchor-size(--foo width);` were specified on the positioned element but no anchor named `--foo` exists in the DOM, the `width` would be `50px` and the `height` declaration would have no effect.

If an element has sizing, position, or margin properties with `anchor-size()` values set on them, but it is not an anchor-positioned element (it does not have its `position` property set to `absolute` or `fixed` or does not have an anchor associated with it via its `position-anchor` property), the fallback value will be used if one is available. If no fallback is available, the declaration is ignored.

For example, if `width: anchor-size(width, 50px);` were specified on the positioned element but no anchor was associated with it, the fallback value would be used, so `width` would get a computed value of `50px`.

For detailed information on anchor features and usage, see the CSS anchor positioning module and the Using CSS anchor positioning guide.

Properties that accept <code>anchor-size()</code> function values

The properties that accept an `anchor-size()` function as a value include:

- Sizing properties:
  - `width`
  - `height`
  - `min-width`
  - `min-height`
  - `max-width`
  - `max-height`
  - `block-size`
  - `inline-size`
  - `min-block-size`
  - `min-inline-size`
  - `max-block-size`
  - `max-inline-size`
- Inset properties:
  - `bottom`
  - `left`
  - `right`
  - `top`
  - `inset` shorthand
  - `inset-block` shorthand
  - `inset-block-end`
  - `inset-block-start`
  - `inset-inline` shorthand
  - `inset-inline-end`
  - `inset-inline-start`
- Margin properties:
  - `margin` shorthand
  - `margin-bottom`
  - `margin-left`
  - `margin-right`
  - `margin-top`
  - `margin-block` shorthand
  - `margin-block-end`
  - `margin-block-start`
  - `margin-inline` shorthand
  - `margin-inline-end`
  - `margin-inline-start`

Using <code>anchor-size()</code> inside <code>calc()</code>

The most common `anchor-size()` functions you'll use will just refer to a dimension of the default anchor. Alternative, include the `anchor-size()` function inside a `calc()` function to modify the size applied to the positioned element.

For example, this rule sizes the positioned element's width equal to the default anchor element's width:

```
.positionedElem {
  width: anchor-size(width);
}
```

This rule sizes the positioned element's inline size to 4 times the anchor element's inline size, with the multiplication being done inside a `calc()` function:

```
.positionedElem {
  inline-size: calc(anchor-size(self-inline) * 4);
}
```

Formal syntax

```
<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width       |
  height      |
  block       |
  inline      |
  self-block  |
  self-inline

<length-percentage> =
  <length>     |
  <percentage>
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic <code>anchor-size()</code> usage

This example shows two elements positioned relative to an anchor and sized using `anchor-size()` functions.

HTML

We specify three `<div>` elements, one `anchor` element and the two `infobox` elements we'll position relative to the anchor. We also include filler text to make the `<body>` tall enough to require scrolling, but this has been hidden for the sake of brevity.

```
<p>Lorem ipsum dolor sit amet, consectetur adipiscing elit.</p>

<p>
  Nisi quis eleifend quam adipiscing vitae proin sagittis nisl rhoncus. In arcu
  cursus euismod quis viverra nibh cras pulvinar. Vulputate ut pharetra sit amet
  aliquam.
</p>
```

```
<div class="anchor">⚓</div>

<div class="infobox" id="infobox1">
  <p>This is the first infobox.</p>
</div>

<div class="infobox" id="infobox2">
  <p>This is the second infobox.</p>
</div>
```

```
<p>
  Malesuada nunc vel risus commodo viverra maecenas accumsan lacus. Vel elit
  scelerisque mauris pellentesque pulvinar pellentesque habitant morbi
  tristique. Porta lorem mollis aliquam ut porttitor. Turpis cursus in hac
  habitasse platea dictumst quisque. Dolor sit amet consectetur adipiscing elit.
  Ornare lectus sit amet est placerat. Nulla aliquet porttitor lacus luctus
  accumsan.
</p>
```

CSS

We declare the `anchor` `<div>` as an anchor element by giving it an `anchor-name`. The positioned elements, with their `position` properties set to `fixed`, are associated with the anchor element via their `position-anchor` properties. We also set absolute `height` and `width` dimensions on the anchor to provide a reference point when checking the positioned element dimensions, for example, with browser developer tools:

```
.anchor {
  font-size: 2rem;
  color: white;
  text-shadow: 1px 1px 1px black;
  background-color: hsl(240 100% 75%);
  text-align: center;
  align-content: center;
  outline: 1px solid black;
}

body {
  width: 80%;
  margin: 0 auto;
}

.infobox {
  align-content: center;
  color: darkblue;
  background-color: azure;
  outline: 1px solid #dddddd;
  font-size: 1rem;
  text-align: center;
}
```

```
.anchor {
  anchor-name: --my-anchor;
  width: 100px;
  height: 50px;
}

.infobox {
  position-anchor: --my-anchor;
  position: fixed;
}
```

We set some distinct property values on the positioned elements:

- The positioned elements are tethered to the anchor with different `position-area` values that position the elements in different places around the anchor element.
- The `height` of the first infobox is set to the same height as the anchor element: `anchor-size(height)` returns the anchor element's height. The element's `width` is set to double the anchor element's width using the `anchor-size()` function within a `calc()` function: `anchor-size(width)` retrieves the anchor element's width, which is then multiplied by two.
- The `height` of the second infobox is set to 80% of the anchor element's height, using a similar technique.
- Margin values are included to provide some separation from the anchor element.

```
#infobox1 {
  position-area: right;
  height: anchor-size(height);
  width: calc(anchor-size(width) * 2);
  margin-left: 5px;
}

#infobox2 {
  position-area: top span-right;
  height: calc(anchor-size(height) / 1.25);
  margin-bottom: 5px;
}
```

Result

Use your browser tools to inspect the anchor-positioned elements. The first infobox will be `50px` tall and `200px` wide, while the second infobox will be `40px` tall, with the `width` defaulting to `max-content`.

<angle> CSS type

The **`<angle>`** CSS data type represents an angle value expressed in degrees, gradians, radians, or turns. It is used, for example, in `<gradient>`s and in some `transform` functions.

Try it

```
transform: rotate(45deg);
```

```
transform: rotate(3.1416rad);
```

```
transform: rotate(-50grad);
```

```
transform: rotate(1.75turn);
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This box can rotate to different angles.
  </div>
</section>
```

```
#example-element {
  background-color: #0118f3;
  padding: 0.75em;
  width: 180px;
  height: 120px;
  color: white;
}
```

Syntax

The `<angle>` data type consists of a `<number>` followed by one of the units listed below. As with all dimensions, there is no space between the unit literal and the number. While some legacy uses accept a unitless `0`, you should always include a unit for zero values, such as: `0deg`, `0grad`, `0rad`, or `0turn`.

Optionally, it may be preceded by a single `+` or `-` sign. Positive numbers represent clockwise angles, while negative numbers represent counterclockwise angles. For static properties of a given unit, any angle can be represented by various equivalent values. For example, `90deg` equals `-270deg`, and `1turn` equals `4turn`. For dynamic properties, like when applying an `animation` or `transition`, the effect will nevertheless be different.

Units

`deg`

Represents an angle in degrees. One full circle is `360deg`. Examples: `0deg`, `90deg`, `14.23deg`.

`grad`

Represents an angle in gradians. One full circle is `400grad`. Examples: `0grad`, `100grad`, `38.8grad`.

`rad`

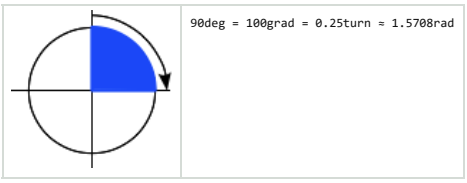
Represents an angle in radians. One full circle is 2π radians which approximates to `6.2832rad`. `1rad` is 180/π degrees. Examples: `0rad`, `1.0708rad`, `6.2832rad`.

`turn`

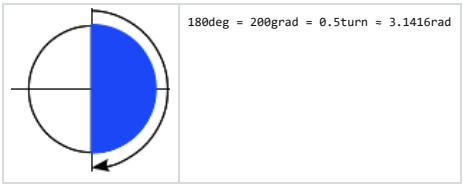
Represents an angle in a number of turns. One full circle is `1turn`. Examples: `0turn`, `0.25turn`, `1.2turn`.

Examples

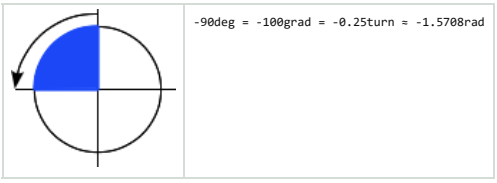
Setting a clockwise right angle



Setting a flat angle



Setting a counterclockwise right angle



Setting a null angle

- Using CSS gradients

<angle-percentage> CSS type

The **`<angle-percentage>`** CSS data type represents a value that can be either an `<angle>` or a `<percentage>`.

Where an `<angle-percentage>` is specified as an allowable type, this means that the percentage resolves to an angle and therefore can be used in a `calc()` expression.

Syntax

Refer to the documentation for `<angle>` and `<percentage>` for details of the individual syntaxes allowed by this type.

Formal syntax

```
<angle-percentage> =
  <angle>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

<animation-action>

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`<animation-action>`** enumerated data type represents keyword values that specify how an animation should behave in certain circumstances — for example, how a triggered animation should behave when its trigger is activated and deactivated.

The `<animation-action>` keyword values are used in the following properties:

- `animation-trigger`

Syntax

The `<animation-action>` enumerated type is specified using one of the following values:

`none`

No action is specified for the animation.

`play`

The animation will play, resume (if paused), or restart (if currently finished) in the same direction as its current direction of play.

`play-forwards`

As `play`, except that the animation's `playbackRate` is adjusted if required (flipping it to positive if negative) so that the animation will play forwards.

`play-backwards`

As `play`, except that the animation's `playbackRate` is adjusted if required (flipping it to negative if positive) so that the animation will play in reverse.

`play-once`

As `play`, except that once the animation has played through all its iterations, it won't be triggered again. Like `play`, if an animation is paused, `play-once` will resume playing it; unlike `play`, it won't replay a finished animation.

`pause`

The animation will pause.

`replay`

As `play`, except that the animation is put back to the start.

`reset`

As `pause`, except that the animation is put back to the start.

Description

The `<animation-action>` type specifies how an animation behaves when certain things happen. For example, when setting an `animation-trigger` value on an animated element to specify the animation as a triggered animation, the value can include one or two `<animation-action>` values, separated by a space. The first value specifies the animation behavior when its trigger activates, while the optional second value specifies the animation behavior when its trigger deactivates. If you only specify a single value, the animation doesn't change its behavior when its trigger deactivates; it continues with the activation behavior. It has the same effect as setting `none` as the second value.

There are some common patterns to observe:

- `play-forwards play-backwards` is very common when you want a UI element to "animate in" when it scrolls into view, and then "animate out" again when it scrolls out of view.
- `play pause` is common for animating an element as it scrolls into view, then pausing the animation as it scrolls out of view.
- `play-once` is often used on its own, when you want an animation to play only once when it scrolls into view.

The eight `<animation-action>` values provide different animation behaviors. It's important to understand how they behave on their own and the effects that can created by changing trigger activation and deactivation values.

Specifying no action

To specify that no action should occur, use the `none` value.

Playing the animation

The `play`, `play-forwards`, `play-backwards`, and `play-once` keyword values all cause the animation to play, but each one specifies a different precise behavior.

`play`

Setting `play` will play the animation through all its iterations, as defined by the `animation-iteration-count` property.

If only `play` is set, the animation will play on activation but never deactivate, as a deactivation action is not specified.

```
animation-trigger: --t play;
```

If `play` is combined with `pause`, `replay` or `reset`, the animation will play on activation, and then `pause`, `replay` or `reset` on deactivation. On subsequent activation, the animation will play again.

```
animation-trigger: --t play reset;
```

When combining `play` with `play-backwards`, the animation will play on activation, then play backward through all the iterations it previously played forwards through on deactivation:

```
animation-trigger: --t play play-backwards;
```

While valid, combining `play` with `play-once` is unnecessary, as it behaves the same as `play`. Similarly, combining `play` with `play-forwards` is unnecessary, because `play-forwards` plays the animation in the same direction as `play`, even when `animation-direction` is set to `reverse` or `alternate`.

`play-forwards` and `play-backwards`

Setting `play-forwards` and `play-backwards` will play the animation through all its iterations, except that the direction of play will change to forwards or backward, respectively. This is achieved by adjusting the animation's `playbackRate`; the `animation-direction` value is not affected.

Specifying an activation action of `play-forwards` only has the same effect as specifying `play` only:

```
animation-trigger: --t play-forwards;
```

Combining `play-forwards` with `play-backwards` causes the animation to play forwards on activation, then play backward through all the iterations it previously played forwards through on deactivation. On subsequent activations, the animation starts playing forwards again.

```
animation-trigger: --t play-forwards play-backwards;
```

Combining `play-forwards` with `pause`, `replay` or `reset` produces the same effect as `play`: the animation will play on activation, and then `pause`, `replay` or `reset` on deactivation. On subsequent activations, the animation will play again.

```
animation-trigger: --t play-forwards pause;
```

It doesn't make sense to combine `play-forwards` with `play` or `play-once`, because all of these actions effectively play the animation forwards; doing the same thing on deactivation as on activation has no discernible effect.

Note that using `play-backwards` as an activation action has no effect if the animation is already at the start of its iterations. With the following example, the animation does not play because it is already at the start:

```
animation-trigger: --t play-backwards;
```

`play-once`

Setting `play-once` will play the animation through all its iterations, but only once. If `animation-iteration-count` is set to `infinite`, there is not much difference in effect between `play-once` and `play`/`play-forwards`. However, with `animation-iteration-count` set to a finite number, you will observe the following behavior.

When combining `play-once` with `pause`, the animation will play on activation and then `pause` on deactivation. However, once the animation has played through all its iterations, the animation will not play again on subsequent activations.

```
animation-trigger: --t play-once pause;
```

If you combine `play-once` with `replay`, the animation will play on activation, then play again from the beginning on deactivation. It won't exceed its iteration count on any playthrough, but it will play again on subsequent deactivations because we reset the animation to the start each time. On subsequent activations, however, the animation will not play again.

```
animation-trigger: --t play-once replay;
```

If `play-once` is combined with `reset`, the animation plays on activation, then resets to the beginning on deactivation. On subsequent activation, the animation will play again.

```
animation-trigger: --t play-once reset;
```

If `play-once` is combined with `play-backwards`, the animation plays on activation, then plays backward through all the iterations on deactivation. On subsequent activation, the animation will not play again, but the animation will play backward again on subsequent deactivations.

```
animation-trigger: --t play-once play-backwards;
```

Pausing the animation

The `pause` value pauses the animation at whatever point it reached in its playback upon activation/deactivation. Using this in combination with other values was discussed earlier, although one case not mentioned was using `pause` as the activation action, for example:

```
animation-trigger: --t pause play;
```

This has an interesting effect of no playback on activation, but playback on subsequent deactivation: useful if you want an animation to play only when the subject leaves the scrollport.

It doesn't make sense to combine `pause` with `reset` because both effectively pause the animation, except that `reset` puts the animation back to the start. If the animation has not been played, `reset` has no discernible effect.

Resetting the animation

The `replay` and `reset` values are similar to `pause`, except that:

- `reset` pauses the animation but also puts it back to the start.
- `replay` puts the animation back to the start and then starts playing it again.

We previously discussed using these values in combination with other values. However, one case was not mentioned: using them as the activation action.

For example:

```
animation-trigger: --t replay pause;
```

This has an interesting effect: it plays on activation (the same as an action like `play`) and pauses on deactivation. However, on subsequent activation, it will play from the start again, regardless of the previous play state. This is useful if you want an animation to play when the subject enters the scrollport, pause when it leaves the scrollport, but then play from the start on each subsequent entry.

Another interesting example is as follows:

```
animation-trigger: --t reset play;
```

This has an interesting effect: it doesn't play on activation but plays on deactivation. On subsequent activation, it resets to progress `0`, regardless of the previous play state. This is useful if you want an animation to play when the subject leaves the scrollport, and then reset to the beginning on each subsequent entry.

Equivalence with the Web Animations API

The behavior specified by the various `<animation-action>` keywords is equivalent to calling various methods of the Web Animations API on the specified animation, as follows:

`play`

: Equivalent to calling `Animation.play()` on the animation.

`play-forwards`

: Equivalent to setting the `Animation.playbackRate` of a playing animation to its absolute positive value.

`play-backwards`

: Equivalent to setting the `Animation.playbackRate` of a playing animation to its absolute positive value multiplied by `-1`.

`play-once`

: Equivalent to calling `Animation.play()` on the animation except that it only plays once.

`pause`

: Equivalent to calling `Animation.pause()` on the animation.

`replay`

Equivalent to setting the `Animation.overallProgress` of a playing animation to `0`.

`reset`

Equivalent to setting the `Animation.overallProgress` of a paused animation to `0`.

Formal syntax

```
<animation-action> =
  none            |
  pause           |

Examples

Basic usage

This example shows how to create a basic scroll-triggered animation that plays forwards on trigger activation and backward on trigger deactivation.

HTML

Our markup contains two `<div>` elements, one to animate and one to create a trigger, plus some basic text content to scroll the page. We have hidden the text content for brevity.

```
<div class="animated">I am animated</div>

...

<div class="trigger">I create the trigger</div>

...
```

```
<div class="animated">I am animated</div>

<p>
  Fusce dictum ex quis ipsum consectetur placerat. Cras sed lectus ex. Quisque
  purus dolor, vulputate ac mi eget, commodo varius odio. Suspendisse faucibus
  ipsum vel libero finibus, in placerat nibh congue. Sed iaculis, metus et
  euismod posuere, mi diam vestibulum felis, ac vulputate eros ipsum id justo.
  Etiam a tincidunt purus. Maecenas semper sed enim at blandit. Aenean ut

</p>
```

CSS

We give the `.animated` element a `position` of `fixed`, positioning it near the top-left of the scrollport so we can see when its animation starts and stops.

```
body {
  width: 80%;
```

```
  margin: 0 auto;
  font-family: "Helvetica", "Arial";
  font-size: 1.3rem;
}

div {
  height: 100px;
  border: 5px solid black;
}

.animated {
  width: 100px;
  background: orange;
}

.trigger {
  background: wheat;
}
```

```
.animated {
  position: fixed;
  top: 25px;
  left: 25px;
}
```

Next, we define the `@keyframes` for a `rotate` animation:

```
@keyframes rotate {
  from {
    rotate: 0deg;
  }

  to {
    rotate: 360deg;
  }
}
```

The `.animated` element has the `rotate` animation applied. We then give it an `animation-trigger` value that references a `timeline-trigger-name` of `--t` with two `<animation-action>` values, `play-forwards` and `play-backwards`. These specify that the animation will play on activation and play in reverse on deactivation.

```
.animated {
  animation: rotate 1.5s infinite linear both;
  animation-trigger: --t play-forwards play-backwards;
}
```

The `.trigger` element creates the animated `<div>`'s trigger using a `timeline-trigger` value of `--t view()`. This value includes the identifier referenced in the animated `<div>`'s `animation-trigger` property value (the `timeline-trigger-name`), associating the two together. It also includes:

- A `timeline-trigger-source` value of `view()`, which sets the timeline trigger as a view progress timeline, and the element providing the timeline trigger as the nearest scrolling ancestor element.
- A `timeline-trigger-activation-range` value of `contain`, which means that the trigger will activate when the `.trigger` element is fully inside the scrollport. Because `timeline-trigger-active-range` defaults to `auto`, its value is the same as the activation range; the trigger therefore deactivates when it stops being fully inside the scrollport.

```
.trigger {
  timeline-trigger: --t view() contain;
}
```

Result

Try scrolling the content up. When the tracked `<div>` fully appears in the scrollport, the animation plays; when it starts to leave the scrollport at either edge, the animation plays in reverse.

Comparing the <code><animation-action></code> values

This example provides a comparison of the various `<animation-action>` values. By applying the same rotation animation to identical side-by-side elements and varying the `animation-trigger` values, you can compare and contrast the effects of the different actions.

HTML

We include a `<section>` element containing five `<div>` elements, each with a number inside. We also include text content to make the page scroll, which we've hidden for brevity.

```
<section>
  <div class="one">1</div>
  <div class="two">2</div>
  <div class="three">3</div>
  <div class="four">4</div>
  <div class="five">5</div>
</section>
```

```
<p>
  Fusce dictum ex quis ipsum consectetur placerat. Cras sed lectus ex. Quisque
  purus dolor, vulputate ac mi eget, commodo varius odio. Suspendisse faucibus
  ipsum vel libero finibus, in placerat nibh congue. Sed iaculis, metus et
  euismod posuere, mi diam vestibulum felis, ac vulputate eros ipsum id justo.
  Etiam a tincidunt purus. Maecenas semper sed enim at blandit. Aenean ut
  sagittis lorem, eget gravida purus. Phasellus eleifend, lectus nec pulvinar
  facilisis, dui dolor feugiat odio, iaculis tempor felis est non tortor. In
  suscipit lorem efficitur molestie tempus. Integer sit amet neque et risus
  iaculis sodales sed eget diam. Quisque sodales nunc sapien, vitae lacinia ex
  luctus quis. Maecenas scelerisque scelerisque elit eu consequat. Etiam ac
  tristique tellus, sed tincidunt velit.
</p>

  iaculis sodales sed eget diam. Quisque sodales nunc sapien, vitae lacinia ex
  luctus quis. Maecenas scelerisque scelerisque elit eu consequat. Etiam ac
  tristique tellus, sed tincidunt velit.
</p>
```

CSS

We apply the same `animation` to each `<div>` element—we play the `rotate` animation infinitely, with each iteration lasting two seconds. We also style each `<div>` to be a `50px` diameter colored circle.

```
body {
  width: 80%;
  margin: 0 auto;
  font-family: "Helvetica", "Arial";
  font-size: 1.3rem;
}

div {
  display: flex;
  justify-content: center;
}

section {
  display: flex;
  justify-content: space-between;
}
```

```
div {
  animation: rotate 2s infinite linear both;
  height: 50px;
  width: 50px;
  border: 5px solid black;
  border-radius: 50%;
  background-color: orange;
}
```

Next, we set the `<section>` element to create an animation trigger, with a `timeline-trigger` value of `--t view() contain 20% contain 80%`. There is nothing unusual here, except that we've set a `timeline-trigger-activation-range` value and defaulted the `timeline-trigger-active-range` to `contain 20% contain 80%`. This means the trigger activates when the `<section>` element has scrolled around `20%` of the way up the scrollport, and deactivates when it has scrolled around `80%` of the way up the scrollport. This allows you to see the `<animation-action>` effects more clearly than if the activation range covered the entire scrollport.

```
section {
  timeline-trigger: --t view() contain 20% contain 80%;
}
```

Next, we set a different `animation-trigger` property value on each `<div>` element. Each one references the `<section>` element's `timeline-trigger-name`, but each one has a different set of `<animation-action>` values applied. The last `<div>` additionally has a new `animation` property value applied, overriding the one we set earlier. It is the same as the original `animation` property, except that the iteration count is set to `1` rather than `infinite`. It is easier to demonstrate the effect of `play-once` when `animation-iteration-count` is not `infinite` (if this were the case, it would play forever, regardless).

```
.one {
  animation-trigger: --t play-forwards play-backwards;
}

.two {
  animation-trigger: --t play;
}

.three {
  animation-trigger: --t play replay;
}

.four {
  animation-trigger: --t pause play;
}
```

```
.five {
  animation: rotate 2s 1 linear both;
  animation-trigger: --t play-once reset;
}
```

```
@supports not (animation-trigger: --t play-once reset) {
  body::before {
    content: "Your browser does not support scroll-triggered animations.";
    background-color: wheat;
    text-align: center;
    padding: 1rem 0;

    z-index: 1;
    position: fixed;
    inset: 40% 0 auto;
  }
}
```

Result

Scroll down to the point where the `<section>` and `<div>` elements enter the scrollport. Move them through the start and end of the trigger activation range, concentrating on a different `<div>` each time, to visualize the effects of each set of `<animation-action>`s.

The effects are:

1. The first `<div>` (far left) has `play-forwards play-backwards` set. When the tracked element enters the activation range, the animation plays forward. When it leaves the activation range (at the top or bottom of the scrollport), it starts playing backward.
2. The second `<div>` has a single `<animation-action>` set — `play`. When the tracked element enters the activation range, the animation starts to play. However, because no deactivation action is set to change its behavior, the animation continues to play forever until the page reloads.
3. The third `<div>` has `play replay` set. When the tracked element enters the activation range, the animation starts playing forward. When it leaves the activation range, the animation resets to progress `0` and then starts playing again.
4. The fourth `<div>` has `pause play` set. When the tracked element enters the activation range, the animation continues not to play due to the paused state. However, when it leaves the activation range, the animation starts to play. From then on, the animation pauses when the tracked element is inside the activation range and plays when it is outside it.
5. The fifth `<div>` (far right, with an iteration count of `1`) has `play-once reset` set. When the tracked element enters the activation range, the animation plays once. When it leaves the activation range, the animation resets to progress `0` and pauses. From then on, the animation plays once whenever the tracked element enters the activation range and resets when it leaves the activation range.

asin() CSS function

The **`asin()`** CSS function is a trigonometric function that returns the inverse sine of a number between `-1` and `1`. The function contains a single calculation that returns an `<angle>` between `-90deg` and `90deg`.

Syntax

```
/* Single <number> values */
transform: rotate(asin(-0.2));
transform: rotate(asin(2 * 0.125));

/* Other values */
transform: rotate(asin(pi / 5));
transform: rotate(asin(e / 3));
```

Parameters

The `asin(number)` function accepts only one value as its parameter.

`number`

A calculation which resolves to a `<number>` between `-1` and `1`.

Return value

The inverse sine of a `number` will always return an `<angle>` between `-90deg` and `90deg`.

- If `number` is less than `-1` or greater than `1`, the result is `NaN`.
- If `number` is `0⁻`, the result is `0⁻`.

Formal syntax

```
<asin()> =
  asin( <calc-sum> )

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Rotate elements

The `asin()` function can be used to `rotate` elements as it returns an `<angle>`.

HTML

```
<div class="box box-1"></div>
<div class="box box-2"></div>
<div class="box box-3"></div>
<div class="box box-4"></div>
<div class="box box-5"></div>
```

CSS

```
body {
  height: 100vh;
  display: flex;
  justify-content: center;
  align-items: center;
  gap: 50px;
}
```

```
div.box {
  width: 100px;
  height: 100px;
  background: linear-gradient(orange, red);
}
div.box-1 {
  transform: rotate(asin(1));
}
div.box-2 {
  transform: rotate(asin(0.5));
}
div.box-3 {
  transform: rotate(asin(0));
}
div.box-4 {
  transform: rotate(asin(-0.5));
}
div.box-5 {
  transform: rotate(asin(-1));
}
```

Result

atan() CSS function

The **`atan()`** CSS function is a trigonometric function that returns the inverse tangent of a number between `-∞` and `+∞`. The function contains a single calculation that returns an `<angle>` between `-90deg` and `90deg`.

Syntax

```
/* Single <number> values */
transform: rotate(atan(1));
transform: rotate(atan(4 * 50));

/* Other values */
transform: rotate(atan(pi / 2));
transform: rotate(atan(e * 3));
```

Parameters

The `atan(number)` function accepts only one value as its parameter.

`number`

A calculation which resolves to a `<number>` between `-∞` and `+∞`.

Return value

The inverse tangent of a `number` will always return an `<angle>` between `-90deg` and `90deg`.

- If `number` is `0⁻`, the result is `0⁻`.
- If `number` is `+∞` the result is `90deg`.
- If `number` is `-∞` the result is `-90deg`.

That is:

- `atan(-infinity)` representing `-90deg`.
- `atan(-1)` representing `-45deg`
- `atan(0)` representing `0deg`
- `atan(1)` representing `45deg`
- `atan(infinity)` representing `90deg`.

Formal syntax

```
<atan()> =
  atan( <calc-sum> )

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Rotate elements

The `atan()` function can be used to `rotate` elements as it returns an `<angle>`.

HTML

```
<div class="box box-1"></div>
<div class="box box-2"></div>
<div class="box box-3"></div>
<div class="box box-4"></div>
<div class="box box-5"></div>
```

CSS

```
body {
  height: 100vh;
  display: flex;
  justify-content: center;
  align-items: center;
  gap: 50px;
}
```

```
div.box {
  width: 100px;
  height: 100px;
  background: linear-gradient(orange, red);
}
div.box-1 {
  transform: rotate(atan(-99999));
}
div.box-2 {
  transform: rotate(atan(-1));
}
div.box-3 {
  transform: rotate(atan(0));
}
div.box-4 {
  transform: rotate(atan(1));
}
div.box-5 {
  transform: rotate(atan(99999));
}
```

atan2() CSS function

The **`atan2()`** CSS function is a trigonometric function that returns the inverse tangent of two values between `-infinity` and `infinity`. The function accepts two arguments and returns an `<angle>` between `-180deg` and `180deg`, without implying any specific unit such as radians.

Syntax

```
/* Two <number> values */
transform: rotate(atan2(3, 2));

/* Two <dimension> values */
transform: rotate(atan2(1rem, -0.5rem));

/* Two <percentage> values */
transform: rotate(atan2(20%, -30%));

/* Other values */
```

```
transform: rotate(atan2(pi, 45));
transform: rotate(atan2(e, 30));
```

Parameters

The `atan2(y, x)` function accepts two comma-separated values as its parameters. Each value can be a `<number>`, a `<dimension>`, or a `<percentage>`. Both values must be of the same type, although if they are `<dimension>` they can be of different units (example: `atan2(100px, 5vw)` is valid).

`y`

The y-coordinate of the point. A calculation which resolves to a `<number>`, a `<dimension>`, or a `<percentage>`.

`x`

The x-coordinate of the point. A calculation which resolves to a `<number>`, a `<dimension>`, or a `<percentage>`.

Return value

Given two values `x` and `y`, the function `atan2(y, x)` calculates and returns the `<angle>` between the positive x-axis and the ray from the origin to the point `(x, y)`.

Formal syntax

```
<atan2()> =
  atan2( <calc-sum> , <calc-sum> )

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Rotate elements

The `atan2()` function can be used to `rotate` elements as it returns an `<angle>`.

HTML

```
<div class="box box-1"></div>
<div class="box box-2"></div>
<div class="box box-3"></div>
<div class="box box-4"></div>
<div class="box box-5"></div>
```

CSS

```
body {
  height: 100vh;
  display: flex;
  justify-content: center;
  align-items: center;
  gap: 50px;
}
```

```
div.box {
  width: 100px;
  height: 100px;
  background: linear-gradient(orange, red);
}
div.box-1 {
  transform: rotate(atan2(3, 2));
}
div.box-2 {
  transform: rotate(atan2(3%, -2%));
}
div.box-3 {
  transform: rotate(atan2(-1, 0.5));
}
div.box-4 {
  transform: rotate(atan2(1, 0.5));
}
div.box-5 {
  transform: rotate(atan2(1rem, -0.5rem));
}
```

attr() CSS function

> **Note:** The `attr()` function can be used with any CSS property, but support for properties other than `content` is experimental.

The **`attr()`** CSS function is used to retrieve the value of an attribute of the selected element and use it in a property value, similar to how the `var()` function substitutes a custom property value. It can also be used with pseudo-elements, in which case the attribute's value on the pseudo-element's originating element is returned.

Try it

```
blockquote {
  margin: 1em 0;
}

blockquote::after {
  display: block;
  content: " (source: " attr(cite) ") ";
  color: hotpink;
}
```

```
<blockquote cite="https://mozilla.org/en-US/about/">
  Mozilla is working to put control of the internet back in the hands of the
  people using it.
</blockquote>

<blockquote cite="https://web.dev/about/">
  Build beautiful, accessible, fast, and secure websites that work
  cross-browser.
</blockquote>
```

Syntax

```
/* Basic usage */
attr(data-count)
attr(href)

/* With type */
attr(data-width px)
attr(data-size rem)
attr(data-name raw-string)
attr(id type(<custom-ident>))
attr(data-count type(<number>))
attr(data-size type(<length> | <percentage>))

/* With fallback */
attr(data-count type(<number>), 0)
attr(data-width px, inherit)
attr(data-something, "default")

/* With namespace */
attr(color|myAttr type(*), red)
```

Parameters

The `attr()` function's syntax is as follows:

```
attr(<attr-name> <attr-type>? , <fallback-value>?)
```

The parameters are:

`<attr-name>`

The attribute name whose value should be retrieved from the selected HTML element(s).

Namespaces

The attribute name can contain a `namespace` which allows the targeting elements of XML-based markup languages such as SVG or MathML.

```
@namespace svg url("http://www.w3.org/2000/svg");
a {
  fill: attr(svg|myAttr type(*), green);
}
```

> **Note:** If no namespace is specified (just an identifier is given, like `attr(foo)`), the null namespace is implied. This is usually what's desired, as namespaced attributes are rare. As with attribute selectors, the case-sensitivity of `<attr-name>` depends on the document language.

`<attr-type>`

Specifies how the attribute value is parsed into a CSS value. This can be the `raw-string` keyword, a `type()` function, or a CSS dimension unit (specified using an `<attr-unit>` identifier). When omitted, it defaults to `raw-string`.

`raw-string`

The `raw-string` keyword causes the attribute's literal value to be treated as the value of a CSS string, with no CSS parsing performed (including CSS escapes, whitespace removal, comments, etc.). The `<fallback-value>` is only used if the attribute is omitted; specifying an empty value doesn't trigger the fallback.

```
attr(data-name raw-string, "stranger")
```

> **Note:** This keyword was originally named and supported in Chromium browsers as `string`. Both keywords will be supported briefly, for backward compatibility purposes.

`type()`

The `type()` function takes a `<syntax>` as its argument that specifies what data type to parse the value into.

> **Note:** For security reasons `<url>` is not allowed as an `attr()` data type.

`<attr-unit>`

The `<attr-unit>` identifier specifies the unit a numeric value should have (if any). It can be the `%` character (percentage) or a CSS distance unit such as `px`, `rem`, `deg`, `s`, etc.

```
attr(data-size rem)
attr(data-width px, inherit)
attr(data-rotation deg)
```

`<fallback-value>`

The value to be used if the specified attribute is missing or contains an invalid value.

Return value

The return value of `attr()` is the value of the HTML attribute whose name is `<attr-name>` parsed as the given `<attr-type>` or parsed as a CSS string.

When an `<attr-type>` is set, `attr()` will try to parse the attribute into that specified `<attr-type>` and return it. If the attribute cannot be parsed into the given `<attr-type>`, the `<fallback-value>` will be returned instead. When no `<attr-type>` is set, the attribute will be parsed into a CSS string.

If no `<fallback-value>` is set, the return value will default to an empty string when no `<attr-type>` is set or the guaranteed-invalid value when an `<attr-type>` is set.

Description

Limitations and security

The `attr()` function can reference attributes that were never intended for styling use and might contain sensitive information (for example, a security token used by scripts on the page). In general, this is fine, but it can become a security threat when used in URLs.

For this reason, you can't use `attr()` to dynamically construct URLs:

```
<!-- This won't work! -->
<span data-icon="https://example.org/icons/question-mark.svg">help</span>
```

```
span[data-icon] {
  background-image: url(attr(data-icon));
}
```

This restriction also applies to any context that could potentially result in a `<url>` value. Values that use `attr()` get marked as *`attr()`-tainted*, and using them as or in a `<url>` makes a declaration become "invalid at computed value time" (IACVT).

So, for example, functions like `image-set()` that take values that resolve to `<url>` also won't work:

```
span[data-icon] {
  background: image-set(attr(data-icon));
}
```

Backwards compatibility

Generally speaking, the modern `attr()` syntax is backward-compatible because the old way of using it — without specifying an `<attr-type>` — behaves the same as before. Having `attr(data-attr)` in your code is the same as writing `attr(data-attr type(<string>))` or the simpler `attr(data-attr string)`).

However, there are two edge cases where the modern `attr()` syntax behaves differently from the old syntax.

In the following snippet, browsers that don't support the modern `attr()` syntax will discard the second declaration because they cannot parse it. The result in those browsers is `"Hello World"`.

```
<div text="Hello"></div>
```

```
div::before {
  content: attr(text) " World";
}
div::before {
  content: attr(text) 1px;
}
```

In browsers with support for the modern syntax, the output will be … nothing. Those browsers will successfully parse the second declaration, but because it is invalid content for the `content` property, the declaration becomes "invalid at computed value time" or IACVT for short.

To prevent this kind of situation, feature detection is recommended.

A second edge case is the following:

```
<div id="parent"><div id="child" data-attr="foo"></div></div>
```

```
#parent {
  --x: attr(data-attr);
}
#child::before {
  content: var(--x);
}
```

Browsers without support for modern syntax display the text `"foo"`. In browsers with modern `attr()` support there is no output.

This is because `attr()` — similar to custom properties that use the `var()` function — gets substituted at computed value time. With the modern behavior, `--x` first tries to read the `data-attr` attribute from the `#parent` element, which results in an empty string because there is no such attribute on `#parent`. That empty string then gets inherited by the `#child` element, resulting in a `content: ;` declaration being set.

To prevent this sort of situation, don't pass inherited `attr()` values onto children unless you explicitly want to.

Feature detection

You can feature detect support for modern `attr()` syntax using the `@supports` at-rule. In the test, try to assign an advanced `attr()` to a (non-custom) CSS property.

For example:

```
@supports (x: attr(x type(*))) {
  /* Browser has modern attr() support */
}

@supports not (x: attr(x type(*))) {
  /* Browser does not have modern attr() support */
}
```

We can perform the same check in JavaScript with `CSS.supports()`:

```
if (CSS.supports("x: attr(x type(*))")) {
  /* Browser has modern attr() support */
}

if (!CSS.supports("x: attr(x type(*))")) {
  /* Browser does not have modern attr() support */
}
```

Formal syntax

```
<attr()> =
  attr( <attr-name> <attr-type>? , <declaration-value>? )

<attr-name> =
  [ <ident-token>? '|' ]? <ident-token>

<attr-type> =
  type( <syntax> )  |
  raw-string        |
  number            |
  <attr-unit>

<syntax> =
  '*'                                              |
  <syntax-component> [ <syntax-combinator> <syntax-component> ]*  |
  <syntax-string>

<attr-unit> =
  <custom-ident>

<syntax-component> =
  <syntax-single-component> <syntax-multiplier>?  |
  '<' transform-list '>'

<syntax-combinator> =
  '|'

<syntax-string> =
  <string>

<syntax-single-component> =
  '<' <syntax-type-name> '>'  |
  <ident>

<syntax-multiplier> =
  '#'  |
  '+'

<syntax-type-name> =
  angle               |
  color               |
  custom-ident        |
  image               |
  integer             |
  length              |
  length-percentage   |
  number              |
  percentage          |
  resolution          |
  string              |
  time                |
  url                 |
  transform-function
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

content property

In this example, we prepend the value of the `data-foo` `data-*` global attribute to the contents of the `<p>` element.

HTML

```
<p data-foo="hello">world</p>
```

CSS

```
[data-foo]::before {
  content: attr(data-foo) " ";
}
```

Result

Using a fallback value

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

In this example, we append the value of `data-browser` `data-*` global attribute to the `<p>` element. If the `data-browser` attribute is missing from the `<p>` element, we append the *fallback* value of "**Unknown**".

HTML

```
<p data-browser="Firefox">My favorite browser is:</p>
<p>Your favorite browser is:</p>
```

CSS

```
p::after {
  content: " " attr(data-browser, "Unknown");
  color: tomato;
}
```

Result

color value

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

In this example, we set the CSS value of `background-color` to the value of the `data-background` `data-*` global attribute assigned to the `<div>` element.

HTML

```
<div class="background" data-background="lime">
  background expected to be red if your browser does not support advanced usage
  of attr()
</div>
```

CSS

```
.background {
  height: 100vh;
}
```

```
.background {
  background-color: red;
}

.background[data-background] {
  background-color: attr(data-background type(<color>), red);
}
```

Result

Using dimension units

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

In this example the `data-rotation` attribute is parsed into a `deg` unit, which specifies the element's rotation.

HTML

```
<div data-rotation="-3">I am rotated by -3 degrees</div>
<div data-rotation="2">And I by 2 degrees</div>
<div>And so am I, using the fallback value of 1.5deg</div>
```

CSS

```
body {
  min-height: 100svh;
  display: grid;
  place-content: center;
  gap: 1em;
}
div {
  margin: 0 auto;
  border: 1px solid;
  border-radius: 0.25em;
  padding: 0.5em;
}
```

```
div {
  width: fit-content;
  transform-origin: 50% 50%;
  rotate: attr(data-rotation deg, 1.5deg);
}
```

Result

Parsing <code>attr()</code> values as <code><custom-ident></code>s

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

In this example, the values for the `view-transition-name` property are derived from the `id` attribute of the element. The attribute gets parsed into a `<custom-ident>`, which is what `view-transition-name` accepts as a value.

The resulting values for `view-transition-name` are `card-1`, `card-2`, `card-3`, etc.

HTML

The HTML contains four cards with different `id` attributes and a "Shuffle cards" `<button>`, which shuffles the cards.

```
<div class="cards">
  <div class="card" id="card-1">1</div>
  <div class="card" id="card-2">2</div>
  <div class="card" id="card-3">3</div>
  <div class="card" id="card-4">4</div>
</div>
<button>Shuffle cards</button>
```

```
<div class="warning">
  <p>
    Your browser does not support advanced <code>attr()</code>. As a result,
    this demo won't do anything.
  </p>
</div>
```

CSS

The cards are laid out in a flex container:

```
.cards {
  display: flex;
  flex-direction: row;
  gap: 1em;
  padding: 1em;
}
```

```
:root {
  view-transition-name: none;
}
::view-transition {
  pointer-events: none;
}

@supports (x: attr(x type(*))) {
  .warning {
    display: none;
  }
}

@layer layout {
  .card {
    border-radius: 0.25em;
    width: 20vw;
    max-width: 5em;
    aspect-ratio: 1 / 1.6;
    background: lightgrey;

    display: grid;
    place-content: center;
    font-size: 2em;
  }

  * {
    box-sizing: border-box;
  }

  body {
    min-height: 100svh;
    display: grid;
    place-content: center;
  }

  button {
    justify-self: center;
  }
}

@layer warning {
  .warning {
    padding: 1em;
    border: 1px solid #cccccc;
    background: rgb(255 255 205 / 0.8);
    text-align: center;
    order: -1;
    margin: 1em;
  }

  .warning > :first-child {
    margin-top: 0;
  }
  .warning > :last-child {
    margin-bottom: 0;
  }
}
```

On each card, the `attr()` function gets the `id` attribute and parses it into a `<custom-ident>`, which is used as the value for the `view-transition-name` property. When there is no `id` set on a card, the fallback value `none` is used instead.

```
.card {
  view-transition-name: attr(id type(<custom-ident>), none);
  view-transition-class: card;
}
```

JavaScript

When the `<button>` is pressed, the cards are shuffled. This is done by randomizing the order of an array containing references to all the cards and then updating the `order` property of each card to its new array index position.

To animate each card to its new position, View Transitions are used. This is done by wrapping the `order` update in a call to `document.startViewTransition`.

```
const shuffle = (array) => {
  for (let i = array.length - 1; i >= 0; i--) {
    const j = Math.floor(Math.random() * (i + 1));
    [array[i], array[j]] = [array[j], array[i]];
  }
};

document.querySelector("button").addEventListener("click", (e) => {
  const $cards = Array.from(document.querySelectorAll(".card"));
  shuffle($cards);
  document.startViewTransition(() => {
    $cards.forEach(($card, i) => {
      $card.style.setProperty("order", i);
    });
  });
});
```

<axis> CSS type

The **`<axis>`** enumerated data type specifies the scrolling direction of the scroll container controlling a scroll timeline.

The `<axis>` keyword values are used in the following CSS functions and properties:

- `scroll-timeline-axis`
- `scroll-timeline` shorthand
- `scroll()`
- `view-timeline-axis`
- `view-timeline` shorthand
- `view()`

Syntax

Valid `<axis>` values:

`block`

> The block axis of the scroller element, which is the axis in the direction perpendicular to the flow of text within a line. For horizontal writing modes, such as standard English, this is the same as `y`, while for vertical writing modes, it is the same as `x`.

`inline`

> The inline axis of the scroller element, which is the axis in the direction parallel to the flow of text in a line. For horizontal writing modes, this is the same as `x`, while for vertical writing modes, this is the same as `y`.

`x`

> The horizontal axis of the scroller element.

`y`

> The vertical axis of the scroller element.

Formal syntax

```
<axis> =
  block   |
  inline  |
  x       |
  y
```

<baseline-position> CSS type

The **`<baseline-position>`** enumerated value type represents the `baseline` keyword values and `first` and `last` modifiers, used for the `align-content`, `align-items`, `align-self`, `justify-items` and `justify-self` properties as well as the `place-content`, `place-items`, and `place-self` shorthand properties.

The `first` and `last` values give a box a baseline alignment preference, defaulting to `first` if the modifier is omitted.

Syntax

```
<baseline-position> = [ first | last ]? && baseline
```

Values

The `<baseline-position>` enumerated value type is specified using an optional `first` or `last` modifier with the `baseline` value. If a box does not belong to a shared alignment context, then the fallback alignment is used. The fallback alignment is also used to align the baseline-sharing group within its alignment container.

`baseline`

> Computes to `first baseline`, as defined below.

`first baseline`

> Aligns the alignment baseline of the box's first baseline set with the corresponding baseline of its baseline-sharing group. The fallback alignment is `safe self-start` for self-alignment or `safe start` for content distribution.

`last baseline`

Aligns the alignment baseline of the box's last baseline set with the corresponding baseline of its baseline-sharing group. The fallback alignment is `safe self-end` for self-alignment or `safe end` for content distribution.

<basic-shape> CSS type

The **`<basic-shape>`** CSS data type represents a shape used in the `border-shape`, `clip-path`, `offset-path`, and `shape-outside` properties.

Try it

```
clip-path: inset(22% 12% 15px 35px);
```

```
clip-path: circle(6rem at 12rem 8rem);
```

```
clip-path: ellipse(115px 55px at 50% 40%);
```

```
clip-path: polygon(
  50% 2.4%,
  34.5% 33.8%,
  0% 38.8%,
  25% 63.1%,
  19.1% 97.6%,
  50% 81.3%,
  80.9% 97.6%,
  75% 63.1%,
  100% 38.8%,
  65.5% 33.8%
);
```

```
clip-path: path("M 50,245 A 160,160 0,0,1 360,120 z");
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element"></div>
</section>
```

```
#default-example {
  background: #ffee99;
}

#example-element {
  background: linear-gradient(to bottom right, #ff5522, #0055ff);
  width: 100%;
  height: 100%;
}
```

Syntax

The `<basic-shape>` data type is used to create basic shapes including rectangles by container inset, by coordinate distance, or by set dimensions, circles, ellipses, polygons, paths, and author created shapes. These basic shapes are defined using one `<basic_shape>` CSS functions, with each value requiring a parameter that follows the shape's function-specific syntax.

Common parameters

The parameters common across the syntax of some basic shape functions include:

`round <'border-radius'>`

Defines rounded corners for rectangles by container insets, rectangles by distance, and rectangles with dimensions using the same syntax as the CSS `border-radius` shorthand property.

`<shape-radius>`

Defines the radius for a circle or an ellipse. Valid values include `<length>`, `<percentage>`, `closest-side` (the default), `farthest-side`, `closest-corner`, and `farthest-corner`. Negative values are invalid.

The `closest-side` keyword value uses the length from the center of the shape to the closest side of the reference box to create the radius length. The `farthest-side` keyword value uses the length from the center of the shape to the farthest side of the reference box. Similarly, the `closest-corner` and `farthest-corner` use the length from the center of the shape to the closest and farthest corners, respectively.

`<position>`

Defines the center `<position>` of a circle or an ellipse. It defaults to `center` if omitted.

`<fill-rule>`

Sets the `fill-rule` that is used to determine how the interior of the shape defined by the basic shapes polygon, path, and shape is to be filled. Possible values are `nonzero` (the default) and `evenodd`.

> **Note:** `<fill-rule>` is not supported in `offset-path` and using it invalidates the property.

Syntax for rectangles: <code><basic-shape-rect></code>

The `<basic-shape-rect>` type, a subset of the `<basic-shape>` type, represents the basic-shape functions limited to creating rectangles, including `inset()`, `rect()`, and `xywh()`.

The `polygon()`, `path()`, and `shape()` functions can also be used to create rectangles, but are not limited to only four-sided, right-angled shapes.

Syntax for rectangles by container insets

The `inset()` function creates an inset rectangle, with its size defined by the offset distance of each of the four sides of its container and, optionally, rounded corners.

```
inset( <length-percentage>{1,4} [ round <'border-radius'> ]? )
```

When all of the first four arguments are supplied, they represent the top, right, bottom, and left offsets from the reference box inward that define the position of the edges of the inset rectangle. These arguments follow the syntax of the `margin` shorthand, which lets you set all four insets with one, two, three, or four values.

If a pair of insets for a dimension adds up to more than 100% of that dimension, both values are proportionally reduced so their sum equals 100%. For example, the value `inset(90% 10% 60% 10%)` has a top inset of `90%` and a bottom inset of `60%`. These values are reduced proportionally to `inset(60% 10% 40% 10%)`. Shapes such as this, that enclose no area and have no `shape-margin`, do not affect wrapping.

Syntax for rectangles by distance

The `rect()` function defines a rectangle using the specified distances from the top and left edges of the reference box, with optional rounded corners.

```
rect( [ <length-percentage> | auto ]{4} [ round <'border-radius'> ]? )
```

When using the `rect()` function, you do not define the width and height of the rectangle. Instead, you specify four values to create the rectangle, with its dimensions determined by the size of the reference box and the four offset values. Each value can be either a `<length>`, a `<percentage>`, or the keyword `auto`. The `auto` keyword is interpreted as `0%` for the top and left values and as `100%` for the bottom and right values.

Syntax for rectangles with dimensions

The `xywh()` function defines a rectangle located at the specified distances from the left (`x`) and top (`y`) edges of the reference box and sized by the specified width (`w`) and height (`h`) of the rectangle, in that order, with optional rounded corners.

```
xywh( <length-percentage>{2} <length-percentage [0,∞]>{2} [ round <'border-radius'> ]? )
```

Syntax for circles

The `circle()` function defines a circle using a radius and a position.

```
circle( <shape-radius>? [ at <position> ]? )
```

The `<shape-radius>` argument represents the radius of the circle defined as either a `<length>` or a `<percentage>`. A percentage value here is resolved from the used width and height of the reference box as `sqrt(width^2+height^2)/sqrt(2)`. If omitted, the radius is defined by `closest-side`.

Syntax for ellipses

The `ellipse()` function defines an ellipse using two radii and a position.

```
ellipse( [ <shape-radius>{2} ]? [ at <position> ]? )
```

The `<shape-radius>` arguments represent *rx* and *ry*, the x-axis and y-axis radii of the ellipse, in that order. These values are specified as either a `<length>` or a `<percentage>`. Percentage values here are resolved against the used width (for the rx value) and the used height (for the ry value) of the reference box. If only one radius value is provided, the `ellipse()` shape function is invalid. If no value is provided, `50% 50%` is used.

Syntax for polygons

The `polygon()` function defines a polygon using a set of comma-separated coordinate pairs, optionally preceded by an SVG `fill-rule`, a corner-rounding parameter, or both.

```
polygon( <'fill-rule'>? [ round <length> ]? , [ <length-percentage> <length-percentage> ]# )
```

The optional first parameter can contain one or both of the following, separated by a space:

- An SVG `fill-rule` value, either `nonzero` or `evenodd`, specifying the algorithm used to fill the polygon shape.
- The keyword `round` followed by a `<length>` value, separated by a space. This specifies that the polygon should have rounded corners, with the `<length>` specifying the corner radius.

Each coordinate pair consists of two space-separated `<length-percentage>` values. These values represent the x- and y-axis coordinates of a polygon vertex.

Syntax for paths

The `path()` function defines a shape using an SVG `fill-rule` and an SVG path definition.

```
path( <'fill-rule'>? , <string> )
```

The required `<string>` is an SVG path as a quoted string. The `path()` function is not a valid `shape-outside` property value.

Syntax for shapes

The `shape()` function defines a shape using an initial starting point and a series of shape commands.

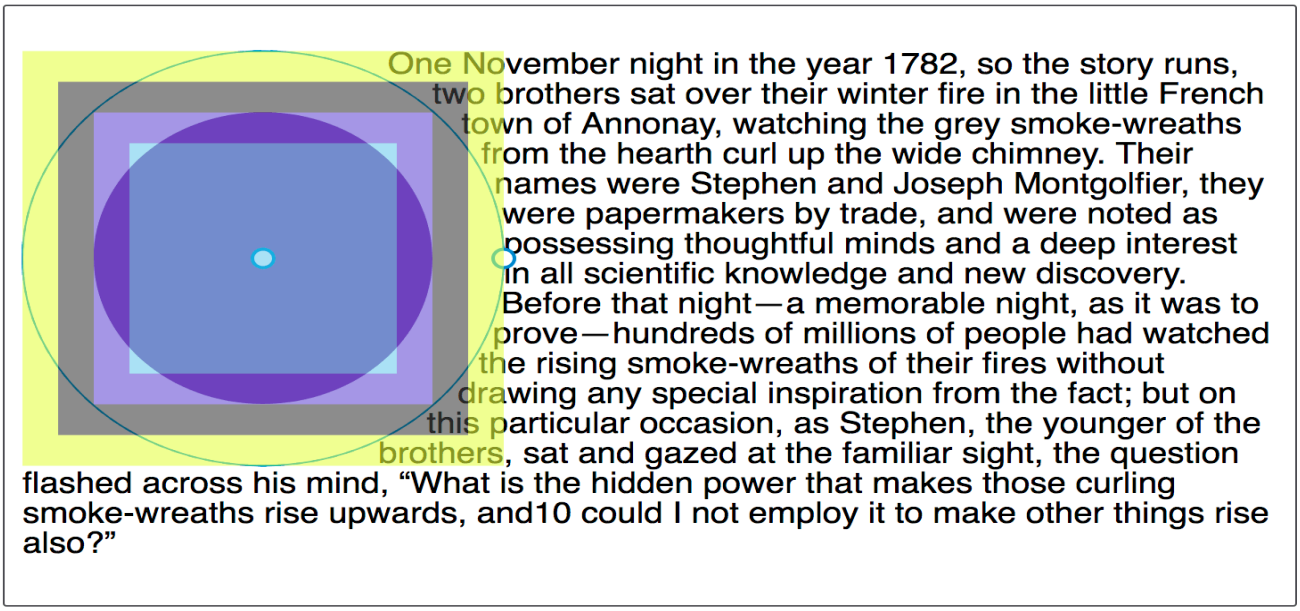
```
shape( <'fill-rule'>? from <coordinate-pair> , <shape-command># )
```

The `from <coordinate-pair>` parameter represents the starting point for the first shape command, and `<shape-command>` defines one or more shape commands, which are similar to the SVG path commands. The `shape()` function is not a valid `shape-outside` property value.

Description

When creating a shape, the reference box is defined by the property that uses `<basic-shape>` values. The coordinate system for the shape has its origin at the top-left corner of the element's margin box by default, with the x-axis running to the right and the y-axis running downwards. All the lengths expressed in percentages are resolved from the dimensions of the reference box.

The default reference box is the `margin-box`, as demonstrated in the image below. The image shows a circle created using `shape-outside: circle(50%)`, highlighting the different parts of the box model as seen in a browser's Developer Tools. The shape here is defined with reference to the margin-box.



Computed values of basic shapes

The values in a `<basic-shape>` function are computed as specified, with the following additional considerations:

- For any omitted values, their defaults are used.
- A `<position>` value in `circle()` or `ellipse()` is computed as a pair of offsets from the top left corner of the reference box: the first offset is horizontal, and the second is vertical. Each offset is specified as a `<length-percentage>` value.
- A `<border-radius>` value in `inset()` is expanded into a list of eight values, each either a `<length>` or a `<percentage>`.
- `inset()`, `rect()`, and `xywh()` functions compute to the equivalent `inset()` function.

Interpolation of basic shapes

When animating between two `<basic-shape>` functions, the interpolation rules listed below are followed. The parameter values of each `<basic-shape>` function form a list. For interpolation to occur between two shapes, both shapes must use the same reference box and the number and type of values in both `<basic-shape>` lists must match.

Each value in the lists of the two `<basic-shape>` functions is interpolated based on its computed value as a `<number>`, `<length>`, `<percentage>`, `<angle>`, or `calc()` where possible. Interpolation can still occur if the values are not one of those data types but are identical between the two interpolating basic shape functions, such as `nonzero`.

- **Both shapes are of type `ellipse()` or type `circle()`**: Interpolation is applied between each corresponding value if their radii are specified as either a `<length>` or a `<percentage>` (rather than keywords such as `closest-side` or `farthest-side`).
- **Both shapes are of type `inset()`**: Interpolation is applied between each corresponding value.
- **Both shapes are of type `polygon()`**: Interpolation is applied between each corresponding value if they use the same `<fill-rule>` and have the same number of comma-separated coordinate pairs.
- **Both shapes are of type `path()`**: Interpolation is applied to each parameter as a `<number>` if the path strings in both the shapes match the number, type, and sequence of path data commands.
- **Both shapes are of type `shape()`**: Interpolation is applied between each corresponding value if they have the identical command keyword and use the same `<by-to>` keyword. If `shape()` is used in the `clip-path` property, the two shapes interpolate if they also have the same `<fill-rule>`.
    - If they use the `<curve-command>` or the `<smooth-command>`, the number of control points must match for interpolation.
    - If they use the `<arc-command>` with different `<arc-sweep>` directions, the interpolated result goes clockwise (`cw`). If they use different `<arc-size>` keywords, the size is interpolated using the `large` value.
- **One shape is of type `path()` and the other is of type `shape()`**: Interpolation is applied between each corresponding value if the list of path data commands is identical in number as well as sequence. The interpolated shape is a `shape()` function, maintaining the same list of path data commands.

In all other cases, no interpolation occurs and the animation is discrete.

Examples

Animated polygon

In this example, we use the @keyframes at-rule to animate a clip path between two polygons. Note that both polygons have the same number of vertices, which is necessary for this type of animation to work.

HTML

```
<div></div>
```

CSS

```
div {
  width: 300px;
  height: 300px;
  background: repeating-linear-gradient(red, orange 50px);
  clip-path: polygon(
    50% 0%,
    60% 40%,
    100% 50%,
    60% 60%,
    50% 100%,
    40% 60%,
    0% 50%,
    40% 40%
  );
  animation: 4s poly infinite alternate ease-in-out;
```

```
  margin: 10px auto;
}

@keyframes poly {
  from {
    clip-path: polygon(
      50% 0%,
      60% 40%,
      100% 50%,
      60% 60%,
      50% 100%,
      40% 60%,
      0% 50%,
      40% 40%
    );
  }

  to {
    clip-path: polygon(
      50% 30%,
      100% 0%,
      70% 50%,
      100% 100%,
      50% 70%,
      0% 100%,
      30% 50%,
      0% 0%
    );
  }
}
```

circle() CSS function

The **`circle()`** CSS function defines a circle using a radius and a position. It is one of the `<basic-shape>` data types.

Try it

```
clip-path: circle(50px);
```

```
clip-path: circle(6rem at right center);
```

```
clip-path: circle(10% at 2rem 90%);
```

```
clip-path: circle(closest-side at 5rem 6rem);
```

```
clip-path: circle(farthest-side);
```

```
clip-path: circle(closest-corner at 70% 70%);
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element"></div>
</section>
```

```
#default-example {
  background: #ffee99;
}

#example-element {
  background: linear-gradient(to bottom right, #ff5522, #0055ff);
  width: 100%;
  height: 100%;
}
```

Syntax

```
shape-outside: circle(50%);
clip-path: circle(6rem at 12rem 8rem);
border-shape: circle(60%);
```

Values

`<shape-radius>`

This may be a `<length>`, a `<percentage>`, or any of the following keyword values:

`closest-side`

The radius is the length from the center of the circle to the closest side of the reference box, so that the circle's boundary just touches that side.

`farthest-side`

The radius is the length from the center of the circle to the farthest side of the reference box, so that the circle's boundary just touches that side.

`closest-corner`

The radius is the length from the center of the circle to the closest corner of the reference box, so that the circle's boundary passes through that corner.

`farthest-corner`

The radius is the length from the center of the circle to the farthest corner of the reference box, so that the circle's boundary passes through that corner.

`<position>`

Moves the center of the circle. May be a `<length>`, or a `<percentage>`, or a value such as `left`. The `<position>` value defaults to center if omitted.

Formal syntax

```
<circle()> =
  circle( <radial-size>? [ at <position> ]? )

<radial-size> =
  <radial-extent>              |
  <length [0,∞]>               |
  <length-percentage [0,∞]>{2}

<position> =
  <position-one>   |
  <position-two>   |
  <position-four>

<radial-extent> =
  closest-corner   |
  closest-side     |
  farthest-corner  |
  farthest-side

<length-percentage> =
  <length>      |
  <percentage>

<position-one> =
  left                |
  center              |
  right               |
  top                 |
  bottom              |
  x-start             |
  x-end               |
  y-start             |
  y-end               |
  block-start         |
  block-end           |
  inline-start        |
  inline-end          |
  <length-percentage>

<position-two> =
  [ left | center | right | x-start | x-end ] && [ top | center | bottom | y-start | y-end ]  |
  [ left | center | right | x-start | x-end | <length-percentage> ] [ top | center | bottom | y-start | y-end | <length-percentage> ]  |
  [ block-start | center | block-end ] && [ inline-start | center | inline-end ]  |
  [ start | center | end ]{2}

<position-four> =
  [ [ left | right | x-start | x-end ] <length-percentage> ] && [ [ top | bottom | y-start | y-end ] <length-percentage> ]  |
  [ [ block-start | block-end ] <length-percentage> ] && [ [ inline-start | inline-end ] <length-percentage> ]  |
  [ [ start | end ] <length-percentage> ]{2}
```

This syntax reflects the latest standard as per CSS Images Module Level 3, CSS Shapes Module Level 1, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic circle

In the example below, the `shape-outside` property has a value of `circle(50%)`, which defines a circle on a floated element for the text to flow round.

```
<div class="box">
  <img
    alt="A hot air balloon"
    src="https://mdn.github.io/shared-assets/images/examples/round-balloon.png" />
  <p>
    One November night in the year 1782, so the story runs, two brothers sat
    over their winter fire in the little French town of Annonay, watching the
    grey smoke-wreaths from the hearth curl up the wide chimney. Their names
    were Stephen and Joseph Montgolfier, they were papermakers by trade, and
    were noted as possessing thoughtful minds and a deep interest in all
    scientific knowledge and new discovery. Before that night—a memorable night,
    as it was to prove—hundreds of millions of people had watched the rising
    smoke-wreaths of their fires without drawing any special inspiration from
    the fact.
  </p>
</div>
```

```
body {
  font: 1.2em / 1.5 sans-serif;
}
img {
  float: left;
  shape-outside: circle(50%);
}
```

Radius keyword interactive example

This example allows you to test the effect of moving the center point of the circle when using each of the four `<shape-radius>` keywords.

HTML

The HTML first defines controls for selecting a chosen radius keyword and setting the position where the circle is to be displayed, followed by a `<pre>` element for displaying the `clip-path` that the control values select. After this a `#support-note` element is provided for indicating when particular radius keywords are not supported.

```
<div class="controls">
  <div class="controls-row">
    <label>
      Shape radius:
      <select id="radius-keyword">
        <option value="closest-side">closest-side</option>
        <option value="closest-corner">closest-corner</option>
        <option value="farthest-side">farthest-side</option>
        <option value="farthest-corner" selected>farthest-corner</option>
      </select>
    </label>
  </div>
  <div class="controls-row">
    <label>
      Position X:
      <input type="range" id="pos-x" min="0" max="200" value="120" />
    </label>
    <label>
      Position Y:
      <input type="range" id="pos-y" min="0" max="120" value="40" />
    </label>
  </div>
</div>

<pre id="declaration"></pre>

<p id="support-note"></p>
```

The HTML then defines a number of `<div>` elements that are used to render the circle, reference box and center marker. The most important elements are the reference box (`#refbox`) and the `.fill` element it contains, which define the gradient that is drawn (as discussed in the following CSS section). A `clipPath` is set on the reference box in JavaScript to clip that gradient to a circular shape.

```
<div class="canvas">
  <div class="refbox" id="refbox">
    <div class="fill"></div>
  </div>
  <div class="outline"></div>
  <div class="center-marker" id="center-marker"></div>
</div>
```

Note that the `.outline` and `.center-marker` are provided to make it easier to see the reference box and the center of the clipping circle, which would otherwise be invisible. The `.outline` element must be placed after `#refbox` in the markup: since it isn't clipped itself, painting it after the reference box means its dashed border always renders on top of the `.fill` gradient, even when the clipping circle extends beyond the reference box.

CSS

The CSS for the canvas, reference box, and fill elements is shown below. Note that the `.fill` defines a gradient that overflows the reference box, filling most of the canvas. This is the gradient that we will clip using the `circle()` (we do this by setting the CSS clip path dynamically in our JavaScript code).

```
.canvas {
  position: relative;
  width: 640px;
  height: 480px;
  overflow: hidden;
  border: 1px solid #888888;
}

.refbox {
  position: absolute;
  top: 180px;
  left: 220px;
  width: 200px;
  height: 120px;
  box-sizing: border-box;
}

.fill {
  position: absolute;
  inset: -240px;
  background: linear-gradient(to bottom right, #ff5522, #0055ff);
}
```

The CSS for the controls and other elements is not shown, as it isn't needed to understand the `circle()` method. Interested readers can view it in the example playground.

```
body {
  display: flex;
  flex-direction: column;
  gap: 20px;
  align-items: flex-start;
}

.controls {
  display: flex;
  flex-direction: column;
  gap: 20px;
}

.controls-row {
  display: flex;
  flex-wrap: wrap;
  gap: 20px;
  align-items: center;
}
```

```
.outline {
  position: absolute;
  top: 180px;
  left: 220px;
  width: 200px;
  height: 120px;
```

```
  box-sizing: border-box;
}

.outline {
  border: 3px dashed #e6007a;
  pointer-events: none;
}

.center-marker {
  position: absolute;
  width: 10px;
  height: 10px;
  border-radius: 50%;
  background: white;
  border: 2px solid black;
  transform: translate(-50%, -50%);
  pointer-events: none;
}

#declaration {
  margin: 0;
}

#support-note {
  margin: 0;
  color: #b3001b;
}
```

JavaScript

First we get handles to each of the elements used by the example.

```
const select = document.getElementById("radius-keyword");
const posX = document.getElementById("pos-x");
const posY = document.getElementById("pos-y");
const refbox = document.getElementById("refbox");
const declaration = document.getElementById("declaration");
const marker = document.getElementById("center-marker");
const supportNote = document.getElementById("support-note");
```

Then we define the `checkSupport()` function used to feature-test whether each radius keyword is supported and enable/disable the associated selection options. This uses the `CSS.supports()` method to check for keyword support.

```
function checkSupport() {
  const unsupported = [];
  for (const option of select.options) {
    if (!CSS.supports("clip-path", `circle(${option.value} at 0px 0px)`)) {
      option.disabled = true;
      option.textContent += " (not supported)";
      unsupported.push(option.value);
    }
  }
  if (unsupported.length > 0) {
    supportNote.textContent = `Your browser doesn't support: ${unsupported.join(", ")}.`;
  }
  if (select.selectedOptions[0]?.disabled) {
    const firstSupported = [...select.options].find(
      (option) => !option.disabled,
    );
    if (firstSupported) {
      select.value = firstSupported.value;
    }
  }
}
```

Next we define an `update()` function that is called whenever the input controls are changed. This sets the clip path on the reference box based on the selected keyword and position, and moves the center marker to match.

```
function update() {
  const keyword = select.value;
  const x = Number(posX.value);
  const y = Number(posY.value);

  // Build the clip-path value and apply it to the reference box
  const value = `circle(${keyword} at ${x}px ${y}px)`;
  refbox.style.clipPath = value;

  // Update the displayed declaration text and marker position
  declaration.textContent = `clip-path: ${value};`;
  marker.style.left = `${refbox.offsetLeft + x}px`;
  marker.style.top = `${refbox.offsetTop + y}px`;
}

select.addEventListener("change", update);
posX.addEventListener("input", update);
posY.addEventListener("input", update);
checkSupport();
update();
```

Result

Change the position of the circle center and the keyword used to see their relative effects. Note that the reference box, together with the selected radius keyword and position, is used to calculate the clipping circle. This circle can extend beyond the reference box (for example, with `closest-corner` or `farthest-corner`); the `.fill` gradient is deliberately sized larger than the reference box so that it always fully covers the clipped circle, however far it extends.

- Guide to Basic Shapes

ellipse() CSS function

The **`ellipse()`** CSS function is one of the `<basic-shape>` data types.

Try it

```
clip-path: ellipse(20px 50px);
```

```
clip-path: ellipse(4rem 50% at right center);
```

```
clip-path: ellipse(closest-side closest-side at 5rem 6rem);
```

```
clip-path: ellipse(closest-side farthest-side);
```

```
clip-path: ellipse(closest-corner closest-corner at 25% 25%);
```

```
clip-path: ellipse(closest-side closest-corner at 25% 25%);
```

```
clip-path: ellipse(closest-side farthest-corner at 25% 25%);
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element"></div>
</section>
```

```
#default-example {
  background: #ffee99;
}

#example-element {
  background: linear-gradient(to bottom right, #ff5522, #0055ff);
  width: 100%;
  height: 100%;
}
```

Syntax

```
shape-outside: ellipse(40% 50% at left);
shape-outside: ellipse(closest-side farthest-side at 30%);
border-shape: ellipse(50% 40%);
```

An ellipse is essentially a squashed circle and so `ellipse()` acts in a very similar way to `circle()` except that we have to specify two radii x and y.

Values

`<shape-radius>`

Two radii, x and y, in that order. These may be a `<length>`, a `<percentage>`, or any of the following keyword values:

`closest-side`

The radius is the length from the center of the ellipse to the closest side of the reference box in the given radius direction, so that the ellipse's boundary just touches that side.

`farthest-side`

The radius is the length from the center of the ellipse to the farthest side of the reference box in the given radius direction, so that the ellipse's boundary just touches that side.

`closest-corner`

The radius is the length from the center of the ellipse to the closest corner of the reference box in the given radius direction.

`farthest-corner`

The radius is the length from the center of the ellipse to the farthest corner of the reference box in the given radius direction.

`<position>`

Moves the center of the ellipse. May be a `<length>`, or a `<percentage>`, or a value such as `left`. The `<position>` value defaults to center if omitted.

Formal syntax

```
<ellipse()> =
  ellipse( <radial-size>? [ at <position> ]? )

<radial-size> =
  <radial-extent>              |
  <length [0,∞]>               |
  <length-percentage [0,∞]>{2}

<position> =
  <position-one>   |
  <position-two>   |
  <position-four>

<radial-extent> =
  closest-corner   |
  closest-side     |
  farthest-corner  |
  farthest-side

<length-percentage> =
  <length>      |
  <percentage>

<position-one> =
  left                |
  center              |
  right               |
  top                 |
  bottom              |
  x-start             |
  x-end               |
```

```
  y-start              |
  y-end                |
  block-start          |
  block-end            |
  inline-start         |
  inline-end           |
  <length-percentage>

<position-two> =
  [ left | center | right | x-start | x-end ] && [ top | center | bottom | y-start | y-end ]  |
  [ left | center | right | x-start | x-end | <length-percentage> ] [ top | center | bottom | y-start | y-end | <length-percentage> ]  |
  [ block-start | center | block-end ] && [ inline-start | center | inline-end ]  |
  [ start | center | end ]{2}

<position-four> =
  [ [ left | right | x-start | x-end ] <length-percentage> ] && [ [ top | bottom | y-start | y-end ] <length-percentage> ]  |
  [ [ block-start | block-end ] <length-percentage> ] && [ [ inline-start | inline-end ] <length-percentage> ]  |
  [ [ start | end ] <length-percentage> ]{2}
```

This syntax reflects the latest standard as per CSS Images Module Level 3, CSS Shapes Module Level 1, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic ellipse() example

This example shows an ellipse that is floated left that has a horizontal radius of 40%, a vertical radius of 50%, and a left position. This means that the center of the ellipse is on the left edge of the box giving us a half ellipse shape to wrap our text around. Click "Play" in the code blocks to change these values to see how the ellipse changes:

```
<div class="box">
  <div class="shape"></div>
  <p>
    One November night in the year 1782, so the story runs, two brothers sat
    over their winter fire in the little French town of Annonay, watching the
    grey smoke-wreaths from the hearth curl up the wide chimney. Their names
    were Stephen and Joseph Montgolfier, they were papermakers by trade, and
    were noted as possessing thoughtful minds and a deep interest in all
    scientific knowledge and new discovery. Before that night—a memorable night,
    as it was to prove—hundreds of millions of people had watched the rising
    smoke-wreaths of their fires without drawing any special inspiration from
    the fact.
  </p>
</div>
```

```
body {
  font: 1.2em / 1.5 sans-serif;
}
.shape {
  float: left;
  shape-outside: ellipse(40% 50% at left);
  margin: 20px;
  width: 100px;
  height: 200px;
}
```

Using closest-side / farthest-side values

The keyword values of `closest-side` and `farthest-side` are useful to create a quick ellipse based on the size of the floated element reference box.

```
<div class="box">
  <div class="shape"></div>
  <p>
    One November night in the year 1782, so the story runs, two brothers sat
    over their winter fire in the little French town of Annonay, watching the
    grey smoke-wreaths from the hearth curl up the wide chimney. Their names
    were Stephen and Joseph Montgolfier, they were papermakers by trade, and
    were noted as possessing thoughtful minds and a deep interest in all
    scientific knowledge and new discovery. Before that night—a memorable night,
    as it was to prove—hundreds of millions of people had watched the rising
    smoke-wreaths of their fires without drawing any special inspiration from
    the fact.
  </p>
</div>
```

```
body {
  font: 1.2em / 1.5 sans-serif;
}
.shape {
  float: left;
  shape-outside: ellipse(closest-side farthest-side at 30%);
  margin: 20px;
  width: 100px;
  height: 140px;
}
```

Radius keyword interactive example

This example allows you to test the effect of moving the center point of the ellipse when using each of the four `<shape-radius>` keywords — chosen independently for the x-radius and the y-radius.

Because `closest-corner` and `farthest-corner` are a newer addition to `ellipse()`, the script feature-tests each keyword with `CSS.supports()` before enabling it. Any keyword your browser doesn't yet support is disabled in both dropdowns (and labeled "not supported").

HTML

The HTML first defines controls for selecting the x-radius and y-radius keywords and setting the position where the ellipse is to be displayed, followed by a `<pre>` element for displaying the `clip-path` that the control values select. After this a `#support-note` element is provided for indicating when particular radius keywords are not supported.

```
<div class="controls">
  <div class="controls-row">
    <label>
      X radius:
```

```
      <select id="radius-x-keyword">
        <option value="closest-side">closest-side</option>
        <option value="closest-corner">closest-corner</option>
        <option value="farthest-side">farthest-side</option>
        <option value="farthest-corner" selected>farthest-corner</option>
      </select>
    </label>
    <label>
      Y radius:
      <select id="radius-y-keyword">
        <option value="closest-side">closest-side</option>
        <option value="closest-corner">closest-corner</option>
        <option value="farthest-side" selected>farthest-side</option>
        <option value="farthest-corner">farthest-corner</option>
      </select>
    </label>
  </div>
  <div class="controls-row">
    <label>
      Position X:
      <input type="range" id="pos-x" min="0" max="200" value="120" />
    </label>
    <label>
      Position Y:
      <input type="range" id="pos-y" min="0" max="120" value="40" />
    </label>
  </div>
</div>

<pre id="declaration"></pre>

<p id="support-note"></p>
```

The HTML then defines several `<div>` elements used to render the ellipse, reference box, and center marker. The most important elements are the reference box (`#refbox`) and the `.fill` element it contains, which define the gradient that is drawn (as discussed in the following CSS section). A `clipPath` is set on the reference box in JavaScript to clip that gradient to an elliptical shape.

```
<div class="canvas">
  <div class="refbox" id="refbox">
    <div class="fill"></div>
  </div>
  <div class="outline"></div>
  <div class="center-marker" id="center-marker"></div>
</div>
```

Note that the `.outline` and `.center-marker` are provided to make it easier to see the reference box and the center of the clipping ellipse, which would otherwise be invisible. The `.outline` element must be placed after `#refbox` in the markup: since it isn't clipped itself, painting it after the reference box means its dashed border always renders on top of the `.fill` gradient, even when the clipping ellipse extends beyond the reference box.

CSS

The CSS for the canvas, reference box, and fill elements is shown below. Note that the `.fill` defines a gradient that overflows the reference box, filling most of the canvas. This is the gradient that we will clip using the `ellipse()` function (we do this by setting the CSS clip path dynamically in our JavaScript code).

```
.canvas {
  position: relative;
  width: 640px;
  height: 480px;
  overflow: hidden;
  border: 1px solid #888888;
}

.refbox {
  position: absolute;
  top: 180px;
  left: 220px;
  width: 200px;
  height: 120px;
  box-sizing: border-box;
}

.fill {
  position: absolute;
  inset: -240px;
  background: linear-gradient(to bottom right, #ff5522, #0055ff);
}
```

The CSS for the controls and other elements is not shown, as it isn't needed to understand the `ellipse()` method. Interested readers can view it in the example playground.

```
body {
  display: flex;
  flex-direction: column;
  gap: 20px;
  align-items: flex-start;
}

.controls {
  display: flex;
  flex-direction: column;
  gap: 20px;
}

.controls-row {
  display: flex;
  flex-wrap: wrap;
  gap: 20px;
  align-items: center;
}
```

```
.outline {
  position: absolute;
```

```
  top: 180px;
  left: 220px;
  width: 200px;
  height: 120px;
  box-sizing: border-box;
}

.outline {
  border: 3px dashed #e6007a;
  pointer-events: none;
}

.center-marker {
  position: absolute;
  width: 10px;
  height: 10px;
  border-radius: 50%;
  background: white;
  border: 2px solid black;
  transform: translate(-50%, -50%);
  pointer-events: none;
}

#declaration {
  margin: 0;
}

#support-note {
  margin: 0;
  color: #b3001b;
}
```

JavaScript

First we get handles to each of the elements used by the example.

```
const selectX = document.getElementById("radius-x-keyword");
const selectY = document.getElementById("radius-y-keyword");
const posX = document.getElementById("pos-x");
const posY = document.getElementById("pos-y");
const refbox = document.getElementById("refbox");
const declaration = document.getElementById("declaration");
const marker = document.getElementById("center-marker");
const supportNote = document.getElementById("support-note");
```

Then we define a `checkSupport()` function to feature-test whether each radius keyword is supported and enable/disable the associated options in both dropdowns. This uses the `CSS.supports()` method to check for keyword support.

```
function checkSupport() {
  const unsupported = new Set();
  for (const option of selectX.options) {
    const test = `ellipse(${option.value} ${option.value} at 0px 0px)`;
    if (!CSS.supports("clip-path", test)) {
      unsupported.add(option.value);
    }
  }
  for (const select of [selectX, selectY]) {
    for (const option of select.options) {
      if (unsupported.has(option.value)) {
        option.disabled = true;
        option.textContent += " (not supported)";
      }
    }
    if (select.selectedOptions[0]?.disabled) {
      const firstSupported = [...select.options].find(
        (option) => !option.disabled,
      );
      if (firstSupported) {
        select.value = firstSupported.value;
      }
    }
  }
  if (unsupported.size > 0) {
    supportNote.textContent = `Your browser doesn't support: ${[...unsupported].join(", ")}.`;
  }
}
```

Next we define an `update()` function that is called whenever the input controls are changed. This sets the clip path on the reference box based on the selected x-radius and y-radius keywords and position, and moves the center marker to match.

```
function update() {
  const xKeyword = selectX.value;
  const yKeyword = selectY.value;
  const x = Number(posX.value);
  const y = Number(posY.value);

  // Build the clip-path value and apply it to the reference box
  const value = `ellipse(${xKeyword} ${yKeyword} at ${x}px ${y}px)`;
  refbox.style.clipPath = value;

  // Update the displayed declaration text and marker position
  declaration.textContent = `clip-path: ${value};`;
  marker.style.left = `${refbox.offsetLeft + x}px`;
  marker.style.top = `${refbox.offsetTop + y}px`;
}

selectX.addEventListener("change", update);
selectY.addEventListener("change", update);
posX.addEventListener("input", update);
posY.addEventListener("input", update);
```

```
checkSupport();
update();
```

Result

Change the position of the center and the keyword for each radius to see their relative effects. Note that the reference box, together with the selected x-radius and y-radius keywords and position, is used to calculate the clipping ellipse. This ellipse can extend beyond the reference box (for example, with `closest-corner` or `farthest-corner`); the `.fill` gradient is deliberately sized larger than the reference box so that it always fully covers the clipped ellipse, however far it extends.

- Guide to Basic Shapes

inset() CSS function

The **`inset()`** CSS function defines a rectangle at the specified inset distances from each side of the reference box. It is a basic shape function used to define one of the `<basic-shape>` data types.

Try it

```
clip-path: inset(30px);
```

```
clip-path: inset(1rem 2rem 3rem 4rem);
```

```
clip-path: inset(20% 30% round 20px);
```

```
clip-path: inset(4rem 20% round 1rem 2rem 3rem 4rem);
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element"></div>
</section>
```

```
#default-example {
  background: #ffee99;
}

#example-element {
  background: linear-gradient(to bottom right, #ff5522, #0055ff);
  width: 100%;
  height: 100%;
}
```

Syntax

```
shape-outside: inset(20px 50px 10px 0 round 50px);
border-shape: inset(10px 20px 10px 20px round 20px);
```

Values

`<length-percentage>{1,4}`

> When all of the four arguments are supplied they represent the top, right, bottom, and left offsets from the reference box inward that define the positions of the edges of the inset rectangle. These arguments follow the syntax of the margin shorthand, which let you set all four insets with one, two, or four values.
>
> If a pair of insets for a dimension adds up to more than 100% of that dimension, both values are proportionally reduced so their sum equals 100%. For example, the value `inset(90% 10% 60% 10%)` has a top inset of `90%` and a bottom inset of `60%`. These values are reduced proportionally to `inset(60% 10% 40% 10%)`. Shapes such as this, that enclose no area and have no `shape-margin`, do not affect wrapping.

`<border-radius>`

> The optional `<border-radius>` argument(s) define rounded corners for the inset rectangle using the border-radius shorthand syntax.

Formal syntax

```
<inset()> =
  inset( <length-percentage>{1,4} [ round <'border-radius'> ]? )

<length-percentage> =
  <length>      |
  <percentage>

<border-radius> =
  <length-percentage [0,∞]>{1,4} [ / <length-percentage [0,∞]>{1,4} ]?
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Shapes Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic inset example

In the example below we have an `inset()` shape used to pull content over the floated element. Change the offset values to see how the shape changes.

```
<div class="box">
  <div class="shape"></div>
  <p>
    One November night in the year 1782, so the story runs, two brothers sat
    over their winter fire in the little French town of Annonay, watching the
    grey smoke-wreaths from the hearth curl up the wide chimney. Their names
    were Stephen and Joseph Montgolfier, they were papermakers by trade, and
    were noted as possessing thoughtful minds and a deep interest in all
    scientific knowledge and new discovery. Before that night—a memorable night,
    as it was to prove—hundreds of millions of people had watched the rising
    smoke-wreaths of their fires without drawing any special inspiration from
    the fact.
  </p>
</div>
```

```
.box {
  width: 400px;
  margin: 0 auto;
}

.shape {
  float: left;
  width: 150px;
  height: 100px;
  clip-path: inset(45px 50px 15px 0 round 50px);
  shape-outside: inset(40px 40px 10px 0 round 50px);
  background-color: coral;
  border-radius: 20px;
  margin: 0;
  padding: 20px;
}
```

path() CSS function

The **`path()`** CSS function accepts an SVG path string, and is used in the CSS shapes and CSS motion path modules to enable a shape to be drawn. The `path()` function is a `<basic-shape>` data type value. It can be used in the CSS `offset-path` and `clip-path` properties and in the SVG `d` attribute.

There are some limitations to using the `path()` function. The path has to be defined as a single string, so a custom path can't be created using variables (`var()` functions). Also, all the lengths in the path are implicitly defined in pixel (`px`) units; other units can't be used. The `shape()` function offers more flexibility than the `path()` function.

Try it

```
clip-path: path(
  "M  20  240 \
 L  20  80 L 160  80 \
 L 160  20 L 280 100 \
 L 160 180 L 160 120 \
 L  60 120 L  60 240 Z"
);
```

```
clip-path: path(
  "M 20 240 \
 C 20 0 300 0 300 240 Z"
);
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element"></div>
</section>
```

```
#default-example {
  background: #ffee99;
}

#example-element {
  background: linear-gradient(to bottom right, #ff5522, #0055ff);
  width: 100%;
  height: 100%;
}
```

Syntax

```
path("M 10 80 C 40 10, 65 10, 95 80 S 150 150, 180 80")

/* When used in clip-path only */
path(evenodd,"M 10 80 C 40 10, 65 10, 95 80 S 150 150, 180 80")
```

Parameters

`<fill-rule>` Optional

Defines what parts of the path are inside the shape. The possible values include:

- `nonzero`: A point is considered inside the shape if a ray drawn from the point crosses more left-to-right than right-to-left path segments, resulting in a non-zero count. This is the default value when `<fill-rule>` is omitted.
- `evenodd`: A point is considered to be inside the shape if a ray drawn from the point crosses an odd number of path segments. This means that for each time the ray enters the shape, it has not exited an equal number of times, indicating an odd count of entries without corresponding exits.

> **Warning:** `<fill-rule>` is not supported in `offset-path` and using it invalidates the property.

`<string>`

A data string, contained in quotes, which defines an SVG path. The SVG path data string contains path commands that implicitly use pixel units. An empty path is considered invalid.

Return value

Returns a `<basic-shape>` value.

Formal syntax

```
<path()> =
  path( <'fill-rule'>? , <string> )

<fill-rule> =
  nonzero  |
  evenodd
```

This syntax reflects the latest standard as per CSS Fill and Stroke Module Level 3, CSS Shapes Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using a <code>path()</code> function as an <code>offset-path</code> value

A `path()` function has been provided as an `offset-path` value in the following example to create an elliptical path for a ball to move along.

```
<div id="path">
  <div id="ball"></div>
</div>
<button>animate</button>
```

```
#path {
  margin: 40px;
  width: 400px;
  height: 200px;

  /* draw the gray ramp */
  background: radial-gradient(at 50% 0%, transparent 70%, grey 70%, grey 100%);
}

#ball {
  width: 30px;
  height: 30px;
  background-color: red;
  border-radius: 50%;

  /* mark the elliptical path */
  offset-path: path("M 15 15 A 6 5.5 10 0 0 385 15");
}
```

```
const btn = document.querySelector("button");
const ball = document.getElementById("ball");

btn.addEventListener("click", () => {
  btn.setAttribute("disabled", true);
  setTimeout(() => btn.removeAttribute("disabled"), 6000);

  ball.animate(
    // animate the offset path
    { offsetDistance: [0, "100%"] },
    {
      duration: 1500,
      iterations: 4,
      easing: "cubic-bezier(.667,0.01,.333,.99)",
      direction: "alternate",
    },
  );
});
```

Modify the value of the SVG path d attribute

The `path()` can be used to modify the value of the SVG `d` attribute, which can also be set to `none` in your CSS.

The "V" symbol will flip vertically when you hover over it, if `d` is supported as a CSS property.

CSS

```
html,
body,
svg {
  height: 100%;
}

/* This path is displayed on hover */
#svg_css_ex1:hover path {
  d: path("M20,80 L50,20 L80,80");
}
```

HTML

```
<svg id="svg_css_ex1" viewBox="0 0 100 100" xmlns="http://www.w3.org/2000/svg">
  <path fill="none" stroke="red" d="M20,20 L50,80 L80,20" />
</svg>
```

Result

polygon() CSS function

The **`polygon()`** CSS function is one of the `<basic-shape>` data types. It's used to draw a polygon by providing one or more pairs of coordinates, each of which represents a vertex of the shape.

Try it

```
clip-path: polygon(
  0% 20%,
  60% 20%,
  60% 0%,
  100% 50%,
  60% 100%,
  60% 80%,
```

```
  0% 80%
);
```

```
clip-path: polygon(50% 0%, 100% 50%, 50% 100%, 0% 50%);
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element"></div>
</section>
```

```
#default-example {
  background: #ffee99;
}

#example-element {
  background: linear-gradient(to bottom right, #ff5522, #0055ff);
  width: 100%;
  height: 100%;
}
```

Syntax

```
/* Coordinate list */
polygon(50% 2.4%, 34.5% 33.8%, 0% 38.8%, 25% 63.1%, 19.1% 97.6%)
polygon(0px 0px, 200px 100px, 0px 200px)
polygon(0% 0px, 100% 100px, 0px 100%)
polygon(0 0, 50% 1rem, 100% 2vw, calc(100% - 20px) 100%, 0 100%)

/* Coordinate list with fill-rule and/or round value */
polygon(nonzero, 0% 0%, 50% 50%, 0% 100%)
polygon(round 20px, 0% 0%, 50% 50%, 0% 100%)
polygon(evenodd round 2em, 0% 0%, 50% 50%, 0% 100%)
```

Parameters

The `polygon()` function accepts an optional first parameter containing values that modify the polygon's appearance — a `fill-rule` keyword, the `round` keyword followed by a `<length>` value, or both. The first parameter's components are separated by spaces. The other parameters are space-separated x/y coordinate pairs of `<length-percentage>` values.

`<fill-rule>` Optional

A keyword equal to `nonzero` (the default) or `evenodd`, which specifies the algorithm used to fill the polygon shape.

`round <length>` Optional

The `round` keyword specifies that the polygon should have rounded corners, and the accompanying `<length>` value specifies the radius of those corners.

`<length-percentage>`

Each vertex, or point, of the polygon is represented by a space-separated pair of `<length-percentage>` values defining the x/y coordinates of the vertex relative to the shape's reference box.

Return value

A `<basic-shape>` value.

Description

You can create almost any shape with the `polygon()` function by specifying the x/y coordinates of its vertices, or points, as comma-separated pairs of `<length-percentage>` values:

`polygon(x1 y1, x2 y2, x3 y3, x4 y4, xn yn)`

Although only a single point is required to create a valid `polygon()` function value, at least 3 points are required to create a shape (a triangle). There is no upper limit on the number of points that can be specified. The shape is drawn through the specified points in the order they appear in the function, with a final line automatically being drawn between the last and first points to close the shape.

We could define the coordinates of a triangle shape like this:

axis	point 1	point 2	point 3
x	0%	100%	100%
y	0%	0%	100%

We can apply those coordinates to the CSS `clip-path` property in a `polygon()` function as follows:

```
clip-path: polygon(0% 0%, 100% 0%, 100% 100%);
```

This creates a triangle shape that covers half the area of its parent container by specifying the coordinates of three of its four corners: top-left (`0% 0%`), top-right (`100% 0%`), and bottom-right (`100% 100%`). If we assume a 200x200px container with a green background:

```
<div class="box"></div>
```

```
.box {
  width: 200px;
  height: 200px;
  background-color: green;
  clip-path: polygon(0% 0%, 100% 0%, 100% 100%);
}
```

The effect of point order

The order in which you define the points can result in different shapes. For example, the following two `clip-path` declarations both use a `polygon()` function with X/Y coordinate pairs for the container's four corners, but in a different order.

```
clip-path: polygon(0% 0%, 100% 0%, 100% 100%, 0% 100%);
clip-path: polygon(0% 0%, 100% 0%, 0% 100%, 100% 100%);
```

```
<div class="box"></div>
<div class="box box2"></div>
```

```
body {
  display: flex;
  gap: 20px;
}

.box {
  width: 200px;
  height: 200px;
  background-color: purple;
  clip-path: polygon(0% 0%, 100% 0%, 100% 100%, 0% 100%);
}

.box2 {
  clip-path: polygon(0% 0%, 100% 0%, 0% 100%, 100% 100%);
}
```

The first function draws a square, while the second draws an hourglass shape.

Specifying polygon modifiers

The `polygon()` function accepts an optional first parameter modifying the rendering of the resulting shape. The parameter value can include either or both of the following, separated by spaces:

- A `<fill-rule>` keyword equal to `nonzero` (the default) or `evenodd`, which specifies the algorithm used to fill the polygon shape. This only has an effect when the lines drawn between coordinate values overlap.
- The `round` keyword followed by a `<length>` value. This specifies that the polygon should have rounded corners, with the `<length>` value specifying the radius of those corners.

For example, we could expand upon the previous triangle example and add rounded corners:

```
clip-path: polygon(round 20px, 0% 0%, 100% 0%, 100% 100%);
```

```
<div class="box"></div>
```

```
.box {
  width: 200px;
  height: 200px;
  background-color: green;
  clip-path: polygon(round 20px, 0% 0%, 100% 0%, 100% 100%);
}
```

This results in the same triangle shape, but with `20px` radius rounded corners:

> **Note:** In each case, the corner radius is clamped to ensure it is never larger than half of any line segment length. The maximum corner radius is clamped to the smaller of `tan(corner-angle/2) * (segment-length / 2)` evaluated against both line segments forming the corner. The specification contains further details for those interested.

Formal syntax

```
<polygon()> =
  polygon( <'fill-rule'>? [ round <length> ]? , [ <length-percentage> <length-percentage> ]# )

<fill-rule> =
  nonzero  |
  evenodd

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Fill and Stroke Module Level 3, CSS Shapes Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Create a triangle

In this example, a triangle is formed by defining the coordinates of its three points.

HTML

```
<div class="triangle"></div>
```

CSS

```
.triangle {
  width: 400px;
  height: 400px;
  background-color: magenta;
  clip-path: polygon(100% 0%, 50% 50%, 100% 100%);
}
```

Result

The coordinates for the triangle are the top-right corner (`100% 0%`), the center point (`50% 50%`), and the bottom-right corner (`100% 100%`) of the container.

Create a rounded star

In this example, we create a star shape and use the `round` keyword to round its corners.

HTML

```
<div class="star"></div>
```

CSS

```
.star {
  width: 400px;
  height: 400px;
  background-color: hotpink;
  clip-path: polygon(
```

```
    round 20px,
    50% 5%,
    60.85% 27.48%,
    85.22% 21.99%,
    74.38% 44.44%,
    93.88% 60.01%,
    69.57% 65.56%,
    69.53% 90.55%,
    50% 75%,
    30.47% 90.55%,
    30.43% 65.56%,
    6.12% 60.01%,
    25.62% 44.44%,
    14.78% 21.99%,
    39.15% 27.48%
  );
}
```

```
@supports not (clip-path: polygon(round 20px, 0% 0%, 100% 0%, 100% 100%)) {
  body::before {
    font-family: sans-serif;
    content: "Your browser does not support the polygon() function's round keyword.";
    background-color: wheat;
    padding: 1rem 0;
    text-align: center;

    z-index: 1;
    position: fixed;
    inset: 40% 0 auto;
  }
}
```

Result

Setting a polygon for shape-outside

In this example a shape is created for text to follow using the `shape-outside` property.

```
<div class="box">
  <div class="shape"></div>
  <p>
    One November night in the year 1782, so the story runs, two brothers sat
    over their winter fire in the little French town of Annonay, watching the
    grey smoke-wreaths from the hearth curl up the wide chimney. Their names
    were Stephen and Joseph Montgolfier, they were papermakers by trade, and
    were noted as possessing thoughtful minds and a deep interest in all
    scientific knowledge and new discovery. Before that night—a memorable night,
    as it was to prove—hundreds of millions of people had watched the rising
    smoke-wreaths of their fires without drawing any special inspiration from
    the fact.
  </p>
</div>
```

```
.box {
  width: 250px;
}

.shape {
  float: left;
  shape-outside: polygon(
    0 5%,
    15% 12%,
    30% 15%,
    40% 26%,
    45% 35%,
    45% 45%,
    40% 55%,
    10% 90%,
    10% 98%,
    8% 100%,
    0 100%
  );
  width: 300px;
  height: 320px;
}

p {
  font-size: 0.9rem;
}
```

- Guide to Basic Shapes

rect() CSS function

The **`rect()`** CSS function creates a rectangle at the specified distance from the top and left edges of the containing block. It is a basic shape function of the `<basic-shape>` data type. You can use the `rect()` function in CSS properties such as `offset-path` to create the rectangular path along which an element moves, in `clip-path` to define the shape of the clipping region, and in `border-shape` to define the shape of an element's border.

Syntax

```
offset-path: rect(0 1% auto 3% round 0 1px);
clip-path: rect(50px 70px 80% 20%);
border-shape: rect(10px 500px 130px 20px round 20px);
```

Values

The inset rectangle is defined by specifying four offset values, starting with the top edge offset and going clockwise, and an optional `round` keyword with the `border-radius` parameter to add rounded corners to the rectangle. Each offset value can be either a `<length>`, a `<percentage>`, or the keyword `auto`.

`<length-percentage>`

> Specifies the `<length-percentage>` value of the distance of the top, right, bottom, or left edge of the rectangle from the top or left edge of the containing block. The first (top) and third (bottom) values are distances from the top edge of the containing block, and the second (right) and fourth (left) values are distances from the left edge of the containing block. The second (right) and third (bottom) values are clamped by the fourth (left) and first (top) values, respectively, to prevent the bottom edge from crossing over the top edge and right edge from crossing over the left edge. For example, `rect(10px 0 0 20px)` is clamped to `rect(10px 20px 10px 20px)`.

`auto`

> Makes the edge for which this value is used to coincide with the corresponding edge of the containing block. If `auto` is used for the first (top) or fourth (left) value, the value of `auto` is `0`, and if used for the second (right) or third (bottom) value, the value of `auto` is `100%`.

`round <'border-radius'>`

> Specifies the radius of the rounded corners of the rectangle using the same syntax as the CSS `border-radius` shorthand property. This parameter is optional.

Formal syntax

```
<rect()> =
  rect( [ <length-percentage> | auto ]{4} [ round <'border-radius'> ]? )

<length-percentage> =
  <length>      |
  <percentage>

<border-radius> =
  <length-percentage [0,∞]>{1,4} [ / <length-percentage [0,∞]>{1,4} ]?
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Shapes Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Creating offset-path using rect()

In this example, the `offset-path` property uses the `rect()` function to define the shape of the path on which the element, a red box in this case, moves. Three different scenarios are shown, each using different values for the `rect()` function. The arrow inside the boxes points to the right edge of the box.

```
<div class="container">
  Rectangular path 1
  <div class="path rect-path-1">→</div>
</div>
<div class="container">
  Rectangular path 2
  <div class="path rect-path-2">→</div>
</div>
<div class="container">
  Rectangular path 3
  <div class="path rect-path-3">→</div>
</div>
```

```
.container {
  position: relative;
  display: inline-block;
  width: 200px;
  height: 200px;
  border: 1px solid black;
  margin: 15px;
  text-align: center;
}

.path {
  width: 40px;
  height: 40px;
  background-color: red;
  position: absolute;
  animation: move 10s linear infinite;
}

.rect-path-1 {
  offset-path: rect(50px 150px 200px 50px round 20%);
}

.rect-path-2 {
  offset-path: rect(50px auto 200px 50px round 20%);
}

.rect-path-3 {
  offset-path: rect(50px auto 200px auto);
}

@keyframes move {
  0% {
    offset-distance: 0%;
  }
  100% {
    offset-distance: 100%;
  }
}
```

Result

- The path 1 rectangle specifies the distances of the four edges (top, right, bottom, and left) from the containing block. The top and bottom values are distances from the top edge of the containing block. The right and left values are distances from the left edge of the containing block. In addition, the corner of the rectangle is rounded at `20%`, making the red box element follow the rounded corners as it moves along this path. Notice how the arrow inside the box follows curve at the rectangular path corners.

- The path 2 rectangle is similar to the path 1 rectangle, except that the right value is `auto`, which is equal to the value `100%`. This causes the right edge of the rectangle to match the right edge of the containing block, creating a wider rectangle than path 1.
- The path 3 rectangle specifies both the left and right edge parameters as `auto` and omits the `round <'border-radius'>` parameter. This creates a rectangle that has the width of the containing block and rectangular corners instead of rounded corners like in path 1 and path 2 rectangles. Notice the movement of the arrow inside this box at the corners.

shape() CSS function

The **`shape()`** CSS function is used to define a shape for the `border-shape`, `clip-path`, and `offset-path` properties. It combines an initial starting point with a series of shape commands that define the path of the shape. The `shape()` function is a member of the `<basic-shape>` data type.

Syntax

```
/* <fill-rule> */
clip-path: shape(nonzero from 0 0, line to 10px 10px);

/* <move-command>, <line-command>, and close */
offset-path: shape(from 10px 10px, move by 10px 5px, line by 20px 40%, close);

/* <hvline-command> */
offset-path: shape(from 10px 10px, hline by 50px, vline to 5rem);

/* <curve-command> */
offset-path: shape(
  from 10px 10px,
  curve to 80px 80px with 160px 1px / 20% 16px
);

/* <smooth-command> */
offset-path: shape(from 10px 10px, smooth to 100px 50pt);

/* <arc-command> */
offset-path: shape(
  from 5% 0.5rem,
  arc to 80px 1pt of 10% ccw large rotate 25deg
);

/* Using a CSS math function */
offset-path: shape(
  from 5px -5%,
  hline to 50px,
  vline by calc(0% + 160px),
  hline by 70.5px,
  close,
  vline by 60px
);

clip-path: shape(
  evenodd from 10px 10px,
  curve to 60px 20% with 40px 0,
  smooth to 90px 0,
  curve by -20px 60% with 10% 40px / 20% 20px,
  smooth by -40% -10px with -10px 70px,
  close
);
```

Parameters

`<fill-rule>` Optional

Specifies how overlapping regions of a shape should be filled. The possible values include:

- `nonzero`: A point is considered inside the shape if a ray drawn from the point crosses more left-to-right than right-to-left path segments, resulting in a non-zero count. This is the default value when `<fill-rule>` is omitted.
- `evenodd`: A point is considered to be inside the shape if a ray drawn from the point crosses an odd number of path segments. This means that for each time the ray enters the shape, it has not exited an equal number of times, indicating an odd count of entries without corresponding exits.

> **Warning:** `<fill-rule>` is not supported in `offset-path` and using it invalidates the property.

`from <coordinate-pair>`

Defines the starting point of the first `<shape-command>` as a pair of coordinates that are measured from the top-left corner of the reference box. The coordinates are specified as space-separated `<x>` `<y>` `<length-percentage>` values representing the left offset and top offset, respectively. Percentage values are relative to the width and height of the element's reference box, respectively. Add a comma after this parameter.

`<shape-command>`

Specifies a list of one or more comma-separated commands that define the shape, using syntax similar to SVG path commands. Commands include `<move-command>`, `<line-command>`, `<hv-line-command>`, `<curve-command>`, `<smooth-command>`, `<arc-command>`, and `close`. Each command's starting point is the previous command's ending point, with the first point of the shape defined by the `from <coordinate-pair>` parameter.

Shape commands

The syntax of most shape commands is a keyword that provides a directive, such as `move` or `line`, followed by the `by` or `to` keyword, and a set of coordinates.

- `by`: Indicates that the `<coordinate-pair>` is relative to the command's starting point (a "relative" value).

- `to`: Indicates that the `<coordinate-pair>` is relative to the top-left corner of the reference box (an "absolute" value).

> **Note:** If a coordinate in a `<coordinate-pair>` is specified as a percentage, the value is calculated relative to the respective width or height of the reference box.

The following `<shape-command>`s can be specified:

`<move-command>`

Specified as `move [by | to] <coordinate-pair>`. This command adds a MoveTo command to the list of shape commands. It draws nothing; instead, it specifies the starting position for the next command. The `by` or `to` keyword specifies whether the `<coordinate-pair>` point is relative or absolute, respectively. If the `<move-command>` follows the `close` command, it identifies the starting point of the next shape or subpath.

`<line-command>`

Specified as `line [by | to] <coordinate-pair>`. This command adds a LineTo command to the list of shape commands. It draws a straight line from the command's starting point to its ending point. The `by` or `to` keyword specifies whether the ending point specified by `<coordinate-pair>` is relative or absolute, respectively.

`<hv-line-command>`

Specified as `[hline | vline] [by | to] <length-percentage>`. This command adds a horizontal (`hline`) or vertical (`vline`) LineTo command to the list of shape commands. With `hline`, a horizontal line is drawn from the command's starting point `to` or `by` the `x` position defined by `<length-percentage>`. With `vline`, a vertical line is drawn from the command's starting point `to` or `by` the `y` position defined by `<length-percentage>`. The `by` or `to` keyword determines the relative or absolute ending point, respectively. This command is equivalent to `<line-command>` with one coordinate value set by the single `<length-percentage>` and the other coordinate value remaining unchanged from its starting command.

`<curve-command>`

Specified as `curve [by | to] <end-point> with <control-point> [/ <control-point>]`. This command adds a Bézier curve command to the list of shape commands. The `by` or `to` keyword determines whether the ending point of the curve, specified by the `<end-point>`, is relative or absolute.

The `with` keyword specifies the control points of the Bézier curve as follows.

- If only a single `<control-point>` is provided, the command draws a quadratic Bézier curve, which is defined by three points (the start point, control point, and end point).
- If two `<control-point>` values are provided, the command draws a cubic Bézier curve, which is defined by four points (the start point, two control points, and the end point).

Valid values for `<end-point>` include:

`<position>` keywords or a `<coordinate-value-pair>`

Can be used if the curve end point is absolute (specified using `to`).

`<coordinate-value-pair>`

Can be used if the curve end point is relative (specified using `by`).

Valid values for `<control-point>` include:

`<position>`

Specifies a position keyword. This value is valid only when the curve end point is absolute (specified using `to`).

`<coordinate-value-pair>`

Specifies a pair of `<length-percentage>` values that define coordinates.

`<relative-control-point>`

Defines a `<coordinate-value-pair>` followed by the `from` keyword and one of the following keywords:

`start`

Indicates that the control point is relative to the start point of the current command.

`end`

Indicates that the control point is relative to the end point of the current command.

`origin`

Indicates that the control point is relative to the top-left (origin) point of the container the shape is being drawn inside.

> **Note:** If the `<relative-control-point>` keywords are not specified, making the `<control-point>` a regular `<coordinate-value-pair>`, the coordinates are relative to the start of the curve. In other words, `start` is the default setting.

`<smooth-command>`

Specified as `smooth [by | to] <end-point> [with <control-point>]`. This command adds a smooth Bézier curve command to the list of shape commands. The `by` or `to` keyword determines whether the ending point of the curve, specified by the `<end-point>`, is relative or absolute.

The `with` keyword specifies an optional control point for the Bézier curve:

- If `with <control-point>` is omitted, the command draws a smooth quadratic Bézier curve, which uses the previous control point and the current endpoint to define the curve.
- If the optional `with` keyword is included, it specifies a control points of the curve through `<control-point>`, drawing a smooth cubic Bézier curve defined by the previous control point, the current control point, and the current endpoint.

Smooth curves ensure a continuous transition from the shape, while quadratic curves do not. Smooth quadratic curves maintain a seamless transition using a single control point, whereas smooth cubic curves provide a more refined transition using two control points.

Valid values for the `<end-point>` and `<control-point>` components are the same as those for `<curve-command>`.

`<arc-command>`

Specified as `arc [by | to] <coordinate-pair> of <length-percentage> [<length-percentage>] [<arc-sweep> | <arc-size> | rotate <angle>]`. This command adds an elliptical arc curve command to the list of shape commands. It draws an elliptical arc between a starting point and an ending point. The `by` or `to` keyword determines whether the ending point of the curve, specified by the first `<coordinate-pair>`, is relative or absolute, respectively.

The elliptical arc curve command defines two possible ellipses, which intersect both the starting and ending points, and each can be traced clockwise or counterclockwise, resulting in four possible arcs depending on the arc size, direction, and angle. The `of` keyword specifies the size of the ellipse from which the arc is taken: the first `<length-percentage>` provides the horizontal radius of the ellipse, and the

second `<length-percentage>` provides the vertical radius.

Specify the following parameters to choose which of the four arcs to use:

- `<arc-sweep>`: Indicates whether the desired arc is the one traced around the ellipse clockwise (`cw`) or counterclockwise (`ccw`). If omitted, this defaults to `ccw`.
- `<arc-size>`: Indicates whether the desired arc is the larger (`large`) or smaller (`small`) of the two arcs. If omitted, this defaults to `small`.
- `<angle>`: Specifies the angle, in degrees, by which to rotate the ellipse relative to the x-axis. A positive angle rotates the ellipse clockwise, and a negative angle rotates it counterclockwise. If omitted, this defaults to `0deg`.

Special situations are handled as follows:

- If only one `<length-percentage>` is provided, the same value is used for both the horizontal and vertical radii, effectively creating a circle. In this case, `<arc-size>` and `<angle>` have no effect.
- If either radius is zero, the command is equivalent to a `<line-command>` to the ending point.
- If either radius is negative, its absolute value is used instead.
- If the horizontal and vertical radii don't describe an ellipse large enough to intersect both the starting point and ending points (after rotation by the specified `<angle>`), the radii are scaled up uniformly until the ellipse is just large enough to intersect both points.
- If the starting and ending points of the arc lie on exactly opposite sides of the ellipse, there is only one possible ellipse and two possible arcs. In this case, `<arc-sweep>` specifies the arc to choose, and `<arc-size>` has no effect.

`close`

Adds a ClosePath command to the list of shape commands, drawing a straight line from the current position (end of the last command) to the first point in the path defined in the `from <coordinate-pair>` parameter. To close the shape without drawing a line, include a `<move-command>` with the originating coordinates before the close command. If the `close` command is immediately followed by a `<move-command>`, it defines the starting point of the next shape or subpath.

Description

The `shape()` function allows you to define complex shapes. It is similar to the `path()` shape function in several ways:

- The `<fill-rule>` parameter in the `shape()` function works exactly like the same parameter in the `path()` function.
- The `shape()` function requires specifying one or more `<shape-command>`s, where each command uses an underlying path command, such as MoveTo, LineTo, and ClosePath.

However, `shape()` offers several advantages over using `path()`:

- `shape()` uses standard CSS syntax, making it easier to create and modify shapes directly in your stylesheet. In comparison, `path()` uses the SVG path syntax, which is less intuitive for those not familiar with SVG.
- `shape()` supports a variety of CSS units, including percentages, `rem`, and `em`. `path()`, on the other hand, defines shapes as a single string and limits units to `px`.
- `shape()` also allows the use of CSS math functions, like `calc()`, `max()`, and `abs()`, providing more versatility when defining shapes.

Formal syntax

```
&lt;shape()&gt; =
  shape( &lt;'fill-rule'&gt;? from &lt;position&gt; , &lt;shape-command&gt;# )

&lt;fill-rule&gt; =
  nonzero  |
  evenodd

&lt;position&gt; =
  &lt;position-one&gt;   |
  &lt;position-two&gt;   |
  &lt;position-four&gt;

&lt;shape-command&gt; =
  &lt;move-command&gt;             |
  &lt;line-command&gt;             |
  close                       |
  &lt;horizontal-line-command&gt;  |
  &lt;vertical-line-command&gt;    |
  &lt;curve-command&gt;            |
  &lt;smooth-command&gt;           |
  &lt;arc-command&gt;

&lt;position-one&gt; =
  left                |
  center              |
  right               |
  top                 |
  bottom              |
  x-start             |
  x-end               |
  y-start             |
  y-end               |
  block-start         |
  block-end           |
  inline-start        |
  inline-end          |
  &lt;length-percentage&gt;

&lt;position-two&gt; =
  [ left | center | right | x-start | x-end ] && [ top | center | bottom | y-start | y-end ]  |
  [ left | center | right | x-start | x-end | &lt;length-percentage&gt; ] [ top | center | bottom | y-start | y-end | &lt;length-percentage&gt; ]  |
  [ block-start | center | block-end ] && [ inline-start | center | inline-end ]  |
  [ start | center | end ]{2}

&lt;position-four&gt; =
  [ [ left | right | x-start | x-end ] &lt;length-percentage&gt; ] && [ [ top | bottom | y-start | y-end ] &lt;length-percentage&gt; ]  |
  [ [ block-start | block-end ] &lt;length-percentage&gt; ] && [ [ inline-start | inline-end ] &lt;length-percentage&gt; ]  |
  [ [ start | end ] &lt;length-percentage&gt; ]{2}

&lt;move-command&gt; =
  move &lt;command-end-point&gt;

&lt;line-command&gt; =
  line &lt;command-end-point&gt;

&lt;horizontal-line-command&gt; =
  hline [ to [ &lt;length-percentage&gt; | left | center | right | x-start | x-end ] | by &lt;length-percentage&gt; ]

&lt;vertical-line-command&gt; =
  vline [ to [ &lt;length-percentage&gt; | top | center | bottom | y-start | y-end ] | by &lt;length-percentage&gt; ]

&lt;curve-command&gt; =
  curve [ [ to &lt;position&gt; with &lt;control-point&gt; [ / &lt;control-point&gt; ]? ] | [ by &lt;coordinate-pair&gt; with &lt;relative-control-point&gt; [ / &lt;relative-control-point&gt; ]? ] ]
```

```
<smooth-command> =
  smooth [ [ to <position> [ with <control-point> ]? ] | [ by <coordinate-pair> [ with <relative-control-point> ]? ] ]

<arc-command> =
  arc <command-end-point> [ [ of <length-percentage>{1,2} ] && <arc-sweep>? && <arc-size>? && [ rotate <angle> ]? ]

<length-percentage> =
  <length>      |
  <percentage>

<command-end-point> =
  to <position>         |
  by <coordinate-pair>

<control-point> =
  <position>               |
  <relative-control-point>

<coordinate-pair> =
  <length-percentage>{2}

<relative-control-point> =
  <coordinate-pair> [ from [ start | end | origin ] ]?

<arc-sweep> =
  cw   |
  ccw

<arc-size> =
  large  |
  small
```

This syntax reflects the latest standard as per CSS Fill and Stroke Module Level 3, CSS Shapes Module Level 1, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using <code>shape()</code> to define a path

This example demonstrates how the `shape()` function can be used in the `offset-path` property to define the shape of the path an element can follow.

The first shape, `shape1`, follows a cubic Bézier curved path defined by the `curve to` command. Next, the `close` command draws a straight line from the curve's end point back to the initial point defined in the `from` command. Finally, `shape1` moves to its new position at `0px 150px` and then proceeds along a horizontal line.

The second shape, `shape2`, initially follows a horizontal line, then moves back to its starting position at `50px 90px`. Next, it follows a vertical line before closing the path back to the initial point.

Both shapes start with their original colors and gradually transition to `hotpink` by the end of the `move` animation, reverting to their initial color as the animation restarts. This cyclic color change provides you a visual cue about the animation's progression and restart.

```
<div class="container">
  Using <code>&lt;curve-command&gt;</code>
  <div class="shape shape1">>></div>
</div>

<div class="container">
  Using <code>&lt;move-command&gt;</code> and
  <code>&lt;hvline-command&gt;</code>
  <div class="shape shape2">>></div>
</div>
```

```
body {
  align-items: center;
  justify-content: center;
  display: flex;
}

.container {
  position: relative;
  display: inline-block;
  width: 250px;
  height: 250px;
  border: 2px dotted green;
  margin: 20px;
}

@supports not (offset-path: shape(from 0 0, move to 0 0)) {
  body::after {
    content: "Your browser doesn't support the `shape()` function yet.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

```
.shape {
  width: 50px;
  height: 50px;
  background: #2bc4a2;
  position: absolute;
  text-align: center;
  line-height: 50px;
  animation: move 6s infinite linear;
}

.shape1 {
  offset-path: shape(
    from 30% 60px,
    curve to 180px 180px with 90px 190px,
    close,
    move by 0px 150px,
    hline by 40%
```

```
  );
}

.shape2 {
  offset-path: shape(
    from 50px 90px,
    hline to 8em,
    move to 50px 90px,
    vline by 20%,
    close
  );
}

@keyframes move {
  0% {
    offset-distance: 0%;
  }
  100% {
    offset-distance: 100%;
    background-color: hotpink;
  }
}
```

Result

Using <code>shape()</code> to define the visible part of an element

This example demonstrates how the `shape()` function can be used in the `clip-path` property to create different shapes for the clipping region. The first shape (`shape1`) uses a triangle defined by straight lines. The second shape (`shape2`) includes curves and smooth transitions; it also illustrates the use of the `<move-command>` after the `close` command, which adds a rectangular shape to the clipping region.

```
<div class="container">
  <div class="shape shape1"></div>
</div>

<div class="container">
  <div class="shape shape2"></div>
</div>
```

```
body {
  align-items: center;
  justify-content: center;
  display: flex;
}

.container {
  position: relative;
  display: inline-block;
  width: 200px;
  height: 200px;
  margin: 20px;
  background-color: lightgray;
}

@supports not (clip-path: shape(from 0 0, move to 0 0)) {
  body::after {
    content: "Your browser doesn't support the `shape()` function yet.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

```
.shape {
  width: 100%;
  height: 100%;
  background: #2bc4a2;
  position: absolute;
  text-align: center;
  line-height: 50px;
}

/* Triangular clipping region */
.shape1 {
  clip-path: shape(from 0% 0%, line to 100% 0%, line to 50% 100%, close);
}

/* A Heart clipping region using curve and arc transitions
   and a box using hline and vline transitions */
.shape2 {
  clip-path: shape(
    from 20px 70px,
    arc to 100px 70px of 1% cw,
    arc to 180px 70px of 1% cw,
    curve to 100px 190px with 180px 130px,
    curve to 20px 70px with 20px 130px,
    close,
    move to 150px 150px,
    hline by 40px,
    vline by 40px,
    hline by -40px,
    close
  );
}
```

Result

Using <code>shape()</code> to draw curves with relative control points

Like previous examples, this example also uses `clip-path` to create different shapes for the clipping regions of the elements. The shapes are specified using a combination of `<curve-command>` and `<smooth-command>`, and the control points are specified using `<relative-control-point>` values.

The first shape (`shape1`) draws two cubic Bézier curves.

- The first curve starts from the center of the left edge of the box and is drawn to a point `200px` along the x-axis — the center of the box's right edge. It uses one control point relative to the start of the curve and one control point relative to the origin (top-left of the box).
- The second curve starts from the center right of the box and is drawn `-200px` along the x-axis — the center of the box's left edge. It uses one control point relative to the origin and one control point relative to the start of the curve.

```
<div class="container">
  <div id="shape1"></div>
  <div id="shape2"></div>
  <div id="shape3"></div>
</div>
```

```
.container {
  display: flex;
  justify-content: center;
  gap: 20px;
}

@supports not (
  clip-path: shape(
      from center left,
      curve by 200px 0 with 50% -50% from start / 50% 0 from origin,
      curve by -200px 0 with 50% 100% from origin / -50% 50% from start,
      close
    )
) {
  body::after {
    content: "Your browser doesn't support `shape()` relative control points.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

```
#shape1 {
  width: 200px;
  height: 200px;
  background: green;
  clip-path: shape(
    from center left,
    curve by 200px 0 with 50% -50% from start / 50% 0 from origin,
    curve by -200px 0 with 50% 100% from origin / -50% 50% from start,
    close
  );
}
```

The second shape (`shape2`) draws one quadratic Bézier curve and one cubic Bézier curve.

- The first curve starts from the center of the left edge of the box and is drawn to an absolute point `200px` from the origin along the x-axis and `100px` from the origin along the y-axis. It uses one control point relative to the start of the curve.
- The second curve starts from the previous curve's end point and is drawn to the center left of the box. It uses one control point relative to the start of the curve and one control point relative to the end.

```
#shape2 {
  width: 200px;
  height: 200px;
  background: purple;
  clip-path: shape(
    from center left,
    curve to 200px 100px with 50% -80% from start,
    curve to center left with 0% 70% from start / 20% 0% from end,
    close
  );
}
```

The third shape (`shape3`) draws one quadratic Bézier curve and one cubic Bézier curve using a `smooth` command.

- The first curve starts from the center of the left edge of the box and is drawn to a point `200px` along the x-axis. It uses one control point relative to the start of the curve.
- The second curve starts from the previous curve's end point and is drawn to the center of the box. It uses one control point relative to the start of the curve (the last control point of the previous curve) and one control point relative to the origin.

```
#shape3 {
  width: 200px;
  height: 200px;
  background: orangered;
  clip-path: shape(
    from center left,
    curve by 200px 0px with 50% -80% from start,
    smooth to center with 50% 100% from origin,
    close
  );
}
```

xywh() CSS function

The **`xywh()`** CSS function creates a rectangle using the specified distances from the left (x) and top (y) edges of the containing block and the specified width (w) and height (h) of the rectangle. It is a basic shape function of the `<basic-shape>` data type. You can use the `xywh()` function in CSS properties such as `offset-path` to create the rectangular path along which an element moves, in `clip-path` to define the shape of the clipping region, and in `border-shape` to define the shape of an element's border.

Syntax

```
offset-path: xywh(0 1% 2px 3% round 0 1px 2% 3px);
clip-path: xywh(1px 2% 3px 4em round 0 1% 2px 3em);
border-shape: xywh(5% 5% 90% 90% round 20px);
```

Values

`<length-percentage>`

Specifies the `<length-percentage>` values for the x and y coordinates of the rectangle.

`<length-percentage [0,∞]>`

Specifies non-negative `<length-percentage>` values for the width and height of the rectangle. The minimum value can be zero, and the maximum value has no limit.

`round <'border-radius'>`

Specifies the radius of the rounded corners of the rectangle using the same syntax as the CSS `border-radius` shorthand property. This parameter is optional.

Formal syntax

```
<xywh()> =
  xywh( <length-percentage>{2} <length-percentage [0,∞]>{2} [ round <'border-radius'> ]? )

<length-percentage> =
  <length>      |
  <percentage>

<border-radius> =
  <length-percentage [0,∞]>{1,4} [ / <length-percentage [0,∞]>{1,4} ]?
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Shapes Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Creating offset-path using xywh()

In the example below, the `offset-path` property uses the `xywh()` function to define the shape of the path on which the element, a magenta box in this case, moves. Two different scenarios are shown, each with different values for the `xywh()` function. The arrow inside the boxes points to the right edge of the box.

```
<div class="container">
  Rectangular path 1
  <div class="path xywh-path-1">→</div>
</div>
<div class="container">
  Rectangular path 2
  <div class="path xywh-path-2">→</div>
</div>
```

```
.container {
  position: relative;
  display: inline-block;
  width: 200px;
  height: 200px;
  border: 1px solid black;
  margin: 30px;
  text-align: center;
}

.path {
  width: 50px;
  height: 50px;
  position: absolute;
  background-color: magenta;
  animation: move 10s linear infinite;
}

.xywh-path-1 {
  offset-path: xywh(20px 20px 100% 100% round 10%);
}

.xywh-path-2 {
  offset-path: xywh(20px 30% 150% 200%);
}

@keyframes move {
  0% {
    offset-distance: 0%;
  }
  100% {
    offset-distance: 100%;
  }
}
```

Result

- The path 1 rectangle is offset by `20px` from the left and top edges of the containing block. This path rectangle has the same dimension as the containing block, that is, the width is `100%` of the width of the containing block, and the height is `100%` of the height of the containing block. Notice how the arrow inside the box follows the `10%` curve (defined by `round 10%`) at the rectangular path corners.
- As the upper limit of both width and height in `xywh()` is infinity, setting the height to `200%` in the path 2 rectangle makes the generated rectangle twice as tall as the containing block. Notice how the arrow inside the box behaves at the corners when no `round <'border-radius'>` is specified.

<blend-mode> CSS type

The **`<blend-mode>`** CSS data type describes how colors should appear when elements overlap. It is used in the `background-blend-mode` and `mix-blend-mode` properties.

Syntax

The `<blend-mode>` data type is defined using a keyword value chosen from the list below.

Values

`normal`

The final color is the top color, regardless of what the bottom color is. The effect is like two opaque pieces of paper overlapping.

`multiply`

The final color is the result of multiplying the top and bottom colors. A black layer leads to a black final layer, and a white layer leads to no change. The effect is like two images printed on transparent film overlapping.

`screen`

The final color is the result of inverting the colors, multiplying them, and inverting that value. A black layer leads to no change, and a white layer leads to a white final layer. The effect is like two images shining onto a projection screen.

`overlay`

The final color is the result of `multiply` if the bottom color is darker, or `screen` if the bottom color is lighter. This blend mode is equivalent to `hard-light` but with the layers swapped.

`darken`

The final color is composed of the darkest values of each color channel.

`lighten`

The final color is composed of the lightest values of each color channel.

`color-dodge`

The final color is the result of dividing the bottom color by the inverse of the top color. A black foreground leads to no change. A foreground with the inverse color of the backdrop leads to a fully lit color. This blend mode is similar to `screen`, but the foreground only needs to be as light as the inverse of the backdrop to create a fully lit color.

`color-burn`

The final color is the result of inverting the bottom color, dividing the value by the top color, and inverting that value. A white foreground leads to no change. A foreground with the inverse color of the backdrop leads to a black final image. This blend mode is similar to `multiply`, but the foreground only needs to be as dark as the inverse of the backdrop to make the final image black.

`hard-light`

The final color is the result of `multiply` if the top color is darker, or `screen` if the top color is lighter. This blend mode is equivalent to `overlay` but with the layers swapped. The effect is similar to shining a *harsh* spotlight on the backdrop.

`soft-light`

The final color is similar to `hard-light`, but softer. This blend mode behaves similar to `hard-light`. The effect is similar to shining a *diffused* spotlight on the backdrop.

`difference`

The final color is the result of subtracting the darker of the two colors from the lighter one. A black layer has no effect, while a white layer inverts the other layer's color.

`exclusion`

The final color is similar to `difference`, but with less contrast. As with `difference`, a black layer has no effect, while a white layer inverts the other layer's color.

`hue`

The final color has the *hue* of the top color, while using the *saturation* and *luminosity* of the bottom color.

`saturation`

The final color has the *saturation* of the top color, while using the *hue* and *luminosity* of the bottom color. A pure gray backdrop, having no saturation, will have no effect.

`color`

The final color has the *hue* and *saturation* of the top color, while using the *luminosity* of the bottom color. The effect preserves gray levels and can be used to colorize the foreground.

`luminosity`

The final color has the *luminosity* of the top color, while using the *hue* and *saturation* of the bottom color. This blend mode is equivalent to `color`, but with the layers swapped.

Description

For each pixel among the layers to which it is applied, a blend mode takes the colors of the foreground and the background, performs a calculation on them, and returns a new color value.

Changes between blend modes are not interpolated. Any change occurs immediately.

Formal syntax

```
<blend-mode> =
  normal       |
  darken       |
  multiply     |
```

```
  color-burn   |
  lighten      |
  screen       |
  color-dodge  |
  overlay      |
  soft-light   |
  hard-light   |
  difference   |
  exclusion    |
  hue          |
  saturation   |
  color        |
  luminosity
```

This syntax reflects the latest standard as per Compositing and Blending Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Example using "normal"

```
<div class="container"></div>
```

```
.container {
  width: 150px;
  height: 150px;
  background: url("br.png"), url("tr.png");
  background-blend-mode: normal;
}
```

Set other values for `background-blend-mode`, you will get different results.

Comparison between different values with <code>background-blend-mode</code>

```
<div class="container"></div>
```

```
.container {
  width: 720px;
  height: 760px;
  display: grid;
  grid: auto-flow 190px / repeat(4, 180px);
  border-top: 1px solid #d8d8d8;
  border-left: 1px solid #d8d8d8;
}

.container > div {
  border-right: 1px solid #d8d8d8;
  border-bottom: 1px solid #d8d8d8;
}

.container div div {
  margin-left: 15px;
  width: 150px;
  height: 150px;
  background: url("br.png"), url("tr.png");
}

.container div p {
  line-height: 30px;
  margin: 0;
  color: #a33333;
  text-align: center;
}
```

```
const list = [
  "normal",
  "multiply",
  "screen",
  "overlay",
  "darken",
  "lighten",
  "color-dodge",
  "color-burn",
  "hard-light",
  "soft-light",
  "difference",
  "exclusion",
  "hue",
  "saturation",
  "color",
  "luminosity",
];

const containerElem = document.querySelector(".container");

list.forEach((item) => {
  const innerElem = document.createElement("div");
  innerElem.style.backgroundBlendMode = item;

  const textElem = document.createElement("p");
  textElem.innerText = item;

  const outerElem = document.createElement("div");
  outerElem.appendChild(textElem);
  outerElem.appendChild(innerElem);

  containerElem.appendChild(outerElem);
});
```

Create multiple `div` elements by traversing a list and set different `backgroundBlendMode` value for each.

Comparison between different values with <code>mix-blend-mode</code>

```
<div class="container"></div>
```

```
.container {
  width: 640px;
  height: 800px;
  display: grid;
  grid: auto-flow 160px / repeat(4, 160px);
  border-top: 1px solid #d8d8d8;
  border-left: 1px solid #d8d8d8;
}

.container > div {
  border-right: 1px solid #d8d8d8;
  border-bottom: 1px solid #d8d8d8;
}

.container > div > div {
  position: relative;
  margin-left: 20px;
  width: 120px;
  height: 120px;
}

.container div p {
  margin: 0;
  line-height: 30px;
  color: #a33333;
  text-align: center;
}
.circle {
  width: 80px;
  height: 80px;
  border-radius: 50%;
  mix-blend-mode: screen;
  position: absolute;
}

.circle-1 {
  background: red;
}

.circle-2 {
  background: lightgreen;
  left: 40px;
}

.circle-3 {
  background: blue;
  left: 20px;
  top: 40px;
}

.isolate {
  isolation: isolate; /* Without isolation, the background color will be taken into account */
  position: relative;
}
```

```
const list = [
  "normal",
  "multiply",
  "screen",
  "overlay",
  "darken",
  "lighten",
  "color-dodge",
  "color-burn",
  "hard-light",
  "soft-light",
  "difference",
  "exclusion",
  "hue",
  "saturation",
  "color",
  "luminosity",
  "plus-darker",
  "plus-lighter",
];

const containerElem = document.querySelector(".container");

list.forEach((item) => {
  const innerElem = document.createElement("div");
  innerElem.innerHTML = `
    <div class="circle circle-1"></div>
    <div class="circle circle-2"></div>
    <div class="circle circle-3"></div>
  `;

  innerElem.querySelectorAll(".circle").forEach((circle) => {
    circle.style.mixBlendMode = item;
  });

  const textElem = document.createElement("p");
  textElem.innerText = item;

  const outerElem = document.createElement("div");
  outerElem.appendChild(textElem);
  outerElem.appendChild(innerElem);
```

```
  containerElem.appendChild(outerElem);
});
```

In the following example, we create multiple `<div>` elements by traversing a list and set different `mixBlendMode` values for each.

Blend mode comparison

In the following example, we have a `<div>` with two background images set on it — a Firefox logo on top of a linear gradient. Below it, we have a provided a `<select>` menu that allows you to change the `background-blend-mode` applied to the `<div>`, allowing you to compare the different blend mode effects.

HTML

```
<div></div>
<p>Choose a blend-mode:</p>
<select>
  <option selected>normal</option>
  <option>multiply</option>
  <option>screen</option>
  <option>overlay</option>
  <option>darken</option>
  <option>lighten</option>
  <option>color-dodge</option>
  <option>color-burn</option>
  <option>hard-light</option>
  <option>soft-light</option>
  <option>difference</option>
  <option>exclusion</option>
  <option>hue</option>
  <option>saturation</option>
  <option>color</option>
  <option>luminosity</option>
</select>
```

CSS

```
div {
  width: 300px;
  height: 300px;
  background:
    url("https://mdn.dev/archives/media/attachments/2020/07/29/17350/3b4892b7e820122ac6dd7678891d4507/firefox.png")
      no-repeat center,
    linear-gradient(to bottom, blue, orange);
}
```

JavaScript

```
const selectElem = document.querySelector("select");
const divElem = document.querySelector("div");

selectElem.addEventListener("change", () => {
  divElem.style.backgroundBlendMode = selectElem.value;
});
```

<box-edge> CSS type

The **`<box-edge>`** value types represent a box edge keyword, such as `content-box` and `border-box`. The box-edge keywords are used to define different aspects of an element's box model and how elements are positioned and rendered on screen.

The box-edge keywords are the components of, but not limited to, the data types `<visual-box>`, `<layout-box>`, `<paint-box>`, `<coord-box>`, and `<geometry-box>`. These types are applied to properties such as `transform-box` and `background-clip`.

Syntax

```
<visual-box> = content-box | padding-box | border-box /* the three <box> values */
<layout-box> or <shape-box> = <visual-box> | margin-box
<paint-box> = <visual-box> | fill-box | stroke-box
<coord-box> = <paint-box> | fill-box | stroke-box | view-box
<geometry-box> = <shape-box> | fill-box | stroke-box | view-box
```

Values

A `<box-edge>` can be of the type `<visual-box>`, `<layout-box>`, `<paint-box>`, `<coord-box>`, or `<geometry-box>`.

`<visual-box>`

> Refers to the rectangular box generated for an element as seen by a user on a web page. It includes the element's content, padding, and border. Also referred to as `<box>`, this value excludes the margin area. This value type is used for the `background-clip` and `overflow-clip-margin` properties.

`<layout-box>`

> Refers to the space occupied by an element, including its content, padding, border, and margin. This value type is used for layout and positioning purposes. Also referred to as `<shape-box>`, this value type is used for the `shape-outside` property.

`<paint-box>`

> Refers to the area within the layout box that is used to visually render the content. This includes the area where the element's background and borders are painted. As an element's paintable area does not include its margins, this value excludes `margin-box`.

`<coord-box>`

Refers to the coordinate box used for positioning and sizing an element within its parent container. It is used to control how content flows around the edges of the box. It excludes the margin area. This value type is used for the `offset-path` property.

`<geometry-box>`

Defines the reference box for a basic shape, or if specified by itself, causes the edges of the specified box, including any corner shaping (such as a `border-radius`), to be the clipping path. This value type is used for the `clip-path`, `mask-clip`, and `mask-origin` properties and the SVG `clip-path` attribute; it is also used as part of the `border-shape` property values.

Keywords

The `<box-edge>` keywords are defined as follows:

`content-box`

Refers to the outer edge of the box's content area. The content box is the innermost box. The content area contains the actual content, such as text, images, or other HTML elements. In SVG, this value is treated as `fill-box`.

`padding-box`

Refers to the outer edge of the padding of the box. If there is no padding on a side, then the value is the same as `content-box`. In SVG, `padding-box` is treated as `fill-box`. The padding area surrounds the content area, starting at the outer edge of the content box.

`border-box`

Refers to the outer edge of the border of the box. If there is no border on a side, then the value is the same as `padding-box`. In SVG, `border-box` is treated as `stroke-box`. The border area surrounds the padding area, starting at the outer edge of the padding box.

`half-border-box`

Refers to a box shape that traverses the center of the border region; the inner half of the border region is inside the shape, and the outer half of the border region is outside the shape.

`margin-box`

Refers to the outer edge of the margin of the box. If there is no margin on a side, then the value is the same as `border-box`. In SVG, `margin-box` is treated as `stroke-box`.

`fill-box`

Refers to the object bounding box in SVG. In CSS, `fill-box` is treated as `content-box`. It is used to wrap the content around the edges defined by the `coord-box` values.

`stroke-box`

Refers to the stroke bounding box in SVG. In CSS, `stroke-box` is treated as `border-box`. It is used to define the shape of the element when strokes are applied.

`view-box`

Refers to the nearest SVG viewport element's origin box. The origin box is a rectangle with the width and height of the initial SVG user coordinate system established by the `viewBox` attribute for that element. The origin box is positioned such that its top left corner is anchored at the coordinate system origin. In CSS, `view-box` is treated as `border-box`.

> **Note:** When the SVG viewport is not anchored at the origin, the origin box does not correspond to the SVG viewport.

calc() CSS function

The **`calc()`** CSS function lets you perform calculations when specifying CSS property values. It can be used with `<length>`, `<frequency>`, `<angle>`, `<time>`, `<percentage>`, `<number>`, `<integer>`, and `<color-function>` values.

Try it

```
width: calc(10px + 100px);
```

```
width: calc(100% - 30px);
```

```
width: calc(2em * 5);
```

```
width: calc(var(--variable-width) + 20px);
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">Change my width.</div>
</section>
```

```
:root {
  --variable-width: 100px;
}

#example-element {
  border: 10px solid black;
  padding: 10px;
}
```

Syntax

```
/* calc(expression) */
calc(100% - 80px)

/* Expression with a CSS function */
calc(100px * sin(pi / 2))

/* Expression containing a variable */
calc(var(--hue) + 180)

/* Expression with color channels in relative colors */
lch(from aquamarine l c calc(h + 180))
```

The `calc()` function takes a single expression as its parameter, and the expression's result is used as the value for a CSS property. In this expression, the operands can be combined using the operators listed below. When the expression contains multiple operands, `calc()` uses the standard operator precedence rules:

`+`

Adds the specified operands.

`-`

Subtracts the second operand from the first operand.

`*`

Multiplies the specified operands.

`/`

Divides the left-side operand (dividend) by the right-side operand (divisor).

All operands, except those of type `<number>`, must be suffixed with an appropriate unit string, such as `px`, `em`, or `%`. You can use a different unit with each operand in your expression. You may also use parentheses to establish computation order when needed.

Description

There are a few points to note about `calc()`, which are detailed in the sections below.

Resulting values

The `calc()` function must stand in place of a full CSS value of one of the following types:

- `<length>`
- `<frequency>`
- `<angle>`
- `<time>`
- `<flex>`
- `<resolution>`
- `<percentage>`
- `<number>`
- `<integer>`
- One of the mixed types like `<length-percentage>`

`calc()` cannot only replace the numeric part of percentage values, length values, etc., without also replacing the unit after it. For example, `calc(100 / 4)%` is invalid, while `calc(100% / 4)` is valid.

The resulting value of `calc()` must be compatible with the context in which it is used. For example, `margin: calc(1px + 2px)` is valid, but `margin: calc(1 + 2)` is not: it is equivalent to specifying `margin: 3`, which results in the property being ignored.

When an `<integer>` is expected, the `calc()` expression can also evaluate to a `<number>`, which gets rounded to the nearest integer. So, `calc(1.4)` will result in a value of `1`. If the fractional part of the value is exactly `0.5`, the value is rounded towards positive infinity. For example, `calc(1.5)` will result in a value of `2`, while `calc(-1.5)` will round to `-1`.

`calc()` performs floating point math following the IEEE-754 standard, which results in some considerations concerning the `infinity` and `NaN` values. For more details on how constants are serialized, see the `<calc-keyword>` page.

Input considerations

- `calc()` cannot perform calculations on intrinsic size values such as `auto` and `fit-content`. Use the `calc-size()` function instead.
- The `*` and `/` operators do not require whitespace, but adding it for consistency is recommended.
- It is permitted to nest `calc()` functions, in which case, the inner ones are treated as simple parentheses.
- Math expressions involving percentages for widths and heights on table columns, table column groups, table rows, table row groups, and table cells in both auto and fixed layout tables *may* be treated as if `auto` is specified.
- See `<calc-sum>` for more information on the syntax of `+` and `-` expressions.

CSS typed arithmetic

When using `calc()` to multiply values, using the `*` operator, only one value can contain a unit. Calculations like `200px * 4px` are not supported as 800px^2 is meaningless in CSS.

Inversely, `200px / 4px` resolves to `50`, which does make sense in CSS. Therefore, when using the `calc()` function to divide numbers, using the `/` operator, supporting browsers allow units on both sides of the operand, provided they are of the same data type. For example, `100vw / 1px` is valid and results in a unitless value.

The quotient can then be used in the values of properties or functions that accept a `<number>` as a value or parameter, or converted into a different data type by multiplying it by a typed value.

For a full explanation of typed arithmetic in CSS, along with examples, see Using CSS typed arithmetic.

Support for computing color channels in relative colors

The `calc()` function can be used to manipulate color channels directly within the context of relative colors. This allows for dynamic adjustments of color channels in color models such as `rgb()`, `hsl()`, and `lch()`.

The relative color syntax defines several color-channel keywords, each of which represents the value of the color channel as a `<number>` (see Channel values resolve to `<number>` values for more information). The `calc()` function can use these color-channel keywords to perform dynamic adjustments on the color channels, for example, `calc(r + 10)`.

Formal syntax

```
<calc()> =
  calc( <calc-sum> )

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
```

```
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Accessibility

When `calc()` is used for controlling text size, be sure that one of the values includes a relative length unit, for example:

```
h1 {
  font-size: calc(1.5rem + 3vw);
}
```

This ensures that text size will scale if the page is zoomed.

- MDN Understanding WCAG, Guideline 1.4 explanations
- Understanding Success Criterion 1.4.4: Resize Text | WAI | W3C

Examples

Positioning an object on screen with a margin

`calc()` enables positioning an object with a set margin. In this example, the CSS creates a banner that stretches across the window, with a 40-pixel gap between both sides of the banner and the edges of the window:

```
.banner {
  position: absolute;
  left: 40px;
  width: calc(100% - 80px);
  border: solid black 1px;
  box-shadow: 1px 2px;
  background-color: yellow;
  padding: 6px;
  text-align: center;
  box-sizing: border-box;
}
```

```
<div class="banner">This is a banner!</div>
```

Automatically sizing form fields to fit their container

Another use case for `calc()` is to help ensure that form fields fit in the available space, without extruding past the edge of their container while maintaining an appropriate margin.

Let's look at some CSS:

```
input {
  padding: 2px;
  display: block;
  width: calc(100% - 1em);
}

#form-box {
  width: calc(100% / 6);
  border: 1px solid black;
  padding: 4px;
}
```

Here, the container is established to use 1/6 of the available window width. Then, to ensure that input fields retain an appropriate size, we use `calc()` again to establish that they should be the width of their container minus 1em. Then, the following HTML makes use of this CSS:

```
<div id="form-box">
  <label for="misc">Type something:</label>
  <input type="text" id="misc" name="misc" />
</div>
```

Nesting with CSS variables

You can use `calc()` with CSS variables. Consider the following code:

```
.foo {
  --width-a: 100px;
  --width-b: calc(var(--width-a) / 2);
  --width-c: calc(var(--width-b) / 2);
  width: var(--width-c);
}
```

After all variables are expanded, `--width-c`'s value will be `calc(calc(100px / 2) / 2)`. When it's assigned to `.foo`'s width property, all inner `calc()` functions (no matter how deeply nested) will be flattened to just parentheses. Therefore, the `width` property's value will eventually be `calc((100px / 2) / 2)`, which equals `25px`. In short, a `calc()` inside of a `calc()` is identical to using parentheses.

Adjusting color channels in relative colors

The `calc()` function can be used to adjust individual color channels in relative colors without the need for storing color channel values as variables.

In the example below, the first paragraph uses a `<named-color>`. In the paragraphs that follow, `calc()` is used with the `rgb()` and `hsl()` functions to adjust the values of each color channel relative to the original named color.

```
<p class="original">Original text color in rebeccapurple</p>
<p class="increase-hue">Hue increased by 80</p>
<p class="increase-lightness">Lightness increased by 20</p>
<p class="decrease-lightness">Lightness decreased by 10</p>
```

```
p {
  font-family: monospace;
  font-size: 16px;
}
```

```
.original {
  color: rebeccapurple;
}

.increase-hue {
  color: lch(from rebeccapurple l c calc(h + 80));
}

.increase-lightness {
  color: lch(from rebeccapurple calc(l + 20) c h);
}

.decrease-lightness {
  color: lch(from rebeccapurple calc(l - 10) c h);
}
```

For another example of using the `calc()` function to derive relative colors, see the Using math functions section on the *Using relative colors* page.

- A Complete Guide to calc() in CSS (CSS-Tricks)

<calc-keyword> CSS type

The **`<calc-keyword>`** CSS data type represents well-defined constants such as `e` and `pi`. Rather than require authors to manually type out several digits of these mathematical constants or calculate them, a few of them are provided directly by CSS for convenience.

Syntax

The `<calc-keyword>` type defines numeric constants that can be used in CSS math functions.

Values

`e`

The base of the natural logarithm, approximately equal to `2.7182818284590452354`.

`pi`

The ratio of a circle's circumference to its diameter, approximately equal to `3.1415926535897932`.

`infinity` & `-infinity`

An infinite value, used to indicate the largest/smallest possible value.

`NaN`

A value representing "Not a Number" canonical casing.

Notes

Serializing the arguments inside `calc()` follows the IEEE-754 standard for floating point math which means there's a few cases to be aware of regarding constants like `infinity` and `NaN`:

- Dividing by zero will return positive or negative `infinity` depending on the sign of the numerator.
- Adding, subtracting or multiplying `infinity` to anything will return `infinity` unless it produces `NaN` (see below).
- Any operation with at least one `NaN` argument will return `NaN`. This means `0 / 0`, `infinity / infinity`, `0 * infinity`, `infinity + (-infinity)`, and `infinity - infinity` will all return `NaN`.
- Positive and negative zero are possible values (`0`⁺ and `0`⁻). This has the following effects:
  - Multiplication or division that produces zero with exactly one negative argument (`-5 * 0` or `1 / (-infinity)`) or negative result from combinations in the other math functions will return `0`⁻.
  - `0`⁻ `+ 0`⁻ or `0`⁻ `- 0` will return `0`⁻. All other additions or subtractions that would produce a zero will return `0`⁺.
  - Multiplying or dividing `0`⁻ with a positive number (including `0`⁺) will return a negative result (either `0`⁻ or `-infinity`), while multiplying or dividing `0`⁻ with a negative number will return a positive result.

Examples of how these rules apply are shown in the Infinity, NaN, and division by zero section.

> **Note:** It's rare to need to use `infinity` as an argument in `calc()`, but it can be used to avoid hardcoded "magic numbers" or making sure a certain value is always larger than another value. It may be useful if you need to make it obvious that a property has "the largest possible value" for that data type.

Formal syntax

```
<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Description

Mathematical constants can only be used inside CSS math functions for calculations. Math constants are not CSS keywords, but if they are used outside of a calculation, they're treated like any other keyword. For example:

- `animation-name: pi;` refers to an animation named "pi", not the `pi` numeric constant.
- `line-height: e;` is invalid, but `line-height: calc(e);` is valid.
- `rotate(1rad * pi);` won't work because `rotate()` is not a math function. Use `rotate(calc(1rad * pi));`

In math functions, `<calc-keyword>` values are evaluated as `<number>` values, therefore `e` and `pi` act as numeric constants.

Both `infinity` and `NaN` are slightly different, they are considered as degenerate numeric constants. While not technically numbers, they act as `<number>` values, so to get an infinite `<length>`, for example, requires an expression like `calc(infinity * 1px)`.

The `infinity` and `NaN` values are included mostly to make serialization simpler and more obvious, but can be used to indicate a "largest possible value", since an infinite value is clamped to the allowed range. It's rare for this to be reasonable, but when using infinity it's much simpler than just putting an enormous number in a stylesheet or hardcoding magic numbers.

All constants are case-insensitive except for `NaN`, which makes `calc(Pi)`, `calc(E)` and `calc(InFiNiTy)` valid:

```
e
-e
E
pi
-pi
Pi
infinity
-infinity
InFiNiTy
NaN
```

The following are all invalid:

```
nan
Nan
NAN
```

Examples

Using e and pi in <code>calc()</code>

The following example shows how to use `e` inside `calc()` to rotate an element with an exponentially-increasing angle. The second box shows how to use `pi` inside a `sin()` function.

```
#wrapper {
  display: flex;
  flex-direction: row;
  justify-content: space-evenly;
}

.container {
  display: flex;
  flex-direction: column;
  align-items: start;
  width: 200px;
}
.container > div {
  width: 100px;
  height: 100px;
  margin: 10px;
}

span {
  font-family: monospace;
  font-size: 0.8em;
}

#e {
  background-color: blue;
}

#pi {
  background-color: blue;
}
```

```
<div id="wrapper">
  <div class="container">
    <div id="e"></div>
    <input type="range" min="0" max="7" step="0.01" value="0" id="e-slider" />
    <label for="e-slider">e:</label>
    <span id="e-value"></span>
  </div>
  <div class="container">
    <div id="pi"></div>
    <input type="range" min="0" max="1" step="0.01" value="0" id="pi-slider" />
    <label for="pi-slider">pi:</label>
    <span id="pi-value"></span>
  </div>
</div>
```

```
// sliders
const eInput = document.querySelector("#e-slider");
const piInput = document.querySelector("#pi-slider");
// spans for displaying values
const eValue = document.querySelector("#e-value");
const piValue = document.querySelector("#pi-value");

eInput.addEventListener("input", function () {
  e.style.transform = `rotate(calc(1deg * pow(${this.value}, e)))`;
  eValue.textContent = e.style.transform;
});

piInput.addEventListener("input", function () {
  pi.style.rotate = `calc(sin(${this.value} * pi) * 100deg)`;
  piValue.textContent = pi.style.rotate;
});
```

Infinity, NaN, and division by zero

The following example shows the computed value of the `width` property when dividing by zero, followed by how serialization with different `calc()` constants look when viewed in the console:

```
<div></div>
```

```
div {
  height: 50px;
```

```
  background-color: red;
  width: calc(1px / 0);
}
```

```
const div = document.querySelector("div");
console.log(div.offsetWidth); // 17895698 (infinity clamped to largest value for width)

function logSerializedWidth(value) {
  div.style.width = value;
  console.log(div.style.width);
}

logSerializedWidth("calc(1px / 0)"); // calc(infinity * 1px)
logSerializedWidth("calc(1px / -0)"); // calc(-infinity * 1px)

logSerializedWidth("calc(1px * -infinity * -infinity)"); // calc(infinity * 1px)
logSerializedWidth("calc(1px * -infinity * infinity)"); // calc(-infinity * 1px)

logSerializedWidth("calc(1px * (NaN + 1))"); // calc(NaN * 1px)
```

calc-size() CSS function

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`calc-size()`** CSS function allows you to perform calculations on intrinsic size values such as `auto`, `fit-content`, and `max-content`; this is not supported by the regular `calc()` function.

`calc-size()` return values can also be interpolated, enabling size keyword values to be used in animations and transitions. In effect, including `calc-size()` in a property value automatically applies `interpolate-size: allow-keywords` to the selection.

Note however that `interpolate-size` is inherited, therefore applying it to an element enables interpolation of intrinsic size keywords for every property applied to that element and its children. As a result, `interpolate-size` is the preferred solution for enabling intrinsic size animations. You should only use `calc-size()` to enable intrinsic size animations if they also require calculations.

Syntax

```
/* Pass a value through calc-size() */
calc-size(auto, size)
calc-size(fit-content, size)

/* Perform a calculation */
calc-size(min-content, size + 100px)
calc-size(fit-content, size / 2)

/* Calculation including a function */
calc-size(auto, round(up, size, 50px))
```

Parameters

The `calc-size()` function's syntax is as follows:

```
calc-size(<calc-size-basis>, <calc-sum>)
```

The parameters are:

`<calc-size-basis>`

The value (most commonly an intrinsic size) that you want to perform a calculation on.

`<calc-sum>`

An expression that defines the calculation to be performed on the `<calc-size-basis>`.

Return value

Returns a value equal to the `<calc-size-basis>` modified by the `<calc-sum>` expression. As the `<calc-size-basis>` value is an intrinsic size value, the return value is a modified intrinsic size value that behaves like the intrinsic size value input into the function.

Description

Certain browser layout algorithms have special behaviors for intrinsic sizing keywords. The `calc-size()` function is explicitly defined to represent an intrinsic size rather than a `<length-percentage>`, thereby enforcing correctness. `calc-size()` enables calculations to be performed on intrinsic size values in a safe, well-defined manner.

Valid values for the first argument (<code><calc-size-basis></code>)

The first `calc-size()` argument can be one of the following intrinsic values:

- `auto`
- `min-content`
- `max-content`
- `fit-content`
- `content` (for containers sized using `flex-basis`).

There are also a few special values that this argument can take:

- A nested `calc-size()` value. This isn't something you'd be likely to do very often, but it is available ensuring using a CSS variable as the `<calc-size-basis>` will always work, provided the variable is a valid value for the property `calc-size()` is being set on. So for example, this will work:

  ```
  section {
    height: calc-size(calc-size(max-content, size), size + 2rem);
  }
  ```

As will this:

```
:root {
  --intrinsic-size: calc-size(max-content, size);
}

section {
  height: calc-size(var(--intrinsic-size), size + 2rem);
}
```

- Another `<calc-sum>`, with the same restrictions as the `<calc-sum>` specified for the second argument, except that the `size` keyword cannot be included. You likely will not do this, as you are no longer doing a calculation on an intrinsic size value, but if a custom property value is a `<calc-sum>`, the function will still work. For example, this will work directly or if you use a custom property with a value of `300px + 2rem`:

  ```
  section {
    height: calc-size(300px + 2rem, size / 2);
  }
  ```

- The keyword `any`, which represents an unspecified definite size. In this case, the `size` keyword cannot be included in the second argument, and the `calc-size()` returns the result of the second argument calculation. For example:

  ```
  section {
    height: calc-size(any, 300px * 1.5); /* Returns 450px */
  }
  ```

Mixing different intrinsic sizes together in the same calculation doesn't work. For example, `max-content - min-content` doesn't make sense. `calc-size()` only allows a single intrinsic size value in each calculation, avoiding this problem.

Valid values for the second argument (<code><calc-sum></code>)

The second `calc-size()` argument is a `<calc-sum>` expression.

In this expression:

- The keyword `size` represents the `<calc-size-basis>` specified as the first argument.
- Operands can include `size`, and any value types that make sense in the context.
- The `+`, `-`, `*`, and `/` operators can be included.
- Other mathematical functions can be included such as `round()`, `max()`, or even a nested `calc-size()`.
- The overall expression must match `<length-percentage>`, and resolve to a `<length>`.

Enabling animation of intrinsic size values

`calc-size()` return values can be interpolated, enabling animations between a `<length-percentage>` value and a `calc-size()` intrinsic size return value.

> **Note:** You should avoid animating box model properties if possible, to cut down on layout events and mitigate the resulting impact on performance (see Critical rendering path > Layout).

For example, you could use a transition to animate a container `width` between `0` and `auto` like so:

```
section {
  width: 0;
  transition: width ease 1s;
}

section:hover,
section:focus {
  width: calc-size(auto, size);
}
```

In the above case, we are not calculating anything — we are putting `auto` into `calc-size()` and returning it unchanged. The `interpolate-size` property makes animations like the above simpler to implement in most cases, especially when there are multiple animations to consider. It is inherited and therefore only needs to be declared once on an ancestor property, meaning we could have transitioned between `0` and `auto` without using `calc-size()`.

The `calc-size()` function should only be used to enable intrinsic size animations if they also require calculations. For example, in the following case we are animating the `width` *and* applying a calculation to the intrinsic size end state:

```
section {
  width: 0;
  transition: width ease 1s;
}

section:hover,
section:focus {
  width: calc-size(auto, size + 2rem);
}
```

One case in which `calc-size()` is useful is when you want to animate between an intrinsic size and a modified version of the same intrinsic size. This is not possible with `interpolate-size` and `calc()`. For example, the following `@keyframes` definition animates a container `width` between `fit-content` and 70% of the `fit-content`.

```
@keyframes narrower {
  from {
    width: fit-content;
  }

  to {
    width: calc-size(fit-content, size * 0.7);
  }
}
```

> **Note:** Note that `calc-size()` does not enable animating between two different intrinsic size values.

Formal syntax

```
<calc-size()> =
  calc-size( <calc-size-basis> , <calc-sum> )

<calc-size-basis> =
  <size-keyword>  |
  <calc-sum>      |
  <calc-size()>   |
  any

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic <code>calc-size</code> usage

This example shows basic dimension sizing of a container using `calc-size()`

HTML

The HTML contains a single `<section>` element that contains some child content.

```
<section>
  <h2>Favorite quote</h2>

  <p>
    Fashion is something so ugly it has to be changed every fifteen minutes.
  </p>
</section>
```

CSS

```
* {
  box-sizing: border-box;
}

section {
  font-family: "Helvetica", "Arial", sans-serif;
  border: 1px solid black;
}

h2 {
  margin: 0;
  font-weight: normal;
  font-size: 1.1rem;
  text-align: center;
  letter-spacing: 1px;
}

p {
  font-size: 0.8rem;
}
```

In the CSS, we use flexbox to center the child elements inside the `<section>`, and set the `width` and `height` of the `<section>` to `calc-size()` functions. The `width` is set equal to `fit-content` plus `6rem`. The `height` is set to `auto` multiplied by two.

```
section {
  display: flex;
  flex-direction: column;
  justify-content: center;
  align-items: center;

  width: calc-size(fit-content, size + 6rem);
  height: calc-size(auto, size * 2);
}
```

The rest of the CSS has been hidden for brevity.

Result

We've created some horizontal and vertical space for the text to be centered in, without the use of padding.

Basic <code>calc-size</code> animations

This example demonstrates how to use `calc-size()` to animate between a specific size and an intrinsic size. The demo features a character badge/"name tag", which can be hovered or focused to reveal information about the character. The reveal is handled by a `height` transition between a set length and `max-content`.

HTML

The HTML contains a single `<section>` element with `tabindex="0"` set on it so it can receive keyboard focus. The `<section>` contains `<header>` and `<main>` elements, each with their own child content.

```
<section tabindex="0">
  <header>
    <h2>Chris Mills</h2>
  </header>
  <main>
    <p>Chris is the silent phantom of MDN.</p>
    <ul>
      <li><strong>Height</strong>: 3.03m</li>
      <li><strong>Weight</strong>: 160kg</li>
      <li><strong>Tech Fu</strong>: 7</li>
      <li><strong>Bad Jokes</strong>: 9</li>
    </ul>
  </main>
</section>
```

CSS

```
* {
  box-sizing: border-box;
}

section {
  font-family: "Helvetica", "Arial", sans-serif;
  width: 175px;
  border-radius: 5px;
  background: #eeeeee;
  box-shadow:
    inset 1px 1px 4px rgb(255 255 255 / 0.5),
    inset -1px -1px 4px rgb(0 0 0 / 0.5);
}

header {
  padding: 10px;
  border-bottom: 2px solid #cccccc;
}

main {
  padding: 0.7rem;
}

h2 {
  margin: 0;
  font-weight: normal;
  font-size: 1.1rem;
  text-align: center;
  letter-spacing: 1px;
}

p,
li {
  font-size: 0.8rem;
  line-height: 1.5;
}

p {
  margin-top: 0;
}
```

In the CSS, we set the `<section>`'s `height` to `2.5rem` and `overflow` to `hidden` so only the `<header>` is shown by default, then specify a `transition` that animates the `<section>` `height` over 1 second during state changes. Finally, we set the `<section>` `height` to a `calc-size()` function call on `:hover` and `:focus`. The function return value is the equivalent of `max-content + 2rem`.

```
section {
  height: 2.5rem;
  overflow: hidden;
  transition: height ease 1s;
}

section:hover,
section:focus {
  height: calc-size(max-content, size + 2rem);
}
```

The rest of the CSS has been hidden for brevity.

Result

Try hovering over the `<section>` or focusing it via the keyboard — it will animate to its full height + 2rem, revealing all the content with 2rems of extra space at the bottom.

Adjusting reading width based on <code>fit-content</code>

This example shows a container with text inside it, and a button that can be clicked to make the container width narrower or wider depending on reading preference.

HTML

The HTML contains a single `<section>` element containing child text content, plus a `<button>` to change the `<section>` width.

```
<section class="easy-reader">
  <h2>Easy reader</h2>

  <p>
    Eius velit aperiam ipsa. Deleniti eum excepturi ut magni maxime maxime
    beatae. Dicta aperiam est laudantium ut illum facere qui officiis. Sunt
    deleniti quam id. Quis sunt voluptatem praesentium minima dolorum autem
    consequatur velit.
  </p>

  <p>
    Vitae ab incidunt velit aspernatur deleniti distinctio rerum. Et natus sed
    et quos mollitia quia quod. Quae officia ex ea. Ducimus ut voluptatem et et
    debitis. Quidem provident laboriosam exercitationem similique deleniti.
    Temporibus vel veniam mollitia magni unde a nostrum.
```

```
  </p>

  <button class="width-adjust">Narrower</button>
</section>
```

CSS

```
* {
  box-sizing: border-box;
}

body {
  width: 600px;
  margin: 0 auto;
}

section {
  margin-top: 20px;
  font-family: "Helvetica", "Arial", sans-serif;
  background: #eeeeee;
  border: 2px solid #cccccc;
  padding: 0 20px;
  position: relative;
}

p,
li {
  font-size: 0.8rem;
  line-height: 1.5;
}

button {
  position: absolute;
  top: 2px;
  right: 2px;
}
```

In the CSS, we set the `<section>`'s `width` to a default of `fit-content`. We then define two sets of `@keyframes`, `narrower`, which animates from `fit-content` to 70% of `fit-content` (calculated using `calc-size()`), and `wider`, which animates the same values but in the opposite direction. Finally, we attach those animations to two classes — `.narrower` and `.wider`. Each animation is defined to last one second and to keep the final state applied once finished.

```
section {
  width: fit-content;
}

@keyframes narrower {
  from {
    width: fit-content;
  }

  to {
    width: calc-size(fit-content, size * 0.7);
  }
}

@keyframes wider {
  from {
    width: calc-size(fit-content, size * 0.7);
  }

  to {
    width: fit-content;
  }
}

.narrower {
  animation: narrower 1s ease forwards;
}

.wider {
  animation: wider 1s ease forwards;
}
```

The rest of the CSS has been hidden for brevity.

JavaScript

The JavaScript provides a narrower/wider toggle that applies the relevant class to the `<section>` when the button is clicked:

```
const widthAdjustBtn = document.querySelector(".width-adjust");
const easyReader = document.querySelector(".easy-reader");

widthAdjustBtn.addEventListener("click", () => {
  if (easyReader.classList.length === 1) {
    easyReader.classList.add("narrower");
    widthAdjustBtn.textContent = "Wider";
  } else if (easyReader.classList.contains("wider")) {
    easyReader.classList.replace("wider", "narrower");
    widthAdjustBtn.textContent = "Wider";
  } else if (easyReader.classList.contains("narrower")) {
    easyReader.classList.replace("narrower", "wider");
    widthAdjustBtn.textContent = "Narrower";
  }
});
```

Result

Try clicking the `<button>` a few times to adjust the `<section>` between the wide and narrow reading width, achieved by manipulating the `width` based on the `fit-content` value.

Using a function inside the <code>calc-size()</code> function

As mentioned earlier, it is possible to use another function inside `calc-size()`. This example sets `field-sizing: content` on `<input>` elements to make them as wide as the entered content, and then uses a `max()` function inside `calc-size()` to ensure that the `<input>`s are at least a minimum size, and only start to grow when the entered text becomes wider than that size — by being set to `fit-content` plus `20px`.

HTML

The HTML contains a `<form>` element containing three textual `<input>` types. Each `<input>` has a `<label>` associated with it to make the form accessible, and a `maxlength` applied to stop entered values getting long enough to break the form layout.

```
<form>
  <div>
    <label for="name">Name:</label>
    <input type="text" id="name" name="name" maxlength="48" />
  </div>
  <div>
    <label for="email">Email:</label>
    <input type="email" id="email" name="email" maxlength="48" />
  </div>
  <div>
    <label for="address">Address:</label>
    <input type="text" id="address" name="address" maxlength="60" />
  </div>
</form>
```

CSS

```
* {
  box-sizing: border-box;
}

body {
  width: 600px;
  margin: 0 auto;
}

form {
  margin-top: 20px;
  padding: 20px;
  font-family: "Helvetica", "Arial", sans-serif;
  background: #eeeeee;
  border: 2px solid #cccccc;
}

div {
  display: flex;
  align-items: center;
}

div:not(div:last-child) {
  margin-bottom: 20px;
}
```

In the CSS, we set the `width` of the `<label>` elements to `100px`. We set `field-sizing: content` on the `<input>` elements to make them as wide as the entered content — by default they would no width because nothing would be entered into them. To counteract this, we set their `width` values to `calc-size(fit-content, max(100px, size + 20px))`. This means that they are a minimum of `100px` wide, even with no value entered. When an entered value becomes wider than `100px`, their `width` changes to `fit-content` plus `20px`, which means they start to grow with the content size but keep a `20px` gap on the right-hand side.

```
label {
  width: 100px;
}

input {
  field-sizing: content;
  width: calc-size(fit-content, max(100px, size + 20px));
}
```

The rest of the CSS has been hidden for brevity.

Result

Try entering some text inside the form inputs, and see how they grow when the values start to become as wide as the minimum width enforced by the `max()` function.

<calc-sum> CSS type

The **`<calc-sum>`** CSS data type represents an expression which performs a calculation in any CSS math function. The expression executes a basic arithmetic operation of addition and subtraction between two values.

Syntax

The `<calc-sum>` type defines two numeric values and one of the following arithmetic operators between them.

`+`

Adds two numbers together.

`-`

Subtracts the right number from the left.

Formal syntax

```
<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*
```

```
<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Description

The operands in the expression may be any `<length>` syntax value. You can use `<length>`, `<frequency>`, `<angle>`, `<time>`, `<percentage>`, `<number>`, or `<integer>`.

The two operands' types must be consistent. For lengths, you can't use `0` to mean `0px` (or another length unit). Instead, you must add an explicit unit: `margin-top: calc(0px + 20px);` is valid, while `margin-top: calc(0 + 20px);` is invalid. Percentage value types are resolved based on the context. For example, `margin-top: calc(50% + 20px);` is valid because `margin-top` resolves percentages to lengths.

Including CSS variables in `calc-sum` expressions is also allowed. The following code `calc(10px + var(--variable))`, is a valid expression.

The `+` and `-` operators **must be surrounded by whitespace**. For instance, `calc(50% -8px)` will be parsed as "a percentage followed by a negative length" — which is an invalid expression — while `calc(50% - 8px)` is "a percentage followed by a subtraction operator and a length". Likewise, `calc(8px + -50%)` is treated as "a length followed by an addition operator and a negative percentage".

clamp() CSS function

The **`clamp()`** CSS function clamps a value within a range of values between a defined minimum bound and a maximum bound. The function takes three parameters: a minimum value, a preferred value, and a maximum allowed value.

Try it

```
font-size: clamp(1rem, 2.5vw, 2rem);
```

```
font-size: clamp(1.5rem, 2.5vw, 4rem);
```

```
font-size: clamp(1rem, 10vw, 2rem);
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    The font-size of this text varies depending on the base font of the page,
    and the size of the viewport.
  </div>
</section>
```

Note that using `clamp()` for font sizes, as in these examples, allows you to set a font-size that grows with the size of the viewport, but doesn't go below a minimum font-size or above a maximum font-size. It has the same effect as the code in Fluid Typography but in one line, and without the use of media queries.

Syntax

```
/* Static values */
width: clamp(200px, 40%, 400px);
width: clamp(20rem, 30vw, 70rem);
width: clamp(10vw, 20em, 100vw);

/* Calculated values */
width: clamp(min(10vw, 20rem), 300px, max(90vw, 55rem));
width: clamp(100px, calc(30% / 2rem + 10px), 900px);
```

Parameters

The `clamp(min, val, max)` function accepts three comma-separated expressions as its parameters.

`min`

The minimum value is the smallest (most negative) value. This is the lower bound in the range of allowed values. If the preferred value is less than this value, the minimum value will be used.

`val`

The preferred value is the expression whose value will be used as long as the result is between the minimum and maximum values.

`max`

The maximum value is the largest (most positive) expression value to which the value of the property will be assigned if the preferred value is greater than this upper bound.

The expressions can be math functions (see `calc()` for more information), literal values, other expressions that evaluate to a valid argument type (like `<length>`), or nested `min()` and `max()` functions. For math expressions, you can use addition, subtraction, multiplication, and division without using the `calc()` function itself. You may also use parentheses to establish computation order when needed.

You can use different units for each value in your expressions and different units in any math function making up any of the arguments.

Keep the following aspects in mind while working with the function:

- Math expressions involving percentages for widths and heights on table columns, table column groups, table rows, table row groups, and table cells in both auto and fixed layout tables *may* be treated as if `auto` had been specified.
- It is permitted to nest `max()` and `min()` functions as expression values, in which case the inner ones are treated as basic parentheses. The expressions are full math expressions, so you can use direct addition, subtraction, multiplication and division without using the `calc()` function itself.

- The expression can be values combining the addition (+), subtraction (-), multiplication (*), and division (/) operators, using standard operator precedence rules. Make sure to put a space on each side of the + and - operands. You can use different units for each value in your expression. You may also use parentheses to establish computation order when needed.
- Oftentimes you will want to use `min()` and `max()` within a `clamp()` function.

Return value

`clamp(MIN, VAL, MAX)` is resolved as `max(MIN, min(VAL, MAX))`.

Based on the provided parameters, the function returns `<length>`, `<frequency>`, `<angle>`, `<time>`, `<percentage>`, `<number>`, or `<integer>`.

Formal syntax

```
<clamp()> =
  clamp( [ <calc-sum> | none ] , <calc-sum> , [ <calc-sum> | none ] )

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

min(), max(), and clamp() comparison

In this example we have a web page that uses `min()`, `max()`, and `clamp()` to set sizes responsively.

The example adjusts the sizes of page elements in three ways:

- the lengths of the lines of text
- the font size of paragraph text
- the font size of heading text

In all three cases, the page uses a combination of a viewport-relative units (`vw` and `<percentage>`), to set a size that varies with the viewport width, and a value that is not viewport relative (`rem` and `px`) to implement minimum and/or maximum sizes.

The example is at https://mdn.github.io/css-examples/min-max-clamp/. Open it in a new window and try adjusting the window width.

The **line length** (controlled by the `width` of the `<body>` element) will increase as the window width increases, but only up to a certain point (`1000px`), and beyond that point, it won't increase anymore. We're using `min()` to set a **maximum line length**: it can go under `1000px`, but won't go over. This is helpful because long lines are harder to read, so we often want to limit how long a line can be. To achieve this we use `min(1000px, calc(70% + 100px))`: when the result of the percentage-based calculation goes above `1000px`, we switch to the fixed `1000px` value.

The **size of the paragraph text**, controlled by the `font-size` of the `<p>` element, decreases as the window gets narrower, but only up to a certain point, and beyond that point (the point where `1.2vw` is less than `1.2rem`) it doesn't get any smaller: it stays at `1.2rem`. We're using `max()` to set a **minimum font size**: the font can grow above `1.2rem` but will never go below it. This is helpful because really small text is hard to read. To achieve this we use `max(1.2rem, 1.2vw)`. This means that the `font-size` will be set at `1.2rem`, unless the computed value of `1.2vw` is greater than that of `1.2rem`, in which case it will be set to `1.2vw` instead.

The **size of the heading text**, controlled by the `font-size` of the `<h1>` element, has a viewport-relative value with both a maximum and a minimum threshold. To achieve this we use `clamp(1.8rem, 2.5vw, 2.8rem)`. The viewport-relative value is `2.5vw` but it is clamped between `1.8rem` and `2.8rem`, so:

- if the calculated value of `2.5vw` is less than `1.8rem`, then `1.8rem` will be used
- if the calculated value of `2.5vw` is greater than `2.8rem`, then `2.8rem` will be used.

This prevents the heading text from getting too small in a very narrow window, or too big in a very wide window.

HTML

```
<h1>Basic responsive test</h1>

  ad litora torquent per conubia nostra, per inceptos himenaeos. Nam non felis
  quis sem lobortis sodales vel id libero. Phasellus sit amet placerat lorem.
</p>
```

CSS

```
html {
  font-family: sans-serif;
}
```

```
body {
  margin: 0 auto;
  width: min(1000px, calc(70% + 100px));
}

h1 {
  letter-spacing: 2px;
  font-size: clamp(1.8rem, 2.5vw, 2.8rem);
}

p {
  line-height: 1.5;
  font-size: max(1.2rem, 1.2vw);
}
```

Accessibility

When `clamp()` is used for controlling text size, make sure that the maximum allowed value is a relative length unit that is no less than twice the minimum allowed value, for example:

```
font-size: clamp(1rem, 2.5vw, 2rem);
```

This helps to ensure that text size can scale to at least 200% if the page is zoomed.

<color> CSS type

The **`<color>`** CSS data type represents a color. A `<color>` may also include an alpha-channel *transparency value*, indicating how the color should composite with its background.

> **Note:** Although `<color>` values are precisely defined, their actual appearance may vary (sometimes significantly) from device to device. This is because most devices are not calibrated, and some browsers do not support output devices' color profiles.

Syntax

```
/* Named colors */
rebeccapurple
aliceblue

/* RGB Hexadecimal */
#f09
#ff0099

/* RGB (Red, Green, Blue) */
rgb(255 0 153)
rgb(255 0 153 / 80%)

/* HSL (Hue, Saturation, Lightness) */
hsl(150 30% 60%)
hsl(150 30% 60% / 80%)

/* HWB (Hue, Whiteness, Blackness) */
hwb(12 50% 0%)
hwb(194 0% 0% / 0.5)

/* Lab (Lightness, A-axis, B-axis) */
lab(50% 40 59.5)
lab(50% 40 59.5 / 0.5)

/* LCH (Lightness, Chroma, Hue) */
lch(52.2% 72.2 50)
lch(52.2% 72.2 50 / 0.5)

/* Oklab (Lightness, A-axis, B-axis) */
oklab(59% 0.1 0.1)
oklab(59% 0.1 0.1 / 0.5)

/* OkLCh (Lightness, Chroma, Hue) */
oklch(60% 0.15 50)
oklch(60% 0.15 50 / 0.5)

/* Relative CSS colors */
/* HSL hue change */
hsl(from red 240deg s l)
/* HWB alpha channel change */
hwb(from green h w b / 0.5)
/* LCH lightness change */
lch(from blue calc(l + 20) c h)

/* light-dark */
light-dark(white, black)
light-dark(rgb(255 255 255), rgb(0 0 0))
```

A `<color>` value can be specified using one of the methods listed below:

- By keywords: `<named-color>` (such as `blue` or `pink`), `<system-color>`, and `currentColor`.
- By hexadecimal notations: `<hex-color>` (such as `#ff0000`).
- By `<color-function>`, with parameters in a color space using functional notations:
  - sRGB color space: `hsl()`, `hwb()`, and `rgb()`.
  - CIELAB color space: `lab()` and `lch()`.

    - Oklab color space: `oklab()` and `oklch()`.
    - Other color spaces: `color()`, `device-cmyk()`.
- By using relative color syntax to output a new color based on an existing color. Any of the above color functions can take an **origin color** preceded by the `from` keyword and followed by definitions of the channel values for the new **output color**.
- By mixing two colors: `color-mix()`.
- By specifying a color that you want a contrasting color returned for: `contrast-color()`.
- By specifying two colors, using the first for light color-schemes and the second for dark color-schemes: `light-dark()`.

<code>currentColor</code> keyword

The `currentColor` keyword represents the value of an element's `color` property. This lets you use the `color` value on properties that do not receive it by default.

If `currentColor` is used as the value of the `color` property, it instead takes its value from the inherited value of the `color` property.

```
<div class="container">
  The color of this text is blue.
  <div class="child"></div>
  This block is surrounded by a blue border.
</div>
```

```
.container {
  color: blue;
  border: 1px dashed currentColor;
}
.child {
  background: currentColor;
  height: 9px;
}
```

Missing color components

Each component of any CSS color functions - except for those using the legacy comma-separated syntax - can be specified as the keyword `none` to be a missing component.

Explicitly specifying missing components in color interpolation is useful for cases where you would like to interpolate some color components but not others. For all other purposes, a missing component will effectively have a zero value in an appropriate unit: `0`, `0%`, or `0deg`. For example, the following colors are equivalent when used outside of interpolation:

```
/* These are equivalent */
color: oklab(50% none -0.25);
color: oklab(50% 0 -0.25);

/* These are equivalent */
background-color: hsl(none 100% 50%);
background-color: hsl(0deg 100% 50%);
```

Interpolation

Color interpolation happens with gradients, transitions, and animations.

When interpolating `<color>` values, they are first converted to a given color space, and then each component of the computed values are interpolated linearly, with interpolation's speed being determined by the easing function in transitions and animations. The interpolation color space defaults to Oklab, but can be overridden through `<color-interpolation-method>` in some color-related functional notations.

Interpolation with missing components

Interpolating colors in the same space

When interpolating colors that are exactly in the interpolation color space, missing components from one color are replaced with existing values of the same components from the other color. For example, the following two expressions are equivalent:

```
color-mix(in oklch, oklch(none 0.2 10), oklch(60% none 30))
color-mix(in oklch, oklch(60% 0.2 10), oklch(60% 0.2 30))
```

> **Note:** If a component is missing from both colors, this component will be missing after the interpolation.

Interpolating colors from different spaces: analogous components

If any color to be interpolated is not in the interpolation color space, its missing components are transferred into the converted color based on **analogous components** of the same category as described in the following table:

Category	Analogous components
Reds	`R`, `X`
Greens	`G`, `Y`
Blues	`B`, `Z`
Lightness	`L`
Colorfulness	`C`, `S`
Hue	`H`
a	`a`
b	`b`

For example:

- `X` (`0.2`) in `color(xyz 0.2 0.1 0.6)` is analogous to `R` (`50%`) in `rgb(50% 70% 30%)`.
- `H` (`0deg`) in `hsl(0deg 100% 80%)` is analogous to `H` (`140`) in `oklch(80% 0.1 140)`.

Using OkLCh as the interpolation color space and the two colors below as an example:

```
lch(80% 30 none)
color(display-p3 0.7 0.5 none)
```

The preprocessing procedure is:

1. Replace the missing components in both colors with a zero value:

```
lch(80% 30 0)
color(display-p3 0.7 0.5 0)
```

2. Convert both colors into the interpolation color space:

```
oklch(83.915% 0.0902 0.28)
oklch(63.612% 0.1522 78.748)
```

3. If any component of the converted colors is analogous to a missing component in the corresponding original color, reset it as a missing component:

```
oklch(83.915% 0.0902 none)
oklch(63.612% 0.1522 78.748)
```

4. Replace any missing component with the same component from the other converted color:

```
oklch(83.915% 0.0902 78.748)
oklch(63.612% 0.1522 78.748)
```

Accessibility

Some people have difficulty distinguishing colors. The WCAG 2.2 recommendation strongly advises against using color as the only means of conveying a specific message, action, or result. See color and color contrast for more information.

Examples

Exploring color values

In this example, we provide a `<div>` and a text input. Entering a valid color into the input causes the `<div>` to adopt that color, allowing you to test our color values.

HTML

```
<div></div>
<hr />
<label for="color">Enter a valid color value:</label>
<input type="text" id="color" />
```

```
div {
  height: 200px;
  width: 200px;
}
```

```
const inputElem = document.querySelector("input");
const divElem = document.querySelector("div");

function validTextColor(stringToTest) {
  if (stringToTest === "inherit" || stringToTest === "transparent") {
    return false;
  }

  const div = document.createElement("div");
  div.style.color = stringToTest;
  return !!div.style.color;
}

inputElem.addEventListener("input", () => {
  if (validTextColor(inputElem.value)) {
    divElem.style.backgroundColor = inputElem.value;
    divElem.textContent = "";
  } else {
    divElem.removeAttribute("style");
    divElem.textContent = "Invalid color value";
  }
});
```

Result

Generating fully saturated sRGB colors

This example shows fully saturated sRGB colors in the sRGB color space.

HTML

```
<div></div>
<div></div>
<div></div>
<div></div>
<div></div>
<div></div>
<div></div>
<div></div>
<div></div>
<div></div>
<div></div>
<div></div>
```

CSS

```
body {
  display: flex;
  flex-wrap: wrap;
}
div {
  height: 80px;
  margin: 10px;
  width: 80px;
}
```

```
div:nth-child(1) {
  background-color: hsl(0 100% 50%);
}
div:nth-child(2) {
  background-color: hsl(30 100% 50%);
}
div:nth-child(3) {
  background-color: hsl(60 100% 50%);
}
div:nth-child(4) {
  background-color: hsl(90 100% 50%);
}
div:nth-child(5) {
  background-color: hsl(120 100% 50%);
}
div:nth-child(6) {
  background-color: hsl(150 100% 50%);
}
div:nth-child(7) {
  background-color: hsl(180 100% 50%);
}
div:nth-child(8) {
  background-color: hsl(210 100% 50%);
}
div:nth-child(9) {
  background-color: hsl(240 100% 50%);
}
```

```
div:nth-child(10) {
  background-color: hsl(270 100% 50%);
}
div:nth-child(11) {
  background-color: hsl(300 100% 50%);
}
div:nth-child(12) {
  background-color: hsl(330 100% 50%);
}
```

Result

Creating different shades of red

This example shows reds of different shades in the sRGB color space.

HTML

```
<div></div>
<div></div>
<div></div>
<div></div>
<div></div>
<div></div>
```

CSS

```
body {

alpha() CSS function

The **`alpha()`** CSS function takes an origin `color` and returns that same color with a modified alpha (transparency) channel. The color components of the origin color are preserved unchanged. The result is in the same color space as the origin color.

Syntax

```
/* Replace alpha with a fixed value */
alpha(from red / 50%)
alpha(from var(--my-color) / 80%)

/* Derive alpha relative to the origin color's alpha */
alpha(from var(--my-color) / calc(alpha * 0.5))
```

Parameters

`from <color>`

> The relative color syntax keyword `from` followed by any valid `<color>` value, defining the **origin color**. The color components of the origin color are carried through to the result unchanged; only the alpha channel is affected.

`/ <alpha-value>`

> An `<alpha-value>` specifying the alpha of the output color. This can be a `<number>` between `0` and `1`, a `<percentage>` between `0%` and `100%`, or a `calc()` expression. Within this value, the keyword **`alpha`** may be used to refer to the alpha channel of the origin color as a `<number>` (where `1.0` is equivalent to `100%`).

Return value

A color value in the same color space as the origin color, with identical color components and a modified alpha channel value as specified.

Description

The `alpha()` function is a relative color function that lets you adjust the transparency of any color without rewriting its other components. This is particularly useful when you need a semi-transparent variant of a design token or custom property color, and you want to derive it automatically from the original rather than maintaining a separate value.

Within the alpha value argument, the component keyword `alpha` resolves to the alpha channel of the origin color as a `<number>` in the range `[0, 1]`. This allows you to express the output alpha relative to the input, for example halving it with `calc(alpha * 0.5)`, or clamping it with `clamp(0.2, alpha, 0.8)`.

Unlike general relative color syntax (e.g., `oklch(from ...)`), the `alpha()` function does not expose the individual color channel keywords of the origin color space. It is solely concerned with the alpha channel, keeping the rest of the color intact.

The return value is always in the same color space as the origin color. For example, if the origin color is an `oklch()` color, the result will also be resolved in OKLCh, with the same lightness, chroma, and hue.

Formal syntax

```
&lt;alpha()&gt; =
  alpha( [ from &lt;color&gt; ] [ / [ &lt;alpha-value&gt; | none ] ]? )

&lt;alpha-value&gt; =
  &lt;number&gt;      |
  &lt;percentage&gt;
```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Color Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Replacing the alpha of a color

In this example, we specify two colors. The second color is defined by passing the first color into the `alpha()` function, setting its alpha channel to a fixed value of `80%` in the process. The two colors are set as the `background-color` of two `<div>` elements to demonstrate the difference.

```
<div class="box1">Original</div>
<div class="box2">Fixed 80% alpha</div>
```

```
:root {
  --my-color: oklch(60% 0.25 315 / 0.3);

  /* Same color, but with alpha set to 80% */
  --my-color-80: alpha(from var(--my-color) / 80%);
}

.box1 {
  background-color: var(--my-color);
}

.box2 {
  background-color: var(--my-color-80);
}
```

```
body {
  font-family: sans-serif;
  display: flex;
  gap: 10%;
  justify-content: center;
```

```
}

div {
  width: 40%;
  height: 100px;
  display: flex;
  justify-content: center;
  align-items: center;
}
```

Deriving a semi-transparent variant

This example is very similar to the previous one, except that this time the alpha of the second color is computed as half of the first color's alpha, using the `alpha` component keyword inside a `calc()` expression.

```
<div class="box1">Original</div>
<div class="box2">Derived 50% alpha</div>
```

```
:root {
  --my-color: oklch(60% 0.25 315 / 0.8);

  /* Half the opacity of --my-color */
  --my-color-half-opacity: alpha(from var(--my-color) / calc(alpha * 0.5));
}

.box1 {
  background-color: var(--my-color);
}

.box2 {
  background-color: var(--my-color-half-opacity);
}
```

Fading a color on hover

In this example, an element's background fades to `40%` opacity on `:hover`, while the color itself stays the same.

```
<button class="card">Hover over me</button>
```

```
:root {
  --brand: oklch(55% 0.22 270);
}

.card {
  background-color: var(--brand);
  color: white;
  padding: 1rem 2rem;
  border: none;
  border-radius: 0.5rem;
  font-size: 1.1rem;
  cursor: pointer;
  transition: background-color 0.3s;
}

.card:hover {
  background-color: alpha(from var(--brand) / 40%);
}
```

```
body {
  padding: 2rem;
}
```

```
@supports not (color: alpha(from red / 50%)) {
  body::before {
    font-family: sans-serif;
    content: "Your browser does not support the CSS alpha() function.";
    background-color: wheat;
    padding: 1rem 0;
    text-align: center;

    z-index: 1;
    position: fixed;
    inset: 30% 0 auto;
  }
}
```

color() CSS function

The **`color()`** functional notation allows a color to be specified in a particular, specified color space rather than the implicit sRGB color space that most of the other color functions operate in.

Support for a particular color space can be detected with the `color-gamut` CSS media feature.

Syntax

```
/* Absolute values */
color(display-p3 1 0.5 0);
color(display-p3 1 0.5 0 / .5);

/* Relative values */
color(from green srgb r g b / 0.5)
color(from #123456 xyz calc(x + 0.75) y calc(z - 0.35))
```

Values

Below are descriptions of the allowed values for both absolute and relative colors.

Absolute value syntax

```
color(colorspace c1 c2 c3[ / A])
```

The parameters are as follows:

`colorspace`

An `<ident>` denoting one of the predefined color spaces: `srgb`, `srgb-linear`, `display-p3`, `display-p3-linear`, `a98-rgb`, `prophoto-rgb`, `rec2020`, `xyz`, `xyz-d50`, or `xyz-d65`.

`c1`, `c2`, `c3`

Each value can be written as a `<number>`, a `<percentage>`, or the keyword `none` (equivalent to `0` in this case). These values represent the component values for the colorspace. When using a `<number>` value, generally, `0` to `1` represents the bounds of the color space. Values outside of that range are permitted but will be out of gamut for the given color space. When using a percentage value, `100%` represents `1` and `0%` represents `0`.

`A` Optional

An `<alpha-value>` representing the alpha channel value of the color, where the number `0` corresponds to `0%` (fully transparent) and `1` corresponds to `100%` (fully opaque). Additionally, the keyword `none` can be used to explicitly specify no alpha channel. If the `A` channel value is not explicitly specified, it defaults to 100%. If included, the value is preceded by a slash (`/`).

> **Note:** See Missing color components for more information on the effect of `none`.

Relative value syntax

```
color(from <color> colorspace c1 c2 c3[ / A])
```

The parameters are as follows:

`from <color>`

The keyword `from` is always included when defining a relative color, followed by a `<color>` value representing the **origin color**. This is the original color that the relative color is based on. The origin color can be *any* valid `<color>` syntax, including another relative color.

`colorspace`

An `<ident>` denoting the color space of the output color, generally one of the predefined color spaces: `srgb`, `srgb-linear`, `display-p3`, `display-p3-linear`, `a98-rgb`, `prophoto-rgb`, `rec2020`, `xyz`, `xyz-d50`, or `xyz-d65`.

`c1`, `c2`, `c3`

Each value can be written as a `<number>`, a `<percentage>`, or the keyword `none` (equivalent to `0` in this case). These values represent the component values for the output color. When using a `<number>` value, generally `0` to `1` represents the bounds of the color space. Values outside of that range are permitted but will be out of gamut for the given color space. Generally, when using a percentage value, `100%` represents `1` and `0%` represents `0`.

`A` Optional

An `<alpha-value>` representing the alpha channel value of the output color, where the number `0` corresponds to `0%` (fully transparent) and `1` corresponds to `100%` (fully opaque). Additionally, the keyword `none` can be used to explicitly specify no alpha channel. If the `A` channel value is not explicitly specified, it defaults to the alpha channel value of the origin color. If included, the value is preceded by a slash (`/`).

Defining relative color output channel components

When using relative color syntax inside a `color()` function, the browser converts the origin color into an equivalent color in the specified color space (if it is not already specified as such). The color is defined as three distinct color channel values plus an alpha channel value (`alpha`). These channel values are made available inside the function to be used when defining the output color channel values:

- The three color channel values of the origin color are resolved to a `<number>`. For predefined color spaces, depending on which is specified, these values will be one of the following:
  - `r`, `g`, and `b`: Color channel values for the RGB-based color spaces `srgb`, `srgb-linear`, `display-p3`, `display-p3-linear`, `a98-rgb`, `prophoto-rgb`, and `rec2020`.
  - `x`, `y`, and `z`: Color channel values for the CIE XYZ-based color spaces `xyz`, `xyz-d50`, and `xyz-d65`.

    > **Note:** Each of these values is usually between `0` and `1` but, as explained above, they may be outside these bounds.

    > **Note:** Referencing `r`, `g`, and `b` values inside a `color()` function with an XYZ-based colorspace, `x`, `y`, and `z` values inside a `color()` function with an RGB-based colorspace, or any other characters, is invalid. The origin color channel values available inside the function must match the specified type of colorspace.
- `alpha`: The color's transparency value, resolved to a `<number>` between `0` and `1`, inclusive.

When defining a relative color, the different channels of the output color can be expressed in several different ways. Below, we'll study some examples to illustrate these.

In the first two examples below, we are using relative color syntax. However, the first one outputs the same color as the origin color and the second one outputs a color not based on the origin color at all. They don't really create relative colors! You'd be unlikely to ever use these in a real codebase, and would probably just use an absolute color value instead. We included these examples as a starting point for learning about relative `color()` syntax.

Let's start with an origin color of `hsl(0 100% 50%)` (equivalent to `red`). While you are unlikely to ever write the following functions because they output the same color as the origin color, this demonstrates how to use the origin color channel values as the output channel values:

```
color(from hsl(0 100% 50%) srgb r g b)
color(from hsl(0 100% 50%) xyz x y z)
```

These functions' output colors are `color(srgb 1 0 0)` and `color(xyz-d65 0.412426 0.212648 0.0193173)`, respectively.

The next functions use absolute values for the output color channel values, outputting completely different colors not based on the origin color:

```
color(from hsl(0 100% 50%) srgb 0.749938 0 0.609579)
/* Computed output color: color(srgb 0.749938 0 0.609579) */

color(from hsl(0 100% 50%) xyz 0.75 0.6554 0.1)
/* Computed output color: color(xyz-d65 0.75 0.6554 0.1 */
```

The following functions use two of the origin color channel values for the output color channel values (`r` and `b`, and `x` and `y`, respectively), but use a new value for the other output channel value (`g` and `z`, respectively), creating a relative color based on the origin color in each case:

```
color(from hsl(0 100% 50%) srgb r 1 b)
/* Computed output color: color(srgb 1 1 0) */

color(from hsl(0 100% 50%) xyz x y 0.5)
/* Computed output color: color(xyz-d65 0.412426 0.212648 0.5) */
```

> **Note:** As mentioned above, if the output color is using a different color model to the origin color, the origin color is converted to the same model as the output color in the background so that it can be represented in a way that is compatible (i.e., using the same channels). For example, the `hsl()` color `hsl(0 100% 50%)` is converted to `color(srgb 1 0 0)` in the first case above and `color(xyz 0.412426 0.212648 0.5)` in the second case.

In the examples we've seen so far in this section, the alpha channels have not been explicitly specified for either the origin or output colors. When the output color alpha channel is not specified, it defaults to the same value as the origin color alpha channel. When the origin color alpha channel is not specified (and it is not a relative color), it defaults to `1`. Therefore, the origin and output alpha channel values are `1` for the above examples.

Let's look at some examples that specify origin and output alpha channel values. The first one specifies the output alpha channel value as being the same as the origin alpha channel value, whereas the second one specifies a different output alpha channel value, unrelated to the origin alpha channel value.

```
color(from hsl(0 100% 50% / 0.8) srgb r g b / alpha)
/* Computed output color: color(srgb 1 0 0 / 0.8) */

color(from hsl(0 100% 50% / 0.8) xyz x y z / 0.5)
/* Computed output color: color(xyz-d65 0.412426 0.212648 0.0193173 / 0.5) */
```

The following examples use `calc()` functions to calculate new channel values for the output colors that are relative to the origin color channel values:

```
color(from hsl(0 100% 50%) srgb calc(r - 0.4) calc(g + 0.1) calc(b + 0.6) / calc(alpha - 0.1))
/* Computed output color: color(srgb 0.6 0.1 0.6 / 0.9)  */

color(from hsl(0 100% 50%) xyz calc(x - 0.3) calc(y + 0.3) calc(z + 0.3) / calc(alpha - 0.1))
/* Computed output color: color(xyz-d65 0.112426 0.512648 0.319317 / 0.9) */
```

> **Note:** Because the origin color channel values are resolved to `<number>` values, you have to add numbers to them when using them in calculations, even in cases where a channel would normally accept `<percentage>`, `<angle>`, or other value types. Adding a `<percentage>` to a `<number>`, for example, doesn't work.

Formal syntax

```
<color()> =
  color( [ from <color> ]? <colorspace-params> [ / [ <alpha-value> | none ] ]? )

<colorspace-params> =
  <custom-params>          |
  <predefined-rgb-params>  |
  <xyz-params>

<alpha-value> =
  <number>      |
  <percentage>

<custom-params> =
  <dashed-ident> [ <number> | <percentage> | none ]+

<predefined-rgb-params> =
  <predefined-rgb> [ <number> | <percentage> | none ]{3}

<xyz-params> =
  <xyz-space> [ <number> | <percentage> | none ]{3}

<predefined-rgb> =
  srgb               |
  srgb-linear        |
  display-p3         |
  display-p3-linear  |
  a98-rgb            |
  prophoto-rgb       |
  rec2020            |
  rec2100-pq         |
  rec2100-hlg        |
  rec2100-linear

<xyz-space> =
  xyz      |
  xyz-d50  |
  xyz-d65
```

This syntax reflects the latest standard as per CSS Color HDR Module Level 1, CSS Color Module Level 4, CSS Color Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using predefined color spaces with color()

The following example shows the effect of varying the lightness, a-axis, and b-axis values of the `color()` function.

HTML

```
<div data-color="red-a98-rgb"></div>
<div data-color="red-prophoto-rgb"></div>
<div data-color="green-srgb-linear"></div>
<div data-color="green-display-p3"></div>
<div data-color="green-display-p3-linear"></div>
<div data-color="blue-rec2020"></div>
<div data-color="blue-srgb"></div>
```

CSS

```
div {
  width: 50px;
  height: 50px;
  padding: 5px;
  margin: 5px;
  display: inline-block;
  border: 1px solid black;
}
```

```
[data-color="red-a98-rgb"] {
  background-color: color(a98-rgb 1 0 0);
}
[data-color="red-prophoto-rgb"] {
  background-color: color(prophoto-rgb 1 0 0);
}
/* sRGB gamut, linear-light — full brightness (green channel 100%) */
[data-color="green-srgb-linear"] {
  background-color: color(srgb-linear 0 1 0);
}
/* P3 gamut (wider), gamma-encoded — low brightness (green channel ~21% light output) */
[data-color="green-display-p3"] {
  background-color: color(display-p3 0 0.5 0);
}
/* P3 gamut (wider), linear-light — half brightness (green channel at 50% light output) */
[data-color="green-display-p3-linear"] {
  background-color: color(display-p3-linear 0 0.5 0);
}
[data-color="blue-rec2020"] {
  background-color: color(rec2020 0 0 1);
}
[data-color="blue-srgb"] {
  background-color: color(srgb 0 0 1);
}
```

Result

Using the xyz color space with color()

The following example shows how to use the `xyz` color space to specify a color.

HTML

```
<div data-color="red"></div>
<div data-color="green"></div>
<div data-color="blue"></div>
```

CSS

```
div {
  width: 50px;
  height: 50px;
  padding: 5px;
  margin: 5px;
  display: inline-block;
  border: 1px solid black;
}
```

```
[data-color="red"] {
  background-color: color(xyz 45 20 0);
}

[data-color="green"] {
  background-color: color(xyz-d50 0.3 80 0.3);
}

[data-color="blue"] {
  background-color: color(xyz-d65 5 0 50);
}
```

Result

Using color-gamut media queries with color()

This example shows how to use the `color-gamut` media query to detect support for a particular color space and use that color space to specify a color.

HTML

```
<div></div>
<div></div>
<div></div>
```

CSS

```
div {
  width: 50px;
  height: 50px;
  padding: 5px;
  margin: 5px;
  display: inline-block;
  border: 1px solid black;
}
```

```
@media (color-gamut: p3) {
  div {
    background-color: color(display-p3 1 0 0);
  }
}

@media (color-gamut: srgb) {
```

```
  div:nth-child(2) {
    background-color: color(srgb 1 0 0);
  }
}

@media (color-gamut: rec2020) {
  div:nth-child(3) {
    background-color: color(rec2020 1 0 0);
  }
}
```

Result

Using relative colors with color()

This example styles three `<div>` elements with different background colors. The middle one is given the unmodified `--base-color`, while the left and right ones are given lightened and darkened variants of that `--base-color`.

These variants are defined using relative colors — the `--base-color` custom property is passed into a `color()` function, and the output colors have their `g` and `b` channels modified to achieve the desired effect via `calc()` functions. The lightened color has 15% added to those channels, and the darkened color has 15% subtracted from those channels.

```
<div id="container">
  <div class="item" id="one"></div>
  <div class="item" id="two"></div>
  <div class="item" id="three"></div>
</div>
```

CSS

```
#container {
  display: flex;
  width: 100vw;
  height: 100vh;
  box-sizing: border-box;
}

.item {
  flex: 1;
  margin: 20px;
}
```

```
:root {
  --base-color: orange;
}

#one {
  background-color: color(
    from var(--base-color) display-p3 r calc(g + 0.15) calc(b + 0.15)
  );
}

#two {
  background-color: var(--base-color);
}

#three {
  background-color: color(
    from var(--base-color) display-p3 r calc(g - 0.15) calc(b - 0.15)
  );
}

/* Use @supports to add in support old syntax that requires r g b values
   to be specified as percentages (with units) in calculations.
   This is required for Safari 16.4+ */
@supports (color: color(from red display-p3 r g calc(b + 30%))) {
  #one {
    background-color: color(
      from var(--base-color) display-p3 r calc(g + 15%) calc(b + 15%)
    );
  }

  #three {
    background-color: color(
      from var(--base-color) display-p3 r calc(g - 15%) calc(b - 15%)
    );
  }
}
```

Result

The output is as follows:

color-mix() CSS function

The **`color-mix()`** functional notation takes one or more `<color>` values and returns the result of mixing them in a given colorspace by a given amount.

Syntax

```
/* Polar color space */
color-mix(in hsl, hsl(200 50 80), coral)
color-mix(in hsl, hsl(200 50 80) 20%, coral 80%)

/* Rectangular color space */
color-mix(in srgb, plum, #123456)
color-mix(in lab, plum 60%, #123456 50%)

/* With hue interpolation method */
color-mix(in lch increasing hue, hsl(200deg 50% 80%), coral)
color-mix(in lch longer hue, hsl(200deg 50% 80%) 44%, coral 16%)

/* With a color argument list */
color-mix(in oklab, teal)
color-mix(in oklab, teal 20%, olive 30%, blue 50%)
color-mix(in oklab, teal, olive, blue, purple)
```

Parameters

The `color-mix( <color-interpolation-method>? , [ <color> && <percentage [0,100]>? ]#)` accepts the following parameters:

`<color-interpolation-method>` Optional

Specifies what interpolation method should be used to mix the colors. It consists of the `in` keyword followed by a color space (one of the color spaces listed in the formal syntax, defaulting to `oklab`), and, optionally, a `<hue-interpolation-method>`, which defaults to `shorter hue`.

`<color>`

A color to mix; can be any valid `<color>` value.

`<percentage>` Optional

A percentage value specifying the amount of the corresponding color to mix; can be any `<percentage>` value between `0%` and `100%`, inclusive.

Return value

A `<color>`; the result of mixing the colors, in the given `<color-space>`, in the specified amounts and hue direction.

Description

The `color-mix()` function enables mixing one or more `<color>` values of any type, in a specific ratio, in a given colorspace, using either a shorter or longer hue interpolation method. Browsers support a plethora of color spaces; the `color-mix()` function enables a wide range of colors to be mixed, not limited to the sRGB color space.

This demo allows you to select two colors, `color-one` and `color-two`, and mix them, optionally setting each color's percentage, the color space in which the colors are mixed, and the interpolation method. The source colors are shown on the outside, and the mixed color is shown in the middle. You can change colors by clicking on them and choosing a new color using the resulting color picker. Change the percentage values of each color using the sliders. Change the color space via the drop-down menu.

Choosing a color space

Choosing the correct color space is important for producing desired results. Given the same colors to mix, different color spaces may be more appropriate depending on the interpolation use case.

- If the result of physically mixing colored lights is desired, the CIE XYZ or srgb-linear color space is appropriate, because they are linear in light intensity.
- If colors need to be evenly spaced perceptually (such as in a gradient), the Oklab (and older Lab) color spaces are appropriate, because they are designed to be perceptually uniform.
- If avoiding graying out in color mixing is desired, i.e., maximizing chroma throughout the transition, the Oklch (and older LCH) color spaces work well.
- Only use sRGB if you need to match the behavior of a specific device or software that uses sRGB. The sRGB color space is neither linear-light nor perceptually uniform, and produces poorer results such as overly dark or grayish mixes.

Color interpolation method

The `<color-interpolation-method>` specifies what interpolation method should be used to mix the colors. It consists of the `in` keyword and the color space the colors should be mixed in. The color space must be one of the available color spaces listed in the formal syntax. Depending on the color space used, you can optionally direct the hue to be mixed along a longer or shorter path.

The `<rectangular-color-space>` category includes `srgb`, `srgb-linear`, `display-p3`, `a98-rgb`, `prophoto-rgb`, `rec2020`, `lab`, `oklab`, `xyz`, `xyz-d50`, and `xyz-d65`.

The `<polar-color-space>` category includes `hsl`, `hwb`, `lch`, and `oklch`. With these you can optionally follow the color space name with a `<hue-interpolation-method>`. This value defaults to `shorter hue`, but can also be set to `longer hue`, `increasing hue`, or `decreasing hue`.

Default color space and interpolation method

When mixing colors without specifying a color space, the `oklab` color space is used.

The following two declarations are equivalent:

```
background-color: color-mix(red, blue);
background-color: color-mix(in oklab, red, blue);
```

When using a polar color space such as `oklch`, the hue interpolation method defaults to `shorter hue`. The following two declarations are equivalent:

```
background-color: color-mix(in oklch, red, blue);
background-color: color-mix(in oklch shorter hue, red, blue);
```

Color percentages

Each color can be declared with a `<percentage>` value between `0%` and `100%`, which specifies the amount of the corresponding color to mix. The percentages are normalized if the total value of the declared percentages does not equal `100%`.

When two colors are being mixed, the two color percentages (we'll refer to them as `p1` and `p2`) are normalized as follows:

- If both `p1` and `p2` are omitted, then `p1 = p2 = 50%`.
- If `p1` is omitted, then `p1 = 100% - p2`.
- If `p2` is omitted, then `p2 = 100% - p1`.
- If `p1 = p2 = 0%`, the function is invalid.
- If `p1 + p2 ≠ 100%`, then `p1' = p1 / (p1 + p2)` and `p2' = p2 / (p1 + p2)`, where `p1'` and `p2'` are the normalization results.
    - If `p1 + p2 < 100%`, then an alpha multiplier of `p1 + p2` is applied to the resulting color. This is similar to mixing in `transparent`, with percentage `pt = 100% - p1 - p2`.

Formal syntax

```
<color-mix()> =
  color-mix( <color-interpolation-method>? , [ <color> && <percentage [0,100]>? ]# )

<color-interpolation-method> =
  in [ <rectangular-color-space> | <polar-color-space> <hue-interpolation-method>? | <custom-color-space> ]

<rectangular-color-space> =
  srgb              |
  srgb-linear       |
  display-p3        |
  display-p3-linear |
  a98-rgb           |
  prophoto-rgb      |
  rec2020           |
  lab               |
  oklab             |
  <xyz-space>

<polar-color-space> =
  hsl   |
  hwb   |
  lch   |
  oklch

<hue-interpolation-method> =
  [ shorter | longer | increasing | decreasing ] hue

<custom-color-space> =
  <dashed-ident>

<xyz-space> =
  xyz     |
  xyz-d50 |
  xyz-d65
```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Color Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Mixing two colors

This example demonstrates mixing two colors, red `#a71e14` at different percentages and white with no percentage given. The higher the percentage of `#a71e14` is mixed, the more red and less white the output color is.

HTML

```
<ul>
  <li>0%</li>
  <li>25%</li>
  <li>50%</li>
  <li>75%</li>
  <li>100%</li>
  <li></li>
</ul>
```

CSS

The `color-mix()` function is used to add increasing percentages of red, up to 100%. The 6th `<li>` doesn't include a percentage for either color.

```
ul {
  display: flex;
  list-style-type: none;
  font-size: 150%;
  gap: 10px;
  border: 2px solid;
  padding: 10px;
}

li {
  padding: 10px;
  flex: 1;
  box-sizing: border-box;
  font-family: monospace;
  outline: 3px solid #a71e14;
  text-align: center;
}
```

```
li:nth-child(1) {
  background-color: color-mix(in oklab, #a71e14 0%, white);
}

li:nth-child(2) {
  background-color: color-mix(in oklab, #a71e14 25%, white);
}

li:nth-child(3) {
  background-color: color-mix(in oklab, #a71e14 50%, white);
}

li:nth-child(4) {
  background-color: color-mix(in oklab, #a71e14 75%, white);
}

li:nth-child(5) {
  background-color: color-mix(in oklab, #a71e14 100%, white);
}

li:nth-child(6) {
  background-color: color-mix(in oklab, #a71e14, white);
}
```

Result

The total value of both colors in a `color-mix()` function is 100%, even if the values set by the developer don't total 100%. In this example, as only one color has a percentage assigned, the other color is implicitly given a percentage value so that the combined total equals 100%. In the last `<li>`, where neither color is assigned a percentage, both default to 50%.

Mixing a list of colors

This example demonstrates passing a color argument list to `color-mix()`. The function accepts any number of colors, not just two, and each of them can optionally be given a percentage.

HTML

```
<ul>
  <li>1 color</li>
  <li>3 colors, with percentages</li>
  <li>4 colors, no percentages</li>
</ul>
```

CSS

The first `<li>` mixes a single color, which resolves to that color. The second mixes three colors whose percentages total 100%. The third mixes four colors with no percentage, so each one gets an equal share.

```
ul {
  display: flex;
  list-style-type: none;
  font-size: 150%;
  gap: 10px;
  border: 2px solid;
  padding: 10px;
}

li {
  padding: 10px;
  flex: 1;
  box-sizing: border-box;
  font-family: monospace;
  text-align: center;
}
```

```
li:nth-child(1) {
  background-color: color-mix(in oklab, teal);
}

li:nth-child(2) {
  background-color: color-mix(in oklab, teal 20%, olive 30%, blue 50%);
}

li:nth-child(3) {
  background-color: color-mix(in oklab, teal, olive, blue, purple);
}
```

```
@supports not (color: color-mix(in oklab, red, white, blue)) {
  body::before {
    content: "Your browser doesn't support color lists in the color-mix() function.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

Result

Adding transparency

This example demonstrates using the `color-mix()` function to add transparency to a color by mixing any color with `transparent`.

HTML

```
<ul>
  <li>0%</li>
  <li>25%</li>
  <li>50%</li>
  <li>75%</li>
  <li>100%</li>
  <li></li>
</ul>
```

CSS

The `color-mix()` function is used to add increasing percentages of `red`, which is declared using a custom property named `--base`, defined on the `:root`. The 6th `<li>` doesn't include a percentage, creating an output color that is half as opaque as the `--base` color. We include a striped background on the `<ul>` to make the transparency visible.

```
ul {
  display: flex;
  list-style-type: none;
  font-size: 150%;
  gap: 10px;
  border: 2px solid;
  padding: 10px;
}

li {
  padding: 10px;
  flex: 1;
  box-sizing: border-box;
  font-family: monospace;
  outline: 1px solid var(--base);
  text-align: center;
}
```

```
:root {
  --base: red;
}

ul {
  background: repeating-linear-gradient(
    45deg,
    chocolate 0px 2px,
    white 2px 12px
  );
}

li:nth-child(1) {
  background-color: color-mix(in srgb, var(--base) 0%, transparent);
}

li:nth-child(2) {
  background-color: color-mix(in srgb, var(--base) 25%, transparent);
}

li:nth-child(3) {
  background-color: color-mix(in srgb, var(--base) 50%, transparent);
}

li:nth-child(4) {
  background-color: color-mix(in srgb, var(--base) 75%, transparent);
}

li:nth-child(5) {
  background-color: color-mix(in srgb, var(--base) 100%, transparent);
}

li:nth-child(6) {
  background-color: color-mix(in srgb, var(--base), transparent);
}
```

Result

In this way, the `color-mix()` function can be used to add transparency to any color, even if the color is already non-opaque (with an alpha channel value < 1). However, `color-mix()` can't be used to make a semi-transparent color fully opaque. For this, use a relative color with a CSS color function. Relative colors can alter the value of any color channel, including increasing a color's alpha channel to render the color fully opaque.

Using hue interpolation in color-mix()

This example demonstrates the hue interpolation methods available to the `color-mix()` function. When using hue interpolation, the resulting hue is between the hue values of the colors being mixed. The value will be different based on which route is taken around the color wheel.

For more information, see `<hue-interpolation-method>`.

```
<p>longer</p>
<ul>
  <li>100%</li>
  <li>80%</li>
  <li>60%</li>

  <li>40%</li>
  <li>20%</li>
  <li>0%</li>
</ul>
```

CSS

The `shorter hue` interpolation method takes the shorter route around the color wheel, whereas the `longer hue` interpolation method takes the longer route. With `increasing hue`, the route starts with increasing values. With `decreasing hue` the value decreases. We mix two `<named-color>` values to create a series of `lch()` intermediary colors that differ based on which route is taken around the color wheel. The mixed colors include `red`, `blue`, and `yellow` with LCH hue values of approximately 41deg, 301deg, and 100deg, respectively.

To reduce code redundancy, we used CSS custom properties for both colors and for the interpolation method, setting different values on each `<ul>`.

```
body {
  font-family: monospace;
}
ul {
  display: flex;
  list-style-type: none;
  font-size: 150%;
```

```
  gap: 10px;
  padding: 10px;
  margin: 0;
}

li {
  padding: 10px;
  flex: 1;
  outline: 1px solid var(--base);
  text-align: center;
}
```

```
ul:nth-of-type(1) {
  --distance: longer; /* 52 degree hue increments */
  --base: red;
  --mixin: blue;
}
ul:nth-of-type(2) {
  /* 20 degree hue decrements */
  --distance: shorter;
  --base: red;
  --mixin: blue;
}
ul:nth-of-type(3) {
  /* 40 degree hue increments */
  --distance: increasing;
  --base: yellow;
  --mixin: blue;
}
ul:nth-of-type(4) {
  /* 32 degree hue decrements */
  --distance: decreasing;
  --base: yellow;
  --mixin: blue;
}

li:nth-child(1) {
  background-color: color-mix(
    in lch var(--distance) hue,
    var(--base) 100%,
    var(--mixin)
  );
}

li:nth-child(2) {
  background-color: color-mix(
    in lch var(--distance) hue,
    var(--base) 80%,
    var(--mixin)
  );
}

li:nth-child(3) {
  background-color: color-mix(
    in lch var(--distance) hue,
    var(--base) 60%,
    var(--mixin)
  );
}

li:nth-child(4) {
  background-color: color-mix(
    in lch var(--distance) hue,
    var(--base) 40%,
    var(--mixin)
  );
}

li:nth-child(5) {
  background-color: color-mix(
    in lch var(--distance) hue,
    var(--base) 20%,
    var(--mixin)
  );
}

li:nth-child(6) {
  background-color: color-mix(
    in lch var(--distance) hue,
    var(--base) 0%,
    var(--mixin)
  );
}
```

Result

With `longer hue` the increments or decrements between colors will always be the same or larger than when using `shorter hue`. Use `increasing hue` or `decreasing hue` when the direction of the hue value change is more important than the length between values.

contrast-color() CSS function

The **`contrast-color()`** CSS function takes a `color` value and returns a contrasting color. The function commonly ensures the WCAG AA minimum contrast. The browsers may use different and better algorithms.

The `contrast-color()` function enables specifying a text color and automatically generating a contrasting background color, or vice versa. It avoids the need to maintain background-text color pairs.

Syntax

```
contrast-color(red)
contrast-color(var(--backgroundColor))
```

Parameters

`color`

Any valid `<color>` value.

Return value

A `<named-color>` of either `white` or `black`.

Description

The `contrast-color()` function returns a value of `white` or `black`, depending on which value has the greatest contrast with the input color. If both `white` and `black` have the same contrast with the input color, `white` is returned.

> **Warning:** WCAG AA (4.5:1) contrast is not capable of producing clearly readable text in all cases. Mid-tone background colors generally don't provide enough contrast with either black or white foreground. For example, `contrast-color()` on a royal bluish (`#2277d3`) background produces black text, which is not readable for small text. It is recommended, therefore, to use light or dark colors with the `contrast-color()` function.

Examples

Contrasting text for a button

In the following example, the browser automatically applies the selected color to the background of the "Button" `<button>`, and the contrasting color (black or white) to its text.

```
<label>
  Select background color of the button:
  <input type="color" id="colorPicker" value="#660066" />
</label>
<br />
<button>Button</button>
```

```
:root {
  --button-color: lightblue;
}

button {
  background-color: var(--button-color);

  /* Set contrasting text color automatically */
  color: contrast-color(var(--button-color));
}
```

```
body {
  padding: 1rem;
}

button {
  margin: 3rem;
  padding: 1rem;
  width: 150px;
  font-size: 2rem;
  border-radius: 1rem;
}

@supports not (color: contrast-color(red)) {
  body::before {
    content: "Your browser doesn't support the contrast-color() function.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

```
const colorPicker = document.getElementById("colorPicker");
const root = document.documentElement;

function updateColor(color) {
  root.style.setProperty("--button-color", colorPicker.value);
}

colorPicker.addEventListener("input", updateColor);
updateColor();
```

Light and dark mode usage

In the following example, the `prefers-color-scheme` media query is used to set a background color based on operating system or browser color scheme settings. The `contrast-color()` function is used to set the text color automatically.

Try changing the browser or OS dark mode setting to see the effect.

```
<pre>
    Q: How does CSS transform light into energy?
  Ans: Using <a href="/en-US/docs/Web/CSS/Reference/Properties/font-synthesis">font-synthesis</a>.
</pre>
```

```
:root {
  --background-color: navy;
}

@media (prefers-color-scheme: light) {
```

```
  :root {
    --background-color: wheat;
  }
}

body,
a {
  background-color: var(--background-color);
  color: contrast-color(var(--background-color));
}
```

```
body {
  padding: 2rem;
  font-size: 1.2rem;
}

pre {
  margin-top: 3rem;
}

@supports not (color: contrast-color(red)) {
  body::before {
    content: "Your browser doesn't support the contrast-color() function.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

device-cmyk() CSS function

The **`device-cmyk()`** functional notation is used to express CMYK colors in a device dependent way, specifying the cyan, magenta, yellow, and black components.

This approach to color is useful when creating material to be output to a particular printer, when the output for particular ink combinations is known. CSS processors may attempt to approximate the color for other media; however, the end result is likely to be different from the printed result without knowing the precise output colorimetry. A `@color-profile` declaration for `device-cmyk` can specify the exact color profile for conversion.

Syntax

```
device-cmyk(0 81% 81% 30%);
device-cmyk(none 0.81 0.81 0.3);
device-cmyk(0 81% 81% 30% / .5);
```

Values

Functional notation: `device-cmyk(C M Y K[ / A])`

`C`, `M`, `Y`, `K`

Each a `<number>` between `0` and `1`, a `<percentage>` between `0%` and `100%`, or the keyword `none` providing the cyan, magenta, yellow, and black components of CMYK color.

> **Note:** See Missing color components for more information on the effect of `none`.

`A` Optional

An `<alpha-value>` representing the alpha channel value of the color, where the number `0` corresponds to `0%` (fully transparent) and `1` corresponds to `100%` (fully opaque). Additionally, the keyword `none` can be used to explicitly specify no alpha channel.

Formal syntax

```
<device-cmyk()> =
  <legacy-device-cmyk-syntax>  |
  <modern-device-cmyk-syntax>

<legacy-device-cmyk-syntax> =
  device-cmyk( <number>#{4} )

<modern-device-cmyk-syntax> =
  device-cmyk( <cmyk-component>{4} [ / [ <alpha-value> | none ] ]? )

<cmyk-component> =
  <number>      |
  <percentage>  |
  none

<alpha-value> =
  <number>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Color Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Browser compatibility

Currently, no browsers support this feature.

hsl() CSS function

> **Note:** The `hsla()` functional notation is an alias for `hsl()`. They are exactly equivalent. It is recommended to use `hsl()`.

The **`hsl()`** functional notation expresses a color in the sRGB color space according to its *hue*, *saturation*, and *lightness* components. An optional *alpha* component represents the color's transparency.

Defining *complementary colors* with `hsl()` can be done by adding or subtracting 180 degrees from the hue value, as they are positioned on the same diameter of the color wheel. For example, if the hue angle of a color is `10deg`, its complementary has `190deg` as its hue angle.

Try it

```
background: hsl(50 80% 40%);
```

```
background: hsl(150deg 30% 60%);
```

```
background: hsl(0.3turn 60% 45% / 0.7);
```

```
background: hsl(0 80% 50% / 25%);
```

```
<section id="default-example">
  <div class="transition-all" id="example-element"></div>
</section>
```

```
#example-element {
  min-width: 100%;
  min-height: 100%;
  padding: 10%;
}
```

Syntax

```
/* Absolute values */
hsl(120deg 75% 25%)
hsl(120 75 25) /* deg and % units are optional */
hsl(120deg 75% 25% / 60%)
hsl(none 75% 25%)

/* Relative values */
hsl(from green h s l / 0.5)
hsl(from #123456 h s calc(l + 20))
hsl(from rgb(200 0 0) calc(h + 30) s calc(l + 30))

/* Legacy 'hsla()' alias */
hsla(120deg 75% 25% / 60%)

/* Legacy format */
hsl(120, 75%, 25%)
hsl(120deg, 75%, 25%, 0.8)
```

> **Note:** `hsl()`/`hsla()` can also be written in a legacy form in which all values are separated with commas, for example `hsl(120, 75%, 25%)` or `hsla(120deg, 75%, 25%, 0.8)`. The `none` value is not permitted in the comma-separated legacy syntax, the `deg` on the hue value is optional, and the `%` units are required for the saturation and lightness values.

Values

Below are descriptions of the allowed values for both absolute and relative colors.

Absolute value syntax

```
hsl(H S L[ / A])
```

The parameters are as follows:

`H`

A `<number>`, an `<angle>`, or the keyword `none` (equivalent to `0deg` in this case) representing the color's `<hue>` angle.

> **Note:** The angles corresponding to particular hues differ across the sRGB (used by `hsl()` and `hwb()`), CIELAB (used by `lch()`), and Oklab (used by `oklch()`) color spaces. See the `<hue>` reference page for more detail and examples.

`S`

A `<percentage>` or the keyword `none` (equivalent to `0%` in this case). This value represents the color's saturation. Here `100%` is completely saturated, while `0%` is completely unsaturated (gray).

`L`

A `<percentage>` or the keyword `none` (equivalent to `0%` in this case). This value represents the color's lightness. Here `100%` is white, `0%` is black, and `50%` is "normal".

`A` Optional

An `<alpha-value>` representing the alpha channel value of the color, where the number `0` corresponds to `0%` (fully transparent) and `1` corresponds to `100%` (fully opaque). Additionally, the keyword `none` can be used to explicitly specify no alpha channel. If the `A` channel value is not explicitly specified, it defaults to 100%. If included, the value is preceded by a slash (`/`).

> **Note:** See Missing color components for more information on the effect of `none`.

> **Note:** Absolute `hsl()` colors are serialized to `rgb()` values. The values of the red, green, and blue components may be rounded in serialization.

Relative value syntax

```
hsl(from <color> H S L[ / A])
```

The parameters are as follows:

`from <color>`

> The keyword `from` is always included when defining a relative color, followed by a `<color>` value representing the **origin color**. This is the original color that the relative color is based on. The origin color can be *any* valid `<color>` syntax, including another relative color.

`H`

> A `<number>`, an `<angle>`, or the keyword `none` (equivalent to `0deg` in this case) representing the output color's `<hue>` angle.

`S`

> A `<percentage>` or the keyword `none` (equivalent to `0%` in this case). This represents the saturation of the output color. Here `100%` is completely saturated, while `0%` is completely unsaturated (gray).

`L`

> A `<percentage>` or the keyword `none` (equivalent to `0%` in this case). This represents the lightness of the output color. Here `100%` is white, `0%` is black, and `50%` is "normal".

`A` Optional

> An `<alpha-value>` representing the alpha channel value of the output color, where the number `0` corresponds to `0%` (fully transparent) and `1` corresponds to `100%` (fully opaque). Additionally, the keyword `none` can be used to explicitly specify no alpha channel. If the `A` channel value is not explicitly specified, it defaults to the alpha channel value of the origin color. If included, the value is preceded by a slash (`/`).

> **Note:** To fully enable the representation of the full spectrum of visible colors, the output of relative `hsl()` color functions is serialized to `color(srgb)`. That means that querying the output color value via the `HTMLElement.style` property or the `CSSStyleDeclaration.getPropertyValue()` method returns the output color as a `color(srgb ...)` value.

Defining relative color output channel components

When using relative color syntax inside an `hsl()` function, the browser converts the origin color into an equivalent HSL color (if it is not already specified as such). The color is defined as three distinct color channel values — `h` (hue), `s` (saturation), and `l` (lightness) — plus an alpha channel value (`alpha`). These channel values are made available inside the function to be used when defining the output color channel values:

- The `h` value is resolved to a `<number>` between `0` and `360`, inclusive, that represents the origin color's `<hue>` degree value.
- The `s` and `l` values are each resolved to a `<number>` between `0` and `100`, inclusive, where `100` is equivalent to `100%`.
- The `alpha` value is resolved to a `<number>` between `0` and `1`, inclusive.

When defining a relative color, the different channels of the output color can be expressed in several different ways. Below, we'll study some examples to illustrate these.

In the first two examples below, we are using relative color syntax. However, the first one outputs the same color as the origin color and the second one outputs a color not based on the origin color at all. They don't really create relative colors! You'd be unlikely to ever use these in a real codebase, and would probably just use an absolute color value instead. We included these examples as a starting point for learning about relative `hsl()` syntax.

Let's start with an origin color of `rgb(255 0 0)` (equivalent to `hsl(0 100% 50%)`). The following function outputs the same color as the origin color — it uses the origin color's `h`, `s`, and `l` channel values (`0`, `100%`, and `50%`) as the output channel values:

```
hsl(from rgb(255 0 0) h s l)
```

This function's output color is the sRGB `color()` equivalent of `hsl(0 100% 50%)`: `color(srgb 1 0 0)`.

The next function uses absolute values for the output color's channel values, outputting a completely different color not based on the origin color:

```
hsl(from rgb(255 0 0) 240 60% 70%)
```

In the above case, the output color is the sRGB `color()` equivalent of `hsl(240 60% 70%)`: `color(srgb 0.52 0.52 0.88)`.

The following function creates a relative color based on the origin color:

```
hsl(from rgb(255 0 0) h 30% 60%)
```

This example:

- Converts the origin color (`rgb(255 0 0)`) into an `hsl()` equivalent (`hsl(0 100% 50%)`).
- Sets the `H` channel value for the output color to those of the origin color `hsl()` equivalent's `H` channel value — `0`.
- Sets the output color's `S` and `L` channel values to new values not based on the origin color: `30%` and `60%`, respectively.

The final output color is the equivalent of `hsl(0 30% 60%)` in the sRGB color space — `color(srgb 0.72 0.48 0.48)`.

> **Note:** As mentioned above, if the output color is using a different color model to the origin color, the origin color is converted to the same model as the output color in the background so that it can be represented in a way that is compatible (i.e., using the same channels).

In the examples we've seen so far in this section, the alpha channels have not been explicitly specified for either the origin or output colors. When the output color alpha channel is not specified, it defaults to the same value as the origin color alpha channel. When the origin color alpha channel is not specified (and it is not a relative color), it defaults to `1`. Therefore, the origin and output alpha channel values are `1` for the above examples.

Let's look at some examples that specify origin and output alpha channel values. The first one specifies the output alpha channel value as being the same as the origin alpha channel value, whereas the second one specifies a different output alpha channel value, unrelated to the origin alpha channel value.

```
hsl(from rgb(255 0 0 / 0.8) h s l / alpha)
/* Computed output color: color(srgb 1 0 0 / 0.8) */

hsl(from rgb(255 0 0 / 0.8) h s l / 0.5)
/* Computed output color: color(srgb 1 0 0 / 0.5) */
```

In the following example, the `rgb()` origin color is again converted into an `hsl()` representation — `hsl(0 100% 50% / 0.8)`. `calc()` calculations are applied to the `H`, `S`, `L`, and `A` values, and the final output color is the equivalent of `hsl(60 80% 30% / 0.7)` in the sRGB color space: `color(srgb 0.72 0.72 0.08 / 0.7)`.

```
hsl(from rgb(255 0 0 / 0.8) calc(h + 60) calc(s - 20) calc(l - 10) / calc(alpha - 0.1))
```

> **Note:** Because the origin color channel values are resolved to `<number>` values, you have to add numbers to them when using them in calculations, even in cases where a channel would normally accept `<percentage>`, `<angle>`, or other value types. Adding a `<percentage>` to a `<number>`, for example, doesn't work.

Formal syntax

```
<hsl()> =
  <legacy-hsl-syntax>  |
  <modern-hsl-syntax>

<legacy-hsl-syntax> =
  hsl( <hue> , <percentage> , <percentage> , <alpha-value>? )

<modern-hsl-syntax> =
  hsl( [ from <color> ]? [ <hue> | none ] [ <percentage> | <number> | none ] [ <percentage> | <number> | none ] [ / [ <alpha-value> | none ] ]? )

<hue> =
  <number>  |
  <angle>

<alpha-value> =
  <number>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Color Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using hsl() with conic-gradient()

The `hsl()` function works well with `conic-gradient()` as both deal with angles.

```
<div></div>
```

CSS

```
div {
  width: 100px;
  height: 100px;
  background: conic-gradient(
    hsl(360 100% 50%),
    hsl(315 100% 50%),
    hsl(270 100% 50%),
    hsl(225 100% 50%),
    hsl(180 100% 50%),
    hsl(135 100% 50%),
    hsl(90 100% 50%),
    hsl(45 100% 50%),
    hsl(0 100% 50%)
  );
  clip-path: circle(closest-side);
}
```

Result

Using relative colors with hsl()

This example styles three `<div>` elements with different background colors. The middle one is given the unmodified `--base-color`, while the left and right ones are given lightened and darkened variants of that `--base-color`.

These variants are defined using relative colors — the `--base-color` custom property is passed into an `hsl()` function, and the output color has its lightness channel modified to achieve the desired effect via a `calc()` function, while the hue and saturation are left unchanged. The lightened color has 20% added to the lightness channel, and the darkened color has 20% subtracted from it.

```
<div id="container">
  <div class="item" id="one"></div>
  <div class="item" id="two"></div>
  <div class="item" id="three"></div>
</div>
```

CSS

```
#container {
  display: flex;
  width: 100vw;
  height: 100vh;
  box-sizing: border-box;
}

.item {
  flex: 1;
  margin: 20px;
}
```

```
:root {
  --base-color: orange;
}

#one {
  background-color: hsl(from var(--base-color) h s calc(l + 20));
}

#two {
  background-color: var(--base-color);
}

#three {
  background-color: hsl(from var(--base-color) h s calc(l - 20));
}

/* Use @supports to add in support for old syntax that requires % units to
```

```
   be specified in lightness calculations */
@supports (color: hsl(from red h s calc(l - 20%))) {
  #one {
    background-color: hsl(from var(--base-color) h s calc(l + 20%));
  }

  #three {
    background-color: hsl(from var(--base-color) h s calc(l - 20%));
  }
}
```

Result

The output is as follows:

Legacy syntax: comma-separated values

For legacy reasons, the `hsl()` function accepts a form in which all values are separated using commas.

HTML

```
<div class="space-separated"></div>
<div class="comma-separated"></div>
```

CSS

```
div {
  width: 100px;
  height: 50px;
  margin: 1rem;
}

div.space-separated {
  background-color: hsl(0 100% 50% / 50%);
}

div.comma-separated {
  background-color: hsl(0, 100%, 50%, 0.5);
}
```

Result

Legacy versus modern syntax

The example demonstrates how the `hsla()` syntax is an alias for `hsl()`; both are supported using both modern and legacy (comma-separated) syntaxes.

HTML

```
<div class="modern">HSL</div>
<div class="legacy">HSL</div>
<div class="modernWithAlpha">HSL</div>
<div class="modernHSLA">HSLA</div>
<div class="legacyHSLA">HSLA</div>
```

CSS

```
div {
  width: 100px;
  min-height: 50px;
  font-family: sans-serif;
  display: flex;
  align-items: center;
  justify-content: center;
}
body {
  display: flex;
  gap: 20px;
}
```

```
div.modern {
  background-color: hsl(90 80% 50%);
}

div.legacy {
  background-color: hsl(90, 80%, 50%);
}

div.modernWithAlpha {
  background-color: hsl(90 80% 50% / 50%);
}

div.modernHSLA {
  background-color: hsla(90 80% 50% / 50%);
}

div.legacyHSLA {
  background-color: hsla(90, 80%, 50%, 0.5);
}
```

Result

hwb() CSS function

The **`hwb()`** functional notation expresses a color in the sRGB color space according to its hue, whiteness, and blackness. An optional alpha component represents the color's transparency.

Try it

```
background: hwb(12 50% 0%);
```

```
background: hwb(50deg 30% 40%);
```

```
background: hwb(0.5turn 10% 0% / 0.5);
```

```
background: hwb(0 100% 0% / 50%);
```

```
<section id="default-example">
  <div class="transition-all" id="example-element"></div>
</section>
```

```
#example-element {
  min-width: 100%;
  min-height: 100%;
  padding: 10%;
}
```

Syntax

```
/* Absolute values */
hwb(194 0% 0%)
hwb(194 0% 0% / .5)

/* Relative values */
hwb(from green h w b / 0.5)
hwb(from #123456 h calc(w + 30) b)
hwb(from lch(40% 70 240deg) h w calc(b - 30))
```

Description

This color function in the sRGB color space is defined by a `<hue>` angle value, a whiteness value, a blackness value, and, optionally, an alpha value representing the color's transparency.

The angles corresponding to particular hues differ across the sRGB (used by `hsl()` and `hwb()`), CIELAB (used by `lch()`), and Oklab (used by `oklch()`) color spaces. `hwb()` is in the same color space as `hsl()`, and therefore has the same hue color angles. See the `<hue>` reference page for more detail and examples, or try changing the hues on the color picker to see it in action.

An `hwb()` color is fully saturated when its whiteness (`W`) and blackness (`B`) values are both `0`. For any hue value `H`, `hwb(H 0% 0%)` is the same color as `hsl(H 100% 50%)`. Increasing the whiteness value lightens the color. Increasing the blackness darkens the color.

When both the blackness and whiteness are greater than 0, the color gets muted, tending towards gray. When the amount of whiteness and blackness added in are equal to or greater than 100% — in other words, if `W + B >= 100%`, the color function defines a shade of gray. When the sum of both values is greater than 100% (`W + B > 100%`), the whiteness and blackness values of the gray color are effectively normalized as `W / (W + B)` and `B / (W + B)`, respectively.

Values

Below are descriptions of the allowed values for both absolute and relative colors.

Absolute value syntax

```
hwb(H W B[ / A])
```

The parameters are as follows:

`H`

A `<number>`, an `<angle>`, or the keyword `none` (equivalent to `0deg` in this case) representing the color's `<hue>` angle.

`W`

A `<percentage>` representing the color's whiteness or the keyword `none` (equivalent to `0%` in this case) to mix in. `0%` represents no whiteness. `100%` represents full whiteness if `B` is `0`, otherwise both the `W` and `B` values are normalized.

`B`

A `<percentage>` representing the color's blackness or the keyword `none` (equivalent to `0%` in this case) to mix in. `0%` represents no blackness. `100%` represents full blackness if `W` is `0`, otherwise both the `W` and `B` values are normalized.

`A` Optional

An `<alpha-value>` representing the alpha channel value of the color, where the number `0` corresponds to `0%` (fully transparent) and `1` corresponds to `100%` (fully opaque). Additionally, the keyword `none` can be used to explicitly specify no alpha channel. If the `A` channel value is not explicitly specified, it defaults to 100%. If included, the value is preceded by a slash (`/`).

> **Note:** See Missing color components for more information on the effect of `none`.

> **Note:** Absolute `hwb()` colors are serialized to `rgb()` values. The values of the red, green, and blue components may be rounded in serialization.

Relative value syntax

```
hwb(from <color> H W B[ / A])
```

The parameters are as follows:

`from <color>`

The keyword `from` is always included when defining a relative color, followed by a `<color>` value representing the **origin color**. This is the original color that the relative color is based on. The origin color can be *any* valid `<color>` syntax, including another relative color.

`H`

A `<number>`, an `<angle>`, or the keyword `none` (equivalent to `0deg` in this case) representing the output color's `<hue>` angle.

`W`

A `<percentage>` representing the color's whiteness or the keyword `none` (equivalent to `0%` in this case) to mix in. `0%` represents no whiteness. `100%` represents full whiteness if `B` is `0`, otherwise both the `W` and `B` values are normalized.

`B`

A `<percentage>` representing the color's blackness or the keyword `none` (equivalent to `0%` in this case) to mix in. `0%` represents no blackness. `100%` represents full blackness if `W` is `0`, otherwise both the `W` and `B` values are normalized.

`A` Optional

An `<alpha-value>` representing the alpha channel value of the output color, where the number `0` corresponds to `0%` (fully transparent) and `1` corresponds to `100%` (fully opaque). Additionally, the keyword `none` can be used to explicitly specify no alpha channel. If the `A` channel value is not explicitly specified, it defaults to the alpha channel value of the origin color. If included, the value is preceded by a slash (`/`).

> **Note:** To fully enable the representation of the full spectrum of visible colors, the output of relative `hwb()` color functions is serialized to `color(srgb)`. That means that querying the output color value via the `HTMLElement.style` property or the `CSSStyleDeclaration.getPropertyValue()` method returns the output color as a `color(srgb ...)` value.

Defining relative color output channel components

When using relative color syntax inside an `hwb()` function, the browser converts the origin color into an equivalent HWB color (if it is not already specified as such). The color is defined as three distinct color channel values — `h` (hue), `w` (white), and `b` (black) — plus an alpha channel value (`alpha`). These channel values are made available inside the function to be used when defining the output color channel values:

- The `h` channel value is resolved to a `<number>` between `0` and `360`, inclusive.
- The `w` and `b` channels are each resolved to a `<number>` between `0` and `100`, inclusive.
- The `alpha` channel is resolved to a `<number>` between `0` and `1`, inclusive.

When defining a relative color, the different channels of the output color can be expressed in several different ways. Below, we'll study some examples to illustrate these.

In the first two examples below, we are using relative color syntax. However, the first one outputs the same color as the origin color and the second one outputs a color not based on the origin color at all. They don't really create relative colors! You'd be unlikely to ever use these in a real codebase, and would probably just use an absolute color value instead. We included these examples as a starting point for learning about relative `hwb()` syntax.

Let's start with an origin color of `hsl(0 100% 50%)` (equivalent to `hwb(0 0% 0%)`). The following function outputs the same color as the origin color — it uses the origin color's `h`, `w`, and `b` channel values (`0`, `0%`, and `0%`) as the output channel values:

```
hwb(from hsl(0 100% 50%) h w b)
```

This function's output color is the sRGB `color()` equivalent of `hwb(0 0% 0%)`: `color(srgb 1 0 0)`.

The next function uses absolute values for the output color's channel values, outputting a completely different color not based on the origin color:

```
hwb(from hsl(0 100% 50%) 240 52% 12%)
```

In the above case, the output color is the sRGB `color()` equivalent of `hwb(240 52% 12%)`: `color(srgb 0.52 0.52 0.88)`.

The following function creates a relative color based on the origin color:

```
hwb(from hsl(0 100% 50%) h 30% b)
```

This example:

- Converts the origin color (`hsl(0 100% 50%)`) into an `hwb()` equivalent (`hwb(0 0% 0%)`).
- Sets the `H` and `B` channel values for the output color to those of the origin color `hwb()` equivalent's `H` and `B` channel values — those values are `0` and `0%`, respectively.
- Sets the output color's `W` channel value to a new value not based on the origin color: `30%`.

The final output color is the equivalent of `hwb(0 30% 0%)` in the sRGB color space — `color(srgb 1 0.3 0.3)`.

> **Note:** As mentioned above, if the output color is using a different color model to the origin color, the origin color is converted to the same model or space as the output color in the background so that it can be represented in a way that is compatible (i.e., using the same channels).

In the examples we've seen so far in this section, the alpha channels have not been explicitly specified for either the origin or output colors. When the output color alpha channel is not specified, it defaults to the same value as the origin color alpha channel. When the origin color alpha channel is not specified (and it is not a relative color), it defaults to `1`. Therefore, the origin and output alpha channel values are `1` for the above examples.

Let's look at some examples that specify origin and output alpha channel values. The first one specifies the output alpha channel value as being the same as the origin alpha channel value, whereas the second one specifies a different output alpha channel value, unrelated to the origin alpha channel value.

```
hwb(from hsl(0 100% 50% / 0.8) h w b / alpha)
/* Computed output color: color(srgb 1 0 0 / 0.8) */

hwb(from hsl(0 100% 50% / 0.8) h w b / 0.5)
/* Computed output color: color(srgb 1 0 0 / 0.5) */
```

In the following example, the `hsl()` origin color is again converted into an `hwb()` representation — `hwb(0 0% 0%)`. `calc()` calculations are applied to the `H`, `W`, `B`, and `A` values, and the final output color is the equivalent of `hwb(120 25% 10% / 0.9)` in the sRGB color space: `color(srgb 0.25 0.9 0.25 / 0.9)`.

```
hwb(from hsl(0 100% 50%) calc(h + 120) calc(w + 25) calc(b + 10) / calc(alpha - 0.1))
```

> **Note:** Because the origin color channel values are resolved to `<number>` values, you have to add numbers to them when using them in calculations, even in cases where a channel would normally accept `<percentage>`, `<angle>`, or other value types. Adding a `<percentage>` to a `<number>`, for example, doesn't work.

Formal syntax

```
<hwb()> =
  hwb( [ from <color> ]? [ <hue> | none ] [ <percentage> | <number> | none ] [ <percentage> | <number> | none ] [ / [ <alpha-value> | none ] ]? )
```

```
<hue> =
  <number>  |
  <angle>

<alpha-value> =
  <number>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Color Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using relative colors with hwb()

This example styles three `<div>` elements with different background colors. The middle one is given the unmodified `--base-color`, while the left and right ones are given lightened and darkened variants of that `--base-color`.

These variants are defined using relative colors — the `--base-color` custom property is passed into an `hwb()` function, and the output colors have their white and black channels modified to achieve the desired effect via a `calc()` function. The lightened color has 30% added to the white channel, and the darkened color has 30% added to the black channel.

```
<div id="container">
  <div class="item" id="one"></div>
  <div class="item" id="two"></div>
  <div class="item" id="three"></div>
</div>
```

CSS

```
#container {
  display: flex;
  width: 100vw;
  height: 100vh;
  box-sizing: border-box;
}

.item {
  flex: 1;
  margin: 20px;
}
```

```
:root {
  --base-color: orange;
}

/* As per the spec, w and b values should resolve to a number between 0-100
   However, Chrome 121+ incorrectly resolves them to numbers between 0-1
   hence currently using calculations like w + 0.3 instead of w + 30 */

#one {
  background-color: hwb(from var(--base-color) h calc(w + 0.3) b);
}

#two {
  background-color: var(--base-color);
}

#three {
  background-color: hwb(from var(--base-color) h w calc(b + 0.3));
}

/* Use @supports to add in support for old syntax that requires % units to
   be specified in w and b calculations. This is required for Safari 16.4+. */
@supports (color: hwb(from red h w calc(b + 30%))) {
  #one {
    background-color: hwb(from var(--base-color) h calc(w + 30%) b);
  }

  #three {
    background-color: hwb(from var(--base-color) h w calc(b + 30%));
  }
}
```

Result

The output is as follows:

lab() CSS function

The **`lab()`** functional notation expresses a given color in the CIE L*a*b* color space.

Lab represents the entire range of colors that humans can see by specifying the color's lightness, a red/green axis value, a blue/yellow axis value, and an optional alpha transparency value.

Syntax

```
/* Absolute values */
lab(29.2345% 39.3825 20.0664);
lab(52.2345% 40.1645 59.9971);
lab(52.2345% 40.1645 59.9971 / .5);

/* Relative values */
lab(from green l a b / 0.5)
```

```
lab(from #123456 calc(l + 10) a b)
lab(from hsl(180 100% 50%) calc(l - 10) a b)
```

Values

Below are descriptions of the allowed values for both absolute and relative colors.

Absolute value syntax

```
lab(L a b[ / A])
```

The parameters are as follows:

`L`

A `<number>` between `0` and `100`, a `<percentage>` between `0%` and `100%`, or the keyword `none` (equivalent to `0%` in this case). This value specifies the color's lightness. Here the number `0` corresponds to `0%` (black) and the number `100` corresponds to `100%` (white).

`a`

A `<number>` between `-125` and `125`, a `<percentage>` between `-100%` and `100%`, or the keyword `none` (equivalent to `0%` in this case). This value specifies the color's distance along the `a` axis, which defines how green (moving towards `-125`) or red (moving towards `+125`) the color is. Note that these values are signed (allowing both positive and negative values) and theoretically unbounded, meaning that you can set values outside the `±125` (`±100%`) limits. In practice, values cannot exceed `±160`.

`b`

A `<number>` between `-125` and `125`, a `<percentage>` between `-100%` and `100%`, or the keyword `none` (equivalent to `0%` in this case). This value specifies the color's distance along the `b` axis, which defines how blue (moving towards `-125`) or yellow (moving towards `+125`) the color is. Note that these values are signed (allowing both positive and negative values) and theoretically unbounded, meaning that you can set values outside the `±125` (`±100%`) limits. In practice, values cannot exceed `±160`.

`A` Optional

An `<alpha-value>` representing the alpha channel value of the color, where the number `0` corresponds to `0%` (fully transparent) and `1` corresponds to `100%` (fully opaque). Additionally, the keyword `none` can be used to explicitly specify no alpha channel. If the `A` channel value is not explicitly specified, it defaults to 100%. If included, the value is preceded by a slash (`/`).

> **Note:** See Missing color components for more information on the effect of `none`.

Relative value syntax

```
lab(from <color> L a b[ / A])
```

The parameters are as follows:

`from <color>`

The keyword `from` is always included when defining a relative color, followed by a `<color>` value representing the **origin color**. This is the original color that the relative color is based on. The origin color can be *any* valid `<color>` syntax, including another relative color.

`L`

A `<number>` between `0` and `100`, a `<percentage>` between `0%` and `100%`, or the keyword `none` (equivalent to `0%` in this case) This value represents the lightness of the output color. Here the number `0` corresponds to `0%` (black) and the number `100` corresponds to `100%` (white).

`a`

A `<number>` between `-125` and `125`, a `<percentage>` between `-100%` and `100%`, or the keyword `none` (equivalent to `0%` in this case). This value represents the output color's distance along the `a` axis, which defines how green (moving towards `-125`) or red (moving towards `+125`) the color is. Note that these values are signed (allowing both positive and negative values) and theoretically unbounded, meaning that you can set values outside the `±125` (`±100%`) limits. In practice, values cannot exceed `±160`.

`b`

A `<number>` between `-125` and `125`, a `<percentage>` between `-100%` and `100%`, or the keyword `none` (equivalent to `0%` in this case). This value represents the output color's distance along the `b` axis, which defines how blue (moving towards `-125`) or yellow (moving towards `+125`) the color is. Note that these values are signed (allowing both positive and negative values) and theoretically unbounded, meaning that you can set values outside the `±125` (`±100%`) limits. In practice, values cannot exceed `±160`.

`A` Optional

An `<alpha-value>` representing the alpha channel value of the output color, where the number `0` corresponds to `0%` (fully transparent) and `1` corresponds to `100%` (fully opaque). Additionally, the keyword `none` can be used to explicitly specify no alpha channel. If the `A` channel value is not explicitly specified, it defaults to the alpha channel value of the origin color. If included, the value is preceded by a slash (`/`).

> **Note:** Usually when percentage values have a numeric equivalent in CSS, `100%` is equal to the number `1`. This is not always the case for Lab's lightness and `a` and `b` axes, as mentioned above. With `L`, the range is from 0 to 100, with `100%` equal to `100`. The `a` and `b` values support both negative and positive values, with `100%` being equal to `125` and `-100%` being equal to `-125`.

Defining relative color output channel components

When using relative color syntax inside a `lab()` function, the browser converts the origin color into an equivalent Lab color (if it is not already specified as such). The color is defined as three distinct color channel values — `l` (lightness), `a` (green/red axis), and `b` (blue/yellow axis) — plus an alpha channel value (`alpha`). These channel values are made available inside the function to be used when defining the output color channel values:

- The `l` channel value is resolved to a `<number>` between `0` and `100`, inclusive.
- The `a` and `b` channels are each resolved to a `<number>` between `-125` and `125`, inclusive.
- The `alpha` channel is resolved to a `<number>` between `0` and `1`, inclusive.

When defining a relative color, the different channels of the output color can be expressed in several different ways. Below, we'll study some examples to illustrate these.

In the first two examples below, we are using relative color syntax. However, the first one outputs the same color as the origin color and the second one outputs a color not based on the origin color at all. They don't really create relative colors! You'd be unlikely to ever use these in a real codebase, and would probably just use an absolute color value instead. We included these examples as a starting point for learning about relative `lab()` syntax.

Let's start with an origin color of `hsl(0 100% 50%)` (equivalent to `red`). The following function outputs the same color as the origin color — it uses the origin color's `l`, `a`, and `b` channel values (`54.29`, `80.8198`, and `69.8997`) as the output channel values:

```
lab(from hsl(0 100% 50%) l a b)
```

This function's output color is `lab(54.29 80.8198 69.8997)`.

The next function uses absolute values for the output color's channel values, outputting a completely different color not based on the origin color:

```
lab(from hsl(0 100% 50%) 29.692% 44.89% -29.034%)
```

In the above case, the output color is `lab(29.692 56.1125 -36.2925)`.

The following function creates a relative color based on the origin color:

```
lab(from hsl(0 100% 50%) l -100 b)
```

This example:

- Converts the `hsl()` origin color to an equivalent `lab()` color — `lab(54.29 80.8198 69.8997)`.
- Sets the `l` and `b` channel values for the output color to those of the origin `lab()` equivalent's `L` and `b` channel values — those values are `54.29` and `69.8997`, respectively.
- Sets the output color's `a` channel value to a new value not based on the origin color: `-100`.

The final output color is `lab(54.29 -100 69.8997)`.

> **Note:** As mentioned above, if the output color is using a different color model to the origin color, the origin color is converted to the same model as the output color in the background so that it can be represented in a way that is compatible (i.e., using the same channels).

In the examples we've seen so far in this section, the alpha channels have not been explicitly specified for either the origin or output colors. When the output color alpha channel is not specified, it defaults to the same value as the origin color alpha channel. When the origin color alpha channel is not specified (and it is not a relative color), it defaults to `1`. Therefore, the origin and output alpha channel values are `1` for the above examples.

Let's look at some examples that specify origin and output alpha channel values. The first one specifies the output alpha channel value as being the same as the origin alpha channel value, whereas the second one specifies a different output alpha channel value, unrelated to the origin alpha channel value.

```
lab(from hsl(0 100% 50% / 0.8) l a b / alpha)
/* Computed output color: lab(54.29 80.8198 69.8997 / 0.8) */

lab(from hsl(0 100% 50% / 0.8) l a b / 0.5)
/* Computed output color: lab(54.29 80.8198 69.8997 / 0.5) */
```

In the following example, the `hsl()` origin color is again converted to the `lab()` equivalent — `lab(54.29 80.8198 69.8997)`. `calc()` calculations are applied to the `L`, `a`, `b`, and `A` values, resulting in an output color of `lab(74.29 60.8198 29.8997 / 0.9)`:

```
lab(from hsl(0 100% 50%) calc(l + 20) calc(a - 20) calc(b - 40) / calc(alpha - 0.1))
```

> **Note:** Because the origin color channel values are resolved to `<number>` values, you have to add numbers to them when using them in calculations, even in cases where a channel would normally accept `<percentage>`, `<angle>`, or other value types. Adding a `<percentage>` to a `<number>`, for example, doesn't work.

Formal syntax

```
<lab()> =
  lab( [ from <color> ]? [ <percentage> | <number> | none ] [ <percentage> | <number> | none ] [ <percentage> | <number> | none ] [ / [ <alpha-value> | none ] ]? )

<alpha-value> =
  <number>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Color Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Adjusting lightness

The following example shows the effect of varying the lightness value of the `lab()` function.

HTML

```
<div data-color="red-dark"></div>
<div data-color="red"></div>
<div data-color="red-light"></div>

<div data-color="green-dark"></div>
<div data-color="green"></div>
<div data-color="green-light"></div>

<div data-color="blue-dark"></div>
<div data-color="blue"></div>
<div data-color="blue-light"></div>
```

CSS

```
body {
  display: flex;
  flex-wrap: wrap;
  gap: 10px;
}
div {
  height: 50px;
  flex: 0 0 28%;
  border: 1px solid black;
}
```

```
[data-color="red-dark"] {
  background-color: lab(5 125 71);
}
[data-color="red"] {
  background-color: lab(40 125 71);
}
[data-color="red-light"] {
```

```
  background-color: lab(95 125 71);
}

[data-color="green-dark"] {
  background-color: lab(10% -120 125);
}
[data-color="green"] {
  background-color: lab(50% -120 125);
}
[data-color="green-light"] {
  background-color: lab(90% -120 125);
}

[data-color="blue-dark"] {
  background-color: lab(10 -120 -120);
}
[data-color="blue"] {
  background-color: lab(50 -120 -120);
}
[data-color="blue-light"] {
  background-color: lab(90 -120 -120);
}
```

Result

Adjusting color axes

This example demonstrates the effects of setting the `a` and `b` values of the `lab()` function to the ends and midpoints of the a-axis, which goes from green (-125) to red (125) and the b-axis, which goes from yellow (-125) to blue (125).

HTML

```
<div data-color="red-yellow"></div>
<div data-color="red-zero"></div>
<div data-color="red-blue"></div>

<div data-color="zero-yellow"></div>
<div data-color="zero-zero"></div>
<div data-color="zero-blue"></div>

<div data-color="green-yellow"></div>
<div data-color="green-zero"></div>
<div data-color="green-blue"></div>
```

CSS

Using the CSS `background-color` property, we vary the `a` and `b` values of the `lab()` color function along the a-axis and b-axis, showing the effects of maximum, midpoint, and minimum values in each case.

```
body {
  display: grid;
  grid-template-columns: 1fr 1fr 1fr;
  gap: 10px;
}
div {
  height: 50px;
  flex: 0 0 28%;
  border: 1px solid black;
}
```

```
/* a-axis max, variable b-axis */
[data-color="red-yellow"] {
  background-color: lab(50 125 125);
}
[data-color="red-zero"] {
  background-color: lab(50 125 0);
}
[data-color="red-blue"] {
  background-color: lab(50 125 -125);
}

/* a-axis center, variable b-axis */
[data-color="zero-yellow"] {
  background-color: lab(50 0 125);
}
[data-color="zero-zero"] {
  background-color: lab(50 0 0);
}
[data-color="zero-blue"] {
  background-color: lab(50 0 -125);
}

/* a-axis min, variable b-axis */
[data-color="green-yellow"] {
  background-color: lab(50 -125 125);
}
[data-color="green-zero"] {
  background-color: lab(50 -125 0);
}
[data-color="green-blue"] {
  background-color: lab(50 -125 -125);
}
```

Result

The left column is at the yellow end (-125) of the b-axis and the right column is at the blue end (125). The top row displays colors at the red end of the a-axis (-125) and the bottom row is at the green end (125). The middle column and row are at the midpoints (0) of each axis, with the middle cell being gray; it contains no red, green, yellow, or blue, with a `0` value for both axes.

Linear gradients along the a-axis and b-axis

This example includes linear gradients to demonstrate the progression of values of the `lab()` function along the a-axis (from red to green) and along the b-axis (from yellow to blue). In each gradient image, one axis remains static while the other axis progresses from the low end to the high end of the axis values.

```
<div data-color="red-to-green-yellow">
  <span>red</span><span>`b`= -125 (yellow)</span><span>green</span>
</div>
<div data-color="red-to-green-zero">
  <span>red</span><span>no yellow or blue</span><span>green</span>
</div>
<div data-color="red-to-green-blue">
  <span>red</span><span>`b`= 125 (blue)</span><span>green</span>
</div>

<div data-color="yellow-to-blue-red">
  <span>yellow</span><span>`a` = -125 (red)</span><span>blue</span>
</div>
<div data-color="yellow-to-blue-zero">
  <span>yellow</span><span>no red or green</span><span>blue</span>
</div>
<div data-color="yellow-to-blue-green">
  <span>yellow</span><span>`a` = 125 (green)</span><span>blue</span>
</div>
```

CSS

```
div {
  height: 50px;
  padding: 5px;
  margin: 5px;
  border: 1px solid black;
  display: flex;
  justify-content: space-between;
  align-items: center;
}
span {
  background-color: #ffffffcc;
  padding: 3px;
}
```

```
/* a-axis gradients */
[data-color="red-to-green-yellow"] {
  background-image: linear-gradient(to right, lab(50 125 125), lab(50 -125 125));
}
[data-color="red-to-green-zero"] {
  background-image: linear-gradient(to right, lab(50 125 0), lab(50 -125 0));
}
[data-color="red-to-green-blue"] {
  background-image: linear-gradient(to right, lab(50 125 -125), lab(50 -125 -125));
}

/* b-axis gradients */
[data-color="yellow-to-blue-red"] {
  background-image: linear-gradient(to right, lab(50 125 125), lab(50 125 -125));
}
[data-color="yellow-to-blue-zero"] {
  background-image: linear-gradient(to right, lab(50 0 125), lab(50 0 -125));
}
[data-color="yellow-to-blue-green"] {
  background-image: linear-gradient(to right, lab(50 -125 125),lab(50 -125 -125));
}
```

Result

Adjusting opacity

The following example shows the effect of varying the `A` (alpha) value of the `lab()` functional notation. The `red` and `red-alpha` elements overlap the `#background-div` element to demonstrate the effect of opacity. Giving `A` a value of `0.4` makes the color 40% opaque.

HTML

```
<div id="background-div">
  <div data-color="red"></div>
  <div data-color="red-alpha"></div>
</div>
```

CSS

```
div {
  width: 50px;
  height: 50px;
  padding: 5px;
  margin: 5px;
  display: inline-block;
  border: 1px solid black;
}
#background-div {
  background-color: lightblue;
  width: 150px;
  height: 40px;
}
```

```
[data-color="red"] {
  background-color: lab(80 125 125);
}
[data-color="red-alpha"] {
  background-color: lab(80 125 125 / 0.4);
}
```

Result

Using relative colors with lab()

This example styles three `<div>` elements with different background colors. The middle one is given the unmodified `--base-color`, while the left and right ones are given lightened and darkened variants of that `--base-color`.

These variants are defined using relative colors — the `--base-color` custom property is passed into a `lab()` function, and the output colors have their lightness channel modified to achieve the desired effect via a `calc()` function. The lightened color has 15% added to the lightness channel, and the darkened color has 15% subtracted from the lightness channel.

```
<div id="container">
  <div class="item" id="one"></div>
  <div class="item" id="two"></div>
  <div class="item" id="three"></div>
</div>
```

CSS

```
#container {
  display: flex;
  width: 100vw;
  height: 100vh;
  box-sizing: border-box;
}

.item {
  flex: 1;
  margin: 20px;
}
```

```
:root {
  --base-color: orange;
  /* equivalent of lab(75 24 79) */
}

#one {
  background-color: lab(from var(--base-color) calc(l + 15) a b);
}

#two {
  background-color: var(--base-color);
}

#three {
  background-color: lab(from var(--base-color) calc(l - 15) a b);
}
```

Result

The output is as follows:

- LCH colors in CSS: what, why, and how? by Lea Verou (2020)
- Safari Technology Preview 122 release notes: includes `lab()` and `lch()` colors

lch() CSS function

The **`lch()`** functional notation expresses a given color using the LCH color space, which represents lightness, chroma, and hue. It uses the same `L` axis as the `lab()` color function of the CIELab color space, but it uses the polar coordinates `C` (Chroma) and `H` (Hue).

Syntax

```
/* Absolute values */
lch(29.2345% 44.2 27);
lch(52.2345% 72.2 56.2);
lch(52.2345% 72.2 56.2 / .5);

/* Relative values */
lch(from green l c h / 0.5)
lch(from #123456 calc(l + 10) c h)
lch(from hsl(180 100% 50%) calc(l - 10) c h)
lch(from var(--color-value) l c h / calc(alpha - 0.1))
```

Values

Below are descriptions of the allowed values for both absolute and relative colors.

> **Note:** Usually when percentage values have a numeric equivalent in CSS, `100%` is equal to the number `1`. This is not the case for `lch()`. Here `100%` is equal to the number `100` for the `L` value and `150` for the `C` value.

Absolute value syntax

```
lch(L C H[ / A])
```

The parameters are as follows:

`L`

A `<number>` between `0` and `100`, a `<percentage>` between `0%` and `100%`, or the keyword `none` (equivalent to `0%`). The number `0` corresponds to `0%` (black), and the number `100` corresponds to `100%` (white). This value specifies the color's brightness in the CIELab color space.

> **Note:** The `L` in `lch()` is the perceived lightness, which refers to the "brightness" we visually perceive with our eyes. This is different from the `L` in `hsl()`, where it represents lightness as compared to other colors.

`C`

A `<number>`, a `<percentage>`, or the keyword `none` (equivalent to `0%` in this case). This value is a measure of the color's chroma (roughly representing the "amount of color"). Its minimum useful value is `0%`, or `0`, while its maximum is theoretically unbounded (but in practice does not exceed `230`), with `100%` being equivalent to `150`.

`H`

A `<number>`, an `<angle>`, or the keyword `none` (equivalent to `0deg`) representing the color's `<hue>` angle.

> **Note:** The angles corresponding to particular hues differ across the sRGB (used by `hsl()` and `hwb()`), CIELAB (used by `lch()`), and Oklab (used by `oklch()`) color spaces. See the hues in LCH example below and the `<hue>` reference page for more detail and examples.

`A` Optional

An `<alpha-value>` representing the alpha channel value of the color, where the number `0` corresponds to `0%` (fully transparent) and `1` corresponds to `100%` (fully opaque). Additionally, the keyword `none` can be used to explicitly specify no alpha channel. If the `A` channel value is not explicitly specified, it defaults to 100%. If included, the value is preceded by a slash (`/`).

> **Note:** See Missing color components for more information on the effect of `none`.

Relative value syntax

```
lch(from <color> L C H[ / A])
```

The parameters are as follows:

`from <color>`

The keyword `from` is always included when defining a relative color, followed by a `<color>` value representing the **origin color**. This is the original color that the relative color is based on. The origin color can be *any* valid `<color>` syntax, including another relative color.

`L`

A `<number>` between `0` and `100`, a `<percentage>` between `0%` and `100%`, or the keyword `none` (equivalent to `0%`). The number `0` corresponds to `0%` (black), and the number `100` corresponds to `100%` (white). This value specifies the color's brightness in the CIELab color space.

`C`

A `<number>`, a `<percentage>`, or the keyword `none` (equivalent to `0%` in this case). This value represents the output color's chroma value (roughly representing the "amount of color"). Its minimum useful value is `0%`, or `0`, while its maximum is theoretically unbounded (but in practice does not exceed `230`), with `100%` being equivalent to `150`.

`H`

A `<number>`, an `<angle>`, or the keyword `none` (equivalent to `0deg`) representing the output color's `<hue>` angle. See the hue example below.

`A` Optional

An `<alpha-value>` representing the alpha channel value of the output color, where the number `0` corresponds to `0%` (fully transparent) and `1` corresponds to `100%` (fully opaque). Additionally, the keyword `none` can be used to explicitly specify no alpha channel. If the `A` channel value is not explicitly specified, it defaults to the alpha channel value of the origin color. If included, the value is preceded by a slash (`/`).

Defining relative color output channel components

When using relative color syntax inside an `lch()` function, the browser converts the origin color into an equivalent Lch color (if it is not already specified as such) The color is defined as three distinct color channel values — `l` (lightness), `c` (chroma), and `h` (hue) — plus an alpha channel value (`alpha`). These channel values are made available inside the function to be used when defining the output color channel values:

- The `l` channel value is resolved to a `<number>` between `0` and `100`, inclusive.
- The `c` channel value is resolved to a `<number>` between `0` and `150`, inclusive.
- The `h` channel value is resolved to a `<number>` between `0` and `360`, inclusive.
- The `alpha` channel is resolved to a `<number>` between `0` and `1`, inclusive.

When defining a relative color, the different channels of the output color can be expressed in several different ways. Below, we'll study some examples to illustrate these.

In the first two examples below, we are using relative color syntax. However, the first one outputs the same color as the origin color and the second one outputs a color not based on the origin color at all. They don't really create relative colors! You'd be unlikely to ever use these in a real codebase, and would probably just use an absolute color value instead. We included these examples as a starting point for learning about relative `lch()` syntax.

Let's start with an origin color of `hsl(0 100% 50%)` (equivalent to `red`). The following function outputs the same color as the origin color — it uses the origin color's `l`, `c`, and `h` channel values (`54.29`, `106.854`, and `40.856`) as the output channel values:

```
lch(from hsl(0 100% 50%) l c h)
```

This function's output color is `lch(54.29 106.854 40.856)`.

The next function uses absolute values for the output color's channel values, outputting a completely different color not based on the origin color:

```
lch(from hsl(0 100% 50%) 29.6871% 66.83 327.109)
```

In the above case, the output color is `lch(29.6871 66.83 327.109)`.

The following function creates a relative color based on the origin color:

```
lch(from hsl(0 100% 50%) 70 150 h)
```

This example:

- Converts the `hsl()` origin color to an equivalent `lch()` color — `lch(54.29 106.854 40.856)`.
- Sets the `H` channel value for the output color to that of the origin `lch()` equivalent's `H` channel value — `40.856`.
- Sets the output color's `L` and `C` channel values to new values not based on the origin color: `70` and `150` respectively.

The final output color is `lch(70 150 40.856)`.

> **Note:** As mentioned above, if the output color is using a different color model to the origin color, the origin color is converted to the same model as the output color in the background so that it can be represented in a way that is compatible (i.e., using the same channels).

In the examples we've seen so far in this section, the alpha channels have not been explicitly specified for either the origin or output colors. When the output color alpha channel is not specified, it defaults to the same value as the origin color alpha channel. When the origin color alpha channel is not specified (and it is not a relative color), it defaults to `1`. Therefore, the origin and output alpha channel values are `1` for the above examples.

Let's look at some examples that specify origin and output alpha channel values. The first one specifies the output alpha channel value as being the same as the origin alpha channel value, whereas the second one specifies a different output alpha channel value, unrelated to the origin alpha channel value.

```
lch(from hsl(0 100% 50% / 0.8) l c h / alpha)
/* Computed output color: lch(54.29 106.854 40.856 / 0.8) */

lch(from hsl(0 100% 50% / 0.8) l c h / 0.5)
/* Computed output color: lch(54.29 106.854 40.856 / 0.5) */
```

In the following example, the `hsl()` origin color is again converted to the `lch()` equivalent — `lch(54.29 106.854 40.856)`. `calc()` calculations are applied to the `L`, `C`, `H`, and `A` values, resulting in an output color of `lch(74.29 86.8541 0.856018 / 0.9)`:

```
lch(from hsl(0 100% 50%) calc(l + 20) calc(c - 20) calc(h - 40) / calc(alpha - 0.1))
```

> **Note:** Because the origin color channel values are resolved to `<number>` values, you have to add numbers to them when using them in calculations, even in cases where a channel would normally accept `<percentage>`, `<angle>`, or other value types. Adding a `<percentage>` to a `<number>`, for example, doesn't work.

Formal syntax

```
<lch()> =
  lch( [ from <color> ]? [ <percentage> | <number> | none ] [ <percentage> | <number> | none ] [ <hue> | none ] [ / [ <alpha-value> | none ] ]? )

<hue> =
  <number>  |
  <angle>

<alpha-value> =
  <number>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Color Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Adjusting the brightness of a color

This example shows the effect of varying the `L` (lightness) value of the `lch()` functional notation.

HTML

```
<div data-color="blue-dark"></div>
<div data-color="blue"></div>
<div data-color="blue-light"></div>

<div data-color="red-dark"></div>
<div data-color="red"></div>
<div data-color="red-light"></div>

<div data-color="green-dark"></div>
<div data-color="green"></div>
<div data-color="green-light"></div>
```

CSS

```
body {
  display: grid;
  grid-template-columns: 1fr 1fr 1fr;
  gap: 20px;
}
div {
  height: 50px;
  border: 1px solid black;
}
```

```
[data-color="blue-dark"] {
  background-color: lch(10% 100 240);
}
[data-color="blue"] {
  background-color: lch(50% 100 240);
}
[data-color="blue-light"] {
  background-color: lch(90% 100 240);
}

[data-color="red-dark"] {
  background-color: lch(10% 130 20);
}
[data-color="red"] {
  background-color: lch(50% 130 20);
}
[data-color="red-light"] {
  background-color: lch(90% 130 20);
}

[data-color="green-dark"] {
  background-color: lch(10% 132 130);
}
[data-color="green"] {
```

```
  background-color: lch(50% 132 130);
}
[data-color="green-light"] {
  background-color: lch(90% 132 130);
}
```

Result

Adjusting color intensity via chroma

The following example shows the effect of varying the `C` (chroma) value of the `lch()` functional notation, with colors decreasing in intensity as the `C` value decreases from fully saturated to almost gray.

HTML

```
<div data-color="blue"></div>
<div data-color="blue-chroma1"></div>
<div data-color="blue-chroma2"></div>
<div data-color="blue-chroma3"></div>

<div data-color="red"></div>
<div data-color="red-chroma1"></div>
<div data-color="red-chroma2"></div>
<div data-color="red-chroma3"></div>

<div data-color="green"></div>
<div data-color="green-chroma1"></div>
<div data-color="green-chroma2"></div>
<div data-color="green-chroma3"></div>
```

CSS

With the initial starting colors blue, red, and green, we declare progressively smaller values for chroma on them: starting from full color saturation at the highest value of `150` (equivalent to `100%`) down to `3` (equivalent to `2%`), which is almost gray for all the colors.

```
body {
  display: grid;
  grid-template-columns: 1fr 1fr 1fr 1fr;
  gap: 20px;
}
div {
  height: 50px;
  border: 1px solid black;
}
```

```
[data-color="blue"] {
  background-color: lch(50% 150 240);
}
[data-color="blue-chroma1"] {
  background-color: lch(50% 105 240);
}
[data-color="blue-chroma2"] {
  background-color: lch(50% 54 240);
}
[data-color="blue-chroma3"] {
  background-color: lch(50% 3 240);
}

[data-color="red"] {
  background-color: lch(50% 100% 20deg);
}
[data-color="red-chroma1"] {
  background-color: lch(50% 70% 20deg);
}
[data-color="red-chroma2"] {
  background-color: lch(50% 36% 20deg);
}
[data-color="red-chroma3"] {
  background-color: lch(50% 2% 20deg);
}

[data-color="green"] {
  background-color: lch(50% 150 130);
}
[data-color="green-chroma1"] {
  background-color: lch(50% 105 130);
}
[data-color="green-chroma2"] {
  background-color: lch(50% 54 130);
}
[data-color="green-chroma3"] {
  background-color: lch(50% 3 130);
}
```

Result

If we had used `0` instead of `3` and `2%`, with the same lightness values, the colors would have all been the same shade of gray. In this example, they are almost gray.

Hues in LCH

The following example shows swatches with different `H` (hue) values of the `lch()` functional notation.

HTML

```
<div data-color="0">0deg</div>
<div data-color="20">20deg</div>
<div data-color="40">40deg</div>
<div data-color="60">60deg</div>
```

and so on.

```
<div data-color="80">80deg</div>
<div data-color="100">100deg</div>
<div data-color="120">120deg</div>
<div data-color="140">140deg</div>
<div data-color="160">160deg</div>
<div data-color="180">180deg</div>
<div data-color="200">200deg</div>
<div data-color="220">220deg</div>
<div data-color="240">240deg</div>
<div data-color="260">260deg</div>
<div data-color="280">280deg</div>
<div data-color="300">300deg</div>
<div data-color="320">320deg</div>
<div data-color="340">340deg</div>
<div data-color="360">360deg</div>
```

CSS

```
body {
  display: flex;
  flex-wrap: wrap;
  gap: 3px;
}
div {
  flex: 0 0 4em;
  text-align: center;
  line-height: 4em;
  display: inline-block;
  border: 1px solid black;
  color: white;
  font-family: monospace;
}
```

```
[data-color="0"] {
  background-color: lch(50% 150 0deg);
}
[data-color="20"] {
  background-color: lch(50% 150 20deg);
}
[data-color="40"] {
  background-color: lch(50% 150 40deg);
}
[data-color="60"] {
  background-color: lch(50% 150 60deg);
}
```

and so on.

```
[data-color="80"] {
  background-color: lch(50% 150 80deg);
}
[data-color="100"] {
  background-color: lch(50% 150 100deg);
}
[data-color="120"] {
  background-color: lch(50% 150 120deg);
}
[data-color="140"] {
  background-color: lch(50% 150 140deg);
}
[data-color="160"] {
  background-color: lch(50% 150 160deg);
}
[data-color="180"] {
  background-color: lch(50% 150 180deg);
}
[data-color="200"] {
  background-color: lch(50% 150 200deg);
}
[data-color="220"] {
  background-color: lch(50% 150 220deg);
}
[data-color="240"] {
  background-color: lch(50% 150 240deg);
}
[data-color="260"] {
  background-color: lch(50% 150 260deg);
}
[data-color="280"] {
  background-color: lch(50% 150 280deg);
}
[data-color="300"] {
  background-color: lch(50% 150 300deg);
}
[data-color="320"] {
  background-color: lch(50% 150 320deg);
}
[data-color="340"] {
  background-color: lch(50% 150 340deg);
}
[data-color="360"] {
  background-color: lch(50% 150 360deg);
}
```

Result

The hue angles in `lch()` are different from those in `hsl()`. See `<hue>` for more information. In `hsl()`, the sRGB color `0deg` represents red. However, in the CIELab color space, `0deg` corresponds to magenta, while red is approximately `41deg`.

Adjusting opacity with lch()

The following example shows the effect of varying the `A` (alpha) value of the `lch()` functional notation. The `red` and `red-alpha` elements overlap the `#background-div` element to demonstrate the effect of opacity. Giving `A` a value of `0.4` makes the color 40% opaque.

HTML

```
<div id="background-div">
  <div data-color="red"></div>
  <div data-color="red-alpha"></div>
</div>
```

CSS

```
div {
  width: 50px;
  height: 50px;
  padding: 5px;
  margin: 5px;
  display: inline-block;
  border: 1px solid black;
}
#background-div {
  background-color: lch(100% 100 240);
  width: 150px;
  height: 40px;
}
```

```
[data-color="red"] {
  background-color: lch(50% 130 20);
}
[data-color="red-alpha"] {
  background-color: lch(50% 130 20 / 0.4);
}
```

Result

Using relative colors with lch()

This example styles three `<div>` elements with different background colors, demonstrating the use of relative colors to change a color's brightness using the `lch()` color function. The middle `<div>` retains the original `--base-color`, while the left and right `<div>`s are given lightened and darkened variants of the `--base-color`.

These variants are defined using relative colors — the `--base-color` custom property is passed into an `lch()` function, and the output colors have their lightness channel modified to achieve the desired effect via a `calc()` function. The lightened color has 15% added to the lightness channel, and the darkened color has 15% subtracted from the lightness channel.

```
<div id="container">
  <div class="item" id="one"></div>
  <div class="item" id="two"></div>
  <div class="item" id="three"></div>
</div>
```

CSS

```
#container {
  display: flex;
  width: 100vw;
  height: 100vh;
  box-sizing: border-box;
}

.item {
  flex: 1;
  margin: 20px;
}
```

```
:root {
  --base-color: orange;
}

#one {
  background-color: lch(from var(--base-color) calc(l + 15) c h);
}

#two {
  background-color: var(--base-color);
}

#three {
  background-color: lch(from var(--base-color) calc(l - 15) c h);
}
```

Result

The output is as follows:

light-dark() CSS function

The **`light-dark()`** CSS function accepts two colors or two images and returns a color or an image based on the active color scheme, without needing a `prefers-color-scheme` media feature.

Syntax

```
/* Named color values */
light-dark(
  black,
  white
);

/* RGB color values */
light-dark(
  rgb(0 0 0),
  rgb(255 255 255)
);

/* image url values */
light-dark(
  url("light-icon.png"),
  url("dark-icon.png")
);

/* linear-gradient values */
light-dark(
  linear-gradient(135deg, ghostwhite 20%, tomato),
  linear-gradient(45deg, darkslategray 20%, gold)
);

/* Custom properties */
light-dark(
  var(--light),
  var(--dark)
);
```

Values

The light-dark() function has two forms:

- Accepts two `<color>` values:

  `<color>` (light)

  > The `<color>` value used when the `color-scheme` is `light` or no preference is set.

  `<color>` (dark)

  > The `<color>` value used when the `color-scheme` is `dark`.

- Accepts two `<image>` values:

  `<image>` (light)

  > The `<image>` value used when the `color-scheme` is `light` or no preference is set.

  `<image>` (dark)

  > The `<image>` value used when the `color-scheme` is `dark`.

  `none`

  > The `none` keyword produces a fully transparent image with no natural size.

Description

Users can indicate their color scheme preference through their operating system settings (e.g., light or dark mode) or their user agent settings. The `light-dark()` function enables providing either two color values where any `<color>` value is accepted or two image values where any `<image>` value is accepted. The `light-dark()` function returns the first value if the used color scheme is `light` or if no preference is set and the second value if the used color scheme is `dark`.

To enable support for the `light-dark()` color function, the `color-scheme` must have a value of `light dark`, usually set on the `:root` pseudo-class.

```
:root {
  color-scheme: light dark;
}
body {
  color: light-dark(#333b3c, #efefec);
  background-color: light-dark(#efedea, #223a2c);
}
```

Formal syntax

```
<light-dark()> =
  <light-dark-color>  |
  <light-dark-image>

<light-dark-color> =
  light-dark( <color> , <color> )

<light-dark-image> =
  light-dark( [ <image> | none ] , [ <image> | none ] )

<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
  <gradient>

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-set()> =
  image-set( <image-set-option># )

<cross-fade()> =
  cross-fade( <cf-image># )
```

```
<element()> =
  element( <id-selector> )

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>      |
  <string>

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Color Module Level 5, CSS Images Module Level 4, CSS Images Module Level 5, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting colors based on a color scheme

By default, in supporting browsers, the color returned by the `light-dark()` color function depends on the user preference set through an operating system's settings (e.g., light or dark mode) or from a user agent setting. You can also change this setting in the browser's developer tools.

HTML

We include three sections to enable targeting light colors, dark colors, and the colors selected based on the user's preferred color scheme.

```
<h1><code>light-dark()</code> CSS function</h1>
<section>
  <h2>Automatic</h2>
  <p>This section will react to the users system or user agent setting.</p>
</section>
<section class="light">
  <h2>Light</h2>
  <p>
    This section will be light due to the <code>color-scheme: light;</code>.
  </p>
</section>
<section class="dark">
  <h2>Dark</h2>
  <p>This section will be dark due to the <code>color-scheme: dark;</code>.</p>
</section>
```

CSS

We include colors for both light and dark themes. We also define `color-scheme` for the document on the `:root` to enable the `light-dark()` color function for the entire document.

```
:root {
  /* this has to be set to switch between light or dark */
  color-scheme: light dark;

  --light-bg: ghostwhite;
  --light-color: darkslategray;
  --light-code: tomato;

  --dark-bg: darkslategray;
  --dark-color: ghostwhite;
  --dark-code: gold;
}
* {
  background-color: light-dark(var(--light-bg), var(--dark-bg));
  color: light-dark(var(--light-color), var(--dark-color));
}
code {
  color: light-dark(var(--light-code), var(--dark-code));
}
```

In addition to enabling the `light-dark()` function, the `color-scheme` property enables overriding a user's color scheme for document sections. Forcing a page section to only use a light or dark color scheme can be done by setting the `color-scheme` property to `light` or `dark`.

> **Note:** Generally this should not be done, we are using it here for demonstration purposes. If the user has made a preference, you generally should not override their preferences.

```
.light {
  /* forces light color-scheme */
  color-scheme: light;
}
.dark {
  /* forces dark color-scheme */
  color-scheme: dark;
}
```

```
section {
  padding: 0.8rem;
}
```

Result

Setting gradient background based on a color scheme

This example uses the same HTML code as the previous example but includes a `<div>` instead of a `<p>`.

```
<h1><code>light-dark()</code> CSS function with images</h1>
<p class="supports">
  Your browser does not support <code>light-dark()</code> with images.
</p>
<div class="wrapper">
  <section>
    <h2>Automatic</h2>
    <div></div>
  </section>
  <section class="light">
    <h2>Light</h2>
    <div></div>
  </section>
  <section class="dark">
    <h2>Dark</h2>
    <div></div>
  </section>
</div>
```

CSS

```
:root {
  /* this has to be set to switch between light or dark */
  color-scheme: light dark;

  --light-bg: ghostwhite;
  --light-color: darkslategray;
  --light-code: tomato;

  --dark-bg: darkslategray;
  --dark-color: ghostwhite;
  --dark-code: gold;
}
* {
  background-color: light-dark(var(--light-bg), var(--dark-bg));
  color: light-dark(var(--light-color), var(--dark-color));
}
.wrapper {
  display: flex;
  justify-content: space-around;
  padding: 0.8rem;
}
.light {
  /* forces light color-scheme */
  color-scheme: light;
}
.dark {
  /* forces dark color-scheme */
  color-scheme: dark;
}
section {
  width: 25%;
  padding: 5px;
  color: light-dark(
    var(--light-code),
    var(--dark-code)
  );
  border: 2px solid light-dark(var(--light-code), var(--dark-code));
}
@supports (background-image: light-dark(url("light.png"), url("dark.png"))) {
  .supports {display:none;}
}
```

Firstly, we define light and dark `linear-gradient()` values as custom properties.

```
:root {
  /*  light dark gradients  */
  --light-grad: linear-gradient(135deg, var(--light-bg) 20%, var(--light-code));
  --dark-grad: linear-gradient(45deg, var(--dark-bg) 30%, var(--dark-code));
}
```

```
section div {
  width: 80%;
  aspect-ratio: 1/1;
  margin: auto;
  border: 1px solid light-dark(var(--light-code), var(--dark-code));
}
@supports not (
  background-image: light-dark(url("light.png"), url("dark.png"))
) {
  section div {
    width: 60%;
  }
}
```

Then we use the custom properties with `light-dark()` to set the `background-image` property based on the active color scheme.

```
section div {
  background-image: light-dark(
    var(--light-grad),
    var(--dark-grad)
  );
}
```

oklab() CSS function

The **`oklab()`** functional notation expresses a given color in the Oklab color space, which attempts to mimic how color is perceived by the human eye.

Oklab is a perceptual color space and is useful to:

- Transform an image to grayscale, without changing its lightness.
- Modify the saturation of colors, while keeping user perception of hue and lightness
- Create smooth and uniform gradients of colors (when interpolated manually, for example, in a `<canvas>` element).

`oklab()` works with a Cartesian coordinate system on the Oklab color space — a- and b-axes. It can represent a wider range of colors than RGB, including wide-gamut and P3 colors. If you want a polar color system, chroma and hue, use `oklch()`.

Syntax

```
/* Absolute values */
oklab(40.1% 0.1143 0.045);
oklab(59.69% 0.1007 0.1191);
oklab(59.69% 0.1007 0.1191 / 0.5);

/* Relative values */
oklab(from green l a b / 0.5)
oklab(from #123456 calc(l + 0.1) a b / calc(alpha * 0.9))
oklab(from hsl(180 100% 50%) calc(l - 0.1) a b)
```

Values

Below are descriptions of the allowed values for both absolute and relative colors.

Absolute value syntax

```
oklab(L a b[ / A])
```

The parameters are as follows:

`L`

A `<number>` between `0` and `1`, a `<percentage>` between `0%` and `100%`, or the keyword `none` (equivalent to `0%` in this case). This value specifies the color's perceived lightness. The number `0` corresponds to `0%` (black) and the number `1` corresponds to `100%` (white).

`a`

A `<number>` between `-0.4` and `0.4`, a `<percentage>` between `-100%` and `100%`, or the keyword `none` (equivalent to `0%` in this case). This value specifies the color's distance along the `a` axis in the Oklab color space, which defines how green (moving towards `-0.4`) or red (moving towards `+0.4`) the color is. Note that these values are signed (allowing both positive and negative values) and theoretically unbounded, meaning that you can set values outside the `±0.4` (`±100%`) limits. In practice, values cannot exceed `±0.5`.

`b`

A `<number>` between `-0.4` and `0.4`, a `<percentage>` between `-100%` and `100%`, or the keyword `none` (equivalent to `0%` in this case). This value specifies the color's distance along the `b` axis in the Oklab color space, which defines how blue (moving towards `-0.4`) or yellow (moving towards `+0.4`) the color is. Note that these values are signed (allowing both positive and negative values) and theoretically unbounded, meaning that you can set values outside the `±0.4` (`±100%`) limits. In practice, values cannot exceed `±0.5`.

`A` Optional

An `<alpha-value>` representing the alpha channel value of the color, where the number `0` corresponds to `0%` (fully transparent) and `1` corresponds to `100%` (fully opaque). Additionally, the keyword `none` can be used to explicitly specify no alpha channel. If the `A` channel value is not explicitly specified, it defaults to 100%. If included, the value is preceded by a slash (`/`).

> **Note:** See Missing color components for more information on the effect of `none`.

Relative value syntax

```
oklab(from <color> L a b[ / A])
```

The parameters are as follows:

`from <color>`

The keyword `from` is always included when defining a relative color, followed by a `<color>` value representing the **origin color**. This is the original color that the relative color is based on. The origin color can be *any* valid `<color>` syntax, including another relative color.

`L`

A `<number>` between `0` and `1`, a `<percentage>` between `0%` and `100%`, or the keyword `none` (equivalent to `0%` in this case). This value represents the lightness of the output color. The number `0` corresponds to `0%` (black) and the number `1` corresponds to `100%` (white).

`a`

A `<number>` between `-0.4` and `0.4`, a `<percentage>` between `-100%` and `100%`, or the keyword `none` (equivalent to `0%` in this case). This value represents the output color's distance along the `a` axis in the Oklab color space, which defines how green (moving towards `-0.4`) or red (moving towards `+0.4`) the color is. Note that these values are signed (allowing both positive and negative values) and theoretically unbounded, meaning that you can set values outside the `±0.4` (`±100%`) limits. In practice, values cannot exceed `±0.5`.

`b`

A `<number>` between `-0.4` and `0.4`, a `<percentage>` between `-100%` and `100%`, or the keyword `none` (equivalent to `0%` in this case). This value represents the output color's distance along the `b` axis in the Oklab color space, which defines how blue (moving towards `-0.4`) or yellow (moving towards `+0.4`) the color is. Note that these values are signed (allowing both positive and negative values) and theoretically unbounded, meaning that you can set values outside the `±0.4` (`±100%`) limits. In practice, values cannot exceed `±0.5`.

`A` Optional

An `<alpha-value>` representing the alpha channel value of the output color, where the number `0` corresponds to `0%` (fully transparent) and `1` corresponds to `100%` (fully opaque). Additionally, the keyword `none` can be used to explicitly specify no alpha channel. If the `A` channel value is not explicitly specified, it defaults to the alpha channel value of the origin color. If included, the value is preceded by a slash (`/`).

Defining relative color output channel components

When using relative color syntax inside an `oklab()` function, the browser converts the origin color into an equivalent Oklab color (if it is not already specified as such). The color defined as three distinct color channel values — `l` (lightness), `a` (green/red axis), and `b` (blue/yellow axis) — plus an alpha channel value (`alpha`). These channel values are made available inside the function to be used when defining the output color channel values:

- The `l` channel value is resolved to a `<number>` between `0` and `1`, inclusive.
- The `a` and `b` channels are each resolved to a `<number>` between `-0.4` and `0.4`, inclusive.
- The `alpha` channel is resolved to a `<number>` between `0` and `1`, inclusive.

When defining a relative color, the different channels of the output color can be expressed in several different ways. Below, we'll study some examples to illustrate these.

In the first two examples below, we are using relative color syntax. However, the first one outputs the same color as the origin color and the second one outputs a color not based on the origin color at all. They don't really create relative colors! You'd be unlikely to ever use these in a real codebase, and would probably just use an absolute color value instead. We included these examples as a starting point for learning about relative `oklab()` syntax.

Let's start with an origin color of `hsl(0 100% 50%)` (equivalent to `red`). The following function outputs the same color as the origin color — it uses the origin color's `l`, `a`, and `b` channel values (`0.627966`, `0.22488`, and `0.125859`) as the output channel values:

```
oklab(from hsl(0 100% 50%) l a b)
```

This function's output color is `oklab(0.627966 0.22488 0.125859)`.

The next function uses absolute values for the output color's channel values, outputting a completely different color not based on the origin color:

```
oklab(from hsl(0 100% 50%) 42.1% 0.165 -0.101)
```

In the above case, the output color is `oklab(0.421 0.165 -0.101)`.

The following function creates a relative color based on the origin color:

```
oklab(from hsl(0 100% 50%) l -0.3 b)
```

This example:

- Converts the `hsl()` origin color to an equivalent `oklab()` color — `oklab(0.627966 0.22488 0.125859)`.
- Sets the `L` and `b` channel values for the output color to those of the origin `oklab()` equivalent's `L` and `b` channel values — those values are `0.627966` and `0.125859`, respectively.
- Sets the output color's `a` channel value to a new value not based on the origin color: `-0.3`.

The final output color is `oklab(0.627966 -0.3 0.125859)`.

> **Note:** As mentioned above, if the output color is using a different color model to the origin color, the origin color is converted to the same model as the output color in the background so that it can be represented in a way that is compatible (i.e., using the same channels).

In the examples we've seen so far in this section, the alpha channels have not been explicitly specified for either the origin or output colors. When the output color alpha channel is not specified, it defaults to the same value as the origin color alpha channel. When the origin color alpha channel is not specified (and it is not a relative color), it defaults to `1`. Therefore, the origin and output alpha channel values are `1` for the above examples.

Let's look at some examples that specify origin and output alpha channel values. The first one specifies the output alpha channel value as being the same as the origin alpha channel value, whereas the second one specifies a different output alpha channel value, unrelated to the origin alpha channel value.

```
oklab(from hsl(0 100% 50% / 0.8) l a b / alpha)
/* Computed output color: oklab(0.627966 0.22488 0.125859 / 0.8) */

oklab(from hsl(0 100% 50% / 0.8) l a b / 0.5)
/* Computed output color: oklab(0.627966 0.22488 0.125859 / 0.5) */
```

In the following example, the `hsl()` origin color is again converted to the `oklab()` equivalent — `oklab(0.627966 0.22488 0.125859)`. `calc()` calculations are applied to the `L`, `a`, `b`, and `A` values, resulting in an output color of `oklab(0.827966 0.14488 -0.0741406 / 0.9)`:

```
oklab(from hsl(0 100% 50%) calc(l + 0.2) calc(a - 0.08) calc(b - 0.2) / calc(alpha - 0.1))
```

> **Note:** Because the origin color channel values are resolved to `<number>` values, you have to add numbers to them when using them in calculations, even in cases where a channel would normally accept `<percentage>`, `<angle>`, or other value types. Adding a `<percentage>` to a `<number>`, for example, doesn't work.

Formal syntax

```
<oklab()> =
  oklab( [ from <color> ]? [ <percentage> | <number> | none ] [ <percentage> | <number> | none ] [ <percentage> | <number> | none ] [ / [ <alpha-value> | none ] ]? )

<alpha-value> =
  <number>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Color Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Adjusting lightness

The following example shows the effect of varying the lightness, a-axis, and b-axis values of the `oklab()` function.

HTML

```
<div data-color="red-dark"></div>
<div data-color="red"></div>
<div data-color="red-light"></div>

<div data-color="green-dark"></div>
<div data-color="green"></div>
```

```
<div data-color="green-light"></div>

<div data-color="blue-dark"></div>
<div data-color="blue"></div>
<div data-color="blue-light"></div>
```

CSS

```
body {
  display: flex;
  flex-wrap: wrap;
  gap: 10px;
}
div {
  height: 50px;
  flex: 0 0 28%;
  border: 1px solid black;
}
```

```
[data-color="red-dark"] {
  background-color: oklab(0.05 0.4 0.4);
}
[data-color="red"] {
  background-color: oklab(0.5 0.4 0.4);
}
[data-color="red-light"] {
  background-color: oklab(0.95 0.4 0.4);
}

[data-color="green-dark"] {
  background-color: oklab(5% -100% 0.4);
}
[data-color="green"] {
  background-color: oklab(50% -100% 0.4);
}
[data-color="green-light"] {
  background-color: oklab(95% -100% 0.4);
}

[data-color="blue-dark"] {
  background-color: oklab(0.05 -0.3 -0.4);
}
[data-color="blue"] {
  background-color: oklab(0.5 -0.3 -0.4);
}
[data-color="blue-light"] {
  background-color: oklab(0.95 -0.3 -0.4);
}
```

Result

Adjusting opacity

The following example shows the effect of varying the `A` (alpha) value of the `oklab()` function. The `red` and `red-alpha` elements overlap the `#background-div` element to demonstrate the effect of opacity. Giving the `red-alpha` element an opacity of `0.4` makes it appear more transparent than the `red` element.

HTML

```
<div id="background-div">
  <div data-color="red"></div>
  <div data-color="red-alpha"></div>
</div>
```

CSS

```
div {
  width: 50px;
  height: 50px;
  padding: 5px;
  margin: 5px;
  display: inline-block;
  border: 1px solid black;
}
#background-div {
  background-color: lightblue;
  width: 150px;
  height: 40px;
}
```

```
[data-color="red"] {
  background-color: oklab(0.628 0.225 0.126);
}
[data-color="red-alpha"] {
  background-color: oklab(0.628 0.225 0.126 / 0.4);
}
```

Result

Adjusting color axes

This example demonstrates the effects of setting the `a` and `b` values of the `oklab()` function to the ends and midpoints of the a-axis and b-axis, respectively. The a-axis goes from green (`-0.4`) to red (`0.4`) and the b-axis goes from yellow (`-0.4`) to blue (`0.4`).

HTML

```
<div data-color="red-yellow"></div>
<div data-color="red-zero"></div>
<div data-color="red-blue"></div>

<div data-color="zero-yellow"></div>
<div data-color="zero-zero"></div>
```

```
<div data-color="zero-blue"></div>

<div data-color="green-yellow"></div>
<div data-color="green-zero"></div>
<div data-color="green-blue"></div>
```

CSS

Using the CSS `background-color` property, we vary the `a` and `b` values of the `oklab()` color function along the a-axis and b-axis, showing the effects of maximum, midpoint, and minimum values in each case.

```
body {
  display: grid;
  grid-template-columns: 1fr 1fr 1fr;
  gap: 10px;
}
div {
  height: 50px;
  flex: 0 0 28%;
  border: 1px solid black;
}
```

```
/* a-axis max, variable b-axis */
[data-color="red-yellow"] {
  background-color: oklab(0.5 0.4 0.4);
}
[data-color="red-zero"] {
  background-color: oklab(0.5 0.4 0);
}
[data-color="red-blue"] {
  background-color: oklab(0.5 0.4 -0.4);
}

/* a-axis center, variable b-axis */
[data-color="zero-yellow"] {
  background-color: oklab(0.5 0 0.4);
}
[data-color="zero-zero"] {
  background-color: oklab(0.5 0 0);
}
[data-color="zero-blue"] {
  background-color: oklab(0.5 0 -0.4);
}

/* a-axis min, variable b-axis */
[data-color="green-yellow"] {
  background-color: oklab(0.5 -0.4 0.4);
}
[data-color="green-zero"] {
  background-color: oklab(0.5 -0.4 0);
}
[data-color="green-blue"] {
  background-color: oklab(0.5 -0.4 -0.4);
}
```

Result

The left column is at the yellow end (`-0.4`) of the b-axis and the right column is at the blue end (`0.4`). The top row displays colors at the red end of the a-axis (`-0.4`) and the bottom row is at the green end (`0.4`). The middle column and row are at the midpoints of each axis, with the middle cell being gray; it contains no red, green, yellow, or blue, with a `0` value for both axes.

Linear gradients along the a-axis and b-axis

This example includes linear gradients to demonstrate the progression of values of the `oklab()` function along the a-axis (from red to green) and along the b-axis (from yellow to blue). In each gradient image, one axis remains static while the other axis progresses from low to high values.

```
<div data-color="red-to-green-yellow">
  <span>red</span><span>`b`= -0.4 (yellow)</span><span>green</span>
</div>
<div data-color="red-to-green-zero">
  <span>red</span><span>no yellow or blue</span><span>green</span>
</div>
<div data-color="red-to-green-blue">
  <span>red</span><span>`b`= 0.4 (blue)</span><span>green</span>
</div>

<div data-color="yellow-to-blue-red">
  <span>yellow</span><span>`a` = -0.4 (red)</span><span>blue</span>
</div>
<div data-color="yellow-to-blue-zero">
  <span>yellow</span><span>no red or green</span><span>blue</span>
</div>
<div data-color="yellow-to-blue-green">
  <span>yellow</span><span>`a` = 0.4 (green)</span><span>blue</span>
</div>
```

CSS

```
div {
  height: 50px;
  padding: 5px;
  margin: 5px;
  border: 1px solid black;
  display: flex;
  justify-content: space-between;
  align-items: center;
}
span {
  background-color: #ffffffcc;
  padding: 3px;
}
```

```
/* a-axis gradients */
[data-color="red-to-green-yellow"] {
  background-image: linear-gradient(to right, oklab(50% 0.4 0.4), oklab(50% -0.4 0.4));
}
[data-color="red-to-green-zero"] {
  background-image: linear-gradient(to right, oklab(50% 0.4 0), oklab(50% -0.4 0));
}
[data-color="red-to-green-blue"] {
  background-image: linear-gradient(to right, oklab(50% 0.4 -0.4), oklab(50% -0.4 -0.4));
}

/* b-axis gradients */
[data-color="yellow-to-blue-red"] {
  background-image: linear-gradient(to right, oklab(50% 0.4 0.4), oklab(50% 0.4 -0.4));
}
[data-color="yellow-to-blue-zero"] {
  background-image: linear-gradient(to right, oklab(50% 0 0.4), oklab(50% 0 -0.4));
}
[data-color="yellow-to-blue-green"] {
  background-image: linear-gradient(to right, oklab(50% -0.4 0.4),oklab(50% -0.4 -0.4));
}
```

Result

Using relative colors with oklab()

This example styles three `<div>` elements with different background colors. The middle one is given the unmodified `--base-color`, while the left and right ones are given lightened and darkened variants of that `--base-color`.

These variants are defined using relative colors — the `--base-color` custom property is passed into an `oklab()` function, and the output colors have their lightness channel modified to achieve the desired effect via a `calc()` function. The lightened color has `0.15` (15%) added to the lightness channel, and the darkened color has `0.15` (15%) subtracted from the lightness channel.

```
<div id="container">
  <div class="item" id="one"></div>
  <div class="item" id="two"></div>
  <div class="item" id="three"></div>
</div>
```

CSS

```
#container {
  display: flex;
  width: 100vw;
  height: 100vh;
  box-sizing: border-box;
}

.item {
  flex: 1;
  margin: 20px;
}
```

```
:root {
  --base-color: orange;
}

#one {
  background-color: oklab(from var(--base-color) calc(l + 0.15) a b);
}

#two {
  background-color: var(--base-color);
}

#three {
  background-color: oklab(from var(--base-color) calc(l - 0.15) a b);
}
```

Result

The output is as follows:

oklch() CSS function

The **`oklch()`** functional notation expresses a given color in the Oklab color space. `oklch()` is the cylindrical form of `oklab()`, using the same `L` axis, but with polar Chroma (`C`) and Hue (`H`) coordinates.

Syntax

```
/* Absolute values */
oklch(40.1% 0.123 21.57)
oklch(59.69% 0.156 49.77)
oklch(59.69% 0.156 49.77 / .5)

/* Relative values */
oklch(from green l c h / 0.5)
oklch(from #123456 calc(l + 0.1) c h)
oklch(from hsl(180 100% 50%) calc(l - 0.1) c h)
oklch(from var(--color) l c h / calc(alpha - 0.1))
```

Values

Below are descriptions of the allowed values for both absolute and relative colors.

> **Note:** Usually when percentage values have a numeric equivalent in CSS, `100%` is equal to the number `1`. This is not the case for all of the `oklch()` component values. Here, `100%` is equal to `0.4` for the `C` value.

Absolute value syntax

```
oklch(L C H[ / A])
```

The parameters are as follows:

`L`

A `<number>` between `0` and `1`, a `<percentage>` between `0%` and `100%`, or the keyword `none` (equivalent to `0%` in this case). In this case, the number `0` corresponds to `0%` (black) and the number `1` corresponds to `100%` (white). This value specifies the color's perceived lightness, or "brightness".

> **Note:** The `L` in `oklch()` is the perceived lightness, which refers to the "brightness" we visually perceive with our eyes. This is different from the `L` in `hsl()`, where it represents lightness as compared to other colors.

`C`

A `<number>`, a `<percentage>`, or the keyword `none` (equivalent to `0%` in this case). This value is a measure of the color's chroma (roughly representing the "amount of color"). Its minimum useful value is `0`, while the maximum is theoretically unbounded (but in practice does not exceed `0.5`). In this case, `0%` is `0` and `100%` is the number `0.4`.

`H`

A `<number>`, an `<angle>`, or the keyword `none` (equivalent to `0deg` in this case) representing the color's `<hue>` angle.

> **Note:** The angles corresponding to particular hues differ across the sRGB (used by `hsl()` and `hwb()`), CIELAB (used by `lch()`), and Oklab (used by `oklch()`) color spaces. See the Hues in `oklch()` example below and the `<hue>` reference page for more details and examples.

`A` Optional

An `<alpha-value>` representing the alpha channel value of the color, where the number `0` corresponds to `0%` (fully transparent) and `1` corresponds to `100%` (fully opaque). Additionally, the keyword `none` can be used to explicitly specify no alpha channel. If the `A` channel value is not explicitly specified, it defaults to 100%. If included, the value is preceded by a slash (`/`).

> **Note:** See Missing color components for more information on the effect of `none`.

Relative value syntax

```
oklch(from &lt;color&gt; L C H[ / A])
```

The parameters are as follows:

`from <color>`

The keyword `from` is always included when defining a relative color, followed by a `<color>` value representing the **origin color**: This is the original color that the relative color is based on. The origin color can be *any* valid `<color>` syntax, including another relative color.

`L`

A `<number>` between `0` and `1`, a `<percentage>` between `0%` and `100%`, or the keyword `none` (equivalent to `0%` in this case). This represents the lightness value of the output color. Here the number `0` corresponds to `0%` (black) and the number `1` corresponds to `100%` (white).

`C`

A `<number>`, a `<percentage>`, or the keyword `none` (equivalent to `0%` in this case). This value represents the output color's chroma value (roughly representing the "amount of color"). Its minimum useful value is `0`, while its maximum is theoretically unbounded (but in practice does not exceed `0.5`). In this case, `0%` is `0` and `100%` is the number `0.4`.

`H`

A `<number>`, an `<angle>`, or the keyword `none` (equivalent to `0deg` in this case) representing the output color's `<hue>` angle. See a sample of different hues in the Examples section below.

`A` Optional

An `<alpha-value>` representing the alpha channel value of the output color, where the number `0` corresponds to `0%` (fully transparent) and `1` corresponds to `100%` (fully opaque). Additionally, the keyword `none` can be used to explicitly specify no alpha channel. If the `A` channel value is not explicitly specified, it defaults to the alpha channel value of the origin color. If included, the value is preceded by a slash (`/`).

Defining relative color output channel components

When using relative color syntax inside an `oklch()` function, the browser converts the origin color into an equivalent OkLCh color (if it is not already specified as such). The color is defined as three distinct color channel values — `l` (lightness), `c` (chroma), and `h` (hue) — plus an alpha channel value (`alpha`). These channel values are made available inside the function to be used when defining the output color channel values:

- The `l` channel value is resolved to a `<number>` between `0` and `1`, inclusive.
- The `c` channel value is resolved to a `<number>` between `0` and `0.4`, inclusive.
- The `h` channel value is resolved to a `<number>` between `0` and `360`, inclusive.
- The `alpha` channel is resolved to a `<number>` between `0` and `1`, inclusive.

When defining a relative color, the different channels of the output color can be expressed in several different ways. Below, we'll study some examples to illustrate these.

In the first two examples below, we are using relative color syntax. However, the first one outputs the same color as the origin color and the second one outputs a color not based on the origin color at all. They don't really create relative colors! You'd be unlikely to ever use these in a real codebase, and would probably just use an absolute color value instead. We included these examples as a starting point for learning about relative `oklch()` syntax.

Let's start with an origin color of `hsl(0 100% 50%)` (equivalent to `red`). The following function outputs the same color as the origin color — it uses the origin color's `l`, `c`, and `h` channel values (`0.627966`, `0.257704`, and `29.2346`) as the output channel values:

```
oklch(from hsl(0 100% 50%) l c h)
```

This function's output color is `oklch(0.627966 0.257704 29.2346)`.

The next function uses absolute values for the output color's channel values, outputting a completely different color not based on the origin color:

```
oklch(from hsl(0 100% 50%) 42.1% 0.25 328.363)
```

In the above case, the output color is `oklch(0.421 0.25 328.363)`.

The following function creates a relative color based on the origin color:

```
oklch(from hsl(0 100% 50%) 0.8 0.4 h)
```

This example:

- Converts the `hsl()` origin color to an equivalent `oklch()` color — `oklch(0.627966 0.257704 29.2346)`.
- Sets the `H` channel value for the output color to that of the origin `oklch()` equivalent's `H` channel value — `29.2346`.
- Sets the output color's `L` and `C` channel values to new values not based on the origin color: `0.8` and `0.4` respectively.

The final output color is `oklch(0.8 0.4 29.2346)`.

> **Note:** As mentioned above, if the output color is using a different color model to the origin color, the origin color is converted to the same model as the output color in the background so that it can be represented in a way that is compatible (i.e., using the same channels).

In the examples we've seen so far in this section, the alpha channels have not been explicitly specified for either the origin or output colors. When the output color alpha channel is not specified, it defaults to the same value as the origin color alpha channel. When the origin color alpha channel is not specified (and it is not a relative color), it defaults to `1`. Therefore, the origin and output alpha channel values are `1` for the above examples.

Let's look at some examples that specify origin and output alpha channel values. The first one specifies the output alpha channel value as being the same as the origin alpha channel value, whereas the second one specifies a different output alpha channel value, unrelated to the origin alpha channel value.

```
oklch(from hsl(0 100% 50% / 0.8) l c h / alpha)
/* Computed output color: oklch(0.627966 0.257704 29.2346 / 0.8) */

oklch(from hsl(0 100% 50% / 0.8) l c h / 0.5)
/* Computed output color: oklch(0.627966 0.257704 29.2346 / 0.5) */
```

In the following example, the `hsl()` origin color is again converted to the `oklch()` equivalent — `oklch(0.627966 0.257704 29.2346)`. `calc()` calculations are applied to the `L`, `C`, `H`, and `A` values, resulting in an output color of `oklch(0.827966 0.357704 9.23462 / 0.9)`:

```
oklch(from hsl(0 100% 50%) calc(l + 0.2) calc(c + 0.1) calc(h - 20) / calc(alpha - 0.1))
```

> **Note:** Because the origin color channel values are resolved to `<number>` values, you have to add numbers to them when using them in calculations, even in cases where a channel would normally accept `<percentage>`, `<angle>`, or other value types. Adding a `<percentage>` to a `<number>`, for example, doesn't work.

Formal syntax

```
<oklch()> =
  oklch( [ from <color> ]? [ <percentage> | <number> | none ] [ <percentage> | <number> | none ] [ <hue> | none ] [ / [ <alpha-value> | none ] ]? )

<hue> =
  <number>  |
  <angle>

<alpha-value> =
  <number>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Color Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Adjusting the brightness of a color

This example shows the effect of varying the `L` (lightness) value of the `oklch()` functional notation.

HTML

```
<div data-color="blue-dark"></div>
<div data-color="blue"></div>
<div data-color="blue-light"></div>

<div data-color="red-dark"></div>
<div data-color="red"></div>
<div data-color="red-light"></div>

<div data-color="green-dark"></div>
<div data-color="green"></div>
<div data-color="green-light"></div>
```

CSS

```
body {
  display: grid;
  grid-template-columns: 1fr 1fr 1fr;
  gap: 20px;
}
div {
  height: 50px;
  border: 1px solid black;
}
```

```
[data-color="blue-dark"] {
  background-color: oklch(10% 0.4 240);
}
[data-color="blue"] {
```

```
  background-color: oklch(50% 0.4 240);
}
[data-color="blue-light"] {
  background-color: oklch(90% 0.4 240);
}

[data-color="red-dark"] {
  background-color: oklch(10% 0.4 20);
}
[data-color="red"] {
  background-color: oklch(50% 0.4 20);
}
[data-color="red-light"] {
  background-color: oklch(90% 0.4 20);
}

[data-color="green-dark"] {
  background-color: oklch(10% 0.4 130);
}
[data-color="green"] {
  background-color: oklch(50% 0.4 130);
}
[data-color="green-light"] {
  background-color: oklch(90% 0.4 130);
}
```

Result

Adjusting color intensity via chroma

The following example shows the effect of varying the `C` (chroma) value of the `oklch()` functional notation, with colors decreasing in intensity as the `C` value decreases from fully saturated to almost gray.

HTML

```
<div data-color="blue"></div>
<div data-color="blue-chroma1"></div>
<div data-color="blue-chroma2"></div>
<div data-color="blue-chroma3"></div>

<div data-color="red"></div>
<div data-color="red-chroma1"></div>
<div data-color="red-chroma2"></div>
<div data-color="red-chroma3"></div>

<div data-color="green"></div>
<div data-color="green-chroma1"></div>
<div data-color="green-chroma2"></div>
<div data-color="green-chroma3"></div>
```

CSS

With the initial starting colors blue, red, and green, we declare progressively smaller values for chroma on them: starting from full color saturation at the high value of `0.4` (equivalent to `100%`) down to `0.01` (equivalent to `2%`), which is almost gray for all the colors.

```
body {
  display: grid;
  grid-template-columns: 1fr 1fr 1fr 1fr;
  gap: 20px;
}
div {
  height: 50px;
  border: 1px solid black;
}
```

```
[data-color="blue"] {
  background-color: oklch(50% 0.4 240);
}
[data-color="blue-chroma1"] {
  background-color: oklch(50% 0.2 240);
}
[data-color="blue-chroma2"] {
  background-color: oklch(50% 0.1 240);
}
[data-color="blue-chroma3"] {
  background-color: oklch(50% 0.01 240);
}

[data-color="red"] {
  background-color: oklch(50% 100% 20deg);
}
[data-color="red-chroma1"] {
  background-color: oklch(50% 50% 20deg);
}
[data-color="red-chroma2"] {
  background-color: oklch(50% 25% 20deg);
}
[data-color="red-chroma3"] {
  background-color: oklch(50% 2% 20deg);
}

[data-color="green"] {
  background-color: oklch(50% 0.4 130);
}
[data-color="green-chroma1"] {
  background-color: oklch(50% 0.2 130);
}
[data-color="green-chroma2"] {
  background-color: oklch(50% 0.1 130);
}
[data-color="green-chroma3"] {
```

```
  background-color: oklch(50% 0.01 130);
}
```

Result

If we had used `0` instead of `0.01` and `2%`, with the same lightness values, the colors would have all been the same shade of gray. In this example, they are almost gray.

Hues in OkLCh

The following example shows swatches with different `H` (hue) values of the `oklch()` functional notation.

HTML

```
<div data-color="0">0deg</div>
<div data-color="20">20deg</div>
<div data-color="40">40deg</div>
<div data-color="60">60deg</div>
```

and so on.

```
<div data-color="80">80deg</div>
<div data-color="100">100deg</div>
<div data-color="120">120deg</div>
<div data-color="140">140deg</div>
<div data-color="160">160deg</div>
<div data-color="180">180deg</div>
<div data-color="200">200deg</div>
<div data-color="220">220deg</div>
<div data-color="240">240deg</div>
<div data-color="260">260deg</div>
<div data-color="280">280deg</div>
<div data-color="300">300deg</div>
<div data-color="320">320deg</div>
<div data-color="340">340deg</div>
<div data-color="360">360deg</div>
```

CSS

```
body {
  display: flex;
  flex-wrap: wrap;
  gap: 3px;
}
div {
  flex: 0 0 4em;
  text-align: center;
  line-height: 4em;
  display: inline-block;
  border: 1px solid black;
  color: white;
  font-family: monospace;
}
```

```
[data-color="0"] {
  background-color: oklch(50% 0.4 0deg);
}
[data-color="20"] {
  background-color: oklch(50% 0.4 20deg);
}
[data-color="40"] {
  background-color: oklch(50% 0.4 40deg);
}
[data-color="60"] {
  background-color: oklch(50% 0.4 60deg);
}
```

and so on.

```
[data-color="80"] {
  background-color: oklch(50% 0.4 80deg);
}
[data-color="100"] {
  background-color: oklch(50% 0.4 100deg);
}
[data-color="120"] {
  background-color: oklch(50% 0.4 120deg);
}
[data-color="140"] {
  background-color: oklch(50% 0.4 140deg);
}
[data-color="160"] {
  background-color: oklch(50% 0.4 160deg);
}
[data-color="180"] {
  background-color: oklch(50% 0.4 180deg);
}
[data-color="200"] {
  background-color: oklch(50% 0.4 200deg);
}
[data-color="220"] {
  background-color: oklch(50% 0.4 220deg);
}
[data-color="240"] {
  background-color: oklch(50% 0.4 240deg);
}
[data-color="260"] {
  background-color: oklch(50% 0.4 260deg);
}
[data-color="280"] {
  background-color: oklch(50% 0.4 280deg);
}
```

```
[data-color="300"] {
  background-color: oklch(50% 0.4 300deg);
}
[data-color="320"] {
  background-color: oklch(50% 0.4 320deg);
}
[data-color="340"] {
  background-color: oklch(50% 0.4 340deg);
}
[data-color="360"] {
  background-color: oklch(50% 0.4 360deg);
}
```

Result

The hue angles in `oklch()` are different from those in `hsl()`. See `<hue>` for more information. In `hsl()`, the sRGB color `0deg` represents red. However, in the CIELab color space, `0deg` corresponds to magenta, while red is approximately `41deg`.

Adjusting the alpha value of a color

The following example shows the effect of varying the `A` (alpha) value of the `oklch()` color function. The `red` and `red-alpha` elements overlap the `#background-div` element to demonstrate the effect of opacity. Giving `A` a value of `0.4` makes the color 40% opaque.

HTML

```
<div id="background-div">
  <div data-color="red"></div>
  <div data-color="red-alpha"></div>
</div>
```

CSS

```
div {
  width: 50px;
  height: 50px;
  padding: 5px;
  margin: 5px;
  display: inline-block;
  border: 1px solid black;
}
#background-div {
  background-color: oklch(100% 0.57 217);
  width: 150px;
  height: 40px;
}
```

```
[data-color="red"] {
  background-color: oklch(50% 0.5 20);
}
[data-color="red-alpha"] {
  background-color: oklch(50% 0.5 20 / 0.4);
}
```

Result

Using relative colors with oklch()

This example styles three `<div>` elements with different background colors. The middle one is given the unmodified `--base-color`, while the left and right ones are given lightened and darkened variants of that `--base-color`.

These variants are defined using relative colors — the `--base-color` custom property is passed into an `oklch()` function, and the output colors have their lightness channel modified to achieve the desired effect via a `calc()` function. The lightened color has `0.15` (15%) added to the lightness channel, and the darkened color has `0.15` (15%) subtracted from the lightness channel.

```
<div id="container">
  <div class="item" id="one"></div>
  <div class="item" id="two"></div>
  <div class="item" id="three"></div>
</div>
```

CSS

```
#container {
  display: flex;
  width: 100vw;
  height: 100vh;
  box-sizing: border-box;
}

.item {
  flex: 1;
  margin: 20px;
}
```

```
:root {
  --base-color: orange;
}

#one {
  background-color: oklch(from var(--base-color) calc(l + 0.15) c h);
}

#two {
  background-color: var(--base-color);
}

#three {
  background-color: oklch(from var(--base-color) calc(l - 0.15) c h);
}
```

Result

The output is as follows:

rgb() CSS function

> **Note:** The `rgba()` functional notation is an alias for `rgb()`. They are exactly equivalent. It is recommended to use `rgb()`.

The **`rgb()`** functional notation expresses a color in the sRGB color space according to its red, green, and blue components. An optional alpha component represents the color's transparency.

Try it

```
background: rgb(31 120 50);
```

```
background: rgb(30% 20% 50%);
```

```
background: rgb(255 122 127 / 80%);
```

```
background: rgb(255 122 127 / 0.2);
```

```
<section id="default-example">
  <div class="transition-all" id="example-element"></div>
</section>
```

```
#example-element {
  min-width: 100%;
  min-height: 100%;
  padding: 10%;
}
```

Syntax

```
/* Absolute values */
rgb(255 255 255)
rgb(255 255 255 / 50%)

/* Relative values */
rgb(from green r g b / 0.5)
rgb(from #123456 calc(r + 40) calc(g + 40) b)
rgb(from hwb(120deg 10% 20%) r g calc(b + 200))

/* Legacy 'rgba()' alias */
rgba(0 255 255)

/* Legacy format */
rgb(0, 255, 255)
rgb(0, 255, 255, 50%)
```

> **Note:** For compatibility reasons, Web API-serialized color values are expressed as `rgb()` colors if the alpha channel value is exactly 1, and `rgba()` colors otherwise. In both cases, legacy syntax is used, with commas as separators (for example `rgb(255, 0, 0)`).

Values

Below are descriptions of the allowed values for both absolute and relative colors.

Absolute value syntax

```
rgb(R G B[ / A])
```

The parameters are as follows:

`R, G, B`

Each value can be represented as a `<number>` between `0` and `255`, a `<percentage>` between `0%` and `100%`, or the keyword `none` (equivalent to `0%` in this case). These values represent the red, green, and blue channels, respectively.

`A` Optional

An `<alpha-value>` representing the alpha channel value of the color, where the number `0` corresponds to `0%` (fully transparent) and `1` corresponds to `100%` (fully opaque). Additionally, the keyword `none` can be used to explicitly specify no alpha channel. If the `A` channel value is not explicitly specified, it defaults to 100%. If included, the value is preceded by a slash (`/`).

> **Note:** See Missing color components for more information on the effect of `none`.

Relative value syntax

```
rgb(from &lt;color&gt; R G B[ / A])
```

The parameters are as follows:

`from <color>`

The keyword `from` is always included when defining a relative color, followed by a `<color>` value representing the **origin color**: This is the original color that the relative color is based on. The origin color can be *any* valid `<color>` syntax, including another relative color.

`R`, `G`, `B`

Each value can be represented as a `<number>` between `0` and `255`, a `<percentage>` between `0%` and `100%`, or the keyword `none` (equivalent to `0%` in this case). These values represent the red, green, and blue channel values of the output color, respectively.

`A` Optional

An `<alpha-value>` representing the alpha channel value of the output color, where the number `0` corresponds to `0%` (fully transparent) and `1` corresponds to `100%` (fully opaque). Additionally, the keyword `none` can be used to explicitly specify no alpha channel. If the `A` channel value is not explicitly specified, it defaults to the alpha channel value of the origin color. If included, the value is preceded by a slash (`/`).

> **Note:** To fully enable the representation of the full spectrum of visible colors, the output of relative `rgb()` color functions is serialized to `color(srgb)`. That means that querying the output color value via the `HTMLElement.style` property or the `CSSStyleDeclaration.getPropertyValue()` method returns the output color as a `color(srgb ...)` value.

Defining relative color output channel components

When using relative color syntax inside an `rgb()` function, the browser converts the origin color into an equivalent RGB color (if it is not already specified as such). The color is defined as three distinct color channel values — `r` (red), `g` (green), and `b` (blue) — plus an alpha channel value (`alpha`). These channel values are made available inside the function to be used when defining the output color channel values:

- The `r`, `g` and `b` values are each resolved to `<number>`s between `0` and `255`, inclusive.
- The `alpha` channel is resolved to a `<number>` between `0` and `1`, inclusive.

When defining a relative color, the different channels of the output color can be expressed in several different ways. Below, we'll study some examples to illustrate these.

In the first two examples below, we are using relative color syntax. However, the first one outputs the same color as the origin color and the second one outputs a color not based on the origin color at all. They don't really create relative colors! You'd be unlikely to ever use these in a real codebase, and would probably just use an absolute color value instead. We included these examples as a starting point for learning about relative `rgb()` syntax.

Let's start with an origin color of `hsl(0 100% 50%)` (equivalent to `rgb(255 0 0)`). The following function outputs the same color as the origin color — it uses the origin color's `r`, `g`, and `b` channel values (`255`, `0`, and `0`) as the output channel values:

```
rgb(from hsl(0 100% 50%) r g b)
```

This function's output color is the sRGB `color()` equivalent of `rgb(255 0 0)`: `color(srgb 1 0 0)`.

The next function uses absolute values for the output color's channel values, outputting a completely different color not based on the origin color:

```
rgb(from hsl(0 100% 50%) 132 132 224)
```

In the above case, the output color is the sRGB `color()` equivalent of `rgb(132 132 224)`: `color(srgb 0.517647 0.517647 0.878431)`.

The following function creates a relative color based on the origin color:

```
rgb(from hsl(0 100% 50%) r 80 80)
```

This example:

- Converts the origin color (`hsl(0 100% 50%)`) into an `rgb()` equivalent (`rgb(255 0 0)`).
- Sets the `R` channel value for the output color to the origin color `rgb()` equivalent's `R` channel value — `255`.
- Sets the output color's `G` and `B` channel values to new values not based on the origin color: `80` and `80`, respectively.

The final output color is the equivalent of `rgb(255 80 80)` in the sRGB color space — `color(srgb 1 0.313726 0.313726)`.

> **Note:** As mentioned above, if the output color is using a different color model to the origin color, the origin color is converted to the same model or space as the output color in the background so that it can be represented in a way that is compatible (i.e., using the same channels).

In the examples we've seen so far in this section, the alpha channels have not been explicitly specified for either the origin or output colors. When the output color alpha channel is not specified, it defaults to the same value as the origin color alpha channel. When the origin color alpha channel is not specified (and it is not a relative color), it defaults to `1`. Therefore, the origin and output alpha channel values are `1` for the above examples.

Let's look at some examples that specify origin and output alpha channel values. The first one specifies the output alpha channel value as being the same as the origin alpha channel value, whereas the second one specifies a different output alpha channel value, unrelated to the origin alpha channel value.

```
rgb(from hsl(0 100% 50% / 0.8) r g b / alpha)
/* Computed output color: color(srgb 1 0 0 / 0.8) */

rgb(from hsl(0 100% 50% / 0.8) r g b / 0.5)
/* Computed output color: color(srgb 1 0 0 / 0.5) */
```

In the following example, the `hsl()` origin color is again converted into an `rgb()` representation — `rgb(255 0 0)`. `calc()` calculations are applied to the `R`, `G`, `B`, and `A` values. After calculating, the R, G, B and A values are `127.5`, `25`, `175`, and `0.9` respectively. The final output color is the equivalent of `rgb(127.5 25 175 / 0.9)` in the sRGB color space: `color(srgb 0.5 0.0980392 0.686275 / 0.9)`.

```
rgb(from hsl(0 100% 50%) calc(r/2) calc(g + 25) calc(b + 175) / calc(alpha - 0.1))
```

> **Note:** Because the origin color channel values are resolved to `<number>` values, you have to add numbers to them when using them in calculations, even in cases where a channel would normally accept `<percentage>`, `<angle>`, or other value types. Adding a `<percentage>` to a `<number>`, for example, doesn't work.

Formal syntax

```
<rgb()> =
  <legacy-rgb-syntax>  |
  <modern-rgb-syntax>

<legacy-rgb-syntax> =
  rgb( <percentage>#{3} , <alpha-value>? )  |
  rgb( <number>#{3} , <alpha-value>? )

<modern-rgb-syntax> =
  rgb( [ from <color> ]? [ <number> | <percentage> | none ]{3} [ / [ <alpha-value> | none ] ]? )
```

```
<alpha-value> =
  <number>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Color Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic syntax

In this example, we have three `<div>` elements with different background colors displayed over a striped background.

HTML

```
<div>
  <div id="integer"></div>
  <div id="percent"></div>
  <div id="alpha"></div>
</div>
```

CSS

The background colors are set using the `rgb()` color function. The three colors are the same. The third is semi-transparent, so we included a `repeating-linear-gradient()` on the `<body>` to better demonstrate the transparency of alpha channels.

```
div {
  display: flex;
  gap: 20px;
  height: 50px;
  flex: 1;
}
body {
  height: calc(100vh - 20px);
}
```

```
body {
  background: repeating-linear-gradient(-45deg, #eeeeee 0 2px, white 2px 6px);
  padding: 10px;
}

#integer {
  background-color: rgb(189 85 218);
}

#percent {
  background-color: rgb(74% 33% 85%);
}

#alpha {
  background-color: rgb(189 85 218 / 0.25);
}
```

Result

Using relative colors with rgb()

This example styles three `<div>` elements with different background colors. The left-hand one is given the unmodified `--base-color`, while the middle and right ones are given variants of that `--base-color` that successively remove more from the red channel and add more to the blue channel.

These variants are defined using relative colors — the `--base-color` custom property is passed into an `rgb()` function, and the output color has its red and blue channels modified to achieve the desired effect via `calc()` functions, while the green channel is left unchanged.

```
<div id="container">
  <div class="item" id="one"></div>
  <div class="item" id="two"></div>
  <div class="item" id="three"></div>
</div>
```

CSS

```
#container {
  display: flex;
  width: 100vw;
  height: 100vh;
  box-sizing: border-box;
}

.item {
  flex: 1;
  margin: 20px;
}
```

```
:root {
  --base-color: orange;
  /* equal to rgb(255 165 0) */
}

#one {
  background-color: var(--base-color);
}

#two {
  background-color: rgb(from var(--base-color) calc(r - 76.5) g calc(b + 76.5));
  /* 76.5 is 30% of 255 */
}

#three {
  background-color: rgb(from var(--base-color) calc(r - 153) g calc(b + 153));
  /* 153 is 60% of 255 */
}
```

```
/* Use @supports to add in support for old syntax that requires r g b values to
   be specified as percentages (with units) in calculations. This is required
   for Safari 16.4+. */
@supports (color: rgb(from red r g calc(b + 30%))) {
  #two {
    background-color: rgb(from var(--base-color) calc(r - 30%) g calc(b + 30%));
  }

  #three {
    background-color: rgb(from var(--base-color) calc(r - 60%) g calc(b + 60%));
  }
}
```

Result

Legacy syntax: comma-separated values

For legacy reasons, the `rgb()` function accepts a form in which all values are separated using commas.

HTML

```
<div class="space-separated"></div>
<div class="comma-separated"></div>
```

CSS

```
div {
  width: 100px;
  height: 50px;
  margin: 1rem;
}

div.space-separated {
  background-color: rgb(255 0 0 / 50%);
}

div.comma-separated {
  background-color: rgb(255, 0, 0, 0.5);
}
```

<color-interpolation-method> CSS type

The **`<color-interpolation-method>`** CSS data type represents the color space used for interpolation between `<color>` values. It can be used to override the default interpolation color space for color-related functional notations such as `color-mix()` and `linear-gradient()`.

When interpolating `<color>` values, the interpolation color space defaults to Oklab.

Syntax

The `<color-interpolation-method>` specifies whether interpolation should use a rectangular color space or a polar color space with an optional hue interpolation method:

```
in <rectangular-color-space>
// or
in <polar-color-space>[ <hue-interpolation method>]
```

Values

`<rectangular-color-space>`

One of the keywords `srgb`, `srgb-linear`, `display-p3`, `a98-rgb`, `prophoto-rgb`, `rec2020`, `lab`, `oklab`, `xyz`, `xyz-d50`, or `xyz-d65`.

`<polar-color-space>`

One of the keywords `hsl`, `hwb`, `lch`, or `oklch`.

`<hue-interpolation-method>` Optional

The algorithm for hue interpolation. It defaults to `shorter hue`.

`<custom-color-space>`

A `<dashed-ident>` referring to a custom @color profile.

Formal syntax

```
<color-interpolation-method> =
  in [ <rectangular-color-space> | <polar-color-space> <hue-interpolation-method>? | <custom-color-space> ]

<rectangular-color-space> =
  srgb               |
  srgb-linear        |
  display-p3         |
  display-p3-linear  |
  a98-rgb            |
  prophoto-rgb       |
  rec2020            |
  lab                |
  oklab              |
  <xyz-space>

<polar-color-space> =
```

```
  hsl    |
  hwb    |
  lch    |
  oklch

<hue-interpolation-method> =
  [ shorter | longer | increasing | decreasing ] hue

<custom-color-space> =
  <dashed-ident>

<xyz-space> =
  xyz      |
  xyz-d50  |
  xyz-d65
```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Color Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Comparing interpolation color spaces using gradients

The following example shows the effect of using different interpolation color spaces for `linear-gradient()`.

HTML

```
<div>sRGB:</div>
<div class="gradient srgb"></div>
<div>Oklab:</div>
<div class="gradient oklab"></div>
<div>Oklch (with <code>longer hue</code>):</div>
<div class="gradient oklch-longer"></div>
```

CSS

```
.gradient {
  height: 50px;
  width: 100%;
}
.srgb {
  background-image: linear-gradient(in srgb to right, blue, red);
}
.oklab {
  background-image: linear-gradient(in oklab to right, blue, red);
}
.oklch-longer {
  background-image: linear-gradient(in oklch longer hue to right, blue, red);
}
```

Result

Color interpolation in repeating gradients

The following example shows how to specify a color space when interpolating colors in repeating gradients. Three boxes show different types of repeating gradients using the `repeating-conic-gradient()`, `repeating-linear-gradient()`, and `repeating-radial-gradient()` functions. The first box uses the Lab color space to interpolate between two color values. The second and third boxes use OkLCh and additionally provide a `<hue-interpolation-method>` to specify how to interpolate between hue values.

HTML

```
<div class="gradient conic">conic</div>
<div class="gradient linear">linear</div>
<div class="gradient radial">radial</div>
```

CSS

We used the same two colors in each gradient to demonstrate the different effects of `<hue-interpolation-method>` and color space on color interpolation in gradients.

```
.gradient {
  height: 200px;
  width: 200px;
  display: inline-block;
  font-family: monospace;
  margin: 10px;
  font-size: 16px;
}
```

```
.conic {
  background-image: repeating-conic-gradient(
    in lab,
    burlywood,
    blueviolet 120deg
  );
}

.linear {
  background-image: repeating-linear-gradient(
    in oklch,
    burlywood,
    blueviolet 75px
  );
}

.radial {
  background-image: repeating-radial-gradient(
    in oklch longer hue,
    blueviolet 50px,
    burlywood 100px
  );
}
```

Result

Comparing the first and second boxes demonstrates the difference of interpolating between two colors in differing color spaces. Comparing the second and third boxes shows the difference between `<hue-interpolation-method>`s, with the linear gradient using the shorter method (default) and the radial gradient using the longer method.

<content-distribution> CSS type

The **`<content-distribution>`** enumerated value type is used by `justify-content` and `align-content` properties, and the `place-content` shorthand, to distribute a container's extra space among its alignment subjects.

Syntax

```
<content-distribution> = space-between | space-around | space-evenly | stretch
```

Values

The following keyword values are represented by the `<content-distribution>` grammar term:

`space-between`

> Evenly distributes the alignment subject within the alignment container. The first item is placed flush with the start edge of the alignment container, the last item subject is placed flush with the end edge of the alignment container, and the remaining items are evenly distributed so that the spacing between any two adjacent items is the same. The default fallback alignment for `space-between` is `safe flex-start` for flex layout, and `start` otherwise. If there is only one item, the item will be flush with the start edge.

`space-around`

> The items are evenly distributed in the container, with a half-size space on either end. The spacing between any two adjacent items is the same, and the spacing before the first and after the last items is half the size of the other spacing. The default fallback alignment for `space-around` is `safe center`. If the container has only one child, the item will be centered.

`space-evenly`

> The items are evenly distributed in the container, with a full-size space on either end. The spacing between any two adjacent items, before the first item, and after the last item, are all the same. The default fallback alignment for `space-evenly` is `safe center`. If the container has only one child, the item will be centered.

`stretch`

> If the combined size of the items is less than the size of the container, any items that can grow will have their size increased equally (not proportionally), while still respecting the constraints imposed by `max-height`, `max-width`, or equivalent functionality, so that the combined size of the items exactly fills the container. The default fallback alignment for `stretch` is `flex-start` in flexbox, and `start` in other layout modes. If there is only one item, and that item can grow, it will grow to fill the container.

<content-position> CSS type

The **`<content-position>`** enumerated value type is used by `justify-content` and `align-content` properties, and the `place-content` shorthand, to align the box's contents within itself.

Syntax

```
<content-position> = center | start | end | flex-start | flex-end
```

Values

The `<content-position>` enumerated value type is specified using one of the following key terms.

`center`

> Centers the alignment subject within its alignment container.

`start`

> Aligns the alignment subject flush with the alignment container's start edge.

`end`

> Aligns the alignment subject flush with the alignment container's end edge.

`flex-start`

> In flex layout, aligns the alignment subject flush with the edge of the alignment container corresponding to the flex container's main-start or cross-start side, as appropriate. It is identical to `start` for layout modes other than flex layout.

`flex-end`

> In flex layout, aligns the alignment subject flush with the edge of the alignment container corresponding to the flex container's main-end or cross-end side, as appropriate. Identical to `end` for layout modes other than flex layout.

> **Note:** The `left` and `right` keywords are excluded from `<content-position>`, despite being valid positional alignment values for the `justify-*` properties (`justify-content`, `justify-self`, and `justify-items`), because they are not allowed in the `align-*` properties (`align-content`, `align-self`, and `align-items`). They are instead explicitly included in the `justify-*` properties' grammars.

<corner-shape-value> CSS type

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`<corner-shape-value>`** CSS data type describes the shape of a container corner. It is used by the `corner-shape` shorthand property and its constituent properties to specify the shape to apply to affected container corners.

Syntax

The `<corner-shape-value>` data type can take a `superellipse()` function that defines a custom shape, or one of six keyword values that describe common `superellipse()` values.

Values

`superellipse()`

Defines a custom corner superellipse shape. A negative parameter creates an inward, or concave, curve while a positive parameter creates an outward, or convex, curve.

Keywords

The available keyword values are as follows:

`bevel`

Defines a straight, diagonal corner, which is neither convex nor concave. The `bevel` keyword is equivalent to `superellipse(0)`.

`notch`

Defines a 90-degree concave square corner. The `notch` keyword is equivalent to `superellipse(-infinity)`.

`round`

Defines a convex ordinary ellipse, which is the standard rounded corner created by `border-radius` without a `corner-shape` applied. The `round` keyword is equivalent to `superellipse(1)`. This is the default (initial) value for all `corner-shape` properties.

`scoop`

Defines a concave ordinary ellipse. The `scoop` keyword is equivalent to `superellipse(-1)`.

`square`

Defines a 90-degree convex square corner, which is the default corner shape when no `border-radius` (or `border-radius: 0`) is applied. The `square` keyword is equivalent to `superellipse(infinity)`.

`squircle`

Defines a "squircle", which is a convex curve in between `round` and `square`. The `squircle` keyword is equivalent to `superellipse(2)`.

> **Note:** You can smoothly animate between different `superellipse()` values, and between different corner shape keywords, as the animation interpolates between their `superellipse()` equivalents.

Formal syntax

```
<corner-shape-value> =
  round             |
  scoop             |
  bevel             |
  notch             |
  square            |
  squircle          |
  <superellipse()>

<superellipse()> =
  superellipse( <number>  |
  infinity                |
  -infinity )
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

<code><corner-shape-value></code> value comparison

In this example, we provide a drop-down menu allowing you to select different `<corner-shape-value>` values and a slider that updates the container's `border-radius`. This enables visualizing the effect of the different keywords and `superellipse()` parameter values.

The `corner-shape` property defines the shape of the box's corners while the region the shape is applied to is specified by the `border-radius` property. The code is hidden for brevity, but you can find a full explanation of `corner-shape` values along with other related examples on the `corner-shape` reference page.

cos() CSS function

The **`cos()`** CSS function is a trigonometric function that returns the cosine of a number, which is a value between `-1` and `1`. The function contains a single calculation that must resolve to either a `<number>` or an `<angle>` by interpreting the result of the argument as radians. That is, `cos(45deg)`, `cos(0.125turn)`, and `cos(3.14159 / 4)` all represent the same value, approximately `0.707`.

Try it

```
transform: translateX(calc(cos(0deg) * 140px))
  translateY(calc(sin(0deg) * -140px));
```

```
transform: translateX(calc(cos(90deg) * 140px))
  translateY(calc(sin(90deg) * -140px));
```

```
transform: translateX(calc(cos(135deg) * 140px))
  translateY(calc(sin(135deg) * -140px));
```

```
transform: translateX(calc(cos(180deg) * 140px))
  translateY(calc(sin(180deg) * -140px));
```

```
transform: translateX(calc(cos(-45deg) * 140px))
  translateY(calc(sin(-45deg) * -140px));
```

```
<div class="circle">
  <span class="dot" id="example-element"></span>
</div>
```

```
:root {
  --radius: 140px;
  --dot-size: 10px;
}
.circle {
  display: grid;
  place-content: center;
  margin: 0 auto;
  width: calc(var(--radius) * 2);
  aspect-ratio: 1;
  border-radius: 50%;
  border: 2px solid #666666;
  background-image:
    radial-gradient(black var(--dot-size), transparent var(--dot-size)),
    linear-gradient(135deg, blue, deepskyblue, lightgreen, lavender, honeydew);
}
.dot {
  display: block;
  width: var(--dot-size);
  aspect-ratio: 1;
  border-radius: 50%;
  border: 2px solid #666666;
  background-color: #ff6666;
  transform: translateX(calc(cos(0deg) * var(--radius)))
    translateY(calc(sin(0deg) * var(--radius) * -1));
}
```

Syntax

```
/* Single <angle> values */
width: calc(100px * cos(45deg));
width: calc(100px * cos(0.125turn));
width: calc(100px * cos(0.785398163rad));

/* Single <number> values */
width: calc(100px * cos(63.673));
width: calc(100px * cos(2 * 0.125));

/* Other values */
width: calc(100px * cos(pi));
width: calc(100px * cos(e / 2));
```

Parameters

The `cos(angle)` function accepts only one value as its parameter.

`angle`

A calculation which resolves to a `<number>` or an `<angle>`. When specifying unitless numbers they are interpreted as a number of radians, representing an `<angle>`.

Return value

The cosine of an `angle` will always return a number between `-1` and `1`.

- If `angle` is `infinity`, `-infinity`, or `NaN`, the result is `NaN`.

Formal syntax

```
<cos()> =
  cos( <calc-sum> )

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Keep the size of a rotated box

The `cos()` function can be used to keep the size of a rotated box.

When the element is rotated using `rotate()`, it goes beyond its initial size. To fix this, we will use `cos()` to update the element size.

For example, if you rotate a `100px`/`100px` square `45deg`, the diamond it creates will be wider and taller than the original square. To shrink the diamond into the box allotted for the original square, you would have to scale down the diamond using this formula: `width = height = 100px * cos(45deg) = 100px * 0.707 = 70.7px`. You need to also adjust the `transform-origin` and add `translate()` to correct the position:

HTML

```
<div class="original-square"></div>
<div class="rotated-diamond"></div>
<div class="rotated-scaled-diamond"></div>
```

CSS

```
body {
  height: 100vh;
  display: flex;
  justify-content: center;
  align-items: center;
  gap: 50px;
}
```

```
div.original-square {
  width: 100px;
  height: 100px;
  background-color: blue;
}
div.rotated-diamond {
  width: 100px;
  height: 100px;
  background-color: red;
  transform: rotate(45deg);
}
div.rotated-scaled-diamond {
  width: calc(100px * cos(45deg));
  height: calc(100px * cos(45deg));
  margin: calc(100px / 4 * cos(45deg));
  transform: rotate(45deg);
  transform-origin: center;
  background-color: green;
}
```

counter() CSS function

The **`counter()`** CSS function returns a string representing the current value of the named counter, if there is one.

The `counter()` function is generally used within pseudo-element through the `content` property but, theoretically, it can be used wherever a `<string>` value is supported.

Try it

```
.double-list {
  counter-reset: count -1;
}

.double-list li {
  counter-increment: count 2;
}

.double-list li::marker {
  content: counter(count, decimal) ") ";
}
```

```
<p>Best Dynamic Duos in Sports:</p>
<ol class="double-list">
  <li>Simone Biles + Jonathan Owens</li>
  <li>Serena Williams + Venus Williams</li>
  <li>Aaron Judge + Giancarlo Stanton</li>
  <li>LeBron James + Dwyane Wade</li>
  <li>Xavi Hernandez + Andres Iniesta</li>
</ol>
```

Syntax

```
/* Basic usage */
counter(counter-name);

/* changing the counter display */
counter(counter-name, upper-roman)
```

Counters have no visible effect by themselves. The `counter()` and `counters()` functions are what make counters useful by returning developer-defined strings (or images).

Values

The `counter()` function accepts up to two parameters. The first parameter is the `<counter-name>`. The optional second parameter is the `<counter-style>`.

`<counter-name>`

> A `<custom-ident>` identifying the counter, which is the same case-sensitive name used with the `counter-reset` and `counter-increment` property values. The counter name cannot start with two dashes and can't be `none`, `unset`, `initial`, or `inherit`.

`<counter-style>`

> A `list-style-type` name, `counter-style-name` or `symbols()` function, where a counter style name is a `numeric`, `alphabetic`, or `symbolic` predefined counter style, a complex longhand east Asian or Ethiopic predefined counter style, or other predefined counter style. If omitted, the counter-style defaults to `decimal`.

> **Note:** To join the counter values when nesting counters, use the `counters()` function, which provides an additional `<string>` parameter.

Formal syntax

```
<counter()> =
  counter( <counter-name> , <counter-style>? )

<counter-name> =
  <custom-ident>

<counter-style> =
  <counter-style-name>  |
  <symbols()>

<counter-style-name> =
  <custom-ident>

<symbols()> =
  symbols( <symbols-type>? [ <string> | <image> ]+ )

<symbols-type> =
  cyclic      |
  numeric     |
  alphabetic  |
  symbolic    |
  fixed

<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
  <gradient>

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-set()> =
  image-set( <image-set-option># )

<cross-fade()> =
  cross-fade( <cf-image># )

<element()> =
  element( <id-selector> )

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Counter Styles Level 3, CSS Images Module Level 4, CSS Images Module Level 5, CSS Lists and Counters Module Level 3, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

lower-roman compared to lower-alpha

In this example, we display a counter using `lower-roman` and `lower-alpha` list styles.

HTML

```
<ol>
  <li></li>
  <li></li>
  <li></li>
</ol>
```

CSS

```
ol {
  counter-reset: count;
}
li {
  counter-increment: count;
}
li::after {
  content:
    "[" counter(count, lower-roman) "] == ["
    counter(count, lower-alpha) "]";
}
```

Result

Displaying a counter using three styles

In this example, we use the `counter()` function three times.

HTML

```
<ol>
  <li></li>
  <li></li>
  <li></li>
</ol>
```

CSS

We include the `counter()` function with three different counter styles, including the default decimal value. We've added padding to the list to provide space for the long `::marker` string.

```
ol {
  counter-reset: listCounter;
  padding-left: 5em;
}
li {
  counter-increment: listCounter;
}
li::marker {
  content:
    "Item #" counter(listCounter) " is: ";
}
li::after {
  content:
    "[" counter(listCounter, decimal-leading-zero) "] == ["
    counter(listCounter, upper-roman) "]";
}
```

counters() CSS function

The **`counters()`** CSS function enables combining markers when nesting counters. The function returns a string that concatenates the current values of the named and nested counters, if any are present, with the string provided. The third, optional parameter enables defining the list style.

The `counters()` function is generally used within pseudo-element through the `content` property, but theoretically, it can be used wherever a `<string>` value is supported.

The `counters()` function has two forms: `counters(<name>, <string>)` and `counters(<name>, <string>, <style>)`. The generated text is the value of all counters with the given `<name>`, arranged from the outermost to the innermost, and separated by the specified `<string>`. The counters are rendered in the `<style>` indicated, defaulting to `decimal` if no `<style>` is specified.

Try it

```
ol {
  counter-reset: index;
  list-style-type: none;
}

li::before {
  counter-increment: index;
  content: counters(index, ".", decimal) " ";
}
```

```
<ol>
  <li>Mars</li>
  <li>
    Saturn
    <ol>
      <li>Mimas</li>
      <li>Enceladus</li>
      <li>
        <ol>
          <li>Voyager</li>
          <li>Cassini</li>
        </ol>
      </li>
      <li>Tethys</li>
    </ol>
  </li>
  <li>
    Uranus
    <ol>
      <li>Titania</li>
    </ol>
  </li>
</ol>
```

Syntax

```
/* Basic usage  - style defaults to decimal */
counters(counter-name, '.');

/* changing the counter display */
counters(counter-name, '-', upper-roman)
```

A counter has no visible effect by itself. The `counters()` function (and `counter()` function) is what makes it useful by returning developer-defined content.

Values

The `counters()` function accepts two or three parameters. The first parameter is the `<counter-name>`. The second parameter is the concatenator `<string>`. The optional third parameter is the `<counter-style>`.

`<counter-name>`

> A `<custom-ident>` identifying the counters, which is the same case-sensitive name used for the `counter-reset` and `counter-increment` properties. The name cannot start with two dashes and can't be `none`, `unset`, `initial`, or `inherit`. Alternatively, for inline, single-use counters, the `symbols()` function can be used instead of a named counter in browsers that support `symbols()`.

`<string>`

> Any number of text characters. Non-Latin characters must be encoded using their Unicode escape sequences: for example, `\000A9` represents the copyright symbol.

`<counter-style>`

> A counter style name or a `symbols()` function. The counter style name can be a predefined style such as numeric, alphabetic, or symbolic, a complex longhand predefined style such as East Asian or Ethiopic, or another predefined counter style. If omitted, the counter-style defaults to decimal.

The return value is a string containing all the values of all the counters in the element's CSS counters set named `<counter-name>` in the counter style defined by `<counter-style>` (or decimal, if omitted). The return string is sorted in outermost-first to innermost-last order, joined by the `<string>` specified.

> **Note:** For information about non-concatenated counters, see the `counter()` function, which omits the `<string>` as a parameter.

Formal syntax

```
<counters()> =
  counters( <counter-name> , <string> , <counter-style>? )

<counter-name> =
  <custom-ident>

<counter-style> =
  <counter-style-name>  |
  <symbols()>

<counter-style-name> =
  <custom-ident>

<symbols()> =
  symbols( <symbols-type>? [ <string> | <image> ]+ )

<symbols-type> =
  cyclic      |
  numeric     |
  alphabetic  |
  symbolic    |
  fixed

<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
  <gradient>

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-set()> =
  image-set( <image-set-option># )

<cross-fade()> =
  cross-fade( <cf-image># )

<element()> =
  element( <id-selector> )

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Counter Styles Level 3, CSS Images Module Level 4, CSS Images Module Level 5, CSS Lists and Counters Module Level 3, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Comparing default counter value to uppercase roman numerals

This example includes two `counters()` functions: one with `<counter-style>` set and the other defaulting to `decimal`.

HTML

```
<ol>
  <li>
    <ol>
      <li></li>
      <li></li>
      <li></li>
    </ol>
```

```
  </li>
  <li></li>
  <li></li>
  <li>
    <ol>
      <li></li>
      <li>
        <ol>
          <li></li>
          <li></li>
          <li></li>
        </ol>
      </li>
    </ol>
  </li>
</ol>
```

CSS

```
ol {
  counter-reset: listCounter;
}
li {
  counter-increment: listCounter;
}
li::marker {
  content:
    counters(listCounter, ".", upper-roman) ") ";
}
li::before {
  content:
    counters(listCounter, ".") " == "
    counters(listCounter, ".", lower-roman);
}
```

Result

Comparing decimal-leading-zero counter value to lowercase letters

This example includes three `counters()` functions, each with different `<string>` and `<counter-style>` values.

HTML

```
<ol>
  <li>
    <ol>
      <li></li>
      <li></li>
      <li></li>
    </ol>
  </li>
  <li></li>
  <li></li>
  <li>
    <ol>
      <li></li>
      <li>
        <ol>
          <li></li>
          <li></li>
          <li></li>
        </ol>
      </li>
    </ol>
  </li>
</ol>
```

CSS

```
ol {
  counter-reset: count;
}
li {
  counter-increment: count;
}
li::marker {
  content:
    counters(count, "-", decimal-leading-zero) ") ";
}
li::before {
  content:
    counters(count, "~", upper-alpha) " == "
    counters(count,  "*", lower-alpha);
}
```

cross-fade() CSS function

The **`cross-fade()`** CSS function can be used to blend two or more images at a defined transparency. It can be used for many basic image manipulations, such as tinting an image with a solid color or highlighting a particular area of the page by combining an image with a radial gradient.

Syntax

> **Warning:** The specification and current implementations have different syntaxes. The specification syntax is explained first.

Specification syntax

The `cross-fade()` function takes a list of images with a percentage defining how much of each image is retained in terms of opacity when it is blended with the other images. The percent value must be coded without quotes, must contain the `'%'` symbol, and its value must be between 0% and 100%.

The function can be used in CSS anywhere an ordinary image reference can be used.

Cross-fade percentages

Think of the percentage as an opacity value for each image. This means a value of 0% means the image is fully transparent while a value of 100% makes the image fully opaque.

```
cross-fade(url("white.png") 0%, url("black.png") 100%); /* fully black */
cross-fade(url("white.png") 25%, url("black.png") 75%); /* 25% white, 75% black */
cross-fade(url("white.png") 50%, url("black.png") 50%); /* 50% white, 50% black */
cross-fade(url("white.png") 75%, url("black.png") 25%); /* 75% white, 25% black */
cross-fade(url("white.png") 100%, url("black.png") 0%); /* fully white */
cross-fade(url("green.png") 75%, url("red.png") 75%); /* both green and red at 75% */
```

If any percentages are omitted, all the specified percentages are summed together and subtracted from `100%`. If the result is greater than 0%, the result is then divided equally between all images with omitted percentages.

In the simplest case, two images are faded between each other. To do that, only one of the images needs to have a percentage, the other one will be faded accordingly. For example, a value of 0% defined for the first image yields only the second image, while 100% yields only the first. A 25% value renders the first image at 25% and the second at 75%. The 75% value is the inverse, showing the first image at 75% and the second at 25%.

The above could also have been written as:

```
cross-fade(url("white.png") 0%, url("black.png")); /* fully black */
cross-fade(url("white.png") 25%, url("black.png")); /* 25% white, 75% black */
cross-fade(url("white.png"), url("black.png")); /* 50% white, 50% black */
cross-fade(url("white.png") 75%, url("black.png")); /* 75% white, 25% black */
cross-fade(url("white.png") 100%, url("black.png")); /* fully white */
cross-fade(url("green.png") 75%, url("red.png") 75%); /* both green and red at 75% */
```

If no percentages are declared, both the images will be 50% opaque, with a cross-fade rendering as an even merge of both images. The 50%/50% example seen above did not need to have the percentages listed, as when a percentage value is omitted, the included percentages are added together and subtracted from 100%. The result, if greater than 0, is then divided equally between all images with omitted percentages.

In the last example, the sum of both percentages is not 100%, and therefore both images include their respective opacities.

If no percentages are declared and three images are included, each image will be 33.33% opaque. The two following are lines (almost) identical:

```
cross-fade(url("red.png"), url("yellow.png"), url("blue.png")); /* all three will be 33.3333% opaque */
cross-fade(url("red.png") 33.33%, url("yellow.png") 33.33%, url("blue.png") 33.33%);
```

Older, implemented syntax

```
cross-fade( <image>, <image>, <percentage> )
```

The specification for the `cross-fade()` function allows for multiple images and for each image to have transparency values independent of the other values. This was not always the case. The original syntax, which has been implemented in some browsers, only allowed for two images, with the sum of the transparency of those two images being exactly 100%. The original syntax is supported in Safari and supported with the `-webkit-` prefix in Chrome, Opera, and other blink-based browsers.

```
cross-fade(url("white.png"), url("black.png"), 0%);   /* fully black */
cross-fade(url("white.png"), url("black.png"), 25%);  /* 25% white, 75% black */
cross-fade(url("white.png"), url("black.png"), 50%);  /* 50% white, 50% black */
cross-fade(url("white.png"), url("black.png"), 75%);  /* 75% white, 25% black */
cross-fade(url("white.png"), url("black.png"), 100%); /* fully white */
```

In the implemented syntax, the two comma-separated images are declared first, followed by a comma and required percent value. Omitting the comma or percent invalidates the value. The percent is the opacity of the first declared image. The included percentage is subtracted from 100%, with the difference being the opacity of the second image.

The green/red example (with the percentages totaling 150%) and the yellow/red/blue example (with three images) from the specification syntax section, are not possible in this implementation.

Accessibility

Browsers do not provide any special information on background images to assistive technology. This is important primarily for screen readers, as a screen reader will not announce its presence and therefore convey nothing to its users. If the image contains information critical to understanding the page's overall purpose, it is better to describe it semantically in the document. When using background images, make sure the contrast in color is great enough that any text is legible over the image as well as if the images are missing.

- MDN Understanding WCAG, Guideline 1.1 explanations
- Understanding Success Criterion 1.1.1 | W3C Understanding WCAG 2.0

Formal syntax

```
<cross-fade()> =
  cross-fade( <cf-image>#? )

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
```

```
  <gradient>

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-set()> =
  image-set( <image-set-option># )

<element()> =
  element( <id-selector> )

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Images Module Level 4, CSS Images Module Level 5, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Older syntax for cross-fade

HTML

```
<div class="cross-fade"></div>
```

CSS

```
.cross-fade {
  width: 300px;
  height: 300px;
  background-image: -webkit-cross-fade(url("br.png"), url("tr.png"), 75%);
  background-image: cross-fade(url("br.png"), url("tr.png"), 75%);
}
```

<custom-ident> CSS type

The **`<custom-ident>`** CSS data type denotes an arbitrary user-defined string used as an identifier. It is case-sensitive, and certain values are forbidden in various contexts to prevent ambiguity.

Syntax

The syntax of `<custom-ident>` is similar to CSS identifiers (such as property names), except that it is case-sensitive. It consists of one or more characters, where characters can be any of the following:

- any alphabetical character (`A` to `Z`, or `a` to `z`),
- any decimal digit (`0` to `9`),
- a hyphen (`-`),
- an underscore (`_`),
- an escaped character (preceded by a backslash, `\`),
- a Unicode character (in the format of a backslash, `\`, followed by one to six hexadecimal digits, representing its Unicode code point)

Note that `id1`, `Id1`, `iD1`, and `ID1` are all different identifiers as they are case-sensitive.

Escaping characters

Any Unicode code point can be included as part of a `<custom-ident>` or quoted `<string>` by escaping it.

In CSS, there are several ways to escape a character. Escape sequences start with a backslash (`\`), and continue with:

- One to six hex (`ABCDEF0123456789`) digits. The hex digits can optionally be followed by white space. The hex escape sequence gets replaced by the Unicode code point whose value is given by those digits. The whitespace allows the sequences to be followed by actual hex digits (versus replaced ones).
- Any Unicode code point that is not a hex digit or a newline character.

Examples:

- "&B" can be written as `\26 B` or `\000026B`.
- "hi.there" can be written as `hi\.there` or `hi\002Ethere`.
- "toto?" can be written as `toto\?`, `toto\3F`, or `toto\00003F`.

To include actual white space after an escape sequence, include two white spaces in the escape sequence.

Forbidden values

A `<custom-ident>` must not be placed between single or double quotes as this would be identical to a `<string>`. Moreover, the first character must not be a decimal digit, nor a hyphen (`-`) followed by a decimal digit.

To prevent ambiguity, each property that uses `<custom-ident>` forbids the use of specific values:

`animation-name`

Forbids the global CSS values (`unset`, `initial`, and `inherit`), as well as `none`.

`counter-reset`, `counter-increment`

Forbids the global CSS values (`unset`, `initial`, and `inherit`), as well as `none`.

`@counter-style`, `list-style-type`

Forbids the global CSS values (`unset`, `initial`, and `inherit`), as well as the values:

- `none`
- `inline`
- `outside`

Also, quite a few predefined values are implemented by the different browsers:

- `disc`
- `circle`
- `square`
- `decimal`
- `cjk-decimal`
- `decimal-leading-zero`
- `lower-roman`
- `upper-roman`
- `lower-greek`
- `lower-alpha`
- `lower-latin`
- `upper-alpha`
- `upper-latin`
- `arabic-indic`
- `armenian`
- `bengali`
- `cambodian`
- `cjk-earthly-branch`
- `cjk-heavenly-stem`
- `cjk-ideographic`
- `devanagari`
- `ethiopic-numeric`
- `georgian`
- `gujarati`
- `gurmukhi`
- `hebrew`
- `hiragana`
- `hiragana-iroha`
- `japanese-formal`
- `japanese-informal`
- `kannada`
- `katakana`
- `katakana-iroha`
- `khmer`
- `korean-hangul-formal`
- `korean-hanja-formal`
- `korean-hanja-informal`
- `lao`
- `lower-armenian`
- `malayalam`
- `mongolian`
- `myanmar`
- `oriya`
- `persian`
- `simp-chinese-formal`
- `simp-chinese-informal`
- `tamil`
- `telugu`
- `thai`
- `tibetan`
- `trad-chinese-formal`
- `trad-chinese-informal`
- `upper-armenian`
- `disclosure-open`
- `disclosure-close`

`grid-row-start`, `grid-row-end`, `grid-column-start`, `grid-column-end`, `grid-template-rows`, `grid-template-columns`

Forbids the `span` and `auto` values.

`view-transition-name`

Forbids the global CSS values (`unset`, `initial`, and `inherit`), as well as `none`.

`will-change`

Forbids the global CSS values (`unset`, `initial`, and `inherit`), as well as the values `will-change`, `auto`, `scroll-position`, and `contents`.

Examples

Valid identifiers

```
nono79            A mix of alphanumeric characters and numbers
ground-level      A mix of alphanumeric characters and a dash
-test             A dash followed by alphanumeric characters
_internal         An underscore followed by alphanumeric characters
```

```
\22 toto          A Unicode character followed by a sequence of alphanumeric characters
scooby\.doo       A correctly escaped period
```

Invalid identifiers

```
34rem             It must not start with a decimal digit.
-12rad            It must not start with a dash followed by a decimal digit.
scooby.doo        Only alphanumeric characters, _, and - needn't be escaped.
'scoobyDoo'       This would be a <string>.
"scoobyDoo"       This would be a <string>.
```

Browser compatibility

As this type is not a real type but a convenience type used to simplify the description of allowed values, there is no browser compatibility information as such.

<dashed-function> CSS type

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`<dashed-function>`** CSS data type represents the syntax used to call CSS custom functions, which are defined using the `@function` at-rule.

Syntax

A `<dashed-function>` value consists of the `--function-name`, followed by parentheses containing the function's arguments (for example, `--my-function(30px, 3)`).

You can include `<dashed-function>` values in place of regular CSS property values or property value components, in cases where you want to dynamically calculate the values based on function logic rather than providing static values.

In cases where you want to pass comma-containing values as arguments, you can do so by wrapping them in curly braces (`{ }`).

Examples

For more examples, see our Using CSS custom functions guide.

Basic <code><dashed-function></code> usage

This example shows a basic function that returns a semi-transparent version of the color passed to it.

HTML

The markup features a `<p>` containing some text content:

```
<p>Some content</p>
```

CSS

In our styles, we first define the CSS custom function. The function is called `--transparent` and accepts two parameters: a color and a numeric alpha channel value. Inside the function body, we use relative color syntax to transform the passed color into an `oklch()` color with an alpha channel equal to the passed alpha value; this becomes the function's `result`:

```
@function --transparent(--color <color>, --alpha <number>) {
  result: oklch(from var(--color) l c h / var(--alpha));
}
```

Next, we define a `--base-color` custom property with a value of `#faa6ff` on the `:root` element. We assign that property to be the value of the `<p>` element's `border` color, and then set its `background-color` value to equal a transparent version of the same color. This is done by setting the value to equal the `<dashed-function>` syntax, specifying the `--transparent()` function and passing it arguments of `var(--base-color)` and `0.8`.

```
html,
body {
  height: 100%;
}

body {
  margin: 0;
  display: grid;
  place-items: center;
  font-family: system-ui;
  background-image: repeating-linear-gradient(
    -45deg,
    transparent 0 20px,
    lightgrey 20px 40px
  );
}
```

```
:root {
  --base-color: #faa6ff;
}

p {
  width: 50%;
  padding: 30px;
  border-radius: 20px;
  border: 3px solid var(--base-color);
  background-color: --transparent(var(--base-color), 0.8);
}
```

<dashed-ident> CSS type

The **`<dashed-ident>`** CSS data type is a case-sensitive `<custom-ident>` starting with two dashes that denotes an arbitrary string used as an identifier.

Syntax

The syntax of `<dashed-ident>` is similar to CSS identifiers (such as property names), except that it is case-sensitive. It is a user-defined identifier preceded by two dashes (`--`).

The double dash at the beginning makes them easily identifiable when reading through a CSS code block, and helps to avoid name clashes with standard CSS keywords.

Just like `<custom-ident>`s, `<dashed-ident>`s are defined by the user. However, some `<custom-ident>`s are defined by the CSS language itself; `<dashed-ident>`s will never be defined in CSS.

Examples

Using with CSS custom properties

When a `<dashed-ident>` is used as a CSS custom property, the property is declared first, and then the `<dashed-ident>` is used within a CSS `var()` function.

```
html {
  --primary-color: red;
  --secondary-color: blue;
  --tertiary-color: green;
}

h1,
h4 {
  color: var(--primary-color);
}

h2,
h5 {
  color: var(--secondary-color);
}

h3,
h6 {
  color: var(--tertiary-color);
}
```

Using with @color-profile

When a `<dashed-ident>` is used with the `@color-profile` at-rule, the at-rule is declared first, and then the `<dashed-ident>` is used within a CSS `color()` function.

```
@color-profile --my-color-profile {
  src: url("https://example.org/SWOP2006_Coated5v2.icc");
}

.header {
  background-color: color(--my-color-profile 0% 70% 20% 0%);
}
```

Using with @font-palette-values

When a `<dashed-ident>` is used with the `@font-palette-values` at-rule, the at-rule is declared first, and then the `<dashed-ident>` is used as the value for the `font-palette` property.

```
@font-palette-values --my-palette {
  font-family: "Bixa";
  base-palette: 1;
  override-colors: 0 red;
}

h1,
h2,
h3,
h4 {
  font-palette: --my-palette;
}
```

Using with env() and param()

When a `<dashed-dent>` is used in an external resource in an `env()` CSS function, it can be updated using the `param()` CSS function.

```
<svg viewBox="0 0 100 100" xmlns="http://www.w3.org/2000/svg">
  <path fill="env(--color, black)" d="..." />
</svg>
```

```
path:hover {
  link-parameters: param(--color, tomato);
}
```

Browser compatibility

As this type is not a real type but a convenience type used to simplify the definition of other CSS syntax, there is no browser compatibility information as such.

CSS data types

CSS data types define typical values (including keywords and units) accepted by CSS properties and functions. They are a special kind of component value type.

The most commonly-used types are defined in the CSS Values and Units module. This module also defines functional notations, which allow for more complex types or processing. Other types are defined in the specifications to which they apply.

Below you will find a reference to the types that you are most likely to come across, however it is not a comprehensive reference for all types defined in every CSS specification.

Syntax

In formal CSS syntax, data types are denoted by a keyword placed between the angle brackets `<` and `>`. They don't correspond to any tangible CSS code entity.

Textual data types

These types include keywords and identifiers as well as strings, and URLs.

Pre-defined keywords

Keywords with a pre-defined meaning, for example, the value of `collapse` for the `border-collapse` property.

CSS-wide keywords

All properties, including custom properties, accept the CSS-wide keywords:

`initial`

The value specified as the property's initial value.

`inherit`

The computed value of the property on the element's parent.

`revert`

Rolls back the cascade to the value of the earlier origin.

`revert-layer`

Rolls back the cascade to the value of the earlier cascade layer.

`revert-rule`

Rolls back the cascade to the value of an earlier matching style rule.

`unset`

Acts as `inherit` or `initial` depending on whether the property is inherited or not.

`<custom-ident>`

A user-defined identifier, for example the name assigned using the `grid-area` property.

`<dashed-ident>`

A `<custom-ident>` with the additional restriction that it must start with two dashes, for example, with CSS Custom Properties.

`<string>`

A quoted string, such as used for a value of the `content` property.

`<url>`

A pointer to a resource, for example as the value of `background-image`.

Numeric data types

These data types are used to indicate quantities, indexes, and positions. The majority of these are defined in the CSS values and units module, however additional types are described in other modules where they are specific to that specification alone — for example the `fr` unit in the CSS grid layout module.

`<integer>`

One or more decimal units 0 through 9, optionally preceded by `-` or `+`.

`<number>`

Real numbers which may also have a fractional component, for example `1` or `1.34`.

`<dimension>`

A number with a unit attached to it, for example `90deg`, `50ms`, or `15em`. This type includes distances (`<length>`), durations (`<time>`), frequencies (`<frequency>`), resolutions (`<resolution>`), and other quantities.

`<percentage>`

A number with a percentage sign attached to it, for example `10%`.

`<ratio>`

A ratio, written with the syntax `<number> / <number>`.

`<flex>`

A flexible length introduced for CSS grid layout, written as a `<number>` with the `fr` unit attached and used for grid track sizing.

Quantities

These `<dimension>` types are used to specify distance and other quantities.

`<length>`

Lengths are a `<dimension>` and refer to distances.

`<angle>`

Angles are used in properties such as `linear-gradient()` and are a `<dimension>` with one of `deg`, `grad`, `rad`, or `turn` units attached.

`<time>`

Duration units are a `<dimension>` with an `s` or `ms` unit.

`<frequency>`

Frequencies are a `<dimension>` with a `Hz` or `kHz` unit attached.

`<resolution>`

Is a `<dimension>` with a unit identifier of `dpi`, `dpcm`, `dppx`, or `x`.

Combinations of types

Some CSS properties can take a `<dimension>` or a `<percentage>` value. In this case the percentage value will be resolved to a quantity that matches the allowable dimension. Properties which can accept a percentage in addition to a dimension will use one of the types listed below.

`<length-percentage>`

A type that can accept a length or a percentage as a value.

`<frequency-percentage>`

A type that can accept a frequency or a percentage as a value.

`<angle-percentage>`

A type that can accept an angle or a percentage as a value.

`<time-percentage>`

A type that can accept a time or a percentage as a value.

Color

The CSS color module defines the `<color>` data type, and other types which relate to color in CSS.

`<color>`

Specified as a keyword or a numerical color value.

`<alpha-value>`

Specifies the transparency of a color. May be a `<number>`, in which case 0 is fully transparent and 1 is fully opaque, or a `<percentage>`, in which case 0% is fully transparent and 100% fully opaque.

`<hue>`

Specifies the `<angle>`, with a unit identifier of `deg`, `grad`, `rad`, or `turn`, or unitless `<number>` interpreted as `deg`, of the color wheel specific to the `<absolute-color-functions>` of which it is a component.

Images

The CSS images module defines the data types which deal with images, including gradients.

`<image>`

A URL reference to an image or a color gradient.

`<color-stop-list>`

A list of two or more color stops with optional transition information using a color hint.

`<linear-color-stop>`

A `<color>` and a `<length-percentage>` to indicate the color stop for this part of the gradient.

`<linear-color-hint>`

A `<length-percentage>` to indicate how the color interpolates.

`<ending-shape>`

Used for radial gradients; can have a keyword value of `circle` or `ellipse`.

`<size>`

Determines the size of the radial gradient's ending shape. This accepts a value of a keyword or a `<length>` but not a percentage.

2D positioning

The `<position>` data type is interpreted as defined for the `background-position` property.

`<position>`

Defines the position of an object area. Accepts a keyword value such as `top` or `left`, or a `<length-percentage>`.

Calculation data types

These data types are used in CSS math function calculations.

`<calc-sum>`

A calculation which is a sequence of calculation values interspersed with addition (`+`) and subtraction (`-`) operators. This data type requires both values to have units.

`<calc-product>`

A calculation which is a sequence of calculation values interspersed with multiplication (`*`) and division (`/`) operators. When multiplying, one value must be unitless. When dividing, the second value must be unitless.

`<calc-value>`

Defines accepted values for calculations, values such as `<number>`, `<dimension>`, `<percentage>`, `<calc-keyword>` or nested `<calc-sum>` calculations.

`<calc-keyword>`

Defines a number of CSS keywords representing numeric constants such as `e` and π, that can be used in CSS math functions.

Shape data types

The CSS shapes and CSS borders and box decorations modules define shape data types:

`<basic-shape>`

Describes shape functions used in the `clip-path`, `shape-outside`, and `offset-path` properties.

`<corner-shape-value>`

Describes the shape of a container corner. It is used by the `corner-shape` shorthand property and its constituent properties to specify the shape applied to affected container corners.

`<dimension>` CSS type

The **`<dimension>`** CSS data type represents a `<number>` with a unit attached to it, for example `10px`.

CSS uses dimensions to specify distances (`<length>`), durations (`<time>`), frequencies (`<frequency>`), resolutions (`<resolution>`), and other quantities.

Syntax

The syntax of `<dimension>` is a `<number>` immediately followed by a unit which is an identifier. Unit identifiers are case insensitive.

Examples

Valid dimensions

```
12px      12 pixels
1rem      1 rem
1.2pt     1.2 points
2200ms    2200 milliseconds
5s        5 seconds
200hz     200 Hertz
200Hz     200 Hertz (values are case insensitive)
```

Invalid dimensions

```
12 px       The unit must come immediately after the number.
12"px"      Units are identifiers and therefore unquoted.
3sec        The seconds unit is abbreviated "s" not "sec".
```

- Learn to style HTML using CSS
- CSS distances (`<length>`), durations (`<time>`), frequencies (`<frequency>`), and resolutions (`<resolution>`)

<display-box> CSS type

These keywords define whether an element generates display boxes at all.

Syntax

Valid `<display-box>` values:

`contents`

> These elements don't produce a specific box by themselves. They are replaced by their pseudo-box and their child boxes. Please note that the CSS Display Level 3 spec defines how the `contents` value should affect "unusual elements" — elements that aren't rendered purely by CSS box concepts such as replaced elements. See Appendix B: Effects of display: contents on Unusual Elements for more details.
>
> *Due to a bug in browsers this will currently remove the element from the accessibility tree — screen readers will not look at what's inside. See the Accessibility section below for more details.*

`none`

> Turns off the display of an element so that it has no effect on layout (the document is rendered as though the element did not exist). All descendant elements also have their display turned off. To have an element take up the space that it would normally take, but without actually rendering anything, use the `visibility` property instead.

Accessibility

Current implementations in most browsers will remove from the accessibility tree any element with a `display` value of `contents`. This will cause the element — and in some browser versions, its descendant elements — to no longer be announced by screen reading technology. This is incorrect behavior according to the CSSWG specification.

- More accessible markup with display: contents | Hidde de Vries
- Display: Contents Is Not a CSS Reset | Adrian Roselli

Formal syntax

```
<display-box> =
  contents  |
  none
```

This syntax reflects the latest standard as per CSS Display Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

In this first example, the paragraph with a class of secret is set to `display: none`; the box and any content is now not rendered.

display: none

HTML

```
<p>Visible text</p>
<p class="secret">Invisible text</p>
```

CSS

```
p.secret {
  display: none;
}
```

Result

display: contents

In this example the outer `<div>` has a 2-pixel red border and a width of 300px. However it also has `display: contents` specified therefore this `<div>` will not be rendered, the border and width will no longer apply, and the child element will be displayed as if the parent had never existed.

HTML

```
<div class="outer">
  <div>Inner div.</div>
</div>
```

CSS

```
.outer {
  border: 2px solid red;
  width: 300px;
  display: contents;
```

```
}

.outer > div {
  border: 1px solid green;
}
```

Result

- Display: Contents Is Not a CSS Reset | Adrian Roselli
- More accessible markup with display: contents by Hidde de Vries (2018)

`<display-inside>` CSS type

These keywords specify the element's inner `display` type, which defines the type of formatting context that lays out its contents (assuming it is a non-replaced element). These keywords are used as values of the `display` property, and can be used for legacy purposes as a single keyword, or as defined in the Level 3 specification alongside a value from the `<display-outside>` keywords.

Syntax

Valid `<display-inside>` values:

`flow`

The element lays out its contents using flow layout (block-and-inline layout).

If its outer display type is `inline`, and it is participating in a block or inline formatting context, then it generates an inline box. Otherwise it generates a block container box.

Depending on the value of other properties (such as `position`, `float`, or `overflow`) and whether it is itself participating in a block or inline formatting context, it either establishes a new block formatting context (BFC) for its contents or integrates its contents into its parent formatting context.

`flow-root`

The element generates a block element box that establishes a new block formatting context, defining where the formatting root lies.

`table`

These elements behave like HTML `<table>` elements. It defines a block-level box.

`flex`

The element behaves like a block element and lays out its content according to the flexbox model.

`grid`

The element behaves like a block element and lays out its content according to the grid model.

`ruby`

The element behaves like an inline element and lays out its content according to the ruby formatting model. It behaves like the corresponding HTML `<ruby>` elements.

> **Note:** Browsers that support the two value syntax, on finding the inner value only, such as when `display: flex` or `display: grid` is specified, will set their outer value to `block`. This will result in expected behavior; for example if you specify an element to be `display: grid`, you would expect that the box created on the grid container would be a block level box.

Formal syntax

```
<display-inside> =
  flow       |
  flow-root  |
  table      |
  flex       |
  grid       |
  ruby
```

This syntax reflects the latest standard as per CSS Display Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

In this example the parent box has been given `display: flow-root` and so establishes a new BFC and contains the floated item.

HTML

```
<div class="box">
  <div class="float">I am a floated box!</div>
  <p>I am content inside the container.</p>
</div>
```

CSS

```
.box {
  background-color: rgb(224 206 247);
  border: 5px solid rebeccapurple;
  display: flow-root;
}

.float {
  float: left;
  width: 200px;
  height: 150px;
  background-color: white;
  border: 1px solid black;
```

```
  padding: 10px;
}
```

Result

  - `<display-legacy>`
- Basic concepts of flexbox
- Basic Concepts of grid layout

<display-internal> CSS type

Some layout models such as `table` and `ruby` have a complex internal structure, with several different roles that their children and descendants can fill. This page defines those "internal" display values, which only have meaning within that particular layout mode.

Syntax

Valid `<display-internal>` values:

`table-row-group`

These elements behave like `<tbody>` HTML elements.

`table-header-group`

These elements behave like `<thead>` HTML elements.

`table-footer-group`

These elements behave like `<tfoot>` HTML elements.

`table-row`

These elements behave like `<tr>` HTML elements.

`table-cell`

These elements behave like `<td>` HTML elements.

`table-column-group`

These elements behave like `<colgroup>` HTML elements.

`table-column`

These elements behave like `<col>` HTML elements.

`table-caption`

These elements behave like `<caption>` HTML elements.

`ruby-base`

These elements behave like `<rb>` HTML elements.

`ruby-text`

These elements behave like `<rt>` HTML elements.

`ruby-base-container`

These elements are generated as anonymous boxes.

`ruby-text-container`

These elements behave like `<rtc>` HTML elements.

Formal syntax

```
<display-internal> =
  table-row-group      |
  table-header-group   |
  table-footer-group   |
  table-row            |
  table-cell           |
  table-column-group   |
  table-column         |
  table-caption        |
  ruby-base            |
  ruby-text            |
  ruby-base-container  |
  ruby-text-container
```

This syntax reflects the latest standard as per CSS Display Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

CSS tables example

The following example demonstrates laying out a form using CSS table layout.

HTML

```
<main>
  <div>
    <label for="name">Name</label>
    <input type="text" id="name" name="name" />
  </div>
  <div>
    <label for="age">Age</label>
    <input type="text" id="age" name="age" />
  </div>
</main>
```

CSS

```
main {
  display: table;
}

div {
  display: table-row;
}

label,
input {
  display: table-cell;
  margin: 5px;
}
```

Result

See also

- display
  - <display-outside>
  - <display-inside>
  - <display-listitem>
  - <display-box>
  - <display-legacy>

<display-legacy> CSS type

CSS 2 used a single-keyword syntax for the display property, requiring separate keywords for block-level and inline-level variants of the same layout mode. This page details those values.

Syntax

Valid <display-legacy> values:

inline-block

The element generates a block element box that will be flowed with surrounding content as if it were a single inline box (behaving much like a replaced element would).

It is equivalent to inline flow-root.

inline-table

The inline-table value does not have a direct mapping in HTML. It behaves like an HTML <table> element, but as an inline box, rather than a block-level box. Inside the table box is a block-level context.

It is equivalent to inline table.

inline-flex

The element behaves like an inline element and lays out its content according to the flexbox model.

It is equivalent to inline flex.

inline-grid

The element behaves like an inline element and lays out its content according to the grid model.

It is equivalent to inline grid.

Formal syntax

```
<display-legacy> =
  inline-block  |
  inline-table  |
  inline-flex   |
  inline-grid
```

This syntax reflects the latest standard as per CSS Display Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

In the below example, we are creating an inline flex container with the legacy keyword inline-flex.

HTML

```
<div class="container">
  <div>Flex Item</div>
  <div>Flex Item</div>
</div>

Not a flex item
```

CSS

```
.container {
  display: inline-flex;
```

```
}
```

Result

In the new syntax the inline flex container would be created using two values, inline for the outer display type, and flex for the inner display type.

```
.container {
  display: inline flex;
}
```

Browser compatibility

See also

- `display`
  - `<display-outside>`
  - `<display-inside>`
  - `<display-listitem>`
  - `<display-internal>`
  - `<display-box>`

<display-listitem> CSS type

The `list-item` keyword causes the element to generate a `::marker` pseudo-element with the content specified by its `list-style` properties (for example a bullet point) together with a principal box of the specified type for its own contents.

Syntax

A single value of `list-item` will cause the element to behave like a list item. This can be used together with `list-style-type` and `list-style-position`.

`list-item` can also be combined with any `<display-outside>` keyword and the `flow` or `flow-root` `<display-inside>` keywords.

> **Note:** In browsers that support the two-value syntax, if no inner value is specified it will default to `flow`. If no outer value is specified, the principal box will have an outer display type of `block`.

Formal syntax

```
<display-listitem> =
  <display-outside>?     &&
  [ flow | flow-root ]?  &&
  list-item

<display-outside> =
  block   |
  inline  |
  run-in
```

This syntax reflects the latest standard as per CSS Display Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<div class="fake-list">I will display as a list item</div>
```

CSS

```
.fake-list {
  display: list-item;
  list-style-position: inside;
}
```

Result

See also

- `display`
  - `<display-outside>`
  - `<display-inside>`
  - `<display-internal>`
  - `<display-box>`
  - `<display-legacy>`

<display-outside> CSS type

The `<display-outside>` keywords specify the element's outer `display` type, which is essentially its role in flow layout. These keywords are used as values of the `display` property, and can be used for legacy purposes as a single keyword, or as defined in the Level 3 specification alongside a value from the `<display-inside>` keywords.

Syntax

Valid `<display-outside>` values:

`block`

The element generates a block element box, generating line breaks both before and after the element when in the normal flow.

`inline`

The element generates one or more inline element boxes that do not generate line breaks before or after themselves. In normal flow, the next element will be on the same line if there is space.

> **Note:** When browsers encounter a display property with only an **outer** `display` value (e.g., `display: block` or `display: inline`), the inner value defaults to `flow` (e.g., `display: block flow` and `display: inline flow`). This is backwards-compatible with single-keyword syntax.

Formal syntax

```
<display-outside> =
  block   |
  inline  |
  run-in
```

This syntax reflects the latest standard as per CSS Display Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

In the following example, span elements (normally displayed as inline elements) are set to `display: block` and so break onto new lines and expand to fill their container in the inline dimension.

HTML

```
<span>span 1</span> <span>span 2</span>
```

CSS

```
span {
  display: block;
  border: 1px solid rebeccapurple;
}
```

dynamic-range-limit-mix() CSS function

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`dynamic-range-limit-mix()`** CSS function creates a custom maximum luminance limit by mixing different `dynamic-range-limit` keywords in specified amounts.

Syntax

```
dynamic-range-limit-mix(standard 70%, no-limit 30%);
dynamic-range-limit-mix(no-limit 10%, constrained 20%);
dynamic-range-limit-mix(no-limit 30%, constrained 30%, standard 30%);
dynamic-range-limit-mix(
    no-limit 20%,
    dynamic-range-limit-mix(standard 25%, constrained 75%) 20%
)
```

Parameters

`dynamic-range-limit` `<percentage>`

A pair consisting of a `dynamic-range-limit` value (which can be another `dynamic-range-limit-mix()` function) and a `<percentage>` between `0%` and `100%` (inclusive). The `<percentage>` specifies the proportion of a `dynamic-range-limit` keyword value in the custom limit. The `dynamic-range-limit-mix()` function can take two or more of these pairs as parameters.

Return value

A custom maximum luminance limit, expressed as a number of photographic stops higher than the HDR reference white. For privacy reasons, the actual calculated result is not exposed.

Description

The `dynamic-range-limit` property allows you to control the brightness of High Dynamic Range (HDR) content. The `dynamic-range-limit-mix()` function can be provided as a value of `dynamic-range-limit`, and enables you to create custom brightness limits by mixing together percentages of the `dynamic-range-limit` keyword values.

Calculating the percentages

When the given percentages add up to `100%`, the result is obvious:

```
/* standard 70%, no-limit 30% */
dynamic-range-limit-mix(standard 70%, no-limit 30%);
```

When the given percentages do not add up to `100%`, the resulting percentages are equal to the given percentages expressed proportionately to one another so the total equals `100%`:

```
/* no-limit 40%, constrained 60% */
dynamic-range-limit-mix(no-limit 20%, constrained 30%);

/* no-limit 20%, constrained 40%, standard 40% */
dynamic-range-limit-mix(no-limit 40%, constrained 80%, standard 80%);
```

If a `dynamic-range-limit` keyword value is used more than once, the percentages for that keyword value are added together to get the total percentage:

```
/* constrained 70%, standard 30% */
dynamic-range-limit-mix(constrained 40%, standard 30%, constrained 30%);

/* no-limit 40%, constrained 60% */
dynamic-range-limit-mix(no-limit 10%, constrained 30%, no-limit 10%);
```

If a specified percentage is less than `0%` or greater than `100%`, the `dynamic-range-limit-mix()` function — and therefore the associated `dynamic-range-limit` property value — is invalid. If a keyword is used more than once and the cumulative percentage is more than `100%`, the value is valid, and the proportion rules described above come into play.

Nesting <code>dynamic-range-limit-mix()</code> functions

You can nest `dynamic-range-limit-mix()` functions inside one another. When doing so, the same rules explained earlier apply, and each set of percentages is calculated separately and then added. In the following example:

```
dynamic-range-limit-mix(
    no-limit 10%,
    dynamic-range-limit-mix(standard 25%, constrained 75%) 20%,
    dynamic-range-limit-mix(constrained 10%, no-limit 30%) 20%
)
```

- The first line gives us `no-limit 10%`.
- Since `25%` and `75%` add up to `100%`, the second line gives us `standard 5%` (`25%` of `20%`) and `constrained 15%` (`75%` of `20%`).
- In the third line, because `10%` and `30%` add up to only `40%`, not `100%`, we normalize both as proportions of `40%`: 10/40 = `25%` and 30/40 = `75%`. This gives us `constrained 5%` (`25%` of `20%`) and `no-limit 15%` (`75%` of `20%`).

Adding these up to get the raw percentages gives us:

```
dynamic-range-limit-mix(standard 5%, constrained 20%, no-limit 25%)
```

The above percentages add up to `50%`, so they need to be doubled to get the final percentages. The computed value is therefore:

```
dynamic-range-limit-mix(standard 10%, constrained 40%, no-limit 50%)
```

Formal syntax

```
<dynamic-range-limit-mix()> =
  dynamic-range-limit-mix( [ <'dynamic-range-limit'> && <percentage [0,100]> ]# )

<dynamic-range-limit> =
  standard                    |
  no-limit                    |
  constrained                 |
  <dynamic-range-limit-mix()>
```

This syntax reflects the latest standard as per CSS Color HDR Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

Consider an `<img>` element being used to embed an HDR image on a web page:

```
<img src="my-hdr-image.jpg" alt="my image" />
```

On HDR displays, the brightest areas of the image could prove to be jarring and uncomfortable to look at. To solve this problem, we could set the image's `dynamic-range-limit` property to `dynamic-range-limit-mix(standard 70%, no-limit 30%)`, which gives it a maximum luminance limit of only slightly brighter than HDR reference white:

```
img {
  dynamic-range-limit: dynamic-range-limit-mix(standard 70%, no-limit 30%);
}
```

You can see the `dynamic-range-limit` property in action in our dynamic-range-limit property demo, which includes an HDR image that can be hovered and focused to transition the `dynamic-range-limit` value. View the example live in a display capable of displaying HDR colors, and try it out.

<easing-function> CSS type

The **`<easing-function>`** CSS data type represents a mathematical function that describes the rate at which a value changes.

This transition between two values may be applied in different situations. It may be used to describe how fast values change during animations. This lets you vary the animation's speed over the course of its duration. You can specify an easing function for CSS transition and animation properties.

Syntax

```
/* Keyword linear easing function */
linear                /* linear(0, 1) */

/* Custom linear easing functions */
linear(0, 0.25, 1)
linear(0, 0.25 75%, 1)

/* Keyword cubic Bézier easing functions */
ease                  /* cubic-bezier(0.25, 0.1, 0.25, 1) */
ease-in               /* cubic-bezier(0.42, 0, 1, 1) */
ease-out              /* cubic-bezier(0, 0, 0.58, 1) */
ease-in-out           /* cubic-bezier(0.42, 0, 0.58, 1) */

/* Custom cubic Bézier easing function */
cubic-bezier(0.25, 0.1, 0.25, 1)

/* Keyword step easing functions */
step-start            /* steps(1, jump-start) */
step-end              /* steps(1, jump-end) */

/* Custom step easing functions */
steps(4, end)
steps(10, jump-both)
```

Values

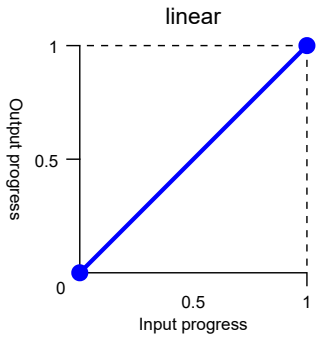
An `<easing-function>` can be one of the following types:

`<linear-easing-function>`

Creates transitions that progress at a constant rate. This function can be specified using one of the following:

`linear`

Specifies a constant rate of interpolation, with no change in the rate of progress throughout the duration (that is, no acceleration or deceleration). This keyword value is equivalent to `linear(0, 1)`. It can also be represented as `cubic-bezier(0, 0, 1, 1)`.



> **Note:** The `linear` keyword is always interpreted as `linear(0, 1)`, whereas the function `linear(0, 1)` is interpreted as `linear(0 0%, 1 100%)`.

`linear()`

Defines multiple points of progress using `<number>` values, with optional `<percentage>` values to control their timing.

`<cubic-bezier-easing-function>`

Creates smooth transitions with variable rates of change. This function can be specified using one of the following:

`ease`

Represents the easing function `cubic-bezier(0.25, 0.1, 0.25, 1)`. It indicates that the interpolation starts slowly, accelerates sharply, and then slows gradually towards the end. It is similar to the `ease-in-out` keyword, though it accelerates more sharply at the beginning.

`ease-in`

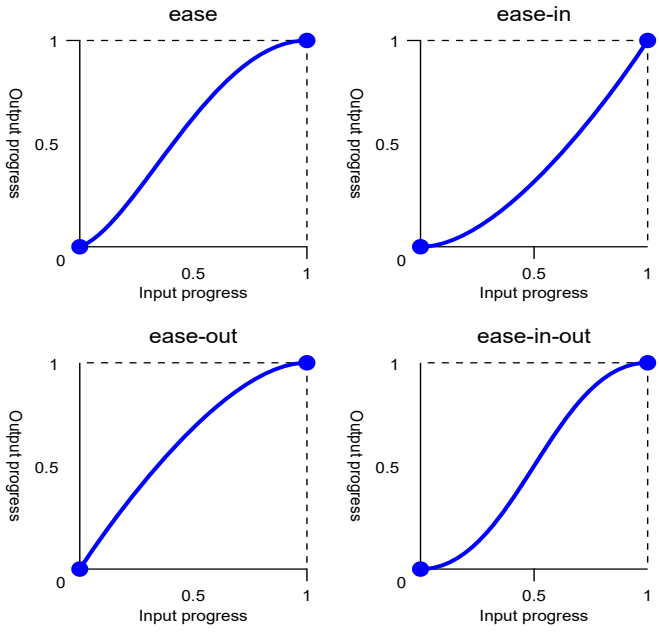
Represents the easing function `cubic-bezier(0.42, 0, 1, 1)`. It indicates that the interpolation starts slowly, then progressively speeds up until the end, at which point it stops abruptly.

`ease-out`

Represents the easing function `cubic-bezier(0, 0, 0.58, 1)`. It indicates that the interpolation starts abruptly and then progressively slows down towards the end.

`ease-in-out`

Represents the easing function `cubic-bezier(0.42, 0, 0.58, 1)`. It indicates that the interpolation starts slowly, speeds up, and then slows down towards the end. At the beginning, it behaves like the `ease-in` keyword; at the end, it is like the `ease-out` keyword.



`cubic-bezier()`

Defines a custom curve using four `<number>` values that specify the coordinates of two control points. The x-coordinates must be in the range `[0, 1]`.

`<step-easing-function>`

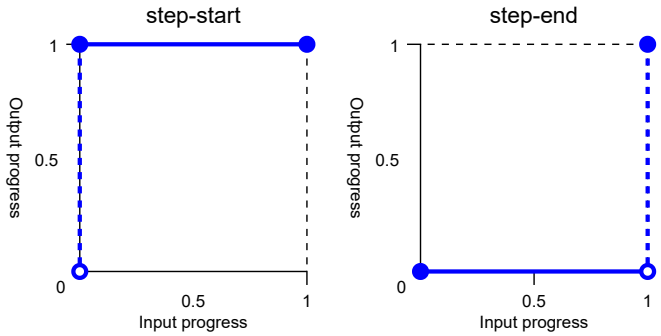
Creates stepped transitions that divides the animation into a set number of equal-length intervals, causing the animation to jump from one step to the next rather than transitioning smoothly. This function can be specified using one of the following:

`step-start`

Represents the easing function `steps(1, jump-start)` or `steps(1, start)`. It indicates that the interpolation jumps immediately to its final state, where it stays until the end.

`step-end`

Represents the easing function `steps(1, jump-end)` or `steps(1, end)`. It indicates that the interpolation stays in its initial state until the end, at which point it jumps directly to its final state.



`steps()`

Creates a stair-shaped curve using an `<integer>` to specify the number of intervals and an optional keyword to control the timing of jumps.

Formal syntax

```
<easing-function> =
  <linear-easing-function>        |
  <cubic-bezier-easing-function>  |
  <step-easing-function>

<linear-easing-function> =
  linear      |
  <linear()>

<cubic-bezier-easing-function> =
  ease              |
  ease-in           |
  ease-out          |
  ease-in-out       |
  <cubic-bezier()>

<step-easing-function> =
  step-start  |
  step-end    |
  <steps()>

<linear()> =
  linear( [ <number> && <percentage>{0,2} ]# )

<cubic-bezier()> =
  cubic-bezier( [ <number [0,1]> , <number> ]#{2} )

<steps()> =
  steps( <integer> , <step-position>? )

<integer> =
  <number-token>

<step-position> =
  jump-start  |
  jump-end    |
  jump-none   |
  jump-both   |
  start       |
  end
```

This syntax reflects the latest standard as per CSS Easing Functions Level 2, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Comparing the easing functions

This example provides a comparison between the different easing functions using an animation. From the drop-down menu, you can select an easing function – there are a couple of keywords and some `cubic-bezier()` and `steps()` options. After selecting an option, you can start and stop the animation using the provided button.

HTML

```
<div>
  <div></div>
</div>
<ul>
  <li>
    <button class="animation-button">Start animation</button>
  </li>
  <li>
    <label for="easing-select">Choose an easing function:</label>
    <select id="easing-select">
      <option selected>linear</option>
      <option>linear(0, 0.5 50%, 1)</option>
      <option>ease</option>
      <option>ease-in</option>
      <option>ease-in-out</option>
      <option>ease-out</option>
```

```
      <option>cubic-bezier(0.1, -0.6, 0.2, 0)</option>
      <option>cubic-bezier(0, 1.1, 0.8, 4)</option>
      <option>steps(5, end)</option>
      <option>steps(3, start)</option>
      <option>steps(4)</option>
    </select>
  </li>
</ul>
```

CSS

```
body > div {
  position: relative;
  height: 100px;
}

div > div {
  position: absolute;
  width: 50px;
  height: 50px;
  background-color: blue;
  background-image: radial-gradient(
    circle at 10px 10px,
    rgb(25 255 255 / 80%),
    rgb(25 255 255 / 40%)
  );
  border-radius: 50%;
  top: 25px;
  animation: 1.5s infinite alternate;
}

@keyframes move-right {
  from {
    left: 10%;
  }

  to {
    left: 90%;
  }
}

li {
  display: flex;
  align-items: center;
  justify-content: center;
  margin-bottom: 20px;
}
```

JavaScript

```
const selectElem = document.querySelector("select");
const startBtn = document.querySelector("button");
const divElem = document.querySelector("div > div");

startBtn.addEventListener("click", () => {
  if (startBtn.textContent === "Start animation") {
    divElem.style.animationName = "move-right";
    startBtn.textContent = "Stop animation";
    divElem.style.animationTimingFunction = selectElem.value;
  } else {
    divElem.style.animationName = "unset";
    startBtn.textContent = "Start animation";
  }
});

selectElem.addEventListener("change", () => {
  divElem.style.animationTimingFunction = selectElem.value;
});
```

cubic-bezier() CSS function

The **`cubic-bezier()`** CSS function creates a smooth transition using a cubic Bézier curve. As an `<easing-function>`, it can be used to smooth out the start and end of the interpolation.

Syntax

```
cubic-bezier(0.25, 0.1, 0.25, 1)
cubic-bezier(0.1, -0.6, 0.2, 0)
cubic-bezier(0, 0, 1, 1)
```

Parameters

The function accepts the following four parameters, which represent the coordinates of two control points:

`<x1>`

A `<number>` representing the x-axis coordinate of the first control point. It must be in the `[0, 1]` range.

`<y1>`

A `<number>` representing the y-axis coordinate of the first control point.

`<x2>`

A `<number>` representing the x-axis coordinate of the second control point. It must be in the `[0, 1]` range.

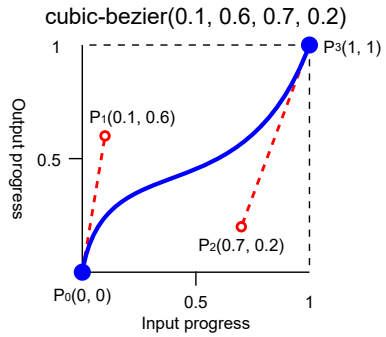
`<y2>`

A `<number>` representing the y-axis coordinate of the second control point.

Description

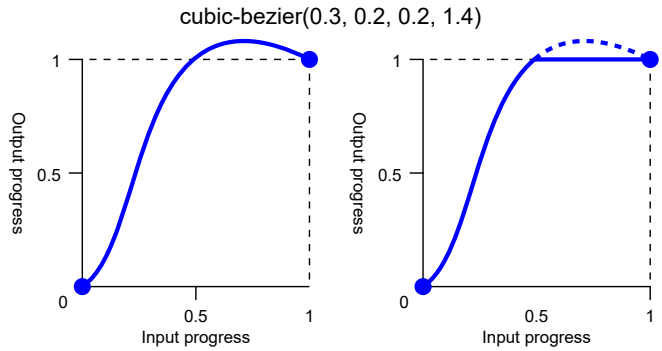
The cubic Bézier functions, often called "smooth" easing functions, correlate an input progress to an output progress, both expressed as `<number>`s, where `0.0` represents the initial state and `1.0` represents the final state. If the cubic Bézier curve is invalid, CSS ignores the whole property.

A cubic Bézier curve is defined by four points: P0, P1, P2, and P3. The points P0 and P3 represent the start and the end of the curve. In CSS, the start point P0 is fixed at `(0, 0)` and the end point P3 is fixed at `(1, 1)`, while intermediate points P1 and P2 are defined by the function parameters `(<x1>, <y1>)` and `(<x2>, <y2>)` respectively. The x-axis represents input progress and the y-axis represents output progress.



Not all cubic Bézier curves are suitable as easing functions because not all are mathematical functions; i.e., curves that for a given x-axis coordinate have zero or one value. With P0 and P3 fixed as defined by CSS, a cubic Bézier curve is a function, and is valid when the x-axis coordinates of P1 and P2 are both in the [0, 1] range.

Cubic Bézier curves with the P1 or P2 ordinate outside the `[0, 1]` range can cause the value to go farther than the final state and then return. In animations, this creates a kind of "bouncing" effect.



However, certain properties will restrict the output if it goes outside an allowable range. For example, a color component greater than `255` or smaller than `0` in `rgb()` will be clipped to the closest allowed value (`255` and `0`, respectively). Some `cubic-bezier()` values exhibit this property.

Formal syntax

```
<cubic-bezier()> =
  cubic-bezier( [ <number [0,1]> , <number> ]#{2} )
```

This syntax reflects the latest standard as per CSS Easing Functions Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Bouncing effect

In this example, the red ball bounces out of the box when transitioned from its original position. This is because one of the P2 values, `2.3`, goes beyond the `[0, 1]` range.

```
<div tabindex="0">
  <span></span>
</div>
```

```
div {
  margin: 8px auto;
  padding: 8px;
  width: 256px;
  border-radius: 40px;
  background-color: wheat;
}

span {
  display: block;
  width: 64px;
  height: 64px;
  border-radius: 50%;
  background: tomato;
}

div:hover span,
div:focus span {
  translate: 192px 0;
}
```

```
span {
  transition: translate 0.3s cubic-bezier(0.3, 0.8, 0.3, 2.3);
}
```

Using the cubic-bezier() function

These cubic Bézier curves are valid for use in CSS:

```
/* The canonical Bézier curve with four <number> in the [0,1] range */
cubic-bezier(0.1, 0.7, 1.0, 0.1)

/* Using <integer> is valid because any <integer> is also a <number> */
cubic-bezier(0, 0, 1, 1)

/* Negative values for ordinates are valid, leading to bouncing effects */
cubic-bezier(0.1, -0.6, 0.2, 0)

/* Values greater than 1.0 for ordinates are also valid */
cubic-bezier(0, 1.1, 0.8, 4)
```

These cubic Bézier curve definitions are invalid:

```
/* Parameters must be numbers */
cubic-bezier(0.1, red, 1.0, green)

/* X coordinates must be in the [0, 1] range */
cubic-bezier(2.45, 0.6, 4, 0.1)

/* There must be exactly four parameters */
cubic-bezier(0.3, 2.1)

/* X coordinates must be in the [0, 1] range */
cubic-bezier(-1.9, 0.3, -0.2, 2.1)
```

- Other easing functions: `linear()` and `steps()`
- CSS easing functions module
- cubic-bezier.com by Lea Verou

linear() CSS function

The **`linear()`** CSS function creates a transition curve that progresses uniformly between points. As an `<easing-function>`, it creates transitions where the interpolation occurs at a constant rate from beginning to end.

Syntax

```
linear(0, 1)
linear(0, 0.25, 1)
linear(0, 0.25 75%, 1)
linear(0, 0.5 25% 75%, 1)
```

Parameters

The function accepts two or more of the following values, which represent progress points in the animation timeline:

`<number>`

> Represents a point in time along the duration of the animation or transition. At least two values must be specified. The value `0` represents the start of the transition, and `1` represents the end. Values outside the `0` to `1` range are also allowed.

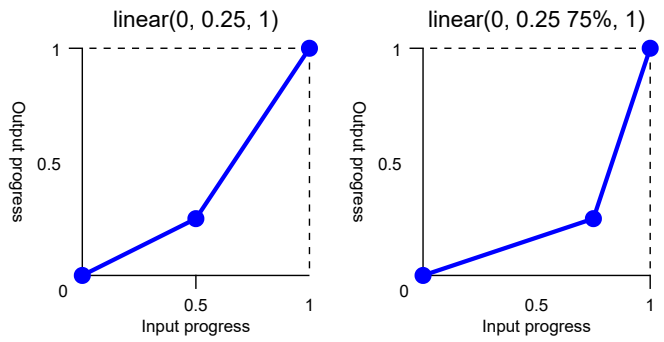
`<percentage>` Optional

> Indicates when the progress `<number>` is reached during the animation timeline. It can be specified after any `<number>` value except the first and last and can take up to two values. If two percentage values are specified, they define the length of the stop: the first percentage indicates the starting point and the second percentage indicates the ending point for that segment in the animation or transition. If no `<percentage>` value is specified, the progress values are distributed evenly along the timeline.

Description

The `linear()` function allows the approximation of complex animations and transitions by interpolating linearly between the specified points. A typical use of the `linear()` function is to provide many points to approximate any curve.

The `linear()` function creates transitions where progress occurs at a constant rate between specified points. For example, `linear(0, 0.25, 1)` has linear stops of `0`, `0.25`, and `1`. The animation starts at point `0`, moves linearly to `0.25`, and then continues linearly to point `1`. Since no percentage is specified, the same duration (`50%`) is used for each segment, that is, from `0` to `0.25` and from `0.25` to `1`.



By default, the stops are equidistant. For example, if there are five stops, they will occur at 0%, 25%, 50%, 75%, and 100% of the duration. You can use optional percentage values to provide finer control, defining when each progress value should occur and allowing for a more controlled progression of the transition.

Consider an animation with a duration time of 100 seconds and a change of 100 pixels. Let's look at a scenario where the easing of the animation is specified as `linear(0, 0.25 75%, 1)`. In this case, the animation progresses to 25 pixels (25% of its total change) in the first 75 seconds (75% of the duration). The last 75 pixels are applied in the remaining 25 seconds of the animation.

For the same animation, suppose the easing function is specified as `linear(0, 0.5 25% 75%, 1)`. Here, the animation reaches 50 pixels (50% of its total change) in 25 seconds (25% of the duration) and remains there for 50 seconds (75% - 25% of the duration). Then the last 50 pixels are applied in the remaining 25 seconds of the duration. Note that `linear(0, 0.5 25% 75%, 1)` is equivalent to `linear(0, 0.5 25%, 0.5 75%, 1)`.

Formal syntax

```
<linear()> =
  linear( [ <number> && <percentage>{0,2} ]# )
```

This syntax reflects the latest standard as per CSS Easing Functions Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using the linear() function

The following `linear()` functions are valid for use in CSS:

```
/* Three evenly distributed progress points */
linear(0, 0.25, 1)

/* Custom timing with percentage values */
linear(0, 0.5 25% 75%, 1)
```

The following `linear()` definitions are invalid:

```
/* At least two parameters are required */
linear(0.5)

/* Percentages must be in ascending order */
linear(0, 0.25 80%, 0.5 60%, 1)

/* Values must be numbers */
linear(start, middle, end)
```

steps() CSS function

The **`steps()`** CSS function defines a transition that divides the input time into a specified number of intervals that are equal in length. This subclass of step functions are sometimes also called *staircase functions*.

Syntax

```
/* Different intervals */
steps(2, end)
steps(4, jump-end)
steps(12, end)

/* Different jump positions */
steps(3, jump-start)
steps(3, jump-end)
steps(3, jump-none)
steps(3, jump-both)
```

Parameters

The function accepts the following parameters:

`<integer>`

Represents the number of equidistant intervals or 'steps'. It must be a positive integer greater than `0` unless the second parameter is `jump-none`, in which case, it must be a positive integer greater than `1`.

`<step-position>`

Specifies when the jump between values occurs. If omitted, it defaults to `end`. The possible keyword values include:

`jump-start` or `start`

Indicates that the first step happens when the animation begins.

`jump-end` or `end`

Indicates that the last step happens when the animation ends.

`jump-none`

Indicates neither early nor late jumps happen.

`jump-both`

Indicates both early and late jumps happen.

Description

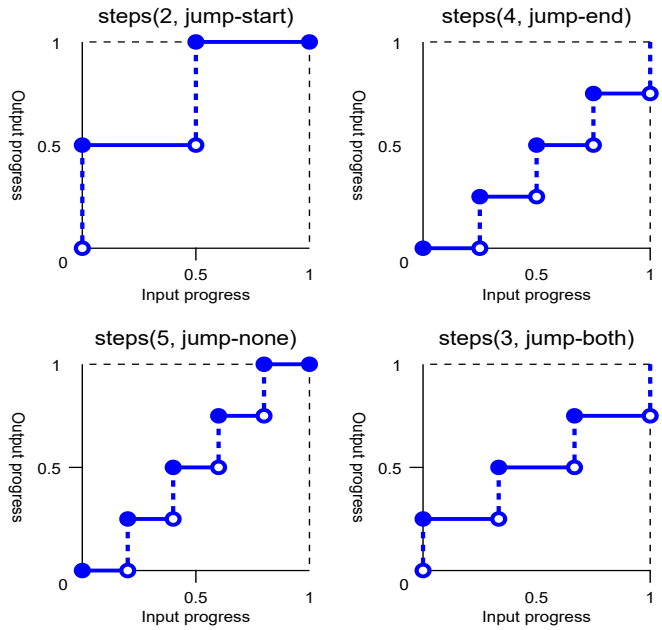
The `steps()` function divides the animation duration into equal intervals. For example, `steps(4, end)` divides the animation into four equal intervals, with values changing at the end of each interval except the last change which occurs at the animation's end.

If an animation contains multiple segments, the specified number of steps applies to each segment. For example, if an animation has three segments and uses `steps(2)`, there will be six steps in total, with two steps per segment.

The following image shows the effect of different `<step-position>` values when the jumps occur:

```
steps(2, jump-start)  /* Or steps(2, start) */
steps(4, jump-end)    /* Or steps(4, end) */
```

```
steps(5, jump-none)
steps(3, jump-both)
```



Formal syntax

```
<steps()> =
  steps( <integer> , <step-position>? )

<integer> =
  <number-token>

<step-position> =
  jump-start  |
  jump-end    |
  jump-none   |
  jump-both   |
  start       |
  end
```

This syntax reflects the latest standard as per CSS Easing Functions Level 2, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using the steps() function

The following `steps()` functions are valid:

```
/* Five steps with jump at the end */
steps(5, end)

/* Two steps with jump at the start */
steps(2, start)

/* Using default second parameter */
steps(2)
```

The following `steps()` functions are invalid:

```
/* First parameter must be an <integer>, not a real value */
steps(2.0, jump-end)

/* Number of steps must be positive */
steps(-3, start)

/* Number of steps must be at least 1 */
steps(0, jump-none)
```

element() CSS function

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`element()`** CSS function defines an `<image>` value generated from an arbitrary HTML element. This image is live, meaning that if the HTML element is changed, the CSS properties using the resulting value are automatically updated.

A particularly useful scenario for using this would be to render an image in an HTML `<canvas>` element, then use that as a background.

On Gecko browsers, you can use the non-standard `document.mozSetImageElement()` method to change the element being used as the background for a given CSS background element.

Syntax

```
element(id)
```

where:

id

The ID of an element to use as the background, specified using the HTML attribute *#id* on the element.

Formal syntax

```
<element()> =
  element( <id-selector> )

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Images Module Level 4, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

These examples work in builds of Firefox that support `-moz-element()`.

A somewhat realistic example

This example uses a hidden `<div>` as a background. The background element uses a gradient, but also includes text that is rendered as part of the background.

```
<div id="target-box">
  <p>This box uses the element with the #my-background ID as its background!</p>
</div>

<div id="background-container">
  <div id="my-background">
    <p>This text is part of the background. Cool, huh?</p>
  </div>
</div>
```

```
#target-box {
  width: 400px;
  height: 400px;
  background: -moz-element(#my-background) no-repeat;
}

#background-container {
  overflow: hidden;
  height: 0;
}

#my-background {
  width: 1024px;
  height: 1024px;
  background-image: linear-gradient(to right, red, orange, yellow, white);
}

#my-background p {
  transform-origin: 0 0;
  rotate: 45deg;
  color: white;
}
```

The `<div>` element with the ID "my-background" is used as the background for the content including the paragraph "This box uses the element with the #my-background ID as its background!".

Page Preview

This example based on Vincent De Oliveira's creates a preview of the `<div id="css-source">` inside `<div id="css-result">`.

HTML

```
<div id="css-source">
  <h1>Page Preview</h1>
</div>
<div id="css-result"></div>
```

CSS

```
#css-result {
  background: -moz-element(#css-source) no-repeat;
  width: 256px;
  height: 32px;
  background-size: 80%;
  border: dashed;
}
```

env() CSS function

The **`env()`** CSS function can be used to insert the value of a user-agent defined environment variable into your CSS. Alternatively `env()` can be used to make dynamic values in external SVG files which updated using the `link-parameters` CSS property.

Syntax

```
/* Without a fallback value */
env(safe-area-inset-top);
env(titlebar-area-width);
env(viewport-segment-right 0 0);

/* With a fallback value */
env(safe-area-inset-right, 1em);
env(titlebar-area-y, 40px);
env(viewport-segment-width 0 0, 40%);
```

```
<svg viewBox="0 0 100 100" xmlns="http://www.w3.org/2000/svg">
  <path fill="env(--color, black)" d="..." />
</svg>
```

Parameters

The `env( <environment-variable> | <dashed-ident>, <fallback> | <declaration-value> )` function accepts the following parameters:

`<environment-variable>`

A `<custom-ident>` specifying the name of the environment variable to be inserted. If the name provided represents an array-like environment variable, the name is followed by `<integer>` values identifying the specific instance the name is referencing. The case-sensitive environment variable name can be one of the following:

`safe-area-inset-top`, `safe-area-inset-right`, `safe-area-inset-bottom`, `safe-area-inset-left`

The safe distance from the top, right, bottom, or left inset edge of the viewport, defining where it is safe to place content into without risking it being cut off by the shape of a non-rectangular display. The four values form a rectangle, inside which all content is visible. The values are `0` if the viewport is a rectangle and no features — such as toolbars or dynamic keyboards — are occupying viewport space; otherwise, it is a `px` value greater than `0`.

`safe-area-max-inset-top`, `safe-area-max-inset-right`, `safe-area-max-inset-bottom`, `safe-area-max-inset-left`

The static maximum values of their dynamic `safe-area-inset-*` variable counterparts when all dynamic user interface features are retracted. While the `safe-area-inset-*` values change as the currently-visible content area changes, the `safe-area-max-inset-*` values are constants.

`titlebar-area-x`, `titlebar-area-y`, `titlebar-area-width`, `titlebar-area-height`

The dimensions of a visible `titlebar-area-*` area. These variables are available when using the `window-controls-overlay` `display_override` manifest field. The variables' values can be used to ensure content doesn't overlap window control buttons (that is, minimize, maximize, and close) with progressive web apps (PWA) installed on desktop devices.

`keyboard-inset-top`, `keyboard-inset-right`, `keyboard-inset-bottom`, `keyboard-inset-left`, `keyboard-inset-width`, `keyboard-inset-height`

The insets from the edge of the viewport and dimensions of the device's on-screen virtual keyboard. Defined in the VirtualKeyboard API.

`preferred-text-scale`

The user's preferred font scaling factor, a number set in browser or OS-level preferences. This can be used to size content proportionally to browser or OS-set font sizes.

`viewport-segment-width`, `viewport-segment-height`, `viewport-segment-top`, `viewport-segment-right`, `viewport-segment-bottom`, `viewport-segment-left`

The dimensions and offset positions of specific viewport segments. The `viewport-segment-*` keyword is followed by two space-separated `<integer>` values that indicate the segment's horizontal and vertical position, or indices. The viewport-segment keywords are only defined when the viewport is made up of two or more segments, as with foldable or hinged devices.

`<dashed-ident>`

A `<dashed-ident>` is a user-defined variable that can be used as an identifier in the `param()` CSS function to update the value.

`<fallback>` Optional

A fallback value to be inserted if the environment variable referenced in the first argument does not exist. Everything after the first comma is deemed to be the fallback value. This can be a single value, another `env()` function, or a comma-separated list of values.

`<declaration_value>` Optional

A `<declaration_value>` is the default value of the SVG attribute being set dynamically. If the `<declaration-value>` is omitted, it represents an empty value.

Description

The `env()` function is used to insert the value of a globally-scoped, user-agent-defined environment variable into your CSS. The `env()` function can be used as a property value or in place of any part of a property value or descriptor (for example, in Media query rules).

The function accepts an `<environment-variable>` as its first argument. This is a case-sensitive `<custom-ident>` equal to the name of the environment variable to be substituted, but it can also include additional space-separated values if required. For example, `env(viewport-segment-width 0 0)` would return the width of the top or left segment in the case of a device with multiple viewport segments.

The second argument, if provided, is the fallback value, which is used if the environment variable referenced in the first argument is not supported or doesn't exist. The fallback can be another environment variable, even with its own fallback.

The syntax of the fallback is similar to the fallback syntax of the `var()` function used to insert CSS custom properties in that it allows for multiple commas. Anything between the first comma and the end of the function is considered the fallback value. However, if the `env()` function is used within a property value or descriptor that doesn't include commas, a fallback value that includes commas will not be valid.

A property or descriptor containing a syntactically valid `env()` function is assumed to be valid at parse time, when the browser first reads and interprets the downloaded CSS text. It is only syntax-checked at compute time, after each `env()` function has been substituted with its browser-provided value (or the fallback value if the environment variable passed as the first parameter is not a recognized environment variable name). If the value is invalid and no fallback is provided, the property or descriptor containing the `env()` function is invalid at computed-value time.

When an `env()` substitution is invalid, and an invalid fallback is included, or the fallback is omitted, the declaration is not ignored. Instead, the initial or inherited value of the property is used. The property is set to a new value, but it may not be the expected one.

Use cases

Originally provided by the iOS browser to allow developers to place their content in a safe area of the viewport, and not be obscured by device notches or rounded corners, the `safe-area-inset-*` values can be used to help ensure content is visible to viewers. This feature was later expanded beyond its initial purpose to enable use cases such as stopping device notifications from covering up some of the app user interface.

Another use case for `env()` variables is for desktop Progressive web apps (PWAs) that use the Window Controls Overlay feature to take advantage of the full application window surface area. Using the `titlebar-area-*` values, developers can position elements where the title bar would have been and ensure content is not obscured by window control buttons.

The `viewport-segment-*` variable names can be used to set your containers to fit neatly into the available segments of a multi-viewport-segment device such as a hinged or foldable device. The integers following the `viewport-segment-*` name indicate which segment of the multiple segments the environment variable is referencing.

The `preferred-text-scale` variable can be used to size website text or other UI features proportionally to browser or OS-set font sizes. For example, you could set the body font size to be a percentage based on the user-defined text scale:

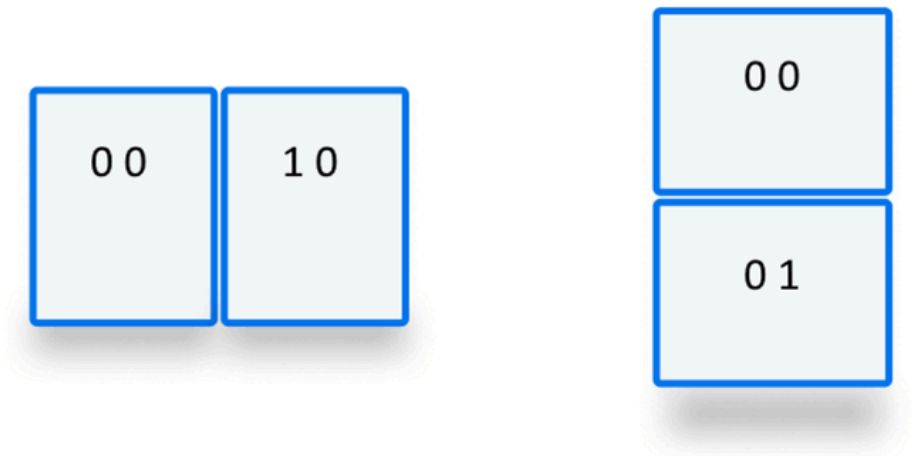
```
body {
  font-size: calc(100% * env(preferred-text-scale));
}
```

Sizes can also be set to be proportional to browser or OS-level font size by including `<meta name="text-scale" content="scale">` inside the document `<head>`. The `<meta>` tag should be used in favor of the `env(preferred-text-scale)` when possible, as the `<meta>` tag is supported across a wider range of platforms and is also simpler to use.

> **Warning:** Be careful using `env(preferred-text-scale)` when `<meta name="text-scale" content="scale">` is set as this will result in text scaling being applied twice when combined with relative sizes, such as `em` and `rem`. For example, when the `<meta>` is set, a declaration such as `font-size: calc(2rem * env(preferred-text-scale))` will cause small font sizes to be made even smaller and large font sizes larger.

Names followed by integers

When the environment variable is array-like, meaning the name may reference more than once value, such as is the case with devices with multiple viewport segments, the `<environment-variable>` parameter includes both the name of the variable and the indices of the specific instance of the variable the function is referencing. For example, in the case of the `viewport-segment-*` variables, the variable names are passed to the `env()` function along with two integers indicating the indices of the segment to return the value for. These values are both integers of `0` or greater. The first integer represents the horizontal index of the segment, with `0` being the left-most segment, and the second value represents the vertical index of the segment, with `0` representing the bottom-most segment:



- In a horizontal side-by-side layout, the left segment is represented by `0 0`, and the right segment is represented by `1 0`.
- In a vertical top-to-bottom layout, the top segment is represented by `0 0`, and the bottom segment is represented by `0 1`.
- In devices with more than two segments, the numbers may be greater. For example, a device with three horizontal segments may have the center segment represented by `1 0`, and the right-hand segment represented by `2 0`.

For example, the following returns the width of the right-hand segment on a two-segment foldable device where the segments are oriented horizontally:

```
env(viewport-segment-width 1 0)
```

See the Viewport segment API demo for a full working demo (source code). Also check out Using the Viewport Segments API for a full demo explanation.

Formal syntax

```
<env()> =
  env( <custom-ident> <integer [0,∞]>* , <declaration-value>? )

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Environment Variables Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using env() to ensure buttons are not obscured by device UI

In the following example, `env()` is used to ensure that fixed app toolbar buttons are not obscured by device notifications appearing at the bottom of the screen. On the desktop `safe-area-inset-bottom` is `0`. However, in devices that display notifications at the bottom of the screen, such as iOS, it contains a value that leaves space for the notification to display. This can then be used in the value for `padding-bottom` to create a gap that appears natural on that device.

HTML

We have a `<main>` section containing a fake application and a `<footer>` containing two `<button>` elements:

```
<main>Main content of app here</main>
<footer>
  <button>Go here</button>
  <button>Or here</button>
</footer>
```

CSS

Using CSS flexible box layout, we create a footer that is only as tall as it needs to be, while the main section containing the application fills up the rest of the viewport:

```
body {
  display: flex;
  flex-direction: column;
  min-height: 100vh;
  font: 1em system-ui;
}
```

```
main {
  flex: 1;
  background-color: #eeeeee;
  padding: 1em;
}

footer {
  flex: none;
  display: flex;
  gap: 1em;
  justify-content: space-evenly;
  background: black;
}

button {
  padding: 1em;
  background: white;
  color: black;
  margin: 0;
  width: 100%;
  border: none;
  font: 1em system-ui;
}
```

We set `position: sticky` to stick the footer to the bottom of the viewport. We then use the `padding` shorthand to add padding to the footer. We include the value of the `safe-area-inset-bottom` environment value to an initial `1em` of bottom padding. A larger black area will display on devices that have a positive value for this variable, ensuring the buttons in the footer are never obscured.

```
footer {
  position: sticky;
  bottom: 0;

  padding: 1em 1em calc(1em + env(safe-area-inset-bottom));
}
```

Results

Using a fallback value

This example makes use of the optional second parameter of `env()`, which provides a fallback value in case the environment variable is not available.

HTML

We include a paragraph of text:

```
<p>
  If the <code>env()</code> function is supported in your browser, this
  paragraph's text will have 50px of padding between it and the left border —
  but not the top, right and bottom. This is because the accompanying CSS is the
  equivalent of <code>padding: 0 0 0 50px</code>, because, unlike other CSS
  properties, user agent property names are case-sensitive.
</p>
```

CSS

We set a `width` of `300px` and a `border`. We then add `padding`, using the `env()` function with a fallback for the size of the padding on each side. We intentionally set an invalid value for the left padding (remember, environment variable names are case-sensitive), to demonstrate the use of the fallback value.

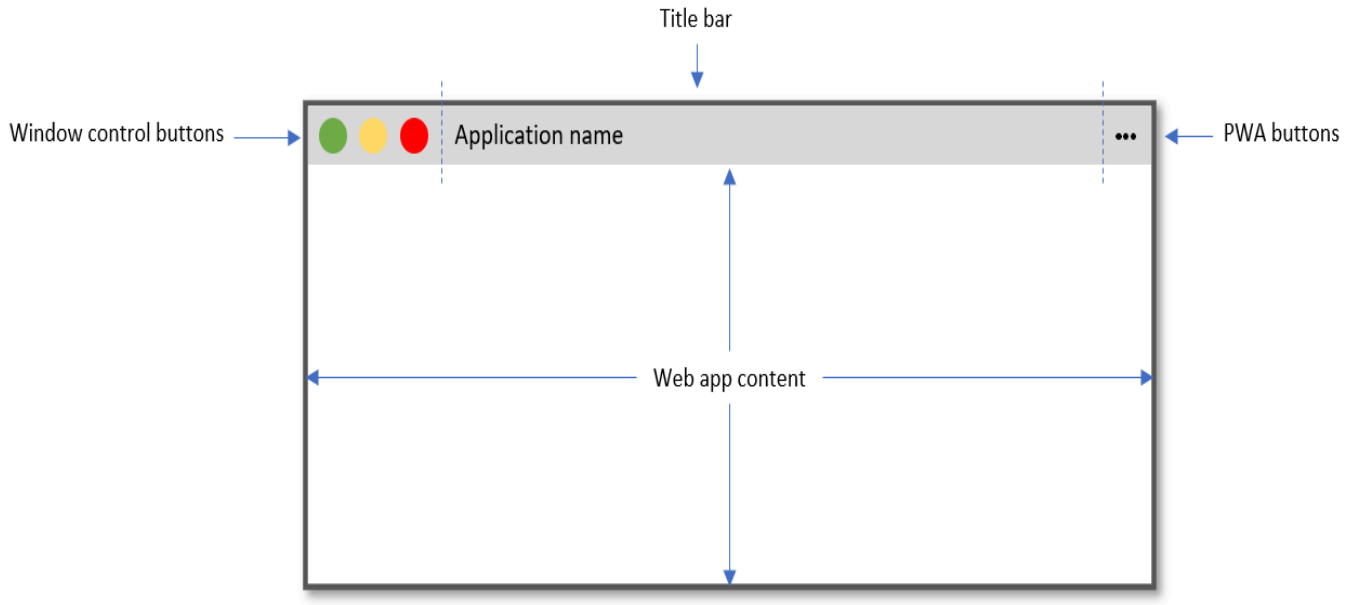
```
p {
  width: 300px;
  border: 2px solid red;
  padding: env(safe-area-inset-top, 50px) env(safe-area-inset-right, 50px)
    env(safe-area-inset-bottom, 50px) env(SAFE-AREA-INSET-LEFT, 50px);
}
```

Results

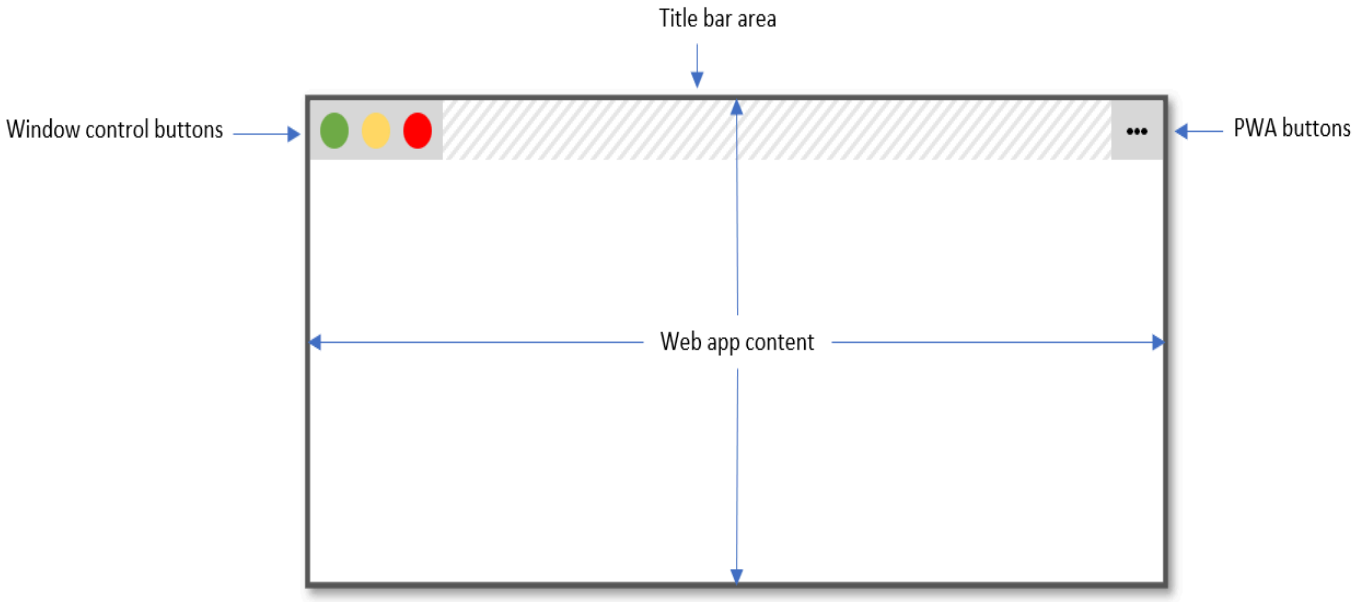
Using env() to ensure content is not obscured by window control buttons in desktop PWAs

In the following example, `env()` ensures that content displayed in a desktop Progressive Web App that uses the Window Controls Overlay API is not obscured by the operating system's window control buttons. The `titlebar-area-*` values define a rectangle where the title bar would normally have been displayed. On devices that do not support the Window Controls Overlay feature, such as mobile devices, the fallback values are used.

Here is what a PWA installed on a desktop device normally looks like:



With the Window Controls Overlay feature, the web content covers the whole app window surface area, with the window controls and PWA buttons displayed as overlays:



```
<header>Title of the app here</header>
<main>Main content of app here</main>
```

```
header {
  position: fixed;
  left: env(titlebar-area-x);
  top: env(titlebar-area-y);
  width: env(titlebar-area-width);
  height: env(titlebar-area-height);
}

main {
  margin-top: env(titlebar-area-height);
}
```

> **Note:** Using `position:fixed` makes sure the header does not scroll with the rest of the content, and instead stays aligned with the window control buttons, even on device/browsers that support elastic overscroll (also known as rubber banding).

Viewport segments

The Viewport segment API demo and Using the Viewport Segments API guide provides a demonstration and explanation of using the `env()` function with the `viewport-segments-*` environment variables.

exp() CSS function

The **`exp()`** CSS function is an exponential function that takes a number as an argument and returns the mathematical constant `e` raised to the power of the given number.

The mathematical constant `e` is the base of natural logarithms, and is approximately `2.718281828459045`.

The `exp(number)` function contains a calculation which returns the same value as `pow(e, number)`.

Syntax

```
/* A <number> value */
width: calc(100px * exp(-1)); /* 100px * 0.367879441171442 = 36.8px */
width: calc(100px * exp(0)); /* 100px * 1 = 100px */
width: calc(100px * exp(1)); /* 100px * 2.718281828459045 = 271.8px */
```

Parameters

The `exp(number)` function accepts only one value as its parameter.

`number`

A calculation which resolves to a `<number>`. Representing the value to be raised by a power of `e`.

Return value

Returns a non-negative `<number>` representing e^{number}, which is the result of calculating `e` raised to the power of `number`.

- If `number` is `-Infinity`, the result is `0`.
- If `number` is `0`, the result is `1`.
- If `number` is `1`, the result is `e` (i.e., `2.718281828459045`).
- If `number` is `Infinity`, the result is `Infinity`.

Formal syntax

```
<exp()> =
  exp( <calc-sum> )

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>       |
  <dimension>    |
  <percentage>   |
  <calc-keyword> |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Rotate elements

The `exp()` function can be used to `rotate` elements as it returns a `<number>`.

HTML

```
<div class="box box-1"></div>
<div class="box box-2"></div>
<div class="box box-3"></div>
<div class="box box-4"></div>
<div class="box box-5"></div>
```

CSS

```
body {
  height: 100vh;
  display: flex;
  justify-content: center;
  align-items: center;
  gap: 50px;
}
```

```
div.box {
  width: 100px;
  height: 100px;
  background: linear-gradient(orange, red);
}
div.box-1 {
  transform: rotate(calc(1turn * exp(-1))); /* 0.3678794411714423turn */
}
div.box-2 {
  transform: rotate(calc(1turn * exp(-0.75))); /* 0.4723665527410147turn */
}
```

```
div.box-3 {
  transform: rotate(calc(1turn * exp(-0.5))); /* 0.6065306597126334turn */
}
div.box-4 {
  transform: rotate(calc(1turn * exp(-0.25))); /* 0.7788007830714049turn */
}
div.box-5 {
  transform: rotate(calc(1turn * exp(0))); /* 1turn */
}
```

Result

Scale headings by fixed ratio

The `exp()` function can be useful for strategies like CSS modular scale, which relates all the font-sizes on a page to each other by a fixed ratio.

HTML

```
<h1>Heading 1</h1>
<h2>Heading 2</h2>
<h3>Heading 3</h3>
<h4>Heading 4</h4>
<h5>Heading 5</h5>
<h6>Heading 6</h6>
```

CSS

```
h1 {
  font-size: calc(1rem * exp(1.25)); /* 3.4903429574618414rem */
}
h2 {
  font-size: calc(1rem * exp(1)); /* 2.718281828459045rem */
}
h3 {
  font-size: calc(1rem * exp(0.75)); /* 2.117000016612675rem */
}
h4 {
  font-size: calc(1rem * exp(0.5)); /* 1.6487212707001282rem */
}
h5 {
  font-size: calc(1rem * exp(0.25)); /* 1.2840254166877414rem */
}
h6 {
  font-size: calc(1rem * exp(0)); /* 1rem */
}
```

<filter-function> CSS type

The **`<filter-function>`** CSS data type represents a graphical effect that can change the appearance of an input image. It is used in the `filter` and `backdrop-filter` properties.

Syntax

The `<filter-function>` data type is specified using one of the filter functions listed below. Each function requires an argument which, if invalid, results in no filter being applied.

`blur()`

Blurs the image.

`brightness()`

Makes the image brighter or darker.

`contrast()`

Increases or decreases the image's contrast.

`drop-shadow()`

Applies a drop shadow behind the image.

`grayscale()`

Converts the image to grayscale.

`hue-rotate()`

Changes the overall hue of the image.

`invert()`

Inverts the colors of the image.

`opacity()`

Makes the image transparent.

`saturate()`

Super-saturates or desaturates the input image.

`sepia()`

Converts the image to sepia.

Formal syntax

```
<filter-function> =
  <blur()>         |
  <brightness()>   |
  <contrast()>     |
  <drop-shadow()>  |
  <grayscale()>    |
  <hue-rotate()>   |
  <invert()>       |
  <opacity()>      |
  <sepia()>        |
  <saturate()>

<blur()> =
  blur( <length>? )

<brightness()> =
  brightness( [ <number> | <percentage> ]? )

<contrast()> =
  contrast( [ <number> | <percentage> ]? )

<drop-shadow()> =
  drop-shadow( [ <color>? && <length>{2,3} ] )

<grayscale()> =
  grayscale( [ <number> | <percentage> ]? )

<hue-rotate()> =
  hue-rotate( [ <angle> | <zero> ]? )

<invert()> =
  invert( [ <number> | <percentage> ]? )

<opacity()> =
  opacity( [ <number> | <percentage> ]? )

<sepia()> =
  sepia( [ <number> | <percentage> ]? )

<saturate()> =
  saturate( [ <number> | <percentage> ]? )
```

This syntax reflects the latest standard as per Filter Effects Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Filter function comparison

This example provides a graphic, a select menu to allow you to choose between the different types of filter function, and a slider to allow you to vary the values used inside the filter function. Updating the controls updates the filter effect in real time, allowing you to investigate the effects of different filters.

The dropdown selects the function name, and the slider sets the parameter value for that function. For `drop-shadow`, the value is used for both the horizontal and vertical offsets, and the radius is set to half the value.

```
<div></div>
<ul>
  <li>
    <label for="filter-select">Choose a filter function:</label>
    <select id="filter-select">
      <option selected>blur</option>
      <option>brightness</option>
      <option>contrast</option>
      <option>drop-shadow</option>
      <option>grayscale</option>
      <option>hue-rotate</option>
      <option>invert</option>
      <option>opacity</option>
      <option>saturate</option>
      <option>sepia</option>
    </select>
  </li>
  <li><input type="range" /><output></output></li>
  <li>
    <p>Current value: <code></code></p>
  </li>
</ul>
```

```
div {
  width: 100%;
  height: 512px;
  background-image: url("https://mdn.github.io/shared-assets/images/examples/fx-nightly-512.png");
  background-repeat: no-repeat;
  background-position: center center;
}

li {
  display: flex;
  align-items: center;
  justify-content: center;
  margin-bottom: 20px;
}

input {
  width: 60%;
}

output {
  width: 5%;
  text-align: center;
}

select {
```

```
  width: 40%;
  margin-left: 2px;
}
```

```
const selectElem = document.querySelector("select");
const divElem = document.querySelector("div");
const slider = document.querySelector("input");
const output = document.querySelector("output");
const curValue = document.querySelector("p code");

selectElem.addEventListener("change", () => {
  setSlider(selectElem.value);
  setDiv(selectElem.value);
});

slider.addEventListener("input", () => {
  setDiv(selectElem.value);
});

function setSlider(filter) {
  switch (filter) {
    case "blur":
      slider.value = 0;
      slider.min = 0;
      slider.max = 30;
      slider.step = 1;
      slider.setAttribute("data-unit", "px");
      break;

- Properties that use this data type: `filter` and `backdrop-filter`

blur() CSS function

The **`blur()`** CSS function applies a Gaussian blur to the input image. Its result is a `<filter-function>`.

Try it

```
filter: blur(0);
```

```
filter: blur(4px);
```

```
filter: blur(1.5rem);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

Syntax

```
blur()         /* No effect */
blur(0)        /* No effect */

blur(8px)      /* Blur with 8px radius */
blur(1.17rem)  /* Blur with 1.17rem radius */
```

Parameters

`<length>` Optional

> Specifies the radius of the blur. It defines the value of the standard deviation to the Gaussian function, that is, how many pixels on the screen blend into each other. Therefore, a larger value will create more blur. A value of `0` leaves the input unchanged. The initial value for interpolation is `0`. Percentage values are invalid. The default value is `0`.

SVG filter

The SVG `<feGaussianBlur>` filter element can also be used to blur content. The filter's `stdDeviation` attribute accepts up to two values enabling creating more complex blur values. To create an equivalent blur, we include one value for `stdDeviation`. This SVG effect can then be referenced by ID:

```
<svg role="none">
  <filter id="blur11">
    <feGaussianBlur stdDeviation="1.1" edgeMode="duplicate" />
  </filter>
</svg>
```

The following declarations produce the same effect:

```
filter: blur(1.1px);
filter: url("#blur11"); /* with embedded SVG */
filter: url("folder/fileName.svg#blur11"); /* external svg filter definition */
```

Formal syntax

```
<blur()> =
  blur( <length>? )
```

This syntax reflects the latest standard as per Filter Effects Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

This example shows three images: the image with a `blur()` filter function applied, the image with the equivalent SVG blur function applied, and the original images for comparison:

```
.filter {
  filter: blur(3.5px);
}
```

```
<svg role="img" aria-label="Flag">
  <filter id="blur">
    <feGaussianBlur stdDeviation="3.5" edgeMode="duplicate" />
  </filter>
  <image
    href="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
    xlink:href="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
    filter="url('#blur')" />
</svg>
```

```
svg:not([height]) {
  display: none;
}

th,
td {
  padding: 5px;
}
```

```
<table>
  <thead>
    <tr>
      <th>Live example</th>
      <th>SVG Equivalent</th>
      <th>Original image</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <td>
```

```
        <img
          class="filter"
          src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
          alt="Pride flag" />
      </td>
      <td>
        <svg id="svg" height="220" width="220" overflow="visible">
          <filter id="svgBlur">
            <feGaussianBlur stdDeviation="3.5" />
          </filter>
          <image
            href="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
            xlink:href="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
            filter="url('#svgBlur')" />
        </svg>
      </td>
      <td>
        <img
          src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
          alt="Pride flag" />
      </td>
    </tr>
  </tbody>
</table>
```

  - `hue-rotate()`
  - `invert()`
  - `opacity()`
  - `saturate()`
  - `sepia()`

brightness() CSS function

The **`brightness()`** CSS `<filter-function>` applies a linear multiplier value on an element or an input image, making the image appear brighter or darker.

Try it

```
filter: brightness(1);
```

```
filter: brightness(1.75);
```

```
filter: brightness(50%);
```

```
filter: brightness(0);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

Syntax

```
brightness(amount)
```

Values

`amount` Optional

> Brightness specified as a `<number>` or a `<percentage>`. A value less than `100%` darkens the input image or element, while a value over `100%` brightens it. A value of `0%` creates a completely black image or element, while a value of `100%` leaves the input unchanged. Other values between `0%` to `100%` have a linear multiplier effect. Values greater than `100%` are allowed, providing brighter results. The initial value for interpolation is `1`. Negative values are not allowed. The default value is `1`.

The following are pairs of equivalent values:

```
brightness(0)   /* Brightness is reduced to zero, so input turns black */
brightness(0%)

brightness(0.4) /* Brightness of input is reduced to 40%, so input is 60% darker */
brightness(40%)

brightness()     /* Brightness of input is not changed */
brightness(1)
brightness(100%)

brightness(2)   /* Brightness of input is doubled */
brightness(200%)
```

Formal syntax

```
<brightness()> =
  brightness( [ <number> | <percentage> ]? )
```

This syntax reflects the latest standard as per Filter Effects Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Applying brightness using the backdrop-filter property

This example shows how to apply the `brightness()` filter to a paragraph via the `backdrop-filter` CSS property.

CSS

```
.container {
  background: url("be_fierce.jpg") no-repeat right / contain #d4d5b2;
}
p {
  backdrop-filter: brightness(150%);
  text-shadow: 2px 2px white;
}
```

```
.container {
  padding: 5rem 3rem 1rem;
  width: 30rem;
}
p {
  padding: 0.5rem;
  color: black;
  font-size: 2rem;
  font-family: sans-serif;
}
```

```
<div class="container">
  <p>
    Text on images can be illegible and inaccessible even with a drop shadow.
  </p>
</div>
```

Result

In this example, the colors in the area behind the `<p>` element shift linearly. If the `backdrop-filter` property was set to `brightness(0%)`, the `<div>` area with the `<p>` element would have been black and hidden the image behind. At `brightness(100%)`, the `<div>` area color would be the same as the input `#d4d5b2`, and the image behind would be completely transparent. With the brightness set to `150%` as in this example, the colors in the image behind are getting hidden by the brightness of the `<div>` element.

Applying brightness using the filter property

In this example, a `brightness()` filter is applied to the entire element, including content, border, and background image via the `filter` CSS property. The result shows three variations of different brightness values.

```
p:first-of-type {
  filter: brightness(50%);
}
p:last-of-type {
  filter: brightness(200%);
}
```

```
p {
  text-shadow: 2px 2px blue;
  background-color: magenta;
  color: palegoldenrod;
  border: 1em solid rebeccapurple;
  box-shadow:
    inset -5px -5px red,
    5px 5px yellow;
  padding: 0.25rem;
  font-size: 1.25rem;
  font-family: sans-serif;
  width: 85vw;
}
```

```
<p>This paragraph has reduced brightness.</p>
<p>This paragraph has normal brightness.</p>
<p>This paragraph has increased brightness.</p>
```

Applying brightness using the url() SVG brightness filter

The SVG `<filter>` element is used to define custom filter effects that can then be referenced by `id`. The `<filter>` element's `<feComponentTransfer>` primitive enables pixel-level color remapping.

In this example, to create a filter that darkens the content on which it is applied by 25% (i.e., 75% of the original brightness), the `slope` attribute is set to `0.75`. We can then reference the filter by `id`.

Given the following:

```
<svg role="none">
  <filter id="darken25" color-interpolation-filters="sRGB">
    <feComponentTransfer>
      <feFuncR type="linear" slope="0.75" />
      <feFuncG type="linear" slope="0.75" />
      <feFuncB type="linear" slope="0.75" />
    </feComponentTransfer>
  </filter>
</svg>
```

The following declarations produce similar effects:

```
filter: brightness(75%);
filter: url("#darken25"); /* with embedded SVG */
filter: url("folder/fileName.svg#darken25"); /* external svg filter definition */
```

In the images below, the first one has a `brightness()` filter function applied, the second one has a similar SVG brightness function applied, and the third is the original image for comparison.

```
<table>
  <thead>
    <tr>
```

```
      <th>Live example</th>
      <th>SVG Equivalent</th>
      <th>Original image</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <td>
        <img
          class="css-filter"
          src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
          alt="darkened pride flag" />
      </td>
      <td>
        <img
          class="svg-filter"
          src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
          alt="darkened pride flag" />
      </td>
      <td>
        <img
          src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
          alt="Pride flag" />
      </td>
    </tr>
  </tbody>
</table>
```

```
.css-filter {
  filter: brightness(0.75);
}
.svg-filter {
  filter: url("#darken25");
}

th,
td {
  padding: 5px;
}
svg:not(:root) {
  display: none;
}
```

See also

- CSS filter effects module
- The other `<filter-function>` functions available to be used in values of the `filter` and `backdrop-filter` properties include:
  - `blur()`
  - `contrast()`
  - `drop-shadow()`
  - `grayscale()`
  - `hue-rotate()`
  - `invert()`
  - `opacity()`
  - `saturate()`
  - `sepia()`

contrast() CSS function

The **`contrast()`** CSS function adjusts the contrast of the input image. Its result is a `<filter-function>`.

Try it

```
filter: contrast(1);
```

```
filter: contrast(1.75);
```

```
filter: contrast(50%);
```

```
filter: contrast(0);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

Syntax

```
contrast(amount)
```

Values

`amount` Optional

> The contrast of the result, specified as a `<number>` or a `<percentage>`. A value under `100%` decreases the contrast, while a value over `100%` increases it. A value of `0` or `0%` will create an image that is completely gray, while a value of `1` or `100%` leaves the input unchanged. Negative values are not allowed. The initial value for interpolation is `1`. The default value is `1`.

The following are pairs of equivalent values:

```
contrast(0)    /* Completely gray */
contrast(0%)

contrast(0.65) /* 65% contrast */
```

```
contrast(65%)

contrast()     /* No effect */
contrast(1)
contrast(100%)

contrast(2)    /* Double contrast */
contrast(200%)
```

Formal syntax

```
<contrast()> =
  contrast( [ <number> | <percentage> ]? )
```

This syntax reflects the latest standard as per Filter Effects Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

With the backdrop-filter property

This example applies a `contrast()` filter via the `backdrop-filter` CSS property to the paragraph and monospaced text, color shifting to the area behind the `<p>` and `<code>`.

```
.container {
  background: url("unity_for_the_people.jpg") no-repeat center / contain #333399;
}
p {
  backdrop-filter: contrast(0.5);
}
code {
  backdrop-filter: contrast(0.15);
}
```

```
.container {
  padding: 3rem;
  width: 30rem;
}
p {
  padding: 0.5rem;
  color: white;
  font-family: sans-serif;
}
```

```
<div class="container">
  <p>
    Always ensure there is enough contrast between text and all background
    colors. If you think your text may land on top of a background image,
    include a <code>backdrop-filter</code>. Reducing the contrast of background
    colors with the <code>contrast()</code> filter may improve legibility but
    does not guarantee accessibility.
  </p>
</div>
```

With the filter property

This example applies a `contrast()` filter via the `filter` CSS property, changing contrast by shifting colors of the entire element, including content, border, background, and shadows.

```
p:first-of-type {
  filter: contrast(30%);
}
p:last-of-type {
  filter: contrast(300%);
}
```

```
p {
  text-shadow: 2px 2px blue;
  background-color: magenta;
  color: palegoldenrod;
  border: 1em solid rebeccapurple;
  box-shadow:
    inset -5px -5px red,
    5px 5px yellow;
  padding: 0.25rem;
  font-size: 1.25rem;
  font-family: sans-serif;
  width: 85vw;
}
```

```
<p>This paragraph has reduced contrast.</p>
<p>This paragraph has normal contrast.</p>
<p>This paragraph has increased contrast.</p>
```

With url() and the SVG contrast filter

The SVG `<filter>` element is used to define custom filter effects that can then be referenced by `id`. The `<filter>`'s `<feComponentTransfer>` primitive enables pixel-level color remapping. Given the following:

```
<svg
  xmlns="http://www.w3.org/2000/svg"
  id="svg"
  viewBox="0 0 240 151"
  height="0"
  width="0"
  overflow="visible"
  color-interpolation-filters="sRGB">
  <filter id="contrast">
    <feComponentTransfer>
      <feFuncR type="linear" slope="2" intercept="-0.5" />
      <feFuncG type="linear" slope="2" intercept="-0.5" />
      <feFuncB type="linear" slope="2" intercept="-0.5" />
    </feComponentTransfer>
```

```
  </filter>
</svg>
```

These values produce the same results:

```
filter: contrast(200%);
filter: url("#contrast"); /* with embedded SVG */
filter: url("folder/fileName.svg#contrast"); /* external svg filter definition */
```

This example shows three images: the image with a `contrast()` filter function applied, the image with an equivalent `url()` filter applied, and the original images for comparison:

```
<table>
  <thead>
    <tr>
      <th><code>contrast()</code></th>
      <th><code>url()</code></th>
      <th>Original image</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <td>
        <img
          class="css-filter"
          src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
          alt="Pride flag" />
      </td>
      <td>
        <img
          class="svg-filter"
          src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
          alt="Pride flag" />
      </td>
      <td>
        <img
          src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
          alt="Pride flag" />
      </td>
    </tr>
  </tbody>
</table>
```

```
.css-filter {
  filter: contrast(200%);
}
.svg-filter {
  filter: url("#contrast");
}

th,
td {
  padding: 5px;
}
svg:not(:root) {
  display: none;
}
```

See also

- CSS filter effects module
- The other `<filter-function>` functions available to be used in values of the `filter` and `backdrop-filter` properties include:
  - `blur()`
  - `brightness()`
  - `drop-shadow()`
  - `grayscale()`
  - `hue-rotate()`
  - `invert()`
  - `opacity()`
  - `saturate()`
  - `sepia()`

drop-shadow() CSS function

The **`drop-shadow()`** CSS function applies a drop shadow effect to the input image. Its result is a `<filter-function>`.

Try it

```
filter: drop-shadow(30px 10px 4px #4444dd);
```

```
filter: drop-shadow(0 -6mm 4mm rgb(160 0 210));
```

```
filter: drop-shadow(0 0 0.75rem crimson);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

A drop shadow is effectively a blurred, offset version of the input image's alpha mask, drawn in a specific color and composited below the image.

> **Note:** This function is somewhat similar to the `box-shadow` property. The `box-shadow` property creates a rectangular shadow behind an element's *entire box*, while the `drop-shadow()` filter function creates a

> shadow that conforms to the shape (alpha channel) of the *image itself*.

Syntax

```
/* Two length values */
/* drop-shadow( <length> <length> ) */
drop-shadow(5px 5px)

/* Three length values */
/* drop-shadow( <length> <length> <length> ) */
drop-shadow(5px 5px 15px)

/* Two length values and a color */
/* drop-shadow( <length> <length> <color> ) */
drop-shadow(5px 5px red)

/* Three length values and a color */
/* drop-shadow( <length> <length> <length> <color> ) */
drop-shadow(5px 5px 15px red)

/* The order of color and length values can be changed */
/* drop-shadow( <color> <length> <length> <length> ) */
drop-shadow(#ee2233 0.5rem 0.5rem 1rem)

/* Pass multiple drop-shadows to a filter to stack them */
drop-shadow(10px 10px red) drop-shadow(-5px -5px yellow)
```

The `drop-shadow()` function accepts a parameter of type `<shadow>` (defined in the `box-shadow` property), with the exception that the `inset` keyword and `spread` parameters are not allowed.

Parameters

`<color>` Optional

> Specifies the color for the shadow. If not specified, the value of the `color` property defined in the parent element is used.

`<length>`

> Specifies the offset length of the shadow. This parameter accepts two or three values. If two values are specified, they are interpreted as `<offset-x>` (horizontal offset) and `<offset-y>` (vertical offset) values. Negative `<offset-x>` value places the shadow to the left of the element. Negative `<offset-y>` value places the shadow above the element. If a third value is specified, it is interpreted as `<standard-deviation>`, which is the value of the standard deviation to the Gaussian blur function. A larger `<standard-deviation>` value creates a larger and more blurred shadow. Negative values for `<standard-deviation>` are not allowed.

Formal syntax

```
<drop-shadow()> =
  drop-shadow( [ <color>? && <length>{2,3} ] )
```

This syntax reflects the latest standard as per Filter Effects Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting a drop shadow

```
<div>drop-shadow(16px 16px)</div>
<div>drop-shadow(16px 16px red)</div>
<div>drop-shadow(red 1rem 1rem 10px)</div>
<div>drop-shadow(-16px -16px red)</div>
<div>
  drop-shadow(1px 1px red) drop-shadow(1px -1px red) drop-shadow(-1px 1px red)
  drop-shadow(-1px -1px red)
</div>
```

```
div {
  display: inline-block;
  margin: 0 0.5rem 2rem 1rem;
  padding: 0.5rem;
  height: 100px;
  width: 190px;
  vertical-align: top;
  background-color: #222222;

  color: lime;
}

div:nth-child(1) {
  filter: drop-shadow(16px 16px);
}

div:nth-child(2) {
  filter: drop-shadow(16px 16px red);
}

div:nth-child(3) {
  filter: drop-shadow(red 1rem 1rem 10px);
}

div:nth-child(4) {
  filter: drop-shadow(-16px -16px red);
}

div:nth-child(5) {
  filter: drop-shadow(1px 1px red) drop-shadow(1px -1px red)
    drop-shadow(-1px 1px red) drop-shadow(-1px -1px red);
}
```

In the absence of a `<color>` value in the `drop-shadow()` function in the first box, the shadow uses the value of the `color` property from the element (`lime`). The second and third shadows illustrate that the length and color values can be specified in any order. The third shadow shows the blurring effect when a third `<length>` value is specified. The fourth shadow uses negative offsets, which shift the shadow to the left and top. The fifth example shows how to use multiple drop-shadows on a single element.

grayscale() CSS function

The **`grayscale()`** CSS function converts the input image to grayscale. Its result is a `<filter-function>`.

Try it

```
filter: grayscale(0);
```

```
filter: grayscale(0.2);
```

```
filter: grayscale(60%);
```

```
filter: grayscale(1);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

Syntax

```
grayscale(amount)
```

Parameters

`amount` Optional

Amount of the input image that is converted to grayscale. It is specified as a `<number>` or a `<percentage>`. A value of `100%` changes the input completely to grayscale, while a value of `0%` leaves the input unchanged. Values between `0%` and `100%` have linear multipliers on the effect. The initial value used for interpolation is `0`. The default value is `1`.

Formal syntax

```
<grayscale()> =
  grayscale( [ <number> | <percentage> ]? )
```

This syntax reflects the latest standard as per Filter Effects Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Examples of correct values for grayscale()

```
grayscale(0)     /* No effect */
grayscale(.7)    /* 70% grayscale */

grayscale()      /* Completely grayscale */
grayscale(1)
grayscale(100%)
```

See also

The other `<filter-function>` functions available to be used in values of the `filter` and `backdrop-filter` properties include:

- `blur()`
- `brightness()`
- `contrast()`
- `drop-shadow()`
- `hue-rotate()`
- `invert()`
- `opacity()`
- `saturate()`
- `sepia()`

hue-rotate() CSS function

The **`hue-rotate()`** CSS function rotates the hue of an element and its contents. Its result is a `<filter-function>`.

> **Note:** `hue-rotate()` is specified as a matrix operation on the RGB color. It does not actually convert the color to the HSL model, which is a non-linear operation. Therefore, it may not preserve the saturation or lightness of the original color, especially for saturated colors.

Try it

```
filter: hue-rotate(0);
```

```
filter: hue-rotate(90deg);
```

```
filter: hue-rotate(-0.25turn);
```

```
filter: hue-rotate(3.142rad);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

Syntax

```
hue-rotate(angle)
```

Values

`angle` Optional

> The relative change in hue of the input sample, specified as an `<angle>`. A value of `0deg` leaves the input unchanged. A positive hue rotation increases the hue value, while a negative rotation decreases the hue value. The initial value for interpolation is `0`. There is no minimum or maximum value. The effect of values above `360deg` are, given `hue-rotate(Ndeg)`, evaluates to `N` modulo 360. The default value is `0deg`.

The `<angle>` CSS data type represents an angle value expressed in degrees, gradians, radians, or turns. The following are equivalent:

```
hue-rotate(-180deg)
hue-rotate(540deg)
hue-rotate(200grad)
hue-rotate(3.14159rad)
hue-rotate(0.5turn)
```

Formal syntax

```
<hue-rotate()> =
  hue-rotate( [ <angle> | <zero> ]? )
```

This syntax reflects the latest standard as per Filter Effects Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

With the backdrop-filter property

This example applies a `hue-rotate()` filter via the `backdrop-filter` CSS property to the paragraph, color shifting to the area behind the `<p>`.

```
.container {
  background: url("/shared-assets/images/examples/listen_to_black_women.jpg")
    no-repeat left / contain #011296;
}
p {
  backdrop-filter: hue-rotate(240deg);
  text-shadow: 2px 2px #011296;
}
```

```
.container {
  padding: 3rem;
  width: 30rem;
}
p {
  padding: 0.5rem;
  color: white;
  font-size: 2rem;
  font-family: sans-serif;
}
```

```
<div class="container">
  <p>
    Text on images can be illegible and inaccessible even with a drop shadow.
  </p>
</div>
```

With the filter property

This example applies a `hue-rotate()` filter via the `filter` CSS property adding the color shift to the entire element, including content, border, and background image.

```
p {
  filter: hue-rotate(-60deg);
  text-shadow: 2px 2px blue;
  background-color: magenta;
  color: goldenrod;
  border: 1em solid rebeccapurple;
  box-shadow:
    inset -5px -5px red,
    5px 5px yellow;
}
```

```
p {
  padding: 0.5rem;
  font-size: 2rem;
  font-family: sans-serif;
  width: 85vw;
}
```

```
<p>The person who wrote this example is not a designer, fortunately.</p>
```

With url() and the SVG hue-rotate filter

The SVG `<filter>` element is used to define custom filter effects that can then be referenced by `id`. The `<filter>`'s `<feColorMatrix>` primitive `hueRotate` type provides the same effect. Given the following:

```
<svg
  xmlns="http://www.w3.org/2000/svg"
  viewBox="0 0 220 220"
  color-interpolation-filters="sRGB"
  height="220"
  width="220">
  <filter id="hue-rotate">
    <feColorMatrix type="hueRotate" values="90" />
  </filter>
</svg>
```

These values produce the same results:

```
filter: hue-rotate(90deg); /* 90deg rotation */
filter: url("#hue-rotate"); /* with embedded SVG */
filter: url("folder/fileName.svg#hue-rotate"); /* external svg filter definition */
```

This example shows three images: the image with a `hue-rotate()` filter function applied, the image with an equivalent `url()` filter applied, and the original images for comparison:

```
<table>
  <thead>
    <tr>
      <th><code>hue-rotate()</code></th>
      <th><code>url()</code></th>
      <th>Original image</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <td>
        <img
          class="css-filter"
          src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
          alt="Pride flag with rotated colors" />
      </td>
      <td>
        <img
          class="svg-filter"
          src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
          alt="Pride flag with rotated colors" />
      </td>
      <td>
        <img
          src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
          alt="Pride flag" />
      </td>
    </tr>
  </tbody>
</table>
```

```
.css-filter {
  filter: hue-rotate(90deg);
}
.svg-filter {
  filter: url("#hue-rotate");
}

th,
td {
  padding: 5px;
}
svg:not(:root) {
  display: none;
}
```

hue-rotate() does not preserve saturation or lightness

The diagram below compares two color gradients starting with red: the first is generated using `hue-rotate()`, and the second uses actual HSL color values. Note how the `hue-rotate()` gradient shows obvious differences in saturation and lightness in the middle.

```
<div>
  <p>Using <code>hue-rotate()</code></p>
  <div id="hue-rotate"></div>
</div>
<div>
  <p>Using <code>hsl()</code></p>
  <div id="hsl"></div>
</div>
```

```
#hue-rotate,
#hsl {
  display: flex;
  margin: 1em 0;
}

#hue-rotate div,
#hsl div {
  width: 2px;
  height: 100px;
}
```

```
const hueRotate = document.getElementById("hue-rotate");
const hsl = document.getElementById("hsl");

for (let i = 0; i < 360; i++) {
  const div1 = document.createElement("div");
  div1.style.backgroundColor = `hsl(${i}, 100%, 50%)`;
  hsl.appendChild(div1);

  const div2 = document.createElement("div");
  div2.style.backgroundColor = "red";
  div2.style.filter = `hue-rotate(${i}deg)`;
  hueRotate.appendChild(div2);
}
```

- CSS filter effects module
- The other `<filter-function>` functions available to be used in values of the `filter` and `backdrop-filter` properties include:
  - `blur()`
  - `brightness()`
  - `contrast()`
  - `drop-shadow()`
  - `grayscale()`
  - `invert()`
  - `opacity()`
  - `saturate()`
  - `sepia()`

invert() CSS function

The **`invert()`** CSS function inverts the color samples in the input image. Its result is a `<filter-function>`.

Try it

```
filter: invert(0);
```

```
filter: invert(0.3);
```

```
filter: invert(50%);
```

```
filter: invert(70%);
```

```
filter: invert(1);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

Syntax

```
/* No inversion */
invert(0)

/* Complete inversion */
invert()
invert(1)
invert(100%)

/* 60% inversion */
invert(.6)
invert(60%)
```

Parameters

`<number>` or `<percentage>` Optional

Specifies the amount of the conversion. A value of `100%` is completely inverted, while a value of `0%` leaves the input unchanged. Values between `0%` and `100%` are linear multipliers on the effect. The initial value for interpolation is `0`. The default value is `1`.

Formal syntax

```
<invert()> =
  invert( [ <number> | <percentage> ]? )
```

This syntax reflects the latest standard as per Filter Effects Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

SVG filter

The SVG `<feComponentTransfer>` filter element can also be used to invert content by creating equivalent inversion on nested `<feFuncR>`, `<feFuncG>`, and `<feFuncB>` table elements. We set the same `tableValue` for the red, green, and blue filter primitives to the same value, then we can reference the SVG effect by the ID of the `<filter>`:

```
<svg role="none">
  <filter id="invert90">
    <feComponentTransfer>
      <feFuncR type="table" tableValues="0.1 0" />
      <feFuncG type="table" tableValues="0.1 0" />
      <feFuncB type="table" tableValues="0.1 0" />
    </feComponentTransfer>
  </filter>
</svg>
```

The following declarations produce the same effect:

```
filter: invert(0.9);
filter: invert(90%);
filter: url("#invert90"); /* with embedded SVG */
filter: url("fileName.svg#invert90"); /* external SVG */
```

Examples

This example shows three images for comparison: an image with an `invert()` filter function applied, an image with the equivalent SVG function applied, and the original image:

SVG

We create an SVG filter that inverts the content on which it is applied by 70%:

```
<svg height="0">
  <filter id="invert">
    <feComponentTransfer>
      <feFuncR type="table" tableValues="0.3 0" />
      <feFuncG type="table" tableValues="0.3 0" />
      <feFuncB type="table" tableValues="0.3 0" />
    </feComponentTransfer>
  </filter>
</svg>
```

CSS

We include CSS that will invert elements based on their `filter` or `svgFilter` class:

```
.filter {
  filter: invert(70%);
}

.svgFilter {
  filter: url("#invert");
}
```

```
th,
td {
  padding: 5px;
}
```

```
<table>
  <thead>
    <tr>
      <th><code>invert()</code> filter</th>
      <th>SVG filter equivalent</th>
      <th>Original image</th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <td>
        <img
          class="svgFilter"
          src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
          alt="Pride flag" />
      </td>
      <td>
        <svg id="svg" height="220" width="220" overflow="visible">
          <filter id="svgInvert">
            <feComponentTransfer>
              <feFuncR type="table" tableValues="0.3 0" />
              <feFuncG type="table" tableValues="0.3 0" />
              <feFuncB type="table" tableValues="0.3 0" />
            </feComponentTransfer>
          </filter>
          <image
            href="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
            xlink:href="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
            filter="url('#svgInvert')" />
        </svg>
      </td>
      <td>
        <img
          src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
          alt="Pride flag" />
      </td>
    </tr>
  </tbody>
</table>
```

See also

The other `<filter-function>` functions available to be used in values of the `filter` and `backdrop-filter` properties include:

- `blur()`
- `brightness()`
- `contrast()`
- `drop-shadow()`
- `grayscale()`
- `hue-rotate()`
- `opacity()`
- `saturate()`
- `sepia()`

opacity() CSS function

The **`opacity()`** CSS function applies transparency to the samples in the input image. Its result is a `<filter-function>`.

Try it

```
filter: opacity(1);
```

```
filter: opacity(80%);
```

```
filter: opacity(50%);
```

```
filter: opacity(0.2);
```

```
filter: opacity(0);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

> **Note:** This function is similar to the more established `opacity` property. The difference is that with filters, some browsers provide hardware acceleration for better performance.

Syntax

```
opacity(amount)
```

Parameters

`amount` Optional

The amount of the conversion, specified as a `<number>` or a `<percentage>`. A value of `0%` is completely transparent, while a value of `100%` leaves the input unchanged. Values between `0%` and `100%` are linear multipliers on the effect. The initial value for interpolation is `1`. The default value is `1`.

Formal syntax

```
<opacity()> =
  opacity( [ <number> | <percentage> ]? )
```

This syntax reflects the latest standard as per Filter Effects Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Examples of correct values for opacity()

```
opacity(0%)   /* Completely transparent */
opacity(50%)  /* 50% transparent */

opacity()     /* No effect */
opacity(1)
```

See also

- The other `<filter-function>` functions available to be used in values of the `filter` and `backdrop-filter` properties include:
  - `blur()`
  - `brightness()`
  - `contrast()`
  - `drop-shadow()`
  - `grayscale()`
  - `hue-rotate()`
  - `invert()`
  - `saturate()`
  - `sepia()`
- The CSS `opacity` property

saturate() CSS function

The **`saturate()`** CSS function super-saturates or desaturates the input image. Its result is a `<filter-function>`.

> **Note:** `saturate()` is specified as a matrix operation on the RGB color. It does not actually convert the color to the HSL model, which is a non-linear operation. Therefore, it may not preserve the hue or lightness of the original color.

Try it

```
filter: saturate(1);
```

```
filter: saturate(4);
```

```
filter: saturate(50%);
```

```
filter: saturate(0);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
```

```
    width="200" />
</section>
```

Syntax

```
saturate(amount)
```

Parameters

`amount` Optional

> The amount of the conversion, specified as a `<number>` or a `<percentage>`. A value under `100%` desaturates the image, while a value over `100%` super-saturates it. A value of `0%` is completely unsaturated, while a value of `100%` leaves the input unchanged. The initial value for interpolation is `1`. The default value is `1`.

Formal syntax

```
<saturate()> =
  saturate( [ <number> | <percentage> ]? )
```

This syntax reflects the latest standard as per Filter Effects Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Examples of correct values for saturate()

```
saturate(0)     /* Completely unsaturated */
saturate(.4)    /* 40% saturated */
saturate()      /* No effect */
saturate(100%)  /* No effect */
saturate(200%)  /* Double saturation */
```

saturate() does not preserve hue or lightness

The diagram below compares two color gradients with `hsl(0 50% 50%)` as the mid-point: the first is generated using `saturate()`, and the second uses actual HSL color values. Note how the `saturate()` gradient shows differences in hue and lightness towards the two ends.

```
<div>
  <p>Using <code>saturate()</code></p>
  <div id="saturate"></div>
</div>
<div>
  <p>Using <code>hsl()</code></p>
  <div id="hsl"></div>
</div>
```

```
#saturate,
#hsl {
  display: flex;
  margin: 1em 0;
}

#saturate div,
#hsl div {
  width: 2px;
  height: 100px;
}
```

```
const saturate = document.getElementById("saturate");
const hsl = document.getElementById("hsl");

for (let i = 0; i <= 200; i++) {
  const div1 = document.createElement("div");
  div1.style.backgroundColor = `hsl(0 ${i / 2}% 50%)`;
  hsl.appendChild(div1);

  const div2 = document.createElement("div");
  div2.style.backgroundColor = "hsl(0 50% 50%)";
  div2.style.filter = `saturate(${i}%)`;
  saturate.appendChild(div2);
}
```

See also

The other `<filter-function>` functions available to be used in values of the `filter` and `backdrop-filter` properties include:

- `blur()`
- `brightness()`
- `contrast()`
- `drop-shadow()`
- `grayscale()`
- `hue-rotate()`
- `invert()`
- `opacity()`
- `sepia()`

sepia() CSS function

The **`sepia()`** CSS function converts the input image to sepia, giving it a warmer, more yellow/brown appearance. Its result is a `<filter-function>`.

Try it

```
filter: sepia(0);
```

```
filter: sepia(0.2);
```

```
filter: sepia(60%);
```

```
filter: sepia(1);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

Syntax

```
sepia(amount)
```

Parameters

`amount` Optional

> The amount of the conversion, specified as a `<number>` or a `<percentage>`. A value of `100%` is completely sepia, while a value of `0%` leaves the input unchanged. Values between `0%` and `100%` are linear multipliers on the effect. The initial value for interpolation is `0`. The default value is `1`.

Formal syntax

```
<sepia()> =
  sepia( [ <number> | <percentage> ]? )
```

This syntax reflects the latest standard as per Filter Effects Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Examples of correct values for sepia()

```
sepia(0)     /* No effect */
sepia(.65)   /* 65% sepia */

sepia()      /* Completely sepia */
sepia(100%)
```

See also

The other `<filter-function>` functions available to be used in values of the `filter` and `backdrop-filter` properties include:

- `blur()`
- `brightness()`
- `contrast()`
- `drop-shadow()`
- `grayscale()`
- `hue-rotate()`
- `invert()`
- `opacity()`
- `saturate()`

fit-content CSS keyword

The `fit-content` sizing keyword represents an element size that adapts to its content while staying within the limits of its container. The keyword ensures that the element is never smaller than its minimum intrinsic size (`min-content`) or larger than its maximum intrinsic size (`max-content`).

> **Note:** This keyword is different from the `fit-content()` function. The function is used for grid track sizing (for example in `grid-template-columns` and `grid-auto-rows`) and for laid-out box sizing for properties such as `width`, `height`, `min-width`, and `max-height`.

Syntax

```
/* Used in sizing properties */
width: fit-content;
height: fit-content;
inline-size: fit-content;
block-size: fit-content;
```

Description

This keyword is used with sizing properties such as `width`, `height`, `block-size`, `inline-size`, `min-width`, and `max-width`. When used on these properties, the calculated size refers to the element's content box.

When `fit-content` is set, the element grows or shrinks to fit its content, but stops expanding after the relevant dimension reaches the size limit of its container.

The `fit-content` size is calculated using the following formula:

```
min(max-content, max(min-content, stretch))
```

where, `stretch` matches the element's margin box to the width of its containing block. The keyword is essentially equivalent to `fit-content(stretch)`.

You can enable animations to and from `fit-content` using the `interpolate-size` property and the `calc-size()` function.

Examples

Sizing boxes with fit-content

HTML

```
<div class="container">
  <div class="item">Item</div>
  <div class="item">Item with more text in it.</div>
  <div class="item">
    Item with more text in it, hopefully we have added enough text so the text
    will start to wrap.
```

```
  </div>
</div>
```

CSS

```
.container {
  border: 2px solid #cccccc;
  padding: 10px;
  width: 20em;
}

.item {
  width: fit-content;
  background-color: #8ca0ff;
  padding: 5px;
  margin-bottom: 1em;
}
```

fit-content() CSS function

The **`fit-content()`** CSS function clamps a given size to an available size according to the formula `min(maximum size, max(minimum size, argument))`.

It is distinct from the `fit-content` keyword, which takes no argument and sizes a box based on its content within the available space. Only `fit-content()` is valid in grid track sizing properties such as `grid-template-columns`.

Try it

```
grid-template-columns: fit-content(8ch) fit-content(8ch) 1fr;
```

```
grid-template-columns: fit-content(100px) fit-content(100px) 1fr;
```

```
grid-template-columns: fit-content(40%) fit-content(40%) 1fr;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">
      <div>One. This column has more text in it.</div>
      <div>Two</div>
      <div>Three</div>
      <div>Four</div>
      <div>Five</div>
    </div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-gap: 10px;
  width: 250px;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
  text-align: left;
}
```

The function can be used as a track size in CSS grid properties, where the maximum size is defined by `max-content` and the minimum size by `auto`, which is calculated similar to `auto` (i.e., `minmax(auto, max-content)`), except that the track size is clamped at *argument* if it is greater than the `auto` minimum.

See the `grid-template-columns` page for more information on the `max-content` and `auto` keywords.

The `fit-content()` function can also be used as laid out box size for `width`, `height`, `min-width`, `min-height`, `max-width` and `max-height`, where the maximum and minimum sizes refer to the content size.

Syntax

```
/* <length> values */
fit-content(200px)
fit-content(5cm)
fit-content(30vw)
fit-content(100ch)

/* <percentage> value */
fit-content(40%)
```

Values

`<length>`

An absolute length.

`<percentage>`

A percentage relative to the available space in the given axis.

In grid properties it is relative to the inline size of the grid container in column tracks and to the block size of the grid container for row tracks. Otherwise it is relative to the available inline size or block size of the laid out box depending on the writing mode.

Formal syntax

```
<fit-content()> =
  fit-content( <length-percentage> )

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Grid Layout Module Level 2, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Sizing grid columns with fit-content

HTML

```
<div id="container">
  <div>Item as wide as the content.</div>
  <div>
    Item with more text in it. Because the contents of it are wider than the
    maximum width, it is clamped at 300 pixels.
  </div>
  <div>Flexible item</div>
</div>
```

CSS

```
#container {
  display: grid;
  grid-template-columns: fit-content(300px) fit-content(300px) 1fr;
  grid-gap: 5px;
  box-sizing: border-box;
  height: 200px;
  width: 100%;
  background-color: #8cffa0;
  padding: 10px;
}

#container > div {
  background-color: #8ca0ff;
  padding: 5px;
}
```

<flex> CSS type

The **`<flex>`** CSS data type denotes a flexible length within a grid container. It is used in `grid-template-columns`, `grid-template-rows` and other related properties.

Syntax

The `<flex>` data type is specified as a `<number>` followed by the unit `fr`. The `fr` unit represents a fraction of the leftover space in the grid container. As with all CSS dimensions, there is no space between the unit and the number.

Examples

Examples of correct values for the fr data type

```
1fr    /* Using an integer value */
2.5fr  /* Using a float value */
```

Example of use in a track listing for CSS grid layout

```
.grid {
  display: grid;
  grid-template-columns: 1fr 1fr 2.5fr 1.5fr;
}
```

See also

- CSS grid layout

<frequency> CSS type

The **`<frequency>`** CSS data type represents a frequency dimension, such as the pitch of a speaking voice. It is not currently used in any CSS properties.

Syntax

The `<frequency>` data type consists of a `<number>` followed by one of the units listed below. As with all CSS dimensions, there is no space between the unit literal and the number.

Units

`Hz`

Represents a frequency in hertz. Examples: `0Hz`, `1500Hz`, `10000Hz`.

`kHz`

Represents a frequency in kilohertz. Examples: `0kHz`, `1.5kHz`, `10kHz`.

> **Note:** Although the number `0` is always the same regardless of unit, the unit may not be omitted. In other words, `0` is invalid and does not represent `0Hz` or `0kHz`. Though the units are case-insensitive, it is good practice to use a capital "H" for `Hz` and `kHz`, as specified in the SI.

Examples

Valid frequency values:

```
12Hz     Positive integer
4.3Hz    Non-integer
14KhZ    The unit is case-insensitive, though non-SI capitalization is not recommended.
+0Hz     Zero, with a leading + and a unit
-0kHz    Zero, with a leading - and a unit
```

Invalid frequency values:

```
12.0     This is a <number>, not an <frequency>, because it is missing a unit.
7 Hz     No space is allowed between the number and the unit.
0        Although unitless zero is an allowable <length>, it's an invalid <frequency>.
```

Browser compatibility

Currently, no browsers support this feature.

- CSS values and units module

<frequency-percentage> CSS type

The **`<frequency-percentage>`** CSS data type represents a value that can be either a `<frequency>` or a `<percentage>`. Frequency values, e.g., the pitch of a speaking voice, are not currently used in any CSS properties.

Syntax

The value of a `<frequency-percentage>` is either a `<frequency>` or a `<percentage>`; see their individual reference pages for details about their syntaxes.

Description

Use in calc()

Where a `<frequency-percentage>` is specified as an allowable type, this means that the percentage resolves to a frequency and therefore can be used in a `calc()` expression.

Formal syntax

```
<frequency-percentage> =
  <frequency>   |
  <percentage>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Valid percentage values

```
90% Positive percentage
+90% Positive percentage with leading +
-90% Negative percentage — not valid for all properties that use percentages
```

Invalid percentage values

```
90 % No space is allowed between the number and the unit
```

Valid frequency values

```
12Hz     Positive integer
4.3Hz    Non-integer
14KhZ    The unit is case-insensitive, though non-SI capitalization is not recommended.
+0Hz     Zero, with a leading + and a unit
-0kHz    Zero, with a leading - and a unit
```

Invalid frequency values

```
12.0     This is a <number>, not an <frequency>, because it is missing a unit.
7 Hz     No space is allowed between the number and the unit.
0        Although unitless zero is an allowable <length>, it's an invalid <frequency>.
```

Browser compatibility

Currently, no browsers support this feature.

CSS value functions

CSS value functions are statements that invoke special data processing or calculations to return a CSS value for a CSS property. CSS value functions represent more complex data types and they may take some input arguments to calculate the return value.

Syntax

```
selector {
  property: function([argument]? [, argument]!);
}
```

The value syntax starts with the **name of the function**, followed by a left parenthesis `(`. Next up are the argument(s), and the function is finished off with a closing parenthesis `)`.

Functions can take multiple arguments, which are formatted similarly to CSS property values. Whitespace is allowed, but they are optional inside the parentheses. In some functional notations multiple arguments are separated by commas, while others use spaces.

> **Note:** The CSS value functions are used as property values and should not be confused with pseudo-classes. The functional pseudo-classes, linguistic pseudo-classes, and several tree-structural pseudo-classes require parameter values, but they're not value functions. The conditional at-rules are also not value functions; the parentheses are used for groupings.

Transform functions

The `<transform-function>` CSS data type represent appearance transformation. It is used as a value of `transform` property.

Translate functions

`translateX()`

Translates an element horizontally.

`translateY()`

Translates an element vertically.

`translateZ()`

Translates an element along the z-axis.

`translate()`

Translates an element on the 2D plane.

`translate3d()`

Translates an element in 3D space.

Rotation functions

`rotateX()`

Rotates an element around the horizontal axis.

`rotateY()`

Rotates an element around the vertical axis.

`rotateZ()`

Rotates an element around the z-axis.

`rotate()`

Rotates an element around a fixed point on the 2D plane.

`rotate3d()`

Rotates an element around a fixed axis in 3D space.

Scaling functions

`scaleX()`

Scales an element up or down horizontally.

`scaleY()`

Scales an element up or down vertically.

`scaleZ()`

Scales an element up or down along the z-axis.

`scale()`

Scales an element up or down on the 2D plane.

`scale3d()`

Scales an element up or down in 3D space.

Skew functions

`skewX()`

Skews an element in the horizontal direction.

`skewY()`

Skews an element in the vertical direction.

`skew()`

Skews an element on the 2D plane.

Matrix functions

`matrix()`

Describes a homogeneous 2D transformation matrix.

`matrix3d()`

Describes a 3D transformation as a 4×4 homogeneous matrix.

Perspective functions

`perspective()`

Sets the distance between the user and the z=0 plane.

Math functions

The math functions allow CSS numeric values to be written as mathematical expressions.

Each of the pages below contains detailed information about a math function's syntax, browser compatibility data, examples, and more. For a holistic introduction to CSS math functions, see Using CSS math functions.

Basic arithmetic

`calc()`

Performs basic arithmetic calculations on numerical values.

`calc-size()`

Perform calculations on intrinsic size values such as `auto`, `fit-content`, and `max-content`, which are not supported by the `calc()` function.

Comparison functions

`min()`

Calculates the smallest of a list of values.

`max()`

Calculates the largest of a list of values.

`clamp()`

Calculates the central of a minimum, central, and maximum values.

Stepped value functions

`round()`

Calculates a rounded number based on a rounding strategy.

`mod()`

Calculates a modulus (with the same sign as the divisor) when dividing one number by another.

`progress()`

Calculates the position of a value between two other values — a start value and an end value. The result represents the progress between the start and end values, where 0 is the start, and 1 is the end.

`rem()`

Calculates a remainder (with the same sign as the dividend) when dividing one number by another.

Trigonometric functions

`sin()`

Calculates the trigonometric sine of a number.

`cos()`

Calculates the trigonometric cosine of a number.

`tan()`

Calculates the trigonometric tangent of a number.

`asin()`

Calculates the trigonometric inverse sine of a number.

`acos()`

Calculates the trigonometric inverse cosine of a number.

`atan()`

Calculates the trigonometric inverse tangent of a number.

`atan2()`

Calculates the trigonometric inverse tangent of two-numbers in a plane.

Exponential functions

`pow()`

Calculates the base raised to the power of a number.

`sqrt()`

Calculates the square root of a number.

`hypot()`

Calculates the square root of the sum of the squares of its arguments.

`log()`

Calculates the logarithm of a number.

`exp()`

Calculates `e` raised to the power of a number.

Random value functions

`random()`

Generates a random value between a minimum and maximum value.

Sign-related functions

`abs()`

Calculates the absolute value of a number.

`sign()`

Calculates the sign (positive or negative) of the number.

Filter functions

The `<filter-function>` CSS data type represents a graphical effect that can change the appearance of an input image. It is used in the `filter` and `backdrop-filter` properties.

`blur()`

Increases the image gaussian blur.

`brightness()`

Brightens or darkens an image.

`contrast()`

Increases or decreases the image contrast.

`drop-shadow()`

Applies a drop shadow behind an image.

`grayscale()`

Converts an image to grayscale.

`hue-rotate()`

Changes the overall hue of an image.

`invert()`

Inverts the colors of an image.

`opacity()`

Adds transparency to an image.

`saturate()`

Changes the overall saturation of an image.

`sepia()`

Increases the sepia of an image.

Color functions

The `<color>` CSS data type specifies different color representations.

`rgb()`

Defines a given color according to its red, green, blue and alpha (transparency) components.

`hsl()`

Defines a given color according to its hue, saturation, lightness and alpha (transparency) components.

`hwb()`

Defines a given color according to its hue, whiteness and blackness components.

`lch()`

Defines a given color according to its lightness, chroma and hue components.

`oklch()`

Defines a given color according to its lightness, chroma, hue and alpha (transparency) components.

`lab()`

Defines a given color according to its lightness, a-axis distance and b-axis distance in the Lab colorspace.

`oklab()`

Defines a given color according to its lightness, a-axis distance, b-axis distance in the Lab colorspace and alpha (transparency).

`color()`

Specifies a particular, specified colorspace rather than the implicit sRGB colorspace.

`color-mix()`

Mixes two color values in a given colorspace by a given amount.

`contrast-color()`

Returns a color with maximum color contrast for a given color.

`device-cmyk()`

Defines CMYK colors in a device-dependent way.

`alpha()`

Returns a color with a modified alpha (transparency) channel.

`light-dark()`

Returns one of two provided colors based on the current color scheme.

`dynamic-range-limit-mix()`

Creates a custom maximum luminance limit that is a mix of different `dynamic-range-limit` keywords in specified percentages.

Image functions

The `<image>` CSS data type provides graphical representation of images or gradients.

Gradient functions

`linear-gradient()`

Linear gradients transition colors progressively along an imaginary line.

`radial-gradient()`

Radial gradients transition colors progressively from a center point (origin).

`conic-gradient()`

Conic gradients transition colors progressively around a circle.

`repeating-linear-gradient()`

Is similar to `linear-gradient()` and takes the same arguments, but it repeats the color stops infinitely in all directions so as to cover its entire container.

`repeating-radial-gradient()`

Is similar to `radial-gradient()` and takes the same arguments, but it repeats the color stops infinitely in all directions so as to cover its entire container.

`repeating-conic-gradient()`

Is similar to `conic-gradient()` and takes the same arguments, but it repeats the color stops infinitely in all directions so as to cover its entire container.

Image functions

`image()`

Defines an `<image>` in a similar fashion to the `<url>` type, but with added functionality including specifying the image's directionality and fallback images for when the preferred image is not supported.

`image-set()`

Picks the most appropriate CSS image from a given set, primarily for high pixel density screens.

`cross-fade()`

Blends two or more images at a defined transparency.

`element()`

Defines an `<image>` value generated from an arbitrary HTML element.

`paint()`

Defines an `<image>` value generated with a PaintWorklet.

Counter functions

CSS counter functions are generally used with the `content` property, although in theory, they may be used wherever a `<string>` is supported.

`counter()`

Returns a string representing the current value of the named counter if there is one.

`counters()`

Enables nested counters, returning a concatenated string representing the current values of the named counters, if there are any.

`symbols()`

Defines the counter styles inline, directly as the value of a property.

Shape functions

Basic shapes

The `<basic-shape>` CSS data type represents a graphical shape. It is used in the `clip-path`, `offset-path`, and `shape-outside` properties.

`circle()`

Defines a circle shape.

`ellipse()`

Defines an ellipse shape.

`inset()`

Defines an inset rectangle shape.

`rect()`

Defines a rectangle shape using the distances from the top and left edges of the reference box.

`xywh()`

Defines a rectangle shape using the specified distances from the top and left edges of the reference box and the rectangle width and height.

`polygon()`

Defines a polygon shape.

`path()`

Accepts an SVG path string to enable a shape to be drawn.

`shape()`

Accepts a comma-separated list of commands defining the shape to be drawn.

Other shape functions

`ray()`

Valid with `offset-path`; defines the line segment an animated element can follow.

`superellipse()`

Defines the curvature of an ellipse; can be used to specify a `<corner-shape-value>`, which is used with `corner-shape` and its constituent and related properties.

Reference functions

The following functions are used as a value of properties to reference a value defined elsewhere:

`attr()`

Uses the attributes defined on HTML element.

`env()`

Uses the user-agent defined as environment variable.

`if()`

Conditionally sets a property value depending on the result of a style query, media query, or feature query.

`url()`

Uses a file from the specified URL.

`var()`

Uses the custom property value instead of any part of a value of another property.

Grid functions

The following functions are used to define a CSS grid:

`fit-content()`

Clamps a given size to an available size according to the formula `min(maximum size, max(minimum size, argument))`.

`minmax()`

Defines a size range greater-than or equal-to *min* and less-than or equal-to *max*.

`repeat()`

Represents a repeated fragment of the track list, allowing a large number of columns or rows that exhibit a recurring pattern.

Font functions

CSS font functions are used with the `font-variant-alternates` property to control the use of alternate glyphs.

`stylistic()`

Enables stylistic alternates for individual characters. The parameter is a font-specific name mapped to a number. It corresponds to the OpenType value `salt`, like `salt 2`.

`styleset()`

Enables stylistic alternatives for sets of characters. The parameter is a font-specific name mapped to a number. It corresponds to the OpenType value `ssXY`, such as `ss02`.

`character-variant()`

Enables specific stylistic alternatives for characters. It is similar to `styleset()`, but doesn't create coherent glyphs for a set of characters; individual characters will have independent and not necessarily coherent styles. The parameter is a font-specific name mapped to a number. It corresponds to the OpenType value `cvXY`, such as `cv02`.

`swash()`

Enables swash glyphs. The parameter is a font-specific name mapped to a number. It corresponds to the OpenType values `swsh` and `cswh`, such as `swsh 2` and `cswh 2`.

`ornaments()`

Enables ornaments such as fleurons and other dingbat glyphs. The parameter is a font-specific name mapped to a number. It corresponds to the OpenType value `ornm`, such as `ornm 2`.

`annotation()`

Enables annotations such as circled digits or inverted characters. The parameter is a font-specific name mapped to a number. It corresponds to the OpenType value `nalt`, such as `nalt 2`.

Easing functions

The `<easing-function>` CSS data type represents a mathematical function. It is used in transition and animation properties:

`linear()`

Easing function that interpolates linearly between its points.

`cubic-bezier()`

Easing function that defines a cubic Bézier curve.

`steps()`

Iteration along a specified number of stops along the transition, displaying each stop for equal lengths of time.

Animation functions

The following functions are used as a value of different `animation-timeline` properties:

`scroll()`

Sets the `animation-timeline` of an element to an *anonymous scroll progress timeline*.

`view()`

Sets the `animation-timeline` of an element to an *anonymous view progress timeline*.

Anchor positioning functions

The anchor positioning functions are used when positioning and sizing anchor-positioned elements relative to the location and size of their associated anchor elements.

`anchor()`

Returns a length relative to the position of the edges of an anchor-positioned element's associated anchor element.

`anchor-size()`

Returns a length relative to the size of the associated anchor element.

Tree counting functions

The following functions return an integer value based on the DOM tree, rather than the flat tree like most CSS values do:

`sibling-index()`

Returns an integer reflecting the position of the selected element among its siblings.

`sibling-count()`

Returns an integer reflecting the total number of siblings, including the selected element.

- Learn: Values and units

<generic-family> CSS type

The **`<generic-family>`** CSS data type represents the keyword values for generic font families used in the `font` shorthand and `font-family` longhand properties. The `<generic-family>` represents one or more locally-installed fonts belonging to that category of fonts.

Syntax

Values

The `<generic-family>` enumerated type is specified using one of the values listed below:

`serif`

A serif is a small line or stroke attached to the end of a larger stroke in a letter. In serif fonts, glyphs have finishing strokes, flared or tapering ends. Examples include Lucida Bright, Lucida Fax, Palatino, Palatino Linotype, Palladio, and URW Palladio.

`sans-serif`

A font without serifs; glyphs have plain stroke endings, without ornamentation. Example sans-serif fonts include Open Sans, Fira Sans, Lucida Sans, Lucida Sans Unicode, Trebuchet MS, Liberation Sans, and Nimbus Sans L.

`monospace`

All glyphs have the same fixed width. Example monospace fonts include Fira Mono, DejaVu Sans Mono, Menlo, Consolas, Liberation Mono, Monaco, and Lucida Console.

`cursive`

Glyphs in cursive fonts generally use a cursive script or other handwriting style, and the result looks more like handwritten pen or brush writing than printed typesetting. CSS uses the term "cursive" to apply to a font for any script, including those that do not have joining strokes. Example cursive fonts include Brush Script MT, Brush Script Std, Lucida Calligraphy, Lucida Handwriting, and Apple Chancery.

`fantasy`

Fantasy fonts are primarily decorative fonts that contain playful representations of characters. Example fantasy fonts include Papyrus, Herculanum, Party LET, Curlz MT, Harrington, and Comic Sans MS.

`system-ui`

Glyphs are taken from the default user interface font on a given platform. Because typographic traditions vary widely across the world, this generic family is provided for typefaces that don't map cleanly into the others.

> **Note:** As the name implies, `system-ui` is intended to make UI elements look like native apps, and not for typesetting large paragraphs of text. It may cause the displayed typeface to be undesirable for some users—for example, the default Windows CJK font may render Latin scripts poorly, and the `lang` attribute may not affect the displayed font. Some operating systems do not allow customizing `system-ui`, while browsers generally allow customizing the `sans-serif` font family. For large paragraphs, use `sans-serif` or some other non-UI font family instead.

`ui-serif`

The default user interface serif font. See the definition of `serif` above.

`ui-sans-serif`

The default user interface sans-serif font. See the definition of `sans-serif` above.

`ui-monospace`

The default user interface monospace font. See the definition of `monospace` above.

`ui-rounded`

The default user interface font that has rounded features.

`math`

Fonts for displaying mathematical expressions, for example superscript and subscript, brackets that cross several lines, nesting expressions, and double-struck glyphs with distinct meanings.

`fangsong`

A particular style of Chinese characters that are between serif-style Song and cursive-style Kai forms. This style is often used for government documents.

Formal syntax

```
<generic-family> =
  serif          |
  sans-serif     |
  monospace      |
  cursive        |
  fantasy        |
  system-ui      |
  ui-serif       |
  ui-sans-serif  |
  ui-monospace   |

Examples

This example demos several of the `<generic-family>` enumerated values for the `font-family` property.

HTML

```
<ul>
  <li class="serif">serif</li>
  <li class="sans-serif">sans-serif</li>
  <li class="monospace">monospace</li>
  <li class="cursive">cursive</li>
  <li class="fantasy">fantasy</li>
  <li class="system-ui">system-ui</li>
</ul>
```

CSS

```
ul {
  font-size: 1.5rem;
  line-height: 2;
}
.serif {
  font-family: serif;
}
.sans-serif {
  font-family: sans-serif;
}
.monospace {
  font-family: monospace;
}
.cursive {
  font-family: cursive;
}
.fantasy {
  font-family: fantasy;
}
.system-ui {
  font-family: system-ui;
}
```

<gradient> CSS type

The **`<gradient>`** CSS data type is a special type of `<image>` that consists of a progressive transition between two or more colors.

A CSS gradient has no intrinsic dimensions; i.e., it has no natural or preferred size, nor a preferred ratio. Its concrete size will match the size of the element to which it applies.

Try it

```
background: linear-gradient(#f69d3c, #3f87a6);
```

```
background: radial-gradient(#f69d3c, #3f87a6);
```

```
background: repeating-linear-gradient(#f69d3c, #3f87a6 50px);
```

```
background: repeating-radial-gradient(#f69d3c, #3f87a6 50px);
```

```
background: conic-gradient(#f69d3c, #3f87a6);
```

```
<section class="display-block" id="default-example">
  <div id="example-element"></div>
</section>
```

```
#example-element {
  min-height: 100%;
}
```

Syntax

The `<gradient>` data type is defined with one of the function types listed below.

Linear gradient

Linear gradients transition colors progressively along an imaginary line. They are generated with the `linear-gradient()` function.

Radial gradient

Radial gradients transition colors progressively from a center point (origin). They are generated with the `radial-gradient()` function.

Conic gradient

Conic gradients transition colors progressively around a circle. They are generated with the `conic-gradient()` function.

Repeating gradient

Repeating gradients duplicate a gradient as much as necessary to fill a given area. They are generated with the `repeating-linear-gradient()`, `repeating-radial-gradient()`, and `repeating-conic-gradient()` functions.

Interpolation

As with any interpolation involving colors, gradients are calculated in the alpha-premultiplied color space. This prevents unexpected shades of gray from appearing when both the color and the opacity are changing. (Be aware that older browsers may not use this behavior when using the transparent keyword.)

Examples

Linear gradient example

A linear gradient.

```
<div class="linear-gradient">Linear gradient</div>
```

```
div {
  width: 240px;
  height: 80px;
}
```

```
.linear-gradient {
  background: linear-gradient(
    to right,
    red,
    orange,
    yellow,
    green,
    blue,
    indigo,
    violet
  );
}
```

Radial gradient example

A radial gradient.

```
<div class="radial-gradient">Radial gradient</div>
```

```
div {
  width: 240px;
  height: 80px;
}
```

```
.radial-gradient {
  background: radial-gradient(red, yellow, dodgerblue);
}
```

Conic gradient example

A conic gradient example.

```
<div class="conic-gradient">Conic gradient</div>
```

```
div {
  width: 200px;
  height: 200px;
}
```

```
.conic-gradient {
  background: conic-gradient(pink, coral, lime);
}
```

Repeating gradient examples

Repeating linear and radial gradient examples.

```
<div class="linear-repeat"></div>
<span>Repeating linear gradient</span>
<hr />
<div class="radial-repeat"></div>
<span>Repeating radial gradient</span>
<hr />
```

```
<div class="conic-repeat"></div>
<span>Repeating conic gradient</span>
```

```
div {
  display: inline-block;
  width: 240px;
  height: 80px;
}

span {
  font-weight: bold;
  vertical-align: top;
}
```

```
.linear-repeat {
  background: repeating-linear-gradient(
    to top left,
    pink,
    pink 5px,
    white 5px,
    white 10px
  );
}

.radial-repeat {
  background: repeating-radial-gradient(
    lime,
    lime 15px,
    white 15px,
    white 30px
  );
}

.conic-repeat {
  background: repeating-conic-gradient(lime, pink 30deg);
}
```

conic-gradient() CSS function

The **`conic-gradient()`** CSS function creates an image consisting of a gradient with color transitions rotated around a center point (rather than radiating from the center). Example conic gradients include pie charts and color wheels. The result of the `conic-gradient()` function is an object of the `<gradient>` data type, which is a special kind of `<image>`.

Try it

```
background: conic-gradient(red, orange, yellow, green, blue);
```

```
background: conic-gradient(
  from 0.25turn at 50% 30%,
  #f69d3c,
  10deg,
  #3f87a6,
  350deg,
  #ebf8e1
);
```

```
background: conic-gradient(from 3.1416rad at 10% 50%, #e66465, #9198e5);
```

```
background: conic-gradient(
  red 6deg,
  orange 6deg 18deg,
  yellow 18deg 45deg,
  green 45deg 110deg,
  blue 110deg 200deg,
  purple 200deg
);
```

```
<section class="display-block" id="default-example">
  <div id="example-element"></div>
</section>
```

```
#example-element {
  min-height: 100%;
}
```

Syntax

```
/* A gradient with a single color of red */
conic-gradient(red)

/* A conic gradient rotated 45 degrees,
   starting blue and finishing red */
conic-gradient(from 45deg, blue, red)

/* A bluish purple box: the gradient goes from blue to red,
   but only the bottom right quadrant is visible, as the
   center of the conic gradient is at the top left corner */
conic-gradient(from 90deg at 0 0, blue, red)

/* Interpolation in polar color space
```

```
  with longer hue interpolation method */
conic-gradient(in hsl longer hue, red, blue, green, red)
```

Values

`<angle>`

Preceded by the `from` keyterm, and taking an angle as its value, defines the gradient rotation in clockwise direction.

`<position>`

Using the same length, order, and keyterm values as the `background-position` property, the `position` value defines center of the gradient. If not specified, the value used for `position` by default is `center`, meaning the gradient will be centered.

`<angular-color-stop>`

A color-stop's `<color>` value, followed by one or two optional stop positions, (an `<angle>` along the gradient's circumference axis).

`<color-hint>`

An interpolation hint defining how the gradient progresses between adjacent color stops. The length defines at which point between two color stops the gradient color should reach the midpoint of the color transition. If omitted, the midpoint of the color transition is the midpoint between two color stops.

> **Note:** Rendering of color stops in conic gradients follows the same rules as color stops in linear gradients.

Description

As with any gradient, a conic gradient has no intrinsic dimensions; i.e., it has no natural or preferred size, nor a preferred ratio. Its concrete size will match the size of the element it applies to, or the size of the `<image>` if it is set to something other than the element size.

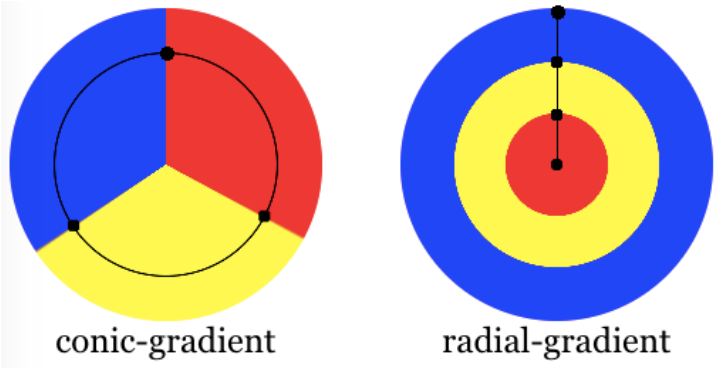
To create a conic gradient that repeats so as to fill a 360 degree rotation, use the `repeating-conic-gradient()` function instead.

Because `<gradient>`s belong to the `<image>` data type, they can only be used where `<image>`s can be used. For this reason, `conic-gradient()` won't work on `background-color` and other properties that use the `<color>` data type.

> **Note:** Why is it called a "conic" gradient? If the color stops are much lighter on one side than the other, it can look like a cone from above.

Composition of a conic gradient

The conic-gradient syntax is similar to the radial-gradient syntax, but the color-stops are placed around a gradient arc, the circumference of a circle, rather than on the gradient line emerging from the center of the gradient. With conic gradients, the colors transition as if spun around the center of a circle, starting at the top and going clockwise. In a radial gradient, the colors transition from the center of an ellipse, outward, in all directions.



A conic gradient is specified by indicating a rotation angle, the center of the gradient, and then specifying a list of color-stops. Unlike linear and radial gradients, whose color-stops are placed by specifying a `<length>`, the color-stops of a conic gradient are specified with an angle. Units include `deg` for degrees, `grad` for gradians, `rad` for radians, and `turn` for turns. There are 360 degrees, 400 gradians, 2π radians, and 1 turn in a circle. Browsers supporting conic gradients also accept percent values, with 100% equaling 360 degrees, but this is not in the specification.

Similar to radial gradients, the conic gradient syntax provides for positioning the center of the gradient anywhere within, or even outside, the image. The values for the position are similar to the syntax for 2-value background-position.

The gradient arc is the circumference of the gradient. The *starting point* of the gradient or arc is north, or 12:00pm. The gradient is then rotated by the *from* angle. The colors of the gradient are determined by the angled color stops, their starting points, ending points, and, in between, and optional angled color-stop points. The transitions between colors can be altered with color hints between adjacent colors' color stops.

Customizing gradients

By adding more angled color-stop points on the gradient arc, you can create a highly customized transition between multiple colors. A color-stop's position can be explicitly defined by using an `<angle>`. If you don't specify the location of a color stop, it is placed halfway between the one that precedes it and the one that follows it. If you don't specify an angle for the first or last color stop, their values are 0deg and 360deg respectively. The following two gradients are equivalent:

```
conic-gradient(red, orange, yellow, green, blue);
conic-gradient(red 0deg, orange 90deg, yellow 180deg, green 270deg, blue 360deg);
```

By default, colors transition smoothly from the color at one color stop to the color at the subsequent color stop, with the midpoint between the colors being the half way point between the color transition. You can move this color transition midpoint to any point between two color stops by adding a color hint, indicating where the middle of the color transition should be. The following is solid red from the start to the 10% mark, transitions from red to blue over 80% of the turn, with the final 10% being solid blue. The midpoint of the red to blue gradient change, however, is at the 20% mark rather than the 50% mark as would have happened without the 80grad, or 20%, color hint.

```
conic-gradient(red 40grad, 80grad, blue 360grad);
```

If two or more color stops are at the same location, the transition will be a hard line between the first and last colors declared at that location. To use conic gradients to create pie charts — which is NOT the correct way to create pie charts as background images are not accessible — use hard color stops, where the color stop angles for two adjacent color stops are the same. The easiest way to do this is to use multiple position colors stops. The following two declarations are equivalent:

```
conic-gradient(white 0.09turn, #bbbbbb 0.09turn, #bbbbbb 0.27turn, #666666 0.27turn, #666666 0.54turn, black 0.54turn);
conic-gradient(white 0turn 0.09turn, #bbbbbb 0.09turn 0.27turn, #666666 0.27turn 0.54turn, black 0.54turn 1turn);
```

Color stops should be listed in ascending order. Subsequent color stops of lower value will override the value of the previous color stop creating a hard transition. The following changes from red to yellow at the 30% mark, and then transitions from yellow to blue over 35% of the gradient:

```
conic-gradient(red .8rad, yellow .6rad, blue 1.3rad);
```

There are other effects you can create with conic gradients. Oddly, a checkerboard is one of them. By creating quadrants with an upper left and lower right white quadrant and lower left and upper right black quadrants, then repeating the gradient 16 times (four times across and four times down) you can make a checkerboard.

```
conic-gradient(white 90deg, black 0.25turn 0.5turn, white calc(pi * 1rad) calc(pi * 1.5rad), black 300grad);
background-size: 25% 25%;
```

And, yes, you can mix and match different angle units, but don't. The above is hard to read.

Formal syntax

```
<conic-gradient()> =
  conic-gradient( [ <conic-gradient-syntax> ] )

<angle-percentage> =
```

```
  <angle>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Color Module Level 5, CSS Images Module Level 4, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Accessibility

Browsers do not provide any special information on background images to assistive technology. This is important primarily for screen readers, as a screen reader will not announce its presence and therefore convey nothing to its users. While it is possible to create pie charts, checkerboards, and other effects with conic gradients, CSS images provide no native way to assign alternative text, and therefore the image represented by the conic gradient will not be accessible to screen reader users. If the image contains information critical to understanding the page's overall purpose, it is better to describe it semantically in the document.

- Understanding Success Criterion 1.1.1 | W3C Understanding WCAG 2.0

Examples

Gradient at 40-degrees

```
div {
  width: 100px;
  height: 100px;
}
```

```
<div></div>
```

```
div {
  background-image: conic-gradient(from 40deg, white, black);
}
```

Off-centered gradient

```
div {
  width: 100px;
  height: 100px;
}
```

```
<div></div>
```

```
div {
  background: conic-gradient(from 0deg at 0% 25%, blue, green, yellow 180deg);
}
```

Gradient pie-chart

This example uses multi-position color stops, with adjacent colors having the same color stop value, creating a striped effect.

```
div {
  width: 100px;
  height: 100px;
}
```

```
<div></div>
```

```
div {
  background: conic-gradient(red 36deg, orange 36deg 170deg, yellow 170deg);
  border-radius: 50%;
}
```

Checkerboard

```
div {
  width: 100px;
  height: 100px;
}
```

```
<div></div>
```

```
div {
  background: conic-gradient(
      white 0.25turn,
      black 0.25turn 0.5turn,
      white 0.5turn 0.75turn,
      black 0.75turn
    )
    top left / 25% 25% repeat;
  border: 1px solid;
}
```

Interpolating with hue

```
<div class="shorter"></div>
<div class="longer"></div>
```

```
div {
  display: inline-block;
  margin-top: 1rem;
  width: 45vw;
  height: 80vh;
}

.shorter::before {
  content: "shorter hue";
  display: block;
  margin-top: -1rem;
```

```
}

.longer::before {
  content: "longer hue";
  display: block;
  margin-top: -1rem;
}
```

In this example for interpolation hsl color system is being used and hue is being interpolated.

```
.shorter {
  background-image: conic-gradient(in hsl shorter hue, red, blue);
}

.longer {
  background-image: conic-gradient(in hsl longer hue, red, blue);
}
```

The box on the left uses shorter interpolation, meaning color goes straight from red to blue using the shorter arc on the color wheel. The box on the right uses longer interpolation, meaning the color goes from red to blue using the longer arc, traversing through greens, yellows, and oranges.

Color Wheel

```
<div></div>
```

```
div {
  width: 100px;
  height: 100px;
  border-radius: 50px;
}
```

```
div {
  background-image: conic-gradient(
    in hsl longer hue,
    hsl(360 100% 50%),
    hsl(0 100% 50%)
  );
}
```

linear-gradient() CSS function

The **`linear-gradient()`** CSS function creates an image consisting of a progressive transition between two or more colors along a straight line. Its result is an object of the `<gradient>` data type, which is a special kind of `<image>`.

Try it

```
background: linear-gradient(#e66465, #9198e5);
```

```
background: linear-gradient(0.25turn, #3f87a6, #ebf8e1, #f69d3c);
```

```
background: linear-gradient(
  to left,
  #333333,
  #333333 50%,
  #eeeeee 75%,
  #333333 75%
);
```

```
background:
  linear-gradient(217deg, rgb(255 0 0 / 0.8), transparent 70.71%),
  linear-gradient(127deg, rgb(0 255 0 / 0.8), transparent 70.71%),
  linear-gradient(336deg, rgb(0 0 255 / 0.8), transparent 70.71%);
```

```
<section class="display-block" id="default-example">
  <div id="example-element"></div>
</section>
```

```
#example-element {
  min-height: 100%;
}
```

Syntax

```
/* A gradient with a single color of red */
linear-gradient(red)

/* A gradient tilted 45 degrees,
   starting blue and finishing red */
linear-gradient(45deg, blue, red)
```

```
/* A gradient going from the bottom right to the top left corner,
   starting blue and finishing red */
linear-gradient(to left top, blue, red)

/* Interpolation in rectangular color space */
linear-gradient(in oklab, blue, red)

/* Interpolation in polar color space */
linear-gradient(in hsl, blue, red)

/* Interpolation in polar color space
  with longer hue interpolation method */
linear-gradient(in hsl longer hue, blue, red)

/* Color stop: A gradient going from the bottom to top,
   starting blue, turning green at 40% of its length,
   and finishing red */
linear-gradient(0deg, blue, green 40%, red)

/* Color hint: A gradient going from the left to right,
   starting red, getting to the midpoint color
   10% of the way across the length of the gradient,
   taking the rest of the 90% of the length to change to blue */
linear-gradient(.25turn, red, 10%, blue)

/* Multi-position color stop: A gradient tilted 45 degrees,
   with a red bottom-left half and a blue top-right half,
   with a hard line where the gradient changes from red to blue */
linear-gradient(45deg, red 0 50%, blue 50% 100%)
```

Values

`<side-or-corner>`

The position of the gradient line's starting point. If specified, it consists of the word `to` and up to two keywords: one indicates the horizontal side (`left` or `right`), and the other the vertical side (`top` or `bottom`). The order of the side keywords does not matter. If unspecified, it defaults to `to bottom`.

The values `to top`, `to bottom`, `to left`, and `to right` are equivalent to the angles `0deg`, `180deg`, `270deg`, and `90deg`, respectively. The other values are translated into an angle.

`<angle>`

The gradient line's angle of direction. A value of `0deg` is equivalent to `to top`; increasing values rotate clockwise from there.

`<linear-color-stop>`

A color-stop's `<color>` value, followed by one or two optional stop positions, (each being either a `<percentage>` or a `<length>` along the gradient's axis).

`<color-hint>`

An interpolation hint defining how the gradient progresses between adjacent color stops. The length defines at which point between two color stops the gradient color should reach the midpoint of the color transition. If omitted, the midpoint of the color transition is the midpoint between two color stops.

> **Note:** Rendering of color stops in CSS gradients follows the same rules as color stops in SVG gradients.

Description

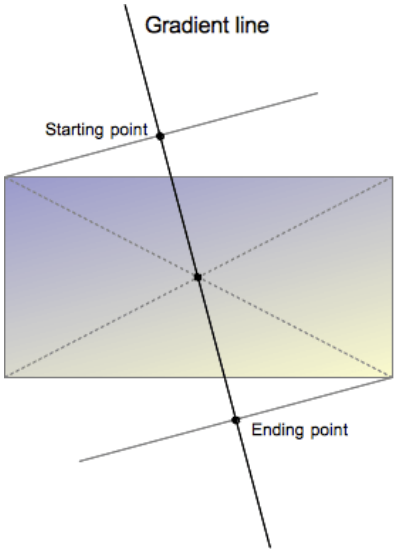
As with any gradient, a linear gradient has no intrinsic dimensions; i.e., it has no natural or preferred size, nor a preferred ratio. Its concrete size will match the size of the element it applies to.

To create a linear gradient that repeats to fill its container, use the `repeating-linear-gradient()` function instead.

Because `<gradient>`s belong to the `<image>` data type, they can only be used where `<image>`s can be used. For this reason, `linear-gradient()` won't work on `background-color` and other properties that use the `<color>` data type.

Composition of a linear gradient

A linear gradient is defined by an axis—the *gradient line*—and two or more *color-stop points*. Each point on the axis is a distinct color; to create a smooth gradient, the `linear-gradient()` function draws a series of colored lines perpendicular to the gradient line, each one matching the color of the point where it intersects the gradient line.



The gradient line is defined by the center of the box containing the gradient image and by an angle. The colors of the gradient are determined by two or more points: the starting point, the ending point, and, in between, optional color-stop points.

The *starting point* is the location on the gradient line where the first color begins. The *ending point* is the point where the last color ends. Each of these two points is defined by the intersection of the gradient line with a perpendicular line passing from the box corner which is in the same quadrant. The ending point can be understood as the symmetrical point of the starting point. These somewhat complex definitions lead to an interesting effect sometimes called *magic corners*: the corners nearest to the starting and ending points have the same color as their respective starting or ending points.

Customizing Gradients

By adding more color-stop points on the gradient line, you can create a highly customized transition between multiple colors. A color-stop's position can be explicitly defined by using a `<length>` or a `<percentage>`. If you don't specify the location of a color, it is placed halfway between the one that precedes it and the one that follows it. The following two gradients are equivalent.

```
linear-gradient(red, orange, yellow, green, blue);
linear-gradient(red 0%, orange 25%, yellow 50%, green 75%, blue 100%);
```

By default, colors transition smoothly from the color at one color-stop to the color at the subsequent color-stop, with the midpoint between the colors being the halfway point between the color transition. You can move this midpoint to any position between two color-stops by adding an unlabeled % color hint between the two colors to indicate where the middle of the color transition should be. The following example is solid red from the start to the 10% mark and solid blue from 90% to the end. Between 10% and 90% the color transitions from red to blue, however, the midpoint of the transition is at the 30% mark rather than 50% as would have happened without the 30% color hint.

```
linear-gradient(red 10%, 30%, blue 90%);
```

If two or more color-stops are at the same location, the transition will be a hard line between the first and last colors declared at that location.

Color-stops should be listed in ascending order. Subsequent color-stops of lower value will override the value of the previous color-stop creating a hard transition. The following changes from red to yellow at the 40% mark, and then transitions from yellow to blue over 25% of the gradient:

```
linear-gradient(red 40%, yellow 30%, blue 65%);
```

Multi-position color-stops are allowed. A color can be declared as two adjacent color-stops by including both positions in the CSS declaration. The following three gradients are equivalent:

```
linear-gradient(red 0%, orange 10%, orange 30%, yellow 50%, yellow 70%, green 90%, green 100%);
linear-gradient(red, orange 10% 30%, yellow 50% 70%, green 90%);
linear-gradient(red 0%, orange 10% 30%, yellow 50% 70%, green 90% 100%);
```

By default, if there is no color with a `0%` stop, the first color declared will be at that point. Similarly, the last color will continue to the `100%` mark, or be at the `100%` mark if no length has been declared on that last stop.

Formal syntax

```
<linear-gradient()> =
  linear-gradient( [ <linear-gradient-syntax> ] )

<linear-gradient-syntax> =
  [ [ <angle> | <zero> | to <side-or-corner> ] || <color-interpolation-method> ]? , <color-stop-list>

<side-or-corner> =
  [ left | right ]  ||
  [ top | bottom ]

<color-interpolation-method> =
  in [ <rectangular-color-space> | <polar-color-space> <hue-interpolation-method>? | <custom-color-space> ]

<color-stop-list> =
  <linear-color-stop> , [ <linear-color-hint>? , <linear-color-stop> ]#?

<rectangular-color-space> =
  srgb               |
  srgb-linear        |

  <xyz-space>

<polar-color-space> =
  hsl    |
  hwb    |
  lch    |
  oklch

<hue-interpolation-method> =
  [ shorter | longer | increasing | decreasing ] hue

<custom-color-space> =
  <dashed-ident>

<linear-color-stop> =
  <color> <color-stop-length>?

<linear-color-hint> =
  <length-percentage>

<xyz-space> =
  xyz      |
  xyz-d50  |
  xyz-d65

<color-stop-length> =
  <length-percentage>{1,2}

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Color Module Level 5, CSS Images Module Level 3, CSS Images Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Gradient at a 45-degree angle

```
body {
  width: 100vw;
  height: 100vh;
}
```

```
body {
  background: linear-gradient(45deg, red, blue);
}
```

Gradient that starts at 60% of the gradient line

```
body {
  width: 100vw;
  height: 100vh;
}
```

```
body {
  background: linear-gradient(135deg, orange 60%, cyan);
}
```

Interpolation in rectangular color space

```
body {
  width: 100vw;
  height: 100vh;
}
```

```
body {
  background: linear-gradient(90deg in oklab, blue, red);
}
```

Interpolating with hue

```
<div class="shorter">shorter hue</div>
<div class="longer">longer hue</div>
```

```
div {
  height: 50vh;
  color: white;
  font-weight: bolder;
}
```

In this example for interpolation, hsl color system is being used and hue is being interpolated.

```
.shorter {
  background: linear-gradient(90deg in hsl shorter hue, red, blue);
}

.longer {
  background: linear-gradient(90deg in hsl longer hue, red, blue);
}
```

The box on the top uses shorter interpolation, meaning color goes straight from red to blue using the shorter arc on color wheel. The box on the bottom uses longer interpolation, meaning the color goes from red to blue using the longer arc, traversing through greens, yellows, and oranges.

Gradient with multi-position color-stops

This example uses multi-position color-stops, with adjacent colors having the same color-stop value, creating a striped effect.

```
body {
  width: 100vw;
  height: 100vh;
}
```

```
body {
  background: linear-gradient(
    to right,
    red 20%,
    orange 20% 40%,
    yellow 40% 60%,
    green 60% 80%,
    blue 80%
  );
}
```

radial-gradient() CSS function

The **`radial-gradient()`** CSS function creates an image consisting of a progressive transition between two or more colors that radiate from an origin. Its shape may be a circle or an ellipse. The function's result is an object of the `<gradient>` data type, which is a special kind of `<image>`.

Try it

```
background: radial-gradient(#e66465, #9198e5);
```

```
background: radial-gradient(closest-side, #3f87a6, #ebf8e1, #f69d3c);
```

```
background: radial-gradient(
  circle at 100%,
  #333333,
  #333333 50%,
  #eeeeee 75%,
  #333333 75%
);
```

```
background:
  radial-gradient(ellipse at top, #e66465, transparent),
  radial-gradient(ellipse at bottom, #4d9f0c, transparent);
```

```
<section class="display-block" id="default-example">
  <div id="example-element"></div>
</section>
```

```
#example-element {
  min-height: 100%;
}
```

Syntax

```
/* A gradient with a single color of red */
radial-gradient(red)

/* A gradient at the center of its container,
   starting red, changing to blue, and finishing green */
radial-gradient(circle at center, red 0, blue, green 100%)

/* hsl color space with longer hue interpolation */
radial-gradient(circle at center in hsl longer hue, red 0, blue, green 100%)
```

A radial gradient is specified by indicating the center of the gradient (where the 0% ellipse will be) and the size and shape of the *ending shape* (the 100% ellipse).

Values

`<position>`

The position of the gradient, interpreted in the same way as `background-position` or `transform-origin`. If unspecified, it defaults to `center`.

`<ending-shape>`

The gradient's ending-shape. The value can be `circle` (meaning that the gradient's shape is a circle with a constant radius) or `ellipse` (meaning that the shape is an axis-aligned ellipse). If unspecified, it defaults to `ellipse`.

`<size>`

Determines the size of the gradient's ending shape. If omitted it defaults to farthest-corner. It can be given explicitly or by keyword. For the purpose of the keyword definitions, consider the gradient box edges as extending infinitely in both directions, rather than being finite line segments.

Both circle and ellipse gradients accept the following keywords for their `<size>`:

Keyword	Description
`closest-side`	The gradient's ending shape meets the side of the box closest to its center (for circles) or meets both the vertical and horizontal sides closest to the center (for ellipses).
`closest-corner`	The gradient's ending shape is sized so that it exactly meets the closest corner of the box from its center.
`farthest-side`	Similar to `closest-side`, except the ending shape is sized to meet the side of the box farthest from its center (or vertical and horizontal sides).
`farthest-corner`	The default value, the gradient's ending shape is sized so that it exactly meets the farthest corner of the box from its center.

If `<ending-shape>` is specified as `circle`, the size may be given explicitly as a `<length>`, which provides an explicit circle radius. Negative values are invalid.

If `<ending-shape>` is specified as `ellipse`, the size may be given as a `<length-percentage>` with two values to provide an explicit ellipse size. The first value represents the horizontal radius and the second is the vertical radius. Percentage values are relative to the corresponding dimension of the gradient box. Negative values are invalid.

When the `<ending-shape>` keyword is omitted, the gradient shape is determined by the size given. One `<length>` value provides a circle, while two values in `<length-percentage>` units provide an ellipse. A single `<percentage>` value is not valid.

`<linear-color-stop>`

A color-stop's `<color>` value, followed by one or two optional stop positions (either a `<percentage>` or a `<length>` along the gradient's axis). A percentage of `0%`, or a length of `0`, represents the center of the gradient; the value `100%` represents the intersection of the ending shape with the virtual gradient ray. Percentage values in between are linearly positioned on the gradient ray. Including two stop positions is equivalent to declaring two color stops with the same color at the two positions.

`<color-hint>`

The color-hint is an interpolation hint defining how the gradient progresses between adjacent color stops. The length defines at which point between two color stops the gradient color should reach the midpoint of the color transition. If omitted, the midpoint of the color transition is the midpoint between two color stops.

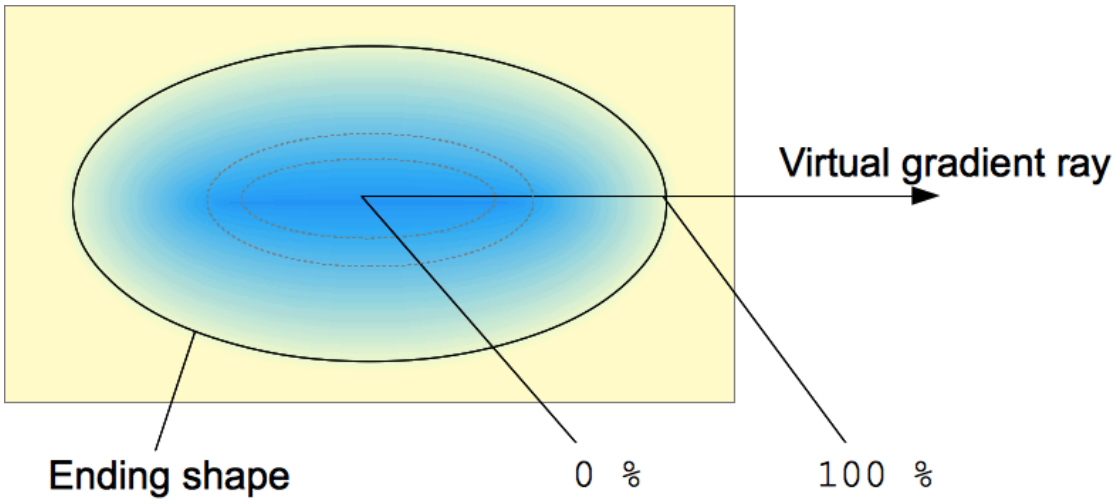
Description

As with any gradient, a radial gradient has no intrinsic dimensions; i.e., it has no natural or preferred size, nor a preferred ratio. Its concrete size will match the size of the element it applies to.

To create a radial gradient that repeats so as to fill its container, use the `repeating-radial-gradient()` function instead.

Because `<gradient>`s belong to the `<image>` data type, they can only be used where `<image>`s can be used. For this reason, `radial-gradient()` won't work on `background-color` and other properties that use the `<color>` data type.

Composition of a radial gradient



A radial gradient is defined by a *center point*, an *ending shape*, and two or more *color-stop points*.

To create a smooth gradient, the `radial-gradient()` function draws a series of concentric shapes radiating out from the center to the *ending shape* (and potentially beyond). The ending shape may be either a circle or an ellipse.

Color-stop points are positioned on a *virtual gradient ray* that extends horizontally from the center towards the right. Percentage-based color-stop positions are relative to the intersection between the ending shape and this gradient ray, which represents `100%`. Each shape is a single color determined by the color on the gradient ray it intersects.

Formal syntax

```
<radial-gradient()> =
  radial-gradient( [ <radial-gradient-syntax> ] )

<radial-gradient-syntax> =
  [ [ [ <radial-shape> || <radial-size> ]? [ at <position> ]? ] || <color-interpolation-method> ]? , <color-stop-list>

<radial-shape> =
  circle   |
  ellipse

<radial-size> =
  <radial-extent>              |
  <length [0,∞]>               |

  [ shorter | longer | increasing | decreasing ] hue

<custom-color-space> =
  <dashed-ident>

<linear-color-stop> =
  <color> <color-stop-length>?

<linear-color-hint> =
  <length-percentage>

<xyz-space> =
  xyz      |
  xyz-d50  |
  xyz-d65

<color-stop-length> =
  <length-percentage>{1,2}
```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Color Module Level 5, CSS Images Module Level 3, CSS Images Module Level 4, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic gradient

```
<div class="radial-gradient"></div>
```

```
.radial-gradient {
  width: 240px;
  height: 120px;
}
```

```
.radial-gradient {
  background-image: radial-gradient(cyan 0%, transparent 20%, salmon 40%);
}
```

Non-centered gradient

```
<div class="radial-gradient"></div>
```

```
.radial-gradient {
  width: 240px;
  height: 120px;
}
```

```
.radial-gradient {
  background-image: radial-gradient(
    farthest-corner at 40px 40px,
    #ff3355 0%,
    #4433ee 100%
  );
}
```

Interpolating with hue

```
<div class="shorter"></div>
<div class="longer"></div>
```

```
div {
  display: inline-block;
  margin-top: 1rem;
  width: 45vw;
  height: 80vh;
}

.shorter::before {
  content: "shorter hue";
  display: block;
  margin-top: -1rem;
}

.longer::before {
  content: "longer hue";
  display: block;
  margin-top: -1rem;
}
```

In this example for interpolation, hsl color system is being used and hue is being interpolated.

```
.shorter {
  background-image: radial-gradient(
    circle at center in hsl shorter hue,
    red,
    blue
  );
}
```

```
.longer {
  background-image: radial-gradient(
    circle at center in hsl longer hue,
    red,
    blue
  );
}
```

The box on the left uses shorter interpolation, meaning the color goes straight from red to blue using the shorter arc on color wheel. The box on the right uses longer interpolation, meaning the color goes from red to blue using the longer arc, traversing through greens, yellows, and oranges.

repeating-conic-gradient() CSS function

The **`repeating-conic-gradient()`** CSS function creates an image consisting of a repeating gradient (rather than a single gradient) with color transitions rotated around a center point (rather than radiating from the center).

Try it

```
background: repeating-conic-gradient(red 0%, yellow 15%, red 33%);
```

```
background: repeating-conic-gradient(
  from 45deg at 10% 50%,
  brown 0deg 10deg,
  darkgoldenrod 10deg 20deg,
  chocolate 20deg 30deg
);
```

```
<section class="display-block" id="default-example">
  <div id="example-element"></div>
</section>
```

```
#example-element {
  min-height: 100%;
}
```

Syntax

```
/* Starburst: a blue on blue starburst: the gradient
   is a starburst of lighter and darker blue,
   centered in the upper left quadrant,
   offset by 3degrees so there is no up/down straight line */
repeating-conic-gradient(
  from 3deg at 25% 25%,
  hsl(200 100% 50%) 0deg 15deg,
  hsl(200 100% 60%) 10deg 30deg
)

/* Interpolation in polar color space
  with shorter hue interpolation method */
repeating-conic-gradient(in hsl shorter hue, red, blue 90deg, green 180deg)
```

Values

`<angle>`

> Preceded by the `from` keyterm, and taking an angle as its value, defines the gradient rotation in clockwise direction.

`<position>`

> Using the same length, order and keyterm values as the background-position property, the position defines center of the gradient. If omitted, the default value is `center`, meaning the gradient will be centered.

`<angular-color-stop>`

> A color-stop's `<color>` value, followed by one or two optional stop positions, (an `<angle>` along the gradient's circumference axis). The last color stop minus the first color-stop angle defines the size of the repeating gradient.

`<color-hint>`

> An interpolation hint defining how the gradient progresses between adjacent color stops. The length defines at which point between two color stops the gradient color should reach the midpoint of the color transition. If omitted, the midpoint of the color transition is the midpoint between two color stops.

> **Note:** Rendering of color stops in repeating conic gradients follows the same rules as color stops in linear gradients.

Description

Example repeating conic gradients include starbursts. The result of the `repeating-conic-gradient()` function is an object of the `<gradient>` data type, which is a special kind of `<image>`.

If neither the first nor the last color stops include a color stop angle greater than 0deg or less than 360 degrees respectively, the conic-gradient will not repeat.

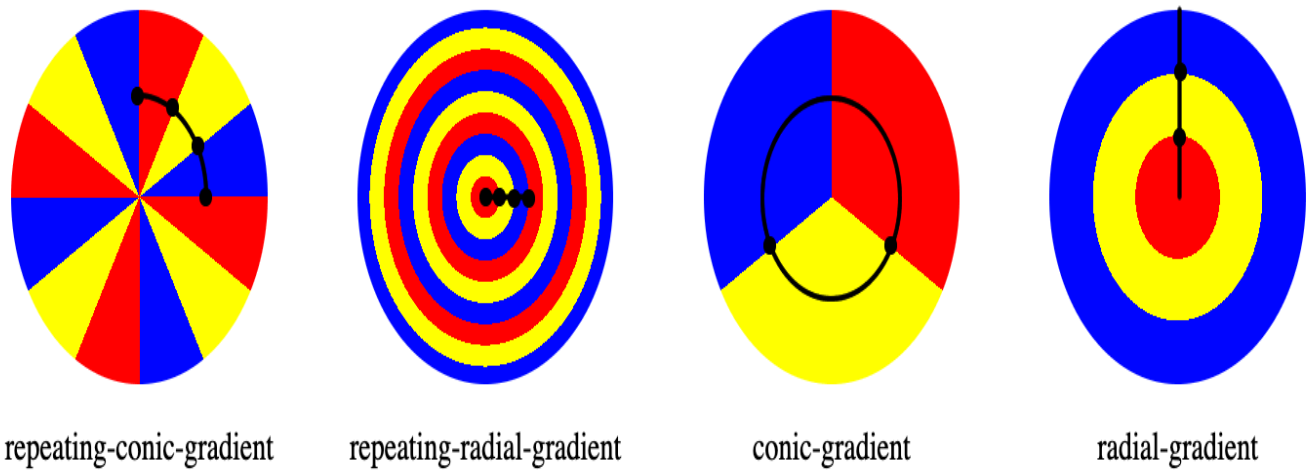
As with any gradient, a repeating-conic gradient has no intrinsic dimensions; i.e., it has no natural or preferred size, nor a preferred ratio. Its concrete size will match the size of the element it applies to, or the size the `<image>` is set to if it's set to something other than the element's size.

Because `<gradient>`s belong to the `<image>` data type, they can only be used where `<image>`s can be used. For this reason, `repeating-conic-gradient()` won't work on `background-color` and other properties that use the `<color>` data type.

> **Note:** To create a conic gradient that does not repeat, make the gradient a full 360 degree rotation, or use the `conic-gradient()` function instead.

Understanding repeating conic gradients

The repeating-conic-gradient syntax is similar to the `conic-gradient()` and `repeating-radial-gradient()` syntax. Like the non-repeating conic-gradient, the color-stops are placed around a gradient arc. Like the repeating radial gradient, the size of the repeating section is the first color stop subtracted from the angle of the last color stop.



The above gradients are defined as being one third blue, one third red, and one third yellow.

```
repeating-conic-gradient(from 0deg, red 0deg 30deg, yellow 30deg 60deg, blue 60deg 90deg);

repeating-radial-gradient(red 0 8%, yellow 8% 16%, blue 16% 24%);

conic-gradient(red 120deg, yellow 120deg 240deg, blue 240deg);

radial-gradient(red 33%, yellow 33% 66%, blue 66%);
```

For a repeating gradient to repeat we define the first and last color stops. Like in non-repeating gradients, the first and last color stops are assumed to be 0 and either 100% or 360deg if not explicitly declared. When defaulting to these values, the repeating arc is 360 degrees, and therefore doesn't repeat.

Like the non-repeating conic gradient, the color-stops are placed around a gradient arc — the circumference of a circle, rather than on the gradient line emerging from the center of the gradient. The colors transition as if spun around the center of a circle, starting at the top if no `from <angle>` is declared, and going clockwise for the size of the angle that is the different between the largest and smallest color angle, then repeating.

A repeating conic gradient is specified by indicating a rotation angle, the center of the gradient, and then specifying a list of color-stops. Like non-repeating conic gradients, the color-stops of a repeating conic gradient are specified with an `<angle>`. Units include `deg` for degrees, `grad` for gradients, `rad` for radians, and `turn` for turns. There are 360 degrees, 400 gradians, 2π radians, and 1 turn in a circle. Browsers supporting repeating conic gradients also accept percent values, with 100% equaling 360 degrees, but this is not in the specification.

Radial and conic gradient syntax provides for positioning the center of the gradient anywhere within, or even outside, the image. The values for the position are similar to the syntax for 2-value `background-position`.

The gradient arc is part of the circumference of the gradient. 0 degrees is north, or 12:00pm. The colors of the gradient are determined by the angled color stops, their starting points, ending points, and, in between, and optional angled color-stop points. The transitions between colors can be altered with color hints between adjacent colors' color stops.

Customizing gradients

By adding more angled color-stop points on the gradient arc, you can create a highly customized transition between multiple colors. A color-stop's position can be explicitly defined by using an `<angle>`. If you don't specify the location of a color stop, it is placed halfway between the one that precedes it and the one that follows it. Like the non-repeating gradient counterpart, if you don't specify an angle for the first or last color stop, the values will be 0deg and 360deg. If you don't declare an angle for either, you'll get a non-repeating conic gradient. If you declare a non 0 or 360degree for the first or last respectively, the gradient will repeat based on that value. For example, if you don't declare an angle for the first color, and declare 10% on the last color stop, the arc will repeat 10 times. Rather, the starting point is the first color stop declared, and the last color stop is the last color stop angle declared. The following two gradients are equivalent:

```
repeating-conic-gradient(red, orange, yellow, green, blue 50%);
repeating-conic-gradient(from -45deg, red 45deg, orange, yellow, green, blue 225deg)
```

By default, colors transition smoothly from the color at one color stop to the color at the subsequent color stop, with the midpoint between the colors being the half way point between the color transition. You can move this color transition midpoint to any point between two color stops by adding a color hint, indicating where the middle of the color transition should be.

If two or more color stops are at the same location, the transition will be a hard line between the first and last colors declared at that location.

While you can mix and match different angle units, don't. It makes CSS hard to read.

Formal syntax

```
<repeating-conic-gradient()> =
  repeating-conic-gradient( [ <conic-gradient-syntax> ] )

<conic-gradient-syntax> =
  [ [ [ from [ <angle> | <zero> ] ]? [ at <position> ]? ] || <color-interpolation-method> ]? , <angular-color-stop-list>

<position> =
  <position-one>    |
  <position-two>    |
  <position-four>
```

```
<color-interpolation-method> =
  in [ <rectangular-color-space> | <polar-color-space> <hue-interpolation-method>? | <custom-color-space> ]

<angular-color-stop-list> =
  <angular-color-stop> , [ <angular-color-hint>? , <angular-color-stop> ]#?

<position-one> =
  left                 |
  center               |
  right                |
  top                  |

```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Color Module Level 5, CSS Images Module Level 4, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Accessibility

Browsers do not provide any special information on background images to assistive technology. This is important primarily for screen readers, as a screen reader will not announce its presence and therefore convey nothing to its users. While it is possible to create pie charts, checkerboards, and other effects with conic gradients, CSS images provide no native way to assign alternative text, and therefore the image represented by the conic gradient will not be accessible to screen reader users. If the image contains information critical to understanding the page's overall purpose, it is better to describe it semantically in the document.

- Understanding Success Criterion 1.1.1 | W3C Understanding WCAG 2.0

Examples

Black and white starburst

```
div {
  width: 200px;
  height: 200px;
}
```

```
<div></div>
```

```
div {
  background-image: repeating-conic-gradient(white 0 9deg, black 9deg 18deg);
}
```

Off-centered gradient

This gradient repeats 18 times, but since we only see the right half, we only see 9 repeats.

```
div {
  width: 200px;
  height: 200px;
}
```

```
<div></div>
```

```
div {
  background: repeating-conic-gradient(
    from 3deg at 25% 25%,
    green,
    blue 2deg 5deg,
    green,
    yellow 15deg 18deg,
    green 20deg
  );
}
```

Interpolating with hue

```
<div class="shorter"></div>
<div class="longer"></div>
```

```
div {
  display: inline-block;
  margin-top: 1rem;
  width: 45vw;
  height: 80vh;
}

.shorter::before {
  content: "shorter hue";
  display: block;
  margin-top: -1rem;
}

.longer::before {
  content: "longer hue";
  display: block;
  margin-top: -1rem;
}
```

In this example for interpolation, hsl color system is being used and hue is being interpolated.

```
.shorter {
  background-image: repeating-conic-gradient(
    in hsl shorter hue,
    red,
    blue 180deg
  );
}

.longer {
  background-image: repeating-conic-gradient(
    in hsl longer hue,
    red,
    blue 180deg
  );
}
```

The box on the left uses shorter interpolation, meaning color goes straight from red to blue using the shorter arc on the color wheel. The box on the right uses longer interpolation, meaning the color goes from red to blue using the longer arc, traversing through greens, yellows, and oranges.

repeating-linear-gradient() CSS function

The **`repeating-linear-gradient()`** CSS function creates an image consisting of repeating linear gradients. It is similar to `linear-gradient()` and takes the same arguments, but it repeats the color stops infinitely in all directions so as to cover its entire container. The function's result is an object of the `<gradient>` data type, which is a special kind of `<image>`.

Try it

```
background: repeating-linear-gradient(
  #e66465,
```

```
  #e66465 20px,
  #9198e5 20px,
  #9198e5 25px
);
```

```
background: repeating-linear-gradient(45deg, #3f87a6, #ebf8e1 15%, #f69d3c 20%);
```

```
background:
  repeating-linear-gradient(transparent, #4d9f0c 40px),
  repeating-linear-gradient(0.25turn, transparent, #3f87a6 20px);
```

```
<section class="display-block" id="default-example">
  <div id="example-element"></div>
</section>
```

```
#example-element {
  min-height: 100%;
}
```

The length of the gradient that repeats is the distance between the first and last color stop. If the first color does not have a color-stop-length, the color-stop-length defaults to 0. With each repetition, the positions of the color stops are shifted by a multiple of the length of the basic linear gradient. Thus, the position of each ending color stop coincides with a starting color stop; if the color values are different, this will result in a sharp visual transition. This can be altered with repeating the first color again as the last color.

As with any gradient, a repeating linear gradient has no intrinsic dimensions; i.e., it has no natural or preferred size, nor a preferred ratio. Its concrete size will match the size of the element it applies to.

Because `<gradient>`s belong to the `<image>` data type, they can only be used where `<image>`s can be used. For this reason, `repeating-linear-gradient()` won't work on `background-color` and other properties that use the `<color>` data type.

Syntax

```
/* A repeating gradient tilted 45 degrees,
   starting blue and finishing red, repeating 3 times */
repeating-linear-gradient(45deg, blue, red 33.3%)

/* A repeating gradient going from the bottom right to the top left,
   starting blue and finishing red, repeating every 20px */
repeating-linear-gradient(to left top, blue, red 20px)

/* A gradient going from the bottom to top,
   starting blue, turning green after 40%,
   and finishing red. This gradient doesn't repeat because
   the last color stop defaults to 100% */
repeating-linear-gradient(0deg, blue, green 40%, red)

/* A gradient repeating five times, going from the left to right,
   starting red, turning green, and back to red */
repeating-linear-gradient(to right, red 0%, green 10%, red 20%)

/* Interpolation in rectangular color space */
repeating-linear-gradient(in oklab, blue, red 50px)

/* Interpolation in polar color space */
repeating-linear-gradient(in hsl, blue, red 50px)

/* Interpolation in polar color space
  with longer hue interpolation method */
repeating-linear-gradient(in hsl longer hue, blue, red 50px)
```

Values

`<side-or-corner>`

The position of the gradient line's starting point. If specified, it consists of the word `to` and up to two keywords: one indicates the horizontal side (`left` or `right`), and the other the vertical side (`top` or `bottom`). The order of the side keywords does not matter. If unspecified, it defaults to `to bottom`.

The values `to top`, `to bottom`, `to left`, and `to right` are equivalent to the angles `0deg`, `180deg`, `270deg`, and `90deg` respectively. The other values are translated into an angle.

`<angle>`

The gradient line's angle of direction. A value of `0deg` is equivalent to `to top`; increasing values rotate clockwise from there.

`<linear-color-stop>`

A color-stop's `<color>` value, followed by one or two optional stop positions, (each being either a `<percentage>` or a `<length>` along the gradient's axis). A percentage of `0%`, or a length of `0`, represents the start of the gradient; the value `100%` is 100% of the image size, meaning the gradient will not repeat.

`<color-hint>`

The color-hint is an interpolation hint defining how the gradient progresses between adjacent color stops. The length defines at which point between two color stops the gradient color should reach the midpoint of the color transition. If omitted, the midpoint of the color transition is the midpoint between two color stops.

> **Note:** Rendering of color stops in repeating linear gradients follows the same rules as color stops in linear gradients.

Formal syntax

```
<repeating-linear-gradient()> =
  repeating-linear-gradient( [ <linear-gradient-syntax> ] )

<linear-gradient-syntax> =
  [ [ <angle> | <zero> | to <side-or-corner> ] || <color-interpolation-method> ]? , <color-stop-list>

<side-or-corner> =
  [ left | right ]  ||
  [ top | bottom ]

<color-interpolation-method> =
  in [ <rectangular-color-space> | <polar-color-space> <hue-interpolation-method>? | <custom-color-space> ]

<color-stop-list> =
```

```
  <linear-color-stop> , [ <linear-color-hint>? , <linear-color-stop> ]#?

<rectangular-color-space> =
  srgb               |
  srgb-linear        |
  display-p3         |
  display-p3-linear  |
  a98-rgb            |
  prophoto-rgb       |
  rec2020            |
  lab                |
  oklab              |
  <xyz-space>

<polar-color-space> =
  hsl    |
  hwb    |
  lch    |
  oklch

<hue-interpolation-method> =
  [ shorter | longer | increasing | decreasing ] hue

<custom-color-space> =
  <dashed-ident>

<linear-color-stop> =
  <color> <color-stop-length>?

<linear-color-hint> =
  <length-percentage>

<xyz-space> =
  xyz      |
  xyz-d50  |
  xyz-d65

<color-stop-length> =
  <length-percentage>{1,2}

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Color Module Level 5, CSS Images Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Zebra stripes

```
body {
  width: 100vw;
  height: 100vh;
}
```

```
body {
  background-image: repeating-linear-gradient(
    -45deg,
    transparent,
    transparent 20px,
    black 20px,
    black 40px
  );
  /* with multiple color stop lengths */
  background-image: repeating-linear-gradient(
    -45deg,
    transparent 0 20px,
    black 20px 40px
  );
}
```

Ten repeating horizontal bars

```
body {
  width: 100vw;
  height: 100vh;
}
```

```
body {
  background-image: repeating-linear-gradient(
    to bottom,
    rgb(26 198 204),
    rgb(26 198 204) 7%,
    rgb(100 100 100) 10%
  );
}
```

Because the last color stop is 10% and the gradient is vertical, each gradient in the repeated gradient is 10% of the height, fitting 10 horizontal bars.

Interpolation in rectangular color space

```
body {
  width: 100vw;
  height: 100vh;
}
```

```
body {
  background: repeating-linear-gradient(90deg in oklab, blue, red 100px);
}
```

Interpolating with hue

```
<div class="shorter">shorter hue</div>
<div class="longer">longer hue</div>
```

```
div {
  height: 50vh;
  color: #333300;
  font-weight: bolder;
  padding-left: 1.5rem;
}
```

In this example for interpolation, hsl color system is being used and hue is being interpolated.

```
.shorter {
  background: repeating-linear-gradient(
    90deg in hsl shorter hue,
    red,
    blue 300px
  );
}

.longer {
  background: repeating-linear-gradient(
    90deg in hsl longer hue,
    red,
    blue 300px
  );
}
```

The box on the top uses shorter interpolation, meaning the color goes from red to blue using the shorter arc on the color wheel. The box on the bottom uses longer interpolation, meaning the color goes from red to blue using the longer arc, traversing through greens, yellows, and oranges.

> **Note:** Please see Using CSS gradients for more examples.

repeating-radial-gradient() CSS function

The **`repeating-radial-gradient()`** CSS function creates an image consisting of repeating gradients that radiate from an origin. It is similar to `radial-gradient()` and takes the same arguments, but it repeats the color stops infinitely in all directions so as to cover its entire container, similar to `repeating-linear-gradient()`. The function's result is an object of the `<gradient>` data type, which is a special kind of `<image>`.

Try it

```
background: repeating-radial-gradient(#e66465, #9198e5 20%);
```

```
background: repeating-radial-gradient(closest-side, #3f87a6, #ebf8e1, #f69d3c);
```

```
background: repeating-radial-gradient(
  circle at 100%,
  #333333,
  #333333 10px,
  #eeeeee 10px,
  #eeeeee 20px
);
```

```
<section class="display-block" id="default-example">
  <div id="example-element"></div>
</section>
```

```
#example-element {
  min-height: 100%;
}
```

With each repetition, the positions of the color stops are shifted by a multiple of the dimensions of the basic radial gradient (the distance between the last color stop and the first). Thus, the position of each ending color stop coincides with a starting color stop; if the color values are different, this will result in a sharp visual transition, which can be mitigated by repeating the first color as the last color.

As with any gradient, a repeating radial gradient has no intrinsic dimensions; i.e., it has no natural or preferred size, nor a preferred ratio. Its concrete size will match the size of the element it applies to.

Because `<gradient>`s belong to the `<image>` data type, they can only be used where `<image>`s can be used. For this reason, `repeating-radial-gradient()` won't work on `background-color` and other properties that use the `<color>` data type.

Syntax

```
/* A gradient at the center of its container,
   starting red, changing to blue, and finishing green,
   with the colors repeating every 30px */
repeating-radial-gradient(circle at center, red 0, blue, green 30px)

/* An elliptical gradient near the top left of its container,
   starting red, changing to green and back again,
   repeating five times between the center and the bottom right corner,
   and only once between the center and the top left corner */
repeating-radial-gradient(farthest-corner at 20% 20%, red 0, green, red 20%)
```

Values

`<position>`

The position of the gradient, interpreted in the same way as `background-position` or `transform-origin`. If unspecified, it defaults to `center`.

`<shape>`

The gradient's shape. The value can be `circle` (meaning that the gradient's shape is a circle with constant radius) or `ellipse` (meaning that the shape is an axis-aligned ellipse). If unspecified, it defaults to `ellipse`.

`<extent-keyword>`

A keyword describing how big the ending shape must be. The possible values are:

Keyword	Description
`closest-side`	The gradient's ending shape meets the side of the box closest to its center (for circles) or meets both the vertical and horizontal sides closest to the center (for ellipses).
`closest-corner`	The gradient's ending shape is sized so that it exactly meets the closest corner of the box from its center.
`farthest-side`	Similar to `closest-side`, except the ending shape is sized to meet the side of the box farthest from its center (or vertical and horizontal sides).
`farthest-corner`	The gradient's ending shape is sized so that it exactly meets the farthest corner of the box from its center.

> **Note:** Early implementations of this function included other keywords (`cover` and `contain`) as synonyms of the standard `farthest-corner` and `closest-side`, respectively. Use the standard keywords only, as some implementations have already dropped those older variants.

`<color-stop>`

A color-stop's `<color>` value, followed by an optional stop position (either a `<percentage>` or a `<length>` along the gradient's axis). A percentage of `0%`, or a length of `0`, represents the center of the gradient; the value `100%` represents the intersection of the ending shape with the virtual gradient ray. Percentage values in between are linearly positioned on the virtual gradient ray.

Formal syntax

```
<repeating-radial-gradient()> =
  repeating-radial-gradient( [ <radial-gradient-syntax> ] )

<radial-gradient-syntax> =
  [ [ [ <radial-shape> || <radial-size> ]? [ at <position> ]? ] || <color-interpolation-method> ]? , <color-stop-list>

<position-four> =
  [ [ left | right | x-start | x-end ] <length-percentage> ] && [ [ top | bottom | y-start | y-end ] <length-percentage> ]  |
  [ [ block-start | block-end ] <length-percentage> ] && [ [ inline-start | inline-end ] <length-percentage> ]  |
  [ [ start | end ] <length-percentage> ]{2}

<rectangular-color-space> =
  srgb               |
  srgb-linear        |
  display-p3         |
  display-p3-linear  |
```

```
  a98-rgb            |
  prophoto-rgb       |
  rec2020            |
  lab                |
  oklab              |
  <xyz-space>

<polar-color-space> =
  hsl    |
  hwb    |
  lch    |
  oklch

<hue-interpolation-method> =
  [ shorter | longer | increasing | decreasing ] hue

<custom-color-space> =
  <dashed-ident>

<linear-color-stop> =
  <color> <color-stop-length>?

<linear-color-hint> =
  <length-percentage>

<xyz-space> =
  xyz      |
  xyz-d50  |
  xyz-d65

<color-stop-length> =
  <length-percentage>{1,2}
```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Color Module Level 5, CSS Images Module Level 3, CSS Images Module Level 4, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Black and white gradient

```
<div class="radial-gradient"></div>
```

```
.radial-gradient {
  width: 120px;
  height: 120px;
}
```

```
.radial-gradient {
  background: repeating-radial-gradient(
    black,
    black 5px,
    white 5px,
    white 10px
  );
}
```

Farthest-corner

```
<div class="radial-gradient"></div>
```

```
.radial-gradient {
  width: 240px;
  height: 120px;
}
```

```
.radial-gradient {
  background: repeating-radial-gradient(
    ellipse farthest-corner at 20% 20%,
    red,
    black 5%,
    blue 5%,
    green 10%
  );
  background: repeating-radial-gradient(
    ellipse farthest-corner at 20% 20%,
    red 0 5%,
    green 5% 10%
  );
}
```

The elliptical gradient will be centered 20% from the top left, and will repeat 10 times between the center and the farthest corner (the bottom right corner). Browsers supporting multi position color stops will display a red and green striped ellipse. Browsers not supporting the syntax yet will see a gradient that goes from red to black and then from blue to green.

Interpolating with hue

```
<div class="shorter"></div>
<div class="longer"></div>
```

```
div {
  display: inline-block;
  margin-top: 1rem;
  width: 45vw;
  height: 80vh;
}

.shorter::before {
  content: "shorter hue";
  display: block;
  margin-top: -1rem;
}
```

```
.longer::before {
  content: "longer hue";
  display: block;
  margin-top: -1rem;
}
```

In this example for interpolation, hsl color system is being used and hue is being interpolated.

```
.shorter {
  background-image: repeating-radial-gradient(
    circle at center in hsl shorter hue,
    red 30px,
    blue 60px
  );
}

.longer {
  background-image: repeating-radial-gradient(
    circle at center in hsl longer hue,
    red 30px,
    blue 60px
  );
}
```

The box on the left uses shorter interpolation, meaning the color goes from red to blue using the shorter arc on color wheel. The box on the right uses longer interpolation, meaning the color goes from red to blue using the longer arc, traversing through greens, yellows, and oranges.

> **Note:** Please see Using CSS gradients for more examples.

<hex-color> CSS type

The **`<hex-color>`** CSS data type is a notation for describing the *hexadecimal color syntax* of an sRGB color using its primary color components (red, green, blue) written as hexadecimal numbers, as well as its transparency.

A `<hex-color>` value can be used everywhere where a `<color>` can be used.

Syntax

```
#RGB        // The three-value syntax
#RGBA       // The four-value syntax
#RRGGBB     // The six-value syntax
#RRGGBBAA   // The eight-value syntax
```

Value

`R` or `RR`

The *red* component of the color, as a case-insensitive hexadecimal number between `0` and `ff` (255). If there is only one number, it is duplicated: `1` means `11`.

`G` or `GG`

The *green* component of the color, as a case-insensitive hexadecimal number between `0` and `ff` (255). If there is only one number, it is duplicated: `c` means `cc`.

`B` or `BB`

The *blue* component of the color, as a case-insensitive hexadecimal number between `0` and `ff` (255). If there is only one number, it is duplicated: `9` means `99`.

`A` or `AA` Optional

The *alpha* component of the color, indicating its transparency, as a case-insensitive hexadecimal number between `0` and `ff` (255). If there is only one number, it is duplicated: `e` means `ee`. `0`, or `00`, represents a fully transparent color, and `f`, or `ff`, a fully opaque one.

> **Note:** The syntax is case-insensitive: `#00ff00` is the same as `#00FF00`.

Examples

Hexadecimal hot pink

This example includes four hot pink squares, with fully opaque or semi-transparent backgrounds created using four different-length case-insensitive hex-color syntaxes.

HTML

```
<div>
  #F09
  <div class="c1"></div>
</div>
<div>
  #f09a
  <div class="c2"></div>
</div>
<div>
  #ff0099
  <div class="c3"></div>
```

```
</div>
<div>
  #FF0099AA
  <div class="c4"></div>
</div>
```

CSS

The hot pink background colors are created using the three-, four-, six-, and eight-value hex notations, using both uppercase and lowercase letters.

```
body {
  display: flex;
  justify-content: space-evenly;
  font-family: monospace;
}
div {
  display: flex;
  flex-direction: column;
  align-items: center;
  justify-content: center;
}
```

```
[class] {
  width: 40px;
  height: 40px;
}
.c1 {
  background: #f09;
}
.c2 {
  background: #f09a;
}
.c3 {
  background: #ff0099;
}
.c4 {
  background: #ff0099aa;
}
```

- CSS color module

<hue> CSS type

The **`<hue>`** CSS data type represents the hue angle of a color. It is used in the color functions that accept hue expressed as a single value, specifically `hsl()`, `hwb()`, `lch()`, and `oklch()` functional notations.

Syntax

A `<hue>` can be either an `<angle>` or a `<number>`.

Values

`<angle>`

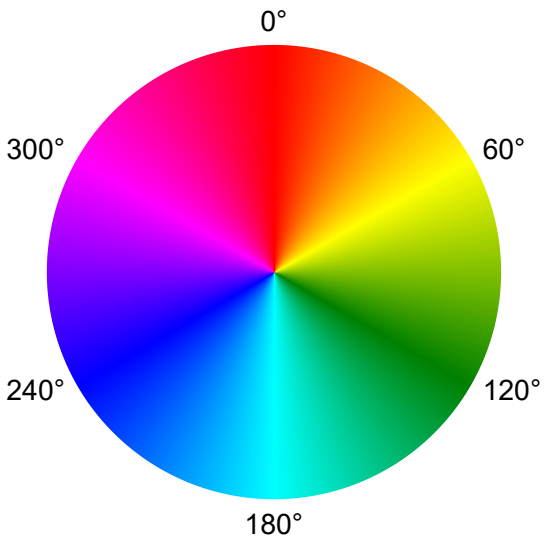
An angle expressed in degrees, gradians, radians, or turns using the `deg`, `grad`, `rad`, or `turn`, respectively.

`<number>`

A real number, representing degrees of the hue angle.

As an `<angle>` is periodic, `<hue>` is normalized to the range `[0deg, 360deg)`. It implicitly wraps around such that `480deg` is the same as `120deg`, `-120deg` is the same as `240deg`, `-1turn` is the same as `1turn`, and so on.

Description



The color wheel above shows hues at all angles in the sRGB color space. In particular, *red* is at `0deg`, *yellow* is at `60deg`, *lime* is at `120deg`, *cyan* is at `180deg`, *blue* is at `240deg`, and *magenta* is at `300deg`.

The angles corresponding to particular hues differ depending on the color space. For example, the hue angle of sRGB green is `120deg` in the sRGB color space, but `134.39deg` in the CIELAB color space.

The following table lists typical colors at various angles in the sRGB (used by `hsl()` and `hwb()`), CIELAB (used by `lch()`), and Oklab (used by `oklch()`) color spaces:

	0°	60°	120°	180°	240°	300°
sRGB						
CIELAB						
Oklab						

Interpolation of <code><hue></code> values

`<hue>` values are interpolated as `<angle>` values, and the default interpolation algorithm is `shorter`. In some color-related CSS functions, this can be overridden by the `<hue-interpolation-method>` component.

Formal syntax

```
<hue> =
  <number>  |
  <angle>
```

This syntax reflects the latest standard as per CSS Color Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Changing the hue of a color using a slider

The following example shows the effect of changing the `hue` value of the `hsl()` functional notation on a color.

HTML

```
<input type="range" min="0" max="360" value="0" id="hue-slider" />
<p>Hue: <span id="hue-value">0deg</span></p>
<div id="box"></div>
```

CSS

```
div {
  width: 100px;
  height: 100px;
  margin: 10px;
  border: 1px solid black;
}
p {
  font-family: sans-serif;
}
span {
  font-family: monospace;
  background: rgb(0 0 0 / 10%);
  padding: 3px;
}
#hue-slider {
  width: 90%;
}
```

```
#box {
  background-color: hsl(0 100% 50%);
}
```

JavaScript

```
const hue = document.querySelector("#hue-slider");
const box = document.querySelector("#box");
hue.addEventListener("input", () => {
  box.style.backgroundColor = `hsl(${hue.value} 100% 50%)`;
  document.querySelector("#hue-value").textContent = `${hue.value}deg`;
});
```

Result

Approximating red hues in different color spaces

The following example shows a similar red color in different color spaces. The values in the `lch()` and `oklch()` functions are rounded for readability.

HTML

```
<div data-color="hsl-red">hsl()</div>
<div data-color="hwb-red">hwb()</div>
<div data-color="lch-red">lch()</div>
<div data-color="oklch-red">oklch()</div>
```

CSS

```
[data-color="hsl-red"] {
  /* hsl(<hue> <saturation> <lightness>) */
  background-color: hsl(0 100% 50%);
}
[data-color="hwb-red"] {
  /* hwb(<hue> <whiteness> <blackness>) */
  background-color: hwb(0 0% 0%);
}
[data-color="lch-red"] {
  /* lch(<lightness> <chroma> <hue>) */
  background-color: lch(50 150 40);
}
[data-color="oklch-red"] {
  /* oklch(<lightness> <chroma> <hue>) */
  background-color: oklch(0.6 0.4 20);
}
```

```
div {
  font-family: monospace;
  width: 100px;
  height: 100px;
  margin: 10px;
  border: 1px solid black;
  display: inline-block;
}
```

`<hue-interpolation-method>` CSS type

The **`<hue-interpolation-method>`** CSS data type represents the algorithm used for interpolation between `<hue>` values. The interpolation method specifies how to find a midpoint between two hue values based on a color wheel. It is used as a component of the `<color-interpolation-method>` data type.

When interpolating `<hue>` values, the hue interpolation algorithm defaults to `shorter`.

Syntax

A `<hue-interpolation-method>` value consists of the name of a hue interpolation algorithm followed by a literal token `hue`:

```
shorter hue
longer hue
increasing hue
decreasing hue
```

Values

Any pair of hue angles correspond to two radii on the color wheel, which cut the circumference into two possible arcs for interpolation. Both arcs start at the first radius and end at the second radius, but one goes clockwise and the other goes counterclockwise.

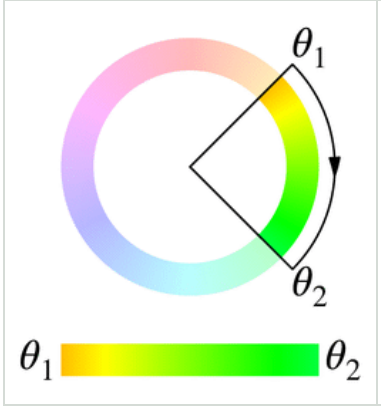
> **Note:** The following descriptions and illustrations are based on color wheels in which hue angles increase in a clockwise direction. Be aware that there are color wheels where an increase in angles will be a counterclockwise operation.

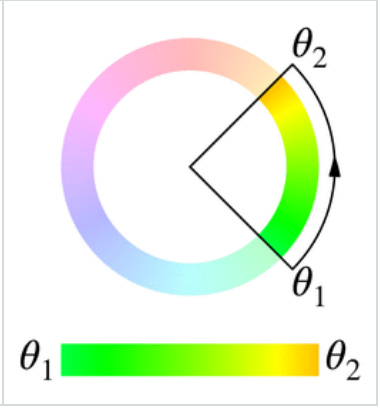
For a pair of hue angles `θ1` and `θ2` normalized to the range `[0deg, 360deg)`, there are four algorithms to determine which arc is used when interpolating from `θ1` to `θ2`:

`shorter`

Use the shorter arc. When the two radii coincide, the arc degenerates to a single point. When both arcs have the same lengths:

- If `θ1 < θ2`, use the clockwise arc;
- If `θ1 > θ2`, use the counterclockwise arc.

θ1 = 45deg, θ2 = 135deg	**θ1 = 135deg, θ2 = 45deg**
	




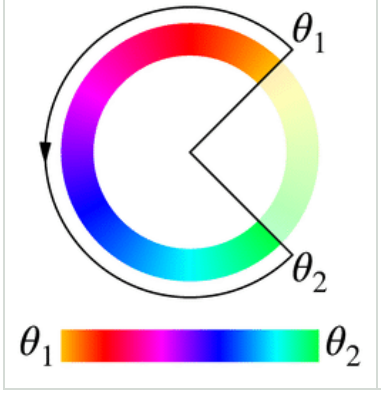
`longer`

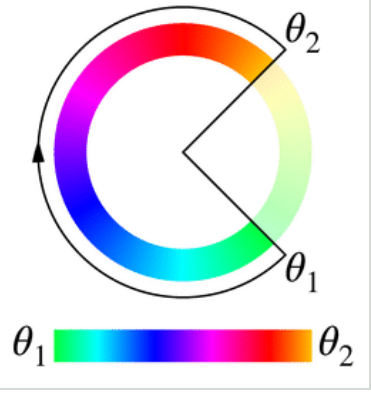
Use the longer arc. When the two radii coincide:

- If `θ1 ≤ θ2`, the arc becomes the full circumference with a clockwise orientation.
- If `θ1 > θ2`, the arc becomes the full circumference with a counterclockwise orientation.

When both arcs have the same lengths:

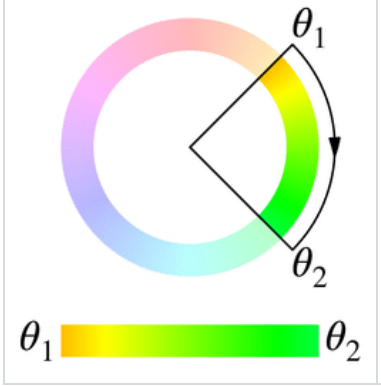
- If `θ1 < θ2`, use the clockwise arc;
- If `θ1 > θ2`, use the counterclockwise arc.

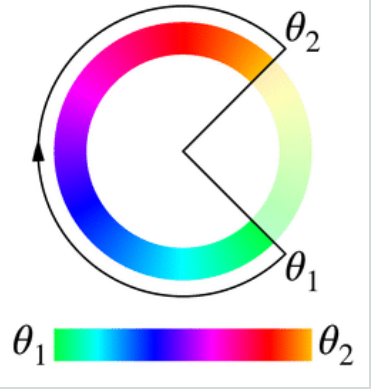
θ1 = 45deg, θ2 = 135deg	θ1 = 135deg, θ2 = 45deg
	




`increasing`

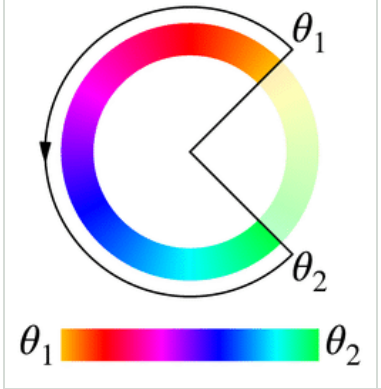
Use the clockwise arc. When the two radii coincide, the arc degenerates to a single point.

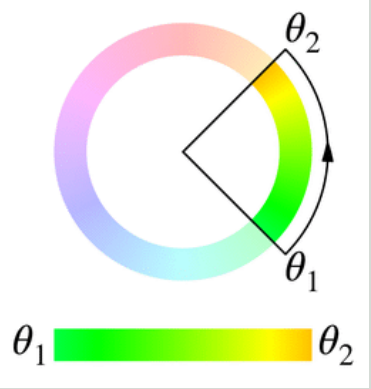
θ1 = 45deg, θ2 = 135deg	θ1 = 135deg, θ2 = 45deg
	




`decreasing`

Use the counterclockwise arc. When the two radii coincide, the arc degenerates to a single point.

θ1 = 45deg, θ2 = 135deg	θ1 = 135deg, θ2 = 45deg
	




As there are only two arcs to choose from, these algorithms are pairwise equivalent under certain circumstances. Specifically:

- If `0deg < θ2 - θ1 < 180deg` or `θ2 - θ1 < -180deg`, `shorter` and `increasing` are equivalent, whereas `longer` and `decreasing` are equivalent.
- If `-180deg < θ2 - θ1 < 0deg` or `θ2 - θ1 > 180deg`, `shorter` and `decreasing` are equivalent, whereas `longer` and `increasing` are equivalent.

A notable feature of `increasing` and `decreasing` is that when the hue angle difference passes through `180deg` during transition or animation, the arc will not flip to the other side like `shorter` and `longer` do.

Formal syntax

```
<hue-interpolation-method> =
  [ shorter | longer | increasing | decreasing ] hue
```

This syntax reflects the latest standard as per CSS Color Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Comparing hue interpolation algorithms

The following example shows the effect of using different hue interpolation algorithms in a `linear-gradient()`.

HTML

```
<div class="hsl">
  <p>HSL</p>
</div>
<div class="hsl-increasing">
```

```
  <p>HSL increasing</p>
</div>
<div class="hsl-decreasing">
  <p>HSL decreasing</p>
</div>
<div class="hsl-shorter">
  <p>HSL shorter</p>
</div>
<div class="hsl-longer">
  <p>HSL longer</p>
</div>
<div class="hsl-named">
  <p>HSL named</p>
</div>
<div class="hsl-named-longer">
  <p>HSL named (longer)</p>
</div>
```

CSS

```
div {
  border: 1px solid black;
  height: 50px;
  margin: 10px;
  width: 90%;
}
p {
  color: white;
  margin: 6px;
}

/* Fallback styles */
.hsl,
.hsl-shorter,
.hsl-named {
  background: linear-gradient(
    to right,
    hsl(39 100% 50%),
    hsl(46 100% 50%),
    hsl(53 100% 50%),
    hsl(60 100% 50%)
  );
}
.hsl-increasing {
  background: linear-gradient(
    to right,
    hsl(190 100% 50%),
    hsl(225 100% 50%),
    hsl(260 100% 50%),
    hsl(295 100% 50%),
    hsl(330 100% 50%),
    hsl(365 100% 50%),
    hsl(400 100% 50%),
    hsl(435 100% 50%),
    hsl(470 100% 50%),
    hsl(505 100% 50%),
    hsl(540 100% 50%)
  );
}
.hsl-decreasing,
.hsl-longer,
.hsl-named-longer {
  background: linear-gradient(
    to right,
    hsl(399 100% 50%),
    hsl(368 100% 50%),
    hsl(337 100% 50%),
    hsl(307 100% 50%),
    hsl(276 100% 50%),
    hsl(245 100% 50%),
    hsl(214 100% 50%),
    hsl(183 100% 50%),
    hsl(152 100% 50%),
    hsl(122 100% 50%),
    hsl(91 100% 50%),
    hsl(60 100% 50%)
  );
}
```

```
.hsl {
  background: linear-gradient(
    to right in hsl,
    hsl(39deg 100% 50%),
    hsl(60deg 100% 50%)
  );
}
.hsl-increasing {
  background: linear-gradient(
    to right in hsl increasing hue,
    hsl(190deg 100% 50%),
    hsl(180deg 100% 50%)
  );
}
.hsl-decreasing {
  background: linear-gradient(
    to right in hsl decreasing hue,
    hsl(39deg 100% 50%),
    hsl(60deg 100% 50%)
  );
}
.hsl-shorter {
  background: linear-gradient(
```

```
    to right in hsl shorter hue,
    hsl(39deg 100% 50%),
    hsl(60deg 100% 50%)
  );
}
.hsl-longer {
  background: linear-gradient(
    to right in hsl longer hue,
    hsl(39deg 100% 50%),
    hsl(60deg 100% 50%)
  );
}
.hsl-named {
  background: linear-gradient(to right in hsl, orange, yellow);
}
.hsl-named-longer {
  background: linear-gradient(to right in hsl longer hue, orange, yellow);
}
```

hypot() CSS function

The **`hypot()`** CSS function is an exponential function that returns the square root of the sum of squares of its parameters.

While `pow()` and `sqrt()` only work on unitless numbers, `hypot()` accepts values with units, but they all must have the same type.

Syntax

```
/* A <number> value */
width: hypot(2em); /* 2em */
width: hypot(3em, 4em); /* 5em */
width: hypot(30px, 40px); /* 50px */
width: hypot(48px, 64px); /* 80px */
width: hypot(3px, 4px, 5px); /* 7.0710678118654755px */
```

Parameters

The `hypot(x [, ...]#)` function accepts one or more comma-separated calculations as its parameters.

`x, x2, ..., xN`

A calculation that resolves to a `<number>`, `<dimension>`, or `<percentage>`.

Return value

Returns a `<number>`, `<dimension>`, or `<percentage>` (based on the inputs), which is the square root of the sum of squares of its parameters.

- If any of the inputs is `infinite`, the result is `+∞`.
- If a single parameter is provided, the result is the absolute value of its input. `hypot(2em)` and `hypot(-2em)` both resolve to `2em`.

Formal syntax

```
<hypot()> =
  hypot( <calc-sum># )

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>       |
  <dimension>    |
  <percentage>   |
  <calc-keyword> |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Sizes based on hypot function

This example shows how you can use the `hypot()` function to calculate sizes.

HTML

```
<div class="boxes">
  <div class="box">100px</div>
  <div class="box one">100px</div>
  <div class="box two">141.42px</div>
  <div class="box three">250px</div>
</div>
```

CSS

Here we are using CSS custom properties to define the sizes to be used. First we declare the first size (`--size-0`) which is then used to calculate the other sizes.

- `--size-1` is calculated with the hypotenuse of `--size-0` (100px). This takes the square value and, as there is no other value, returns the square root of the value, which results in 100px.
- `--size-2` is calculated with the hypotenuse of `--size-0` (100px), twice. This takes the square of the value (100px * 100px = 10000px^2) and adds it to the square of `--size-0` again (10000px^2 + 10000px^2 = 20000px^2) and returns the square root of the sum (√(20000px^2)), which results in 141.42px.
- `--size-3` is calculated with the hypotenuse `--size-0` * 1.5 (150px) and `--size-0` * 2 (200px). The result is the square root of the sum of their squares: The values are squared (22500px^2 and 40000px^2) and added together (62500px^2), with the sum square-rooted (√(62500px^2)) being 250px.

```
:root {
  --size-0: 100px;
  --size-1: hypot(var(--size-0)); /*  100px */
  --size-2: hypot(var(--size-0), var(--size-0)); /*  141.42px */
  --size-3: hypot(
    calc(var(--size-0) * 1.5),
    calc(var(--size-0) * 2)
  ); /*  250px */
}
```

```
.boxes {
  display: flex;
  flex-wrap: wrap;
  justify-content: space-around;
}

.box {
  width: var(--size-0);
  height: var(--size-0);
  background-color: tomato;
  color: white;
  display: flex;
  align-items: center;
  justify-content: center;
}
```

The sizes are then applied as the `width` and `height` values of the selectors.

```
.one {
  width: var(--size-1);
  height: var(--size-1);
}
.two {
  width: var(--size-2);
  height: var(--size-2);
}
.three {
  width: var(--size-3);
  height: var(--size-3);
}
```

<ident> CSS type

The **`<ident>`** CSS data type denotes an arbitrary unquoted string of characters used as an identifier.

Syntax

A CSS identifier consists of one or more characters, which can be any of the following:

- any ASCII character in the ranges `A-Z` and `a-z`
- any decimal digit (`0` to `9`)
- a hyphen (`-`)
- an underscore (`_`)
- any other Unicode character `U+00A0` and higher (that is, any other non-ASCII Unicode character)
- an escaped character

Additionally, an identifier must not start with an unescaped digit, and must not start with an unescaped hyphen followed by an unescaped digit.

Note that `id1`, `Id1`, `iD1` and `ID1` are all different identifiers because they are case-sensitive. On the other hand, since there are several ways to escape a character, `toto\?` and `toto\3F` are the same identifiers.

Escaping characters

Escaping a character means representing it in a way that changes how it is interpreted by a software system. In CSS, you can escape a character by adding a backslash (`\`) in front of the character. Any character, except the hexadecimal digits `0-9`, `a-f`, and `A-F`, can be escaped in this way. For example, `&` can be escaped as `\&`.

You can also escape any character with a backslash followed by the character's Unicode code point represented by one to six hexadecimal digits. For example, `&` can be escaped as `\26`. In this usage, if the escaped character is followed by a hexadecimal digit, do one of the following:

- Place a space or other whitespace character after the Unicode code point.
- Provide the full six-digit Unicode code point of the character being escaped.

For example, the string `&123` can be escaped as `\26 123` (with a whitespace) or `\000026123` (with the six-digit Unicode code point for `&`) to ensure that `123` is not considered as part of the escape pattern.

Examples

Valid identifiers

```
nono79        /* A mix of alphanumeric characters and numbers */
ground-level  /* A mix of alphanumeric characters and a dash */
-test         /* A hyphen followed by alphanumeric characters */
--toto        /* A custom-property like identifier */
_internal     /* An underscore followed by alphanumeric characters */
```

```
\22 toto      /* An escaped character followed by alphanumeric characters */
\000022toto   /* Same as the previous example */
scooby\.doo   /* A correctly escaped period */
🔥123         /* A non-ASCII character followed by numbers */
```

Invalid identifiers

```
34rem     /* Must not start with a decimal digit */
-12rad    /* Must not start with a dash followed by a decimal digit */
scooby.doo  /* ASCII characters apart from alphanumerics must be escaped */
'scoobyDoo' /* Treated as a string */
"scoobyDoo" /* Treated as a string */
```

Browser compatibility

As this type is not a real type but a convenience type used to simplify the definition of other CSS syntax, there is no browser compatibility information as such.

if() CSS function

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`if()`** CSS function allows different values to be set for a property depending on the result of a conditional test. The test can be based on a style query, a media query, or a feature query.

Syntax

```
/* Single <if-test> */
if(style(--scheme: dark): #eeeeee;)
if(media(print): black;)
if(media(width > 700px): 0 auto;)
if(supports(color: lch(7.1% 60.23 300.16)): lch(7.1% 60.23 300.16);)

/* <if-test> with else */
if(style(--size: "2xl"): 1em; else: 0.25em;)
if(media(print): white; else: black;)
if(media(width < 700px): 0 auto; else: 20px auto)
if(
  supports(color: lch(7.1% 60.23 300.16)): lch(7.1% 60.23 300.16);
  else: #03045e;
)
if(
  supports(color: lch(75% 0 0)): 3px solid lch(75% 0 0);
  else: 3px solid silver;
)

/* Multiple <if-test>s */
if(
  style(--scheme: ice): linear-gradient(#caf0f8, white, #caf0f8);
  style(--scheme: fire): linear-gradient(#ffc971, white, #ffc971);
  else: none;
)

/* <if-test> within a shorthand */
3px yellow if(
  style(--color: green): dashed;
  style(--color: yellow): inset;
  else: solid;
)
```

Parameters

The parameter is a semi-colon–separated list of `<if-branch>`es. Each `<if-branch>` is an `<if-condition>` followed by a colon and a `<value>`:

```
<if-branch> = <if-condition> : <value>;
```

`<if-condition>`

An `<if-test>` or the `else` keyword.

`<if-test>`

A style query, media query, or feature query.

`else`

A keyword representing an `<if-condition>` that always evaluates to true.

`<value>`

A property value.

Return value

A value or guaranteed-invalid.

Description

The CSS `if()` function provides conditional logic to CSS property values, and works in a similar fashion to JavaScript `if...else` statements.

The `if()` function can be used inside the value of any property, and can contain zero or more semi-colon-separated `<if-condition>`s. Each `<if-condition>` is either an `<if-test> : <value>` pair or an `else : <value>` pair. The semi-colon after the last `<if-condition>` is optional.

The return value is calculated as follows:

1. The `<if-condition>` expressions are evaluated, in the order they appear in the function.
2. The first `<if-condition>` that evaluates to `true` has its associated `<value>` returned.
3. If no `<if-condition>` evaluates to `true`, the function returns a <guaranteed-invalid>:. This behaves as invalid or `false` if the `if()` function is used in a value statement that has a fallback, such as a custom property or an `anchor()` function.

For example:

```
div {
  background-image: if(
    style(--scheme: ice): linear-gradient(#caf0f8, white, #caf0f8);
    style(--scheme: fire): linear-gradient(#ffc971, white, #ffc971);
    else: none;
  );
}
```

In this case, we are setting a different `linear-gradient()` as the `background-image` on `<div>` elements, depending on whether a `--scheme` custom property is set to `ice` or `fire`. If `--scheme` doesn't exist, or it exists and is set to any other value, the `else` value comes into play, and the `background-image` property is set to `none`.

> **Note:** Each condition must be separated from its associated value with a colon, and each `<if-condition> : <value>` pair must be separated with a semi-colon. The semi-colon is optional for the last `<if-condition> : <value>` pair.

> **Warning:** There must be no space between the `if` and the opening parenthesis (`(`). If there is, the whole declaration is invalid.

If a single `<if-condition>` or `<value>` is invalid, it does not invalidate the entire `if()` function; instead, the parser moves on to the next `<if-condition> : <value>` pair. If no `<if-condition>` nor `<value>` is valid, the function returns guaranteed-invalid.

Frequency and position of <code>else : <value></code> pairs

You can include multiple `else : <value>` pairs inside an `if()` function, in any position. However, in most cases, a single `else : <value>` pair at the end of the semi-colon-separated list is used to provide the default value that is always returned if none of the `<if-test>`s evaluate to true.

If you include an `else : <value>` pair before any `<if-test> : <value>` pairs, the conditions that follow it are not evaluated because `else` always evaluates to `true`. The following `if()` therefore always returns `none`, and the two `<if-test> : <value>` pairs are never evaluated:

```
div {
  background-image: if(
    else: none;
    style(--scheme: ice): linear-gradient(#caf0f8, white, #caf0f8);
    style(--scheme: fire): linear-gradient(#ffc971, white, #ffc971)
  );
}
```

Debugging a value that is not behaving as expected is one case where you might want to put an `else : <value>` in a position other than the end of the value list. In the following example, we are trying to work out whether the first `<if-test> : <value>` pair is working properly. If it isn't, the `else : <value>` pair returns a value of `url("debug.png")` to display an image indicating that the first `<if-test> : <value>` pair needs fixing. The last two `<if-test> : <value>` pairs are again never evaluated.

```
div {
  background-image: if(
    style(--scheme: ice): linear-gradient(#caf0f8, white, #caf0f8);
    else: url("debug.png");
    style(--scheme: fire): linear-gradient(#ffc971, white, #ffc971);
    else: none;
  );
}
```

Note that an `if()` function is still valid if it contains only an `else : <value>` pair, or nothing at all. The following property values are both valid:

```
background-color: if(else: yellow);
background-image: if();
```

These functions are not useful. They were included to demonstrate their validity. In this case, the `background-color` value will always be set to `yellow` and the `background-image` will be set to its initial value. You would be better off setting the `background-color` directly to `yellow`, and the `background-image` to `initial` or `none`.

Types of if-tests

An `<if-test>` accepts one of three query types. This section looks at each one in detail.

Style queries

A style query `<if-test>` allows you to test whether a particular property value is set on an element, and apply a value to a different property as a result. We walked through several style query examples earlier on; let's look at another example:

```
background-image: if(
  style(--scheme: ice): linear-gradient(#caf0f8, white, #caf0f8);
  else: none;
);
```

If the `--scheme` custom property is set to a value of `ice` on the same element, the provided `linear-gradient()` value is returned. If not, then `none` is returned.

Using style queries inside `if()` statements has an advantage over `@container` queries — you can target an element with styles directly, based on whether a custom property is set on it, rather than having to check set styles on a container parent element.

You can also use `and`, `or`, or `not` logic inside style queries. For example:

```
background-color: if(
  style((--scheme: dark) or (--scheme: very-dark)): black;
);

background-color: if(
  style((--scheme: dark) and (--contrast: hi)): black;
);

background-color: if(
```

```
  not style(--scheme: light): black;
);
```

A `@container` query does have some advantages — you can only set single property values at a time with `if()` style queries, whereas `@container` queries can be used to conditionally apply whole sets of rules. The two approaches are complementary, and have different uses.

Note that container style queries currently don't support regular CSS properties, just CSS custom properties. For example, the following won't work:

```
if(
  background-color: if(style(color: white): black;);
)
```

Media queries

A media query `<if-test>` can be used to set a value for a property depending on whether a media query test returns true.

You can use media types. For example, the following `<if-test> : <value>` pair returns a value of `white` on print media, while the `else` clause causes `#eeeeee` to be returned on non-print media.

```
background-color: if(
  media(print): white;
  else: #eeeeee;
)
```

You can also use media features — the following returns a value of `0 auto` if the current viewport width is less than `700px`, or `20px auto` if this is not the case:

```
margin: if(
  media(width < 700px): 0 auto;
  else: 20px auto;
)
```

This is really useful when you need to vary a single property value based on a media query result.

You can also use `and`, `or`, or `not` logic inside media queries. For example:

```
border-color: if(
  media((width > 700px) and (width < 1000px)): blue;
);

border-color: if(
  media((width < 500px) or (orientation: landscape)): blue;
);

background-color: if(
  not media(width < 500px): blue;
  else: red
);
```

When you want to set multiple declarations or rules based on one media query, a regular `@media` construct is needed. The two approaches are complementary, and have different uses.

Feature queries

A feature query `<if-test>` can be used to set a value for a property depending on whether the browser supports a particular property value.

For example, the following returns an `lch()` color if `lch()` colors are supported, or an `rgb()` color if not:

```
color: if(
  supports(color: lch(75% 0 0)): lch(75% 0 0);
  else: rgb(185 185 185);
)
```

Selector support queries also work. The following will return a value of `1em` if the browser supports the `:buffering` pseudo-class, or `initial` if not:

```
margin-top: if(
  supports(selector(:buffering)): 1em;
  else: initial;
)
```

You can also use `and`, `or`, or `not` logic inside feature queries. For example:

```
margin-top: if(
  supports((selector(:buffering)) and (color: blue)): 1em;
);

margin-top: if(
  supports((selector(:buffering)) or (color: not-a-color)): 1em;
);

margin-top: if(
  supports(not selector(:buffering)): 1em;
);
```

Feature queries are really useful inside `if()` statements when you need to vary a single property value based on support for a particular value or a separate property. When you want to set multiple declarations or rules based on one feature query, a regular `@supports` construct is better. The two approaches are complementary, and have different uses.

Providing fallback values

The `if()` statement does not gracefully degrade; an explicit fallback needs to be provided for non-supporting browsers.

For example, in this case we provide a static `padding` value for browsers that don't support `if()`. Browsers that support `if()` will override the first declaration with the second one, which sets different padding values depending on whether or not the `--size: "2xl"` custom property is set.

```
padding: 1em;
padding: if(style(--size: "2xl"): 1em; else: 0.25em);
```

> **Note:** Remember to include the `else` condition. In `if()`-supporting browsers, if no `else` value were included and `--size` was not equal to `"2xl"`, the padding would be set to `initial`.

Whole and partial values

An `if()` function can be set as the value of any CSS property, but it can also be used to determine parts of property values. For example, the following sets a different `border-color` inside a `border` shorthand property, depending on whether `lch()` colors are supported:

```
border: if(
  supports(color: lch(75% 0 0)): 3px solid lch(75% 0 0);
  else: 3px solid silver;
);
```

However, we could use the `if()` function to determine the `border-color` component only:

```
border: 3px solid
  if(
    supports(color: lch(75% 0 0)): lch(75% 0 0); else: silver;
  );
```

Nesting if() functions

Because an `if()` function can take the place of whole property values or individual components, it is possible to nest `if()` functions within other `if()` functions, and inside other functions such as `calc()`.

For example, in this declaration we are using `if()` to set a `color` property value depending on various conditions. We have an outer `if()` function that returns a particular value depending on whether the `--scheme` custom property is set to `ice` or `fire` (with an `else` value of `black` that is returned if neither of the conditions return true).

However, the two `<value>`s are also `if()` functions. These inner `if()` functions return a light color value if the user prefers a dark color scheme (determined using the `prefers-color-scheme` media query), and a dark color value otherwise.

```
color: if(
  style(--scheme: ice):
    if(
      media(prefers-color-scheme: dark): #caf0f8;
      else: #03045e;
    );
  style(--scheme: fire):
    if(
      media(prefers-color-scheme: dark): #ffc971;
      else: #621708;
    );
  else: black
);
```

In the next example, we set the `width` property equal to a `calc()` function that subtracts `50px` from a percentage of the parent element's width. The percentage is represented by an `if()` function, which test whether the `--scheme: wide` custom property is set. If so, the percentage is `70%`, so the outer function resolves to `calc(70% - 50px)`. If not, the percentage is `50%`, so the outer function resolves to `calc(50% - 50px)`.

```
width: calc(if(
    style(--scheme: wide): 70%;
    else: 50%;
  ) - 50px);
```

Formal syntax

```
<if()> =
  if( [ <if-branch> ; ]* <if-branch> ;? )

Examples

Basic <code>if()</code> usage

In this example, we'll show basic usage of each of the three types of `<if-test>`.

HTML

Our HTML features a `<section>` element with two `<article>` elements inside it, containing `<h2>` headings. The `<section>` has a custom property set on it inside its `style` attribute — `--show-apple:true` — which we use later on to conditionally set a property value.

```
<section style="--show-apple:true">
  <article><h2>First article</h2></article>
  <article><h2>Second article</h2></article>
</section>
```

CSS

In our CSS, we first target the `<section>` element, laying it out with flexbox and setting a `gap` between the two child `<article>` elements. We then use an `if()` function with an `orientation` media query `<if-test>` to set the value of the `flex-direction` property to `row` if the document is in landscape orientation, or `column` if it is in portrait orientation. This lays out the `article` elements side-by-side in wide screens, and top-to-bottom in narrow screens.

```
html {
  height: 100%;
  font-family: sans-serif;
}

body,
section {
  height: inherit;
}

h2 {
  text-align: center;
}

article {
  background-color: cyan;
  border: 3px solid gray;
  flex: 1;
}
```

```
section {
  display: flex;
  gap: 16px;
  flex-direction: if(
    media(orientation: landscape): row;
    else: column;
  )
}
```

Next, we target the `<h2>` element's `::before` pseudo-element, setting its `content` property to an apple emoji, but only if `--show-apple: true` is set (we did this earlier with an inline `<style>` in our HTML). We achieve this using an `if()` function with a style query `<if-test>`:

```
h2::before {
  content: if(
    style(--show-apple: true): "🍎 ";
  );
}
```

Finally, we target the `<h2>` element itself. We use a feature query `<if-test>` to test whether the browser supports `lch()` colors, and set the `color` property to an `lch()` color if so, or a hex equivalent if not.

```
h2 {
  color: if(
    supports(color: lch(29.57% 43.25 344.44)): lch(29.57% 43.25 344.44);
    else: #792359;
  )
}
```

Result

Note how the styling is applied. Test out the conditional styling for the first two `if()` queries by modifying the rendered demo using your browser's devtools:

- Remove the `<section>` element's `style` attribute and note how the apple emojis are no longer rendered.
- Change the `height` attribute of the embedding `<iframe>` to `1200px`. This will change the orientation from landscape to portrait. Note how the layout changes as a result.

Controlling a color scheme with <code>if()</code>

This demo shows how you can start to have some real fun with CSS `if()` functions. Among other things, we use `if()` functions to conditionally set the values of some custom properties, enabling us to control the entire color scheme!

HTML

Our HTML contains an `<article>` element with some content inside it — a top-level heading, a couple of `<p>` elements, and an `<aside>`. We also include a `<form>` containing a `<select>` drop-down that enables selecting a color scheme.

```
<article>
  <h1>Main heading</h1>
  <p>
    Lorem ipsum dolor sit amet consectetur adipiscing elit.
    Quisque faucibus ex sapien vitae pellentesque sem placerat.
    In id cursus mi pretium tellus duis convallis.
  </p>
  <aside>
    <h2>An aside</h2>
    <p>
      Tempus leo eu aenean sed diam urna tempor. Pulvinar vivamus
      fringilla lacus nec metus bibendum egestas.
    </p>
  </aside>
  <p>
    Iaculis massa nisl malesuada lacinia integer nunc posuere. Ut
    hendrerit semper vel class aptent taciti sociosqu. Ad litora
    torquent per conubia nostra inceptos himenaeos.
  </p>
</article>
<form>
  <label for="scheme">Choose color scheme:</label>
  <select id="scheme">
    <option value="">Default</option>
    <option value="ice">Ice</option>
    <option value="fire">Fire</option>
  </select>
</form>
```

JavaScript

Our JavaScript adds a `change` event listener to the `<select>` element. When a new value is selected, our script sets the `<article>` element's `class` attribute to equal that value.

```
const articleElem = document.querySelector("article");
const selectElem = document.querySelector("select");

selectElem.addEventListener("change", () => {
  articleElem.className = selectElem.value;
});
```

CSS

In our CSS, we give the `<body>` element a `max-width` of `700px` and center it using `auto` `margin` values. However, we use an `if()` function with a media query `<if-test>` to set the `margin-top` component inside the `margin` shorthand to `0` if the viewport's width is less than `700px`, and `20px` if it is wider. This means that on wide screens we get a bit of margin at the top of the content, but this is removed on narrow screens, where it looks a bit weird.

```
* {
  box-sizing: border-box;
}

html {
  font-family: "Helvetica", "Arial", sans-serif;
}

p {
  line-height: 1.5;
}

form {
  padding-left: 20px;
  margin-top: 20px;
}

article h2 {
  margin: 0;
  font-size: 1.8rem;
}
```

```
body {
  max-width: 700px;
  margin: if(
    media(width < 700px): 0;
    else: 20px;
  ) auto 0;
}
```

We then set the `--scheme` custom property to match the `<article>` element's `class` name. The class will be set by our JavaScript when a new value is selected in our `<select>` element. You'll see the significance of the custom element value in the next CSS block.

```
.ice {
  --scheme: ice;
}

.fire {
  --scheme: fire;
}
```

We can see the real power of CSS `if()` functions when we combine them with custom properties. Here we use `if()` functions to set our `--color1` and `--color2` custom properties to different color values depending on the value of the `--scheme` custom property. We then use the `--color1` and `--color2` values in our `<article>` element's `color`, `border`, and `background-image` properties, and our `<aside>` element's `color` and `background-color` properties.

We are controlling our entire color scheme via custom properties, with different values set via `if()` functions.

```
article {
  padding: 20px;
  --color1: if(
    style(--scheme: ice): #03045e;
    style(--scheme: fire): #621708;
    else: black;
  );
  --color2: if(
    style(--scheme: ice): #caf0f8;
    style(--scheme: fire): #ffc971;
    else: white;
  );

  color: var(--color1);
  border: 3px solid var(--color1);
  background-image: linear-gradient(
    to left,
    var(--color2),
    white,
    var(--color2)
  );
}

aside {
  color: var(--color2);
  background-color: var(--color1);
  padding: 20px;
}
```

Finally, we use `if()` functions in a couple more places:

- We set our `<h1>` element's `font-size` to be `calc(3rem + 2vw)` if the viewport is wider than `700px`, and `3rem` otherwise. This means the font size updates dynamically with viewport width changes on wider screens, but stays the same on narrow screens.
- We set a suitable emoji as the `content` of our `<h1>` element's `::before` pseudo-class, depending on the value of the `--scheme` custom property.

```
h1 {
  margin: 0;
  font-size: if(
    media(width > 700px): calc(3rem + 2vw);
    else: 3rem;
  );
}

h1::before {
  content: if(
    style(--scheme: ice): "❄️ ";
    style(--scheme: fire): "🔥 ";
    else: "";
  );
}
```

Result

This demo renders as follows:

Try selecting different color scheme values to see the effect on the look and feel.

<image> CSS type

The **`<image>`** CSS data type represents a two-dimensional image.

Syntax

The `<image>` data type can be represented with any of the following:

- An image denoted by the `<url>` data type
- A `<gradient>` data type
- A part of the webpage, defined by the `element()` function
- An image, image fragment or solid patch of color, defined by the `image()` function
- A blending of two or more images defined by the `cross-fade()` function.
- A selection of images chosen based on resolution defined by the `image-set()` function.
- Generated by a paint worklet with the `paint()` function.

Description

CSS can handle the following kinds of images:

- Images with *intrinsic dimensions* (a natural size), like a JPEG, PNG, or other raster format.
- Images with *multiple intrinsic dimensions*, existing in multiple versions inside a single file, like some .ico formats. (In this case, the intrinsic dimensions will be those of the image largest in area and the aspect ratio most similar to the containing box.)
- Images with no intrinsic dimensions but with *an intrinsic aspect ratio* between its width and height, like an SVG or other vector format.
- Images with *neither intrinsic dimensions, nor an intrinsic aspect ratio*, like a CSS gradient.

Concrete size

CSS determines an object's *concrete size* using (1) its *intrinsic dimensions*; (2) its *specified size*, defined by CSS properties like `width`, `height`, or `background-size`; and (3) its *default size*, determined by the kind of property the image is used with:

Kind of Object (CSS Property)	Default object size
`background-image`	The size of the element's background positioning area
`list-style-image`	The size of a `1em` character
`border-image-source`	The size of the element's border image area
`cursor`	The browser-defined size matching the usual cursor size on the client's system
`mask-image`	?
`shape-outside`	?
`mask-border-source`	?
`symbols()` for @counter-style	At risk feature. If supported, the browser-defined size matching the usual cursor size on the client's system
`content` for a pseudo-element (`::after`/`::before`)	A 300px × 150px rectangle

The concrete object size is calculated using the following algorithm:

- If the specified size defines *both the width and the height*, these values are used as the concrete object size.
- If the specified size defines *only the width or only the height*, the missing value is determined using the intrinsic ratio, if there is any, the intrinsic dimensions if the specified value matches, or the default object size for that missing value.
- If the specified size defines *neither the width nor the height*, the concrete object size is calculated so that it matches the intrinsic aspect ratio of the image but without exceeding the default object size in any dimension. If the image has no intrinsic aspect ratio, the intrinsic aspect ratio of the object it applies to is used; if this object has none, the missing width or height are taken from the default object size.

> **Note:** Not all browsers support every type of image on every property. See the browser compatibility section for details.

Accessibility

Browsers do not provide any special information on background images to assistive technology. This is important primarily for screen readers, as a screen reader will not announce its presence and therefore convey nothing to its users. If the image contains information critical to understanding the page's overall purpose, it is better to describe it semantically in the document.

Formal syntax

```
<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
  <gradient>

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-set()> =
  image-set( <image-set-option># )

<cross-fade()> =
  cross-fade( <cf-image># )

<element()> =
  element( <id-selector> )

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Images Module Level 4, CSS Images Module Level 5, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Valid images

```
url("test.jpg")               /* A <url>, as long as test.jpg is an actual image */
linear-gradient(blue, red)  /* A <gradient> */
element(#real-id)            /* A part of the webpage, referenced with the element() function,
                                if "real-id" is an existing ID on the page */
image(ltr "arrow.png#xywh=0,0,16,16", red)
                            /* A section 16x16 section of <url>, starting from the top, left of the original
                               image as long as arrow.png is a supported image, otherwise a solid
                               red swatch. If language is rtl, the image will be horizontally flipped. */
cross-fade(20% url("twenty.png"), url("eighty.png"))
                            /* cross faded images, with twenty being 20% opaque
                               and eighty being 80% opaque. */
image-set("test.jpg' 1x, 'test-2x.jpg" 2x)
                            /* a selection of images with varying resolutions */
```

Invalid images

```
"no-url.jpg"           /* An image file must be defined using the url() function. */
url("report.pdf")      /* A file pointed to by the url() function must be an image. */
element(#fakeid)     /* An element ID must be an existing ID on the page. */
image(z.jpg#xy=0,0)  /* The spatial fragment must be written in the format of xywh=#,#,#,# */
image-set("cat.jpg" 1x, "dog.jpg" 1x) /* every image in an image set must have a different resolution */
```

image() CSS function

The **`image()`** CSS function defines an `<image>` in a similar fashion to the `url()` function, but with added functionality including specifying the image's directionality, displaying just a part of that image defined by a media fragment, and specifying a solid color as a fallback in case none of the specified images are able to be rendered.

> **Note:** The CSS `image()` function should not be confused with `Image()`, the `HTMLImageElement` constructor.

Syntax

```
/* Basic usage */
image("image1.jpg");
image(url("image2.jpg"));

/* Bidi-sensitive Images */
image(ltr "image1.jpg");
image(rtl "image1.jpg");

/* Image Fallbacks */
image("image1.jpg", black);

/* Image Fragments */
image("image1.jpg#xywh=40,0,20,20");
```

```
/* Solid-color Images */
image(rgb(0 0 255 / 0.5)), url("bg-image.png");
```

Values

`image-tags` Optional

The directionality of the image, either `ltr` for left-to-right or `rtl` for right-to-left.

`image-src` Optional

Zero or more `<url>`s or `<string>`s specifying the image sources, with optional image fragment identifiers.

`color` Optional

A color, specifying a solid background color to use as a fallback if no `image-src` is found, supported, or declared.

Bi-directional awareness

The first, optional parameter of the `image()` notation is the directionality of the image. If included, and the image is used on an element with opposite directionality, the image will be flipped horizontally in horizontal writing modes. If the directionality is omitted, the image won't be flipped if the language direction is changed.

Image fragments

One key difference between `url()` and `image()` is the ability to add a media fragment identifier — a starting point along the x and y axis, along with a width and height — onto the image source to display only a section of the source image. The section of the image defined in the parameter becomes a standalone image. The syntax looks like so:

```
background-image: image("my-image.webp#xywh=0,20,40,60");
```

The background image of the element will be the portion of the image *myImage.webp* that starts at the coordinate 0px, 20px (the top left-hand corner) and is 40px wide and 60px tall.

The `#xywh=#,#,#,#` media fragment syntax takes four comma separated numeric values. The first two represent the X and Y coordinates for the starting point of the box that will be created. The third value is the width of the box, and the last value is the height. By default, these are pixel values. The spatial dimension definition in the media specification indicates that percentages will be supported as well:

```
xywh=160,120,320,240        /* results in a 320x240 image at x=160 and y=120 */
xywh=pixel:160,120,320,240  /* results in a 320x240 image at x=160 and y=120 */
xywh=percent:25,25,50,50    /* results in a 50%x50% image at x=25% and y=25% */
```

The image fragments can be used in `url()` notation as well. The `#xywh=#,#,#,#` media fragment syntax is 'backwards compatible' in that a media fragment will be ignored if not understood, and won't break the source call when used with `url()`. If the browser doesn't understand the media fragments notation, it ignores the fragment, displaying the entire image.

Browsers that understand `image()` also understand the fragment notation. Therefore, if the fragment is not understood within `image()`, the image will be considered invalid.

Color fallback

If a color is specified in `image()` along with your image sources, it acts as a fallback if the images are invalid and do not appear. In such cases, the `image()` function renders as if no image were included, generating a solid-color image. As a use case, consider a dark image being used as a background for some white text. A dark background color may be needed for foreground text to be legible, if the image does not render.

Omitting image sources while including a color is valid and creates a color swatch. Unlike declaring a `background-color`, which is placed under or behind all the background images, this can be used to put (generally semi-transparent) colors over other images.

The size of the color swatch can be set with the `background-size` property. This is different from the `background-color`, which sets a color to cover the entire element. Both `image(color)` and `background-color` placements are impacted by the `background-clip` and `background-origin` properties.

Formal syntax

```
<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>
```

This syntax reflects the latest standard as per CSS Images Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Accessibility

Browsers do not provide any special information on background images to assistive technology. This is important primarily for screen readers, as a screen reader will not announce its presence and therefore convey nothing to its users. If the image contains information critical to understanding the page's overall purpose, it is better to describe it semantically in the document.

- MDN Understanding WCAG, Guideline 1.1 explanations
- Understanding Success Criterion 1.1.1 | W3C Understanding WCAG 2.0

This feature can help improve accessibility by providing a fallback color when an image fails to load. While this can and should be done by including a background-color on every background image, the CSS `image()` function allows adding allows only including background colors should an image fail to load, which means you can add a fallback color should a transparent PNG/GIF/WebP not load.

Examples

Directionally-sensitive images

```
<ul>
  <li dir="ltr">Bullet is a right facing arrow on the left</li>
  <li dir="rtl">Bullet is the same arrow, flipped to point left.</li>
</ul>
```

```
ul {
  list-style-image: image(ltr "rightarrow.png");
}
```

In the left-to-right list items — those with `dir="ltr"` set on the element itself or inheriting the directionality from an ancestor or default value for the page — the image will be used as-is. List items with `dir="rtl"` set on the `<li>` or inheriting the right-to-left directionality from an ancestor, such as documents set to Arabic or Hebrew, will have the bullet display on the right, horizontally flipped, as if `transform: scaleX(-1)` had been set. The text will also be displayed left-to-right.

Displaying a section of the background image

```
<div class="box">Hover over me. What cursor do you see?</div>
```

```
.box:hover {
  cursor: image("sprite.png#xywh=32,64,16,16"), auto;
}
```

When the user hovers over the box, the cursor will change to display the 16x16 px section of the sprite image, starting at x=32 and y=64.

Putting color on top of a background image

```
.quarter-logo {
  height: 200px;
  width: 200px;
  border: 1px solid;
}
```

```
.quarter-logo {
  background-image: image(rgb(0 0 0 / 25%)), url("firefox.png");
  background-size: 25%;
  background-repeat: no-repeat;
}
```

```
<div class="quarter-logo">
  If supported, a quarter of this div has a darkened logo
</div>
```

The above will put a semi-transparent black mask over the Firefox logo background image. Had we used the `background-color` property instead, the color would have appeared behind the logo image instead of on top of it. Additionally, the entire container would have had the same background color. Because we used `image()` along with the `background-size` property (and prevented the image from repeating with the `background-repeat` property), the color swatch will only cover a quarter of the container.

Browser compatibility

Currently, no browsers support this feature.

- `cross-fade()`
- CSS images module

image-set() CSS function

The **`image-set()`** CSS functional notation is a method of letting the browser pick the most appropriate CSS image from a given set, primarily for high pixel density screens.

Resolution and bandwidth differ by device and network access. The `image-set()` function delivers the most appropriate image resolution for a user's device, providing a set of image options — each with an associated resolution declaration — from which the browser picks the most appropriate for the device and settings. Resolution can be used as a proxy for filesize — a user agent on a slow mobile connection with a high-resolution screen may prefer to receive lower-resolution images rather than waiting for a higher resolution image to load.

`image-set()` allows the author to provide options rather than determining what each individual user needs.

Syntax

```
/* Select image based on resolution */
image-set(
  "image1.jpg" 1x,
  "image2.jpg" 2x
);

image-set(
  url("image1.jpg") 1x,
  url("image2.jpg") 2x
);

/* Select gradient based on resolution */
image-set(
  linear-gradient(blue, white) 1x,
  linear-gradient(blue, green) 2x
);

/* Select image based on supported formats */
image-set(
  url("image1.avif") type("image/avif"),
  url("image2.jpg") type("image/jpeg")
);
```

Values

`<image>`

The `<image>` can be any image type except for an image set. The `image-set()` function may not be nested inside another `image-set()` function.

`<string>`

A URL to an image.

`<resolution>` Optional

`<resolution>` units include `x` or `dppx`, for dots per pixel unit, `dpi`, for dots per inch, and `dpcm` for dots per centimeter. Every image within an `image-set()` must have a unique resolution.

`type(<string>)` Optional

A valid MIME type string, for example "image/jpeg".

Formal syntax

```
<image-set()> =
  image-set( <image-set-option># )

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
  <gradient>

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<cross-fade()> =
  cross-fade( <cf-image># )

<element()> =
  element( <id-selector> )

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Images Module Level 4, CSS Images Module Level 5, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Accessibility

Browsers do not provide any special information on background images to assistive technology. This is important primarily for screen readers, as a screen reader will not announce its presence and therefore convey nothing to its users. If the image contains information critical to understanding the page's overall purpose, it is better to describe it semantically in the document.

- MDN Understanding WCAG, Guideline 1.1 explanations
- Understanding Success Criterion 1.1.1 | W3C Understanding WCAG 2.0

Examples

Using image-set() to provide alternative background-image options

This example shows how to use `image-set()` to provide two alternative `background-image` options, chosen depending on the resolution needed: a normal version and a high-resolution version.

```
<div class="box"></div>
```

```
.box {
  width: 400px;
  height: 200px;
  background-repeat: no-repeat;
  background-size: cover;

  background-image: image-set(
    url("https://mdn.github.io/shared-assets/images/examples/balloons-small.jpg")
      1x,
    url("https://mdn.github.io/shared-assets/images/examples/balloons-landscape.jpg")
      2x
  );
}
```

Using image-set() to provide alternative image formats

In the next example the `type()` function is used to serve the image in AVIF and JPEG formats. If the browser supports avif, it will choose that version. Otherwise it will use the jpeg version.

```
<div class="box"></div>
```

```
.box {
  width: 400px;
  height: 200px;
  background-repeat: no-repeat;
  background-size: cover;

  background-image: image-set(
    "https://mdn.github.io/shared-assets/images/examples/balloons-landscape.avif"
      type("image/avif"),
    "https://mdn.github.io/shared-assets/images/examples/balloons-landscape.jpg"
      type("image/jpeg")
  );
}
```

paint() CSS function

The **`paint()`** CSS function defines an `<image>` value generated with a PaintWorklet.

Syntax

```
paint(workletName, ...parameters)
```

where:

workletName

The name of the registered worklet.

parameters Optional

Optional additional parameters to pass to the paintWorklet

Formal syntax

```
<paint()> =
  paint( <ident> , <declaration-value>? )
```

This syntax reflects the latest standard as per CSS Painting API Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic CSS paint() usage

Given the following HTML:

```
<ul>
  <li>item 1</li>
  <li>item 2</li>
  <li>item 3</li>
  <li>item 4</li>
  <li>item 5</li>
  <li>item 6</li>
  <li>item 7</li>
  <li>item 8</li>
  <li>item 9</li>
  <li>item 10</li>
  <li>item N</li>
</ul>
```

In JavaScript, we register the paint worklet:

```
CSS.paintWorklet.addModule(
  "https://mdn.github.io/houdini-examples/cssPaint/intro/worklets/boxbg.js",
);
```

In the CSS, we define the `background-image` as a `paint()` type with the worklet name, `boxbg`, along with any variables (ex. `--box-color` and `--width-subtractor`) the worklet will use:

```
body {
  font: 1.2em / 1.2 sans-serif;
}
li {
  background-image: paint(boxbg);
  --box-color: hsl(55 90% 60%);
}

li:nth-of-type(3n) {
  --box-color: hsl(155 90% 60%);
  --width-subtractor: 20;
}

li:nth-of-type(3n + 1) {
  --box-color: hsl(255 90% 60%);
  --width-subtractor: 40;
}
```

CSS paint() with parameters

You can pass optional arguments in the CSS `paint()` function. In this example, we passed two arguments that control whether the `background-image` on a group of list items is `filled` or has a `stroke` outline, and the `width` of that outline:

```
<ul>
  <li>item 1</li>
  <li>item 2</li>
  <li>item 3</li>
  <li>item 4</li>
  <li>item 5</li>
  <li>item 6</li>
  <li>item 7</li>
  <li>item 8</li>
  <li>item 9</li>
  <li>item 10</li>
  <li>item N</li>
</ul>
```

```
CSS.paintWorklet.addModule(
  "https://mdn.github.io/houdini-examples/cssPaint/intro/worklets/hilite.js",
);
```

```
body {
  font: 1.2em / 1.2 sans-serif;
```

```
}

li {
  --box-color: hsl(55 90% 60% / 100%);
  background-image: paint(hollow-highlights, stroke, 2px);
}

li:nth-of-type(3n) {
  --box-color: hsl(155 90% 60% / 100%);
  background-image: paint(hollow-highlights, filled, 3px);
}

li:nth-of-type(3n + 1) {
  --box-color: hsl(255 90% 60% / 100%);
  background-image: paint(hollow-highlights, stroke, 1px);
}
```

We've included a custom property in the selector block defining a boxColor. Custom properties are accessible to the PaintWorklet.

!important CSS keyword

A `!` delimiter followed by the `important` keyword marks the declaration as important. The `!important` flag alters the rules selecting declarations inside the cascade. A declaration that is not *important* is called *normal*.

To mark a declaration important, add the *important flag* (`!important`) after the value in the declaration. While white space is allowed between the delimiter and the keyword, the flag is generally written as `!important` without any white space.

```
selector {
  property: value; /* normal declaration */
  property: value !important; /* important declaration (preferred) */
  property: value ! important; /* important declaration (not preferred) */
}
```

The `!important` comes after the value of the property value pair declaration, preceded by zero or more spaces. The important flag must be the last token in the declaration. In other words, there can be white space and comments between the flag and the declaration's ending semicolon, but nothing else.

Impact on the cascade

When it comes to important declarations, the cascade origin and layer orders are reversed. Without the important flag, declarations in the author's style sheets override declarations in a user's style sheet, which override declarations in the user-agent's default style sheet.

When a declaration is important, the order of precedence is reversed. Declarations marked as important in the user-agent style sheets override all important declarations in the user style sheets. Similarly, all important declarations in the user style sheets override all important declarations in the author's style sheets. Finally, all important declarations take precedence over all animations.

> **Note:** All important declarations take precedence over all animations. `!important` is not valid within @keyframes animation declarations.

Reversing the precedence order for important declarations ensures users with special needs, such as personalized color schemes or large fonts, can override author styles when needed by marking some declarations in their user's style sheet as important. It also guarantees malicious extensions can't override important user-agent styles, which might break functionality or negatively impact security.

Does anything have precedence over important declarations? Yes, transitions. CSS transitions are a way to control the speed at which the property changes from one value to another. While transitioning from one value to another, a property will not match a specific important declaration.

```
a {
  color: red !important;
  background-color: yellow;
  transition: all 2s linear;
}
a:hover {
  color: blue !important;
  background-color: orange !important;
}
```

In this example, the `color` and `background-color` properties will transition to the hovered state over two seconds. Even though default states are normal declarations and hover states are `!important` declarations, the transition does happen.

Cascade layers

Within each of the three origins for style sheets – author, user, and user-agent – normal declarations in unlayered styles override layered style declarations, with the last declared having precedence over the layers declared before it. Important declarations reverse the order of precedence: important declarations in the first layer take precedence over important declarations in the next layer, and so on. Also, all the important declarations have precedence over important declarations made outside any layer.

Inline styles

Inline styles are styles defined using the `style` attributes. They can also be normal or important. Inline *normal* styles take precedence over all *normal* declarations, no matter the origin. Inline *important* styles take precedence over all other *important* author styles, no matter the layer, but important styles from user's or user-agent's style sheets and transitions override them.

!important and specificity

While `!important` is not part of determining specificity, it is related. Important declarations override all other declarations from the same origin and cascade layer.

```
#myElement#myElement#myElement .myClass.myClass p:hover {
  color: blue;
}

p {
  color: red !important;
}
```

This example displays a case of over-specifying a selector. No matter how high the selector specificity matches a normal declaration, an important declaration from the same source and cascade layer will always have precedence. In this case, the paragraph will always be red.

When two important declarations from the same origin and layer apply to the same element, browsers select and use the declaration with the highest specificity.

```
#myElement p {
  color: green !important;
}

p {
  color: purple !important;
}
```

In this case, the selector specificity matters. Only if the selectors had the same specificity would source order matter.

Impact on shorthand properties

Declaring a shorthand property with `!important` sets all of sub-properties as important. The two following selector style blocks are equivalent:

```
p {
  background: blue !important;
}

p {
  background-image: none !important;
  background-position: 0 0 !important;
  background-size: auto auto !important;
  background-repeat: repeat !important;
  background-origin: padding-box !important;
  background-clip: border-box !important;
  background-attachment: scroll !important;
  background-color: blue !important;
}
```

This example shows one of the several reasons avoiding the important flag is generally recommended.

Impact on custom properties

When the `!important` flag is added to a custom property value declaration, it makes the value assignment important. The `!important` flag is then stripped from the custom property value. The `!important` flag is not passed as part of the custom property value to the `var()` function.

```
:root {
  --my-color: red !important;
  --my-color: blue;
}
p {
  color: var(--my-color);
}
blockquote {
  color: var(--my-color);
  color: purple;
}
```

```
<p>This is a paragraph</p>
<blockquote>This is a blockquote</blockquote>
```

In this example, the paragraph will be red, not blue, as the custom property value assignment is important. The blockquote will be purple, because the purple normal declaration comes after the normal red declaration.

Best practices

Avoid using `!important` to override specificity. When intentionally creating important declarations for UI requirements, comment in your CSS code to explain to maintainers why they should not override that feature.

Even when working to override high-specificity styles not under your control, such as styles in a third-party plugin declared with an id selector, you don't need to use `!important`. Consider instead importing the third-party stylesheet script into a named or anonymous layer as your first cascade layer, instead of using `!important`. As long as the external styles do not include important declarations, your styles will take precedence over the widget styles, no matter the specificity.

If you need to override an external stylesheet containing important declarations, create a cascade layer containing the needed overrides, and declare that layer first.

Accessibility concerns

Important styles from a user stylesheet take precedence over the author style sheet's important declarations, meaning adding an `!important` flag to a site's styles will not prevent individual users with special requirements, such as large fonts, from being able to override your styles by adding important styles in their own user's style sheet.

Browser compatibility

This feature is supported in all browsers.

- CSS Cascade

inherit CSS keyword

The **`inherit`** CSS keyword causes the element to take the computed value of the property from its parent element. It can be applied to any CSS property, including the CSS shorthand property `all`.

For inherited properties, this reinforces the default behavior, and is only needed to override another rule.

> **Note:** Inheritance is always from the parent element in the document tree, even when the parent element is not the containing block.

Examples

Basic usage

In this example, we demonstrate the effect of the `inherit` keyword by comparing two paragraphs with nested elements: the inline elements in one use their browser default styles, while those in the other inherit individual property values from their parent.

HTML

We include two identical paragraphs with several inline elements.

```
<p>
  This paragraph has <em>emphasized text</em>, <strong>strong text</strong>, and
  <a href="#">a link to top</a>.
</p>
<p>
  This paragraph has <em>emphasized text</em>, <strong>strong text</strong>, and
  <a href="#">a link to top</a>.
</p>
```

CSS

We don't style the inline elements in the first paragraph, so they use their default browser styles. In the second paragraph, we set properties on each inline element to `inherit`, so they get the computed styles from the parent `<p>` element.

```
p:nth-of-type(2) {
  a {
    text-decoration: inherit;
    color: inherit;
  }
  em {
    font-style: inherit;
  }
  strong {
    font-weight: inherit;
  }
}
```

Result

Inheriting all property values

In this example, we use the same HTML as in the previous example to demonstrate the issues that can occur when the `inherit` keyword is applied to all properties.

```
<p>
  This paragraph has <em>emphasized text</em>, <strong>strong text</strong>, and
  <a href="#">a link to top</a>.
</p>
<p>
  This paragraph has <em>emphasized text</em>, <strong>strong text</strong>, and
  <a href="#">a link to top</a>.
</p>
```

CSS

In the second paragraph, instead of setting individual properties to `inherit`, we set the `all` property on all inline elements to `inherit`, so they all get computed styles from their parent `<p>`.

```
p:nth-of-type(2) > * {
  all: inherit;
}
```

Result

Notice how the inline element inherit all the properties of the parent `<p>`, including the paragraph's block-level `display` value. This is likely not the effect you would want.

Excluding selected elements from a rule

This example demonstrates how the `inherit` keyword can be used to exclude selected elements from a color rule, allowing them to use their parent's color instead.

HTML

We include some semantically structured content.

```
<header>
  <h1>This is my blog</h1>
  <h2>This is the subtitle of my blog in the HEADER</h2>
  <p>My blog is not very interesting</p>
</header>
<main>
  <h2>This first blog post in MAIN</h2>
  <p>I really have nothing to say.</p>
  <section>
    <h2>This second blog post is in a SECTION within MAIN</h2>
    <p>
      It is in a section because it is important even though it isn't the least
      bit interesting.
    </p>
  </section>
</main>
<footer>
  <h2>Contact in FOOTER</h2>
  <p>Find me on Mastodon</p>
  <section>
    <h2>Copyright in SECTION within FOOTER</h2>
    <p>1996</p>
  </section>
</footer>
```

CSS

We set the text color of the `<main>` element to `blue` and all `<h2>` elements to `green` in `monospace` font. The `<h2>` elements inside a `<section>` are set to `inherit` their parent's text color.

```
main {
  color: blue;
}

h2 {
  color: green;
  font-family: monospace;
}

section h2 {
  color: inherit;
}
```

Result

The `<h2>` elements are all `green`. However, if they are nested in a `<section>` element, they inherit their color from their parent, which is `blue` within `<main>`. The default text color is black otherwise.

- Inheritance

initial CSS keyword

The **`initial`** CSS keyword applies the initial (or default) value of a property to an element. It can be applied to any CSS property, including the CSS shorthand property `all`. With `all` set to `initial`, all CSS properties can be restored to their respective initial values in one go instead of restoring each one separately.

On inherited properties, the initial value may be unexpected. You should consider using the `inherit`, `unset`, `revert`, `revert-layer`, or `revert-rule` keywords instead.

Examples

Basic usage

In this example, we use the `initial` keyword to reset an element's `color` and `font-size` property values.

HTML

```
<p>
  This text is red and large.
  <em
    >This text is in the initial color (typically black) and initial size
    (typically 16px).</em
  >
  This is red and large again.
</p>
```

CSS

We set `color` and `font-size` on the `<p>` element, then set those properties to `initial` on the `<em>` element to reset them.

```
p {
  color: red;
  font-size: 2rem;
}

em {
  color: initial;
  font-size: initial;
}
```

Result

With the `initial` keyword in this example, the `color` and `font-size` values on the `em` element are restored to the initial values for `color` and `font-size`, respectively.

<integer> CSS type

The **`<integer>`** CSS data type is a special type of `<number>` that represents a positive or negative whole number. Integers can be used in numerous CSS properties and descriptors, such as the `column-count`, `counter-increment`, `grid-column`, `grid-row`, and `z-index` properties and the `range` descriptor.

Syntax

The `<integer>` data type consists of one or several decimal digits, 0 through 9 inclusive, optionally preceded by a single `+` or `-` sign. There is no unit associated with integers.

> **Note:** There is no official range of valid `<integer>` values, and the specifications do not specify a range.

Interpolation

When animated, values of the `<integer>` data type are interpolated using discrete, whole steps. The calculation is done as if they were real, floating-point numbers; the discrete value is obtained using the floor function. The speed of the interpolation is determined by the easing function associated with the animation.

Examples

Valid integers

```
12          Positive integer (without a leading + sign)
+123        Positive integer (with a leading + sign)
-456        Negative integer
```

```
0          Zero
+0         Zero, with a leading +
-0         Zero, with a leading -
```

Invalid integers

```
12.0       This is a <number>, not an <integer>, though it represents an integer.
12.        Decimal points are not allowed.
+---12     Only one leading +/- is allowed.
ten        Letters are not allowed.
_5         Special characters are not allowed.
\35        Escaped Unicode characters are not allowed, even if they are an integer (here: 5).
\4E94      Non-arabic numerals are not allowed, even when escaped (here: the Japanese 5, 五).
3e4        Scientific notation is not allowed.
```

- `<number>`

<length> CSS type

The **`<length>`** CSS data type represents a distance value. Lengths can be used in numerous CSS properties, such as `width`, `height`, `margin`, `padding`, `border-width`, `font-size`, and `text-shadow`.

> **Note:** Although `<percentage>` values are usable in some of the same properties that accept `<length>` values, they are not themselves `<length>` values. See `<length-percentage>`.

Syntax

The `<length>` data type consists of a `<number>` followed by one of the units listed below. As with all CSS dimensions, there is no space between the number and the unit literal. Specifying the length unit is optional if the number is `0`.

> **Note:** Some properties allow negative `<length>` values, while others do not.

Specified vs. computed values

The specified value of a length (*specified length*) is represented by its quantity and unit. The computed value of a length (*computed length*) is the specified length resolved to an absolute length, and its unit is not distinguished.

For some properties, such as `border-width`, `outline-width`, `column-rule-width`, and `outline-offset`, the computed `<length>` values are rounded to an integer number of device pixels to ensure reasonable visual display:

- A non-zero value less than 1 device pixel is rounded up.
- A value greater than 1 device pixel is rounded down to the nearest whole device pixel.

For example, on a screen with a `devicePixelRatio` of 3, `border-width: 1.5px` computes to approximately `1.33px` (rounded down from 4.5 to 4 device pixels), and `outline-width: 0.2px` computes to approximately `0.33px` (rounded up from 0.6 to 1 device pixel).

Relative vs. absolute lengths

The `<length>` units can be relative or absolute. Relative lengths represent a measurement in terms of some other distance. Depending on the unit, this distance can be the size of a specific character, the line height, or the size of the viewport. Style sheets that use relative length units can more easily scale from one output environment to another.

> **Note:** Child elements do not inherit the relative values as specified for their parent; they inherit the computed values.

Relative length units

CSS relative length units are based on font, container, or viewport sizes.

Relative length units based on font

Font lengths define the `<length>` value in terms of the size of a particular character or font attribute in the font currently in effect in an element or its parent.

> **Note:** These units, especially `em` and the root relative `rem`, are often used to create scalable layouts, which maintain the vertical rhythm of the page even when the user changes the font size.

`cap`

: Equal to the "cap height" (nominal height of capital letters) of the element's `font`.

`ch`

: Represents the width or, more precisely, the advance measure of the glyph `0` (zero, the Unicode character U+0030) in the element's `font`. In cases where determining the measure of the `0` glyph is impossible or impractical, it must be assumed to be `0.5em` wide by `1em` tall.

`em`

: Represents the calculated `font-size` of the element. If used on the `font-size` property itself, it represents the *inherited* font-size of the element.

`ex`

: Equal to the x-height of the element's `font`. In fonts with the `x` letter, this is generally the height of lowercase letters in the font; `1ex ≈ 0.5em` in many fonts.

`ic`

: Represents the used advance measure of the "水" glyph (CJK water ideograph, U+6C34), found in the font used to render it.

`lh`

: Equal to the computed value of the `line-height` property of the element on which it is used, converted to an absolute length. This unit enables length calculations based on the theoretical size of an ideal empty line. However, the size of actual line boxes may differ based on their content.

Relative length units based on root element's font

Root element font relative length units define the `<length>` value in terms of the size of a particular character or font attribute of the root element:

`rcap`

Equal to the "cap height" (nominal height of capital letters) of the root element's `font`.

`rch`

Equal to the width or the advance measure of the glyph `0` (zero, the Unicode character U+0030) in the root element's `font`.

`rem`

Represents the `font-size` of the root element (typically `<html>`). When used within the root element `font-size`, it represents its initial value. A common browser default is `16px`, but user-defined preferences may modify this.

`rex`

Equal to the x-height of the root element's `font`.

`ric`

Equal to the value of `ic` unit on the root element's font.

`rlh`

Equal to the value of `lh` unit on the root element's font. This unit enables length calculations based on the theoretical size of an ideal empty line. However, the size of actual line boxes may differ based on their content.

Relative length units based on viewport

The **viewport-percentage length units** are based on four different viewport sizes: small, large, dynamic, and default. The allowance for the different viewport sizes is in response to browser interfaces expanding and retracting dynamically and hiding and showing the content underneath.

Small viewport units

When you want the smallest possible viewport in response to browser interfaces expanding dynamically, you should use the small viewport size. The small viewport size allows the content you design to fill the entire viewport when browser interfaces are expanded. Choosing this size might also possibly leave empty spaces when browser interfaces retract.

For example, an element that is sized using viewport-percentage units based on the small viewport size, the element will fill the screen perfectly without any of its content being obscured when all the dynamic browser interfaces are shown. When those browser interfaces are hidden, however, there might be extra space visible around the element. Therefore, the small viewport-percentage units are "safer" to use in general, but might not produce the most attractive layout after a user starts interacting with the page.

The small viewport size is represented by the `sv` prefix and results in the `sv*` viewport-percentage length units. The sizes of the small viewport-percentage units are fixed, and therefore stable, unless the viewport itself is resized.

Large viewport units

When you want the largest possible viewport in response to browser interfaces retracting dynamically, you should use the large viewport size. The large viewport size allows the content you design to fill the entire viewport when browser interfaces are retracting. You need to be aware that the content might get hidden when browser interfaces expand.

For example, on mobile phones where screen real-estate is at a premium, browsers often hide part or all of the title and address bar after a user starts scrolling the page. When an element is sized using a viewport-percentage unit based on the large viewport size, the content of the element will fill the entire visible page when these browser interfaces are hidden. However, when these retractable browser interfaces are shown, they can hide the content that is sized or positioned using the *large* viewport-percentage units.

The large viewport unit is represented by the `lv` prefix and results in the `lv*` viewport-percentage units. The sizes of the large viewport-percentage units are fixed and therefore stable, unless the viewport itself is resized.

Dynamic viewport units

When you want the viewport to be automatically sized in response to browser interfaces dynamically expanding or retracting, you can use the dynamic viewport size. The dynamic viewport size allows the content you design to fit exactly within the viewport, irrespective of the presence of dynamic browser interfaces.

The dynamic viewport unit is represented by the `dv` prefix and results in the `dv*` viewport-percentage units. The sizes of the dynamic viewport-percentage units are not stable, even when the viewport itself is unchanged.

> **Note:** While the dynamic viewport size can give you more control and flexibility, using viewport-percentage units based on the dynamic viewport size can cause the content to resize while a user is scrolling a page. This can lead to degradation of the user interface and cause a performance hit.

Default viewport units

The default viewport size is defined by the browser. The behavior of the resulting viewport-percentage unit could be equivalent to the viewport-percentage unit based on the small viewport size, the large viewport size, an intermediate size between the two, or the dynamic viewport size.

> **Note:** For example, a browser might implement the default viewport-percentage unit for height (`vh`) that is equivalent to the large viewport-percentage height unit (`lvh`). If so, this could obscure content on a full-page display while the browser interface is expanded. Currently, all default viewport units (`vh`, `vw`, etc.) are equivalent to their large viewport counterparts (`lvh`, `lvw`, etc.).

Viewport-percentage lengths define `<length>` values in percentage relative to the size of the initial containing block, which in turn is based on either the size of the viewport or the page area, i.e., the visible portion of the document. When the height or width of the initial containing block is changed, the elements that are sized based on them are scaled accordingly. There is a viewport-percentage length unit variant corresponding to each of the viewport sizes, as described below.

> **Note:** Viewport lengths are invalid in `@page` declaration blocks.

`vh`

Represents a percentage of the height of the viewport's initial containing block. `1vh` is 1% of the viewport height. For example, if the viewport height is `300px`, then a value of `70vh` on a property will be `210px`.

The respective viewport-percentage units for small, large, and dynamic viewport sizes are `svh`, `lvh`, and `dvh`. `vh` is equivalent to `lvh`, representing the viewport-percentage length unit based on the large viewport size.

`vw`

Represents a percentage of the width of the viewport's initial containing block. `1vw` is 1% of the viewport width. For example, if the viewport width is `800px`, then a value of `50vw` on a property will be `400px`.

For small, large, and dynamic viewport sizes, the respective viewport-percentage units are `svw`, `lvw`, and `dvw`. `vw` is equivalent to `lvw`, representing the viewport-percentage length unit based on the large viewport size.

`vmax`

Represents in percentage the largest of `vw` and `vh`.

For small, large, and dynamic viewport sizes, the respective viewport-percentage units are `svmax`, `lvmax`, and `dvmax`. `vmax` is equivalent to `lvmax`, representing the viewport-percentage length unit based on the large viewport size.

`vmin`

Represents in percentage the smallest of `vw` and `vh`.

For small, large, and dynamic viewport sizes, the respective viewport-percentage units are `svmin`, `lvmin`, and `dvmin`. `vmin` is equivalent to `lvmin`, representing the viewport-percentage length unit based on the large viewport size.

`vb`

Represents the percentage of the size of the initial containing block, in the direction of the root element's block axis.

For small, large, and dynamic viewport sizes, the respective viewport-percentage units are `svb`, `lvb`, and `dvb`, respectively. `vb` is equivalent to `lvb`, representing the viewport-percentage length unit based on the large viewport size.

`vi`

Represents a percentage of the size of the initial containing block, in the direction of the root element's inline axis.

For small, large, and dynamic viewport sizes, the respective viewport-percentage units are `svi`, `lvi`, and `dvi`. `vi` is equivalent to `lvi`, representing the viewport-percentage length unit based on the large viewport size.

Container query length units

When applying styles to a container using container queries, you can use container query length units. These units specify a length relative to the dimensions of a query container. Components that use units of length relative to their container are more flexible to use in different containers without having to recalculate concrete length values.

If no eligible container is available for the query, the container query length unit defaults to the small viewport unit for that axis (`sv*`).

For more information, see Container queries.

`cqw`

Represents a percentage of the width of the query container. `1cqw` is 1% of the query container's width. For example, if the query container's width is `800px`, then a value of `50cqw` on a property will be `400px`.

`cqh`

Represents a percentage of the height of the query container. `1cqh` is 1% of the query container's height. For example, if the query container's height is `300px`, then a value of `10cqh` on a property will be `30px`.

`cqi`

Represents a percentage of the inline size of the query container. `1cqi` is 1% of the query container's inline size. For example, if the query container's inline size is `800px`, then a value of `50cqi` on a property will be `400px`.

`cqb`

Represents a percentage of the block size of the query container. `1cqb` is 1% of the query container's block size. For example, if the query container's block size is `300px`, then a value of `10cqb` on a property will be `30px`.

`cqmin`

Represents a percentage of the smaller value of either the query container's inline size or block size. `1cqmin` is 1% of the smaller value of either the query container's inline size or block size. For example, if the query container's inline size is `800px` and its block size is `300px`, then a value of `50cqmin` on a property will be `150px`.

`cqmax`

Represents a percentage of the larger value of either the query container's inline size or block size. `1cqmax` is 1% of the larger value of either the query container's inline size or block size. For example, if the query container's inline size is `800px` and its block size is `300px`, then a value of `50cqmax` on a property will be `400px`.

Absolute length units

Absolute length units represent a physical measurement when the physical properties of the output medium are known, such as for print layout. This is done by anchoring one of the units to a **physical unit** or the **visual angle unit** and then defining the others relative to it. Physical units include `cm`, `in`, `mm`, `pc`, `pt`, `px`, and `Q`.The anchoring is done differently for low-resolution devices, such as screens, versus high-resolution devices, such as printers.

For low-dpi devices, the unit `px` represents the physical *reference pixel*; other units are defined relative to it. Thus, `1in` is defined as `96px`, which equals `72pt`. The consequence of this definition is that on such devices, dimensions described in inches (`in`), centimeters (`cm`), or millimeters (`mm`) don't necessarily match the size of the physical unit with the same name.

For high-dpi devices, inches (`in`), centimeters (`cm`), and millimeters (`mm`) are the same as their physical counterparts. Therefore, the `px` unit is defined relative to them (1/96 of `1in`).

> **Note:** Many users increase their user agent's default font size to make text more legible. Absolute lengths can cause accessibility problems because they are fixed and do not scale according to user settings. For this reason, prefer relative lengths (such as `em` or `rem`) when setting `font-size`.

`px`

One pixel. For screen displays, it traditionally represents one device pixel (dot). However, for *printers* and *high-resolution screens*, one CSS pixel implies multiple device pixels. `1px = 1in / 96`.

`cm`

One centimeter. `1cm = 96px / 2.54`.

`mm`

One millimeter. `1mm = 1cm / 10`.

`Q`

One quarter of a millimeter. `1Q = 1cm / 40`.

`in`

One inch. `1in = 2.54cm = 96px`.

`pc`

One pica. `1pc = 12pt = 1in / 6`.

`pt`

One point. `1pt = 1in / 72`.

Interpolation

When animated, values of the `<length>` data type are interpolated as real, floating-point numbers. The interpolation happens on the calculated value. The speed of the interpolation is determined by the easing function associated with the animation.

Examples

Comparing different length units

The following example provides you with an input field in which you can enter a `<length>` value (e.g., `300px`, `50%`, `30vw`) to set the width of a result bar that will appear below it once you've pressed the `Enter` or the `Return` key.

This allows you to compare and contrast the effects of different length units.

HTML

```
<div class="outer">
  <div class="input-container">
    <label for="length">Enter width:</label>
    <input type="text" id="length" />
  </div>
  <div class="inner"></div>
</div>
<div class="results"></div>
```

CSS

```
html {
  font-family: sans-serif;
  font-weight: bold;
  box-sizing: border-box;
}

.outer {
  width: 100%;
  height: 50px;
  background-color: #eeeeee;
  position: relative;
}

.inner {
  height: 50px;
  background-color: #999999;
  box-shadow:
    inset 3px 3px 5px rgb(255 255 255 / 50%),
    inset -3px -3px 5px rgb(0 0 0 / 50%);
}

.result {
  height: 20px;
  box-shadow:
    inset 3px 3px 5px rgb(255 255 255 / 50%),
    inset -3px -3px 5px rgb(0 0 0 / 50%);
  background-color: orange;
  display: flex;
  align-items: center;
  margin-top: 10px;
}

.result code {
  position: absolute;
  margin-left: 20px;
}

.results {
  margin-top: 10px;
}

.input-container {
  position: absolute;
  display: flex;
  justify-content: flex-start;
  align-items: center;
  height: 50px;
}

label {
  margin: 0 10px 0 20px;
}
```

JavaScript

```
const inputDiv = document.querySelector(".inner");
const inputElem = document.querySelector("input");
const resultsDiv = document.querySelector(".results");

inputElem.addEventListener("change", () => {
  inputDiv.style.width = inputElem.value;

  const result = document.createElement("div");
  result.className = "result";
  result.style.width = inputElem.value;
  const code = document.createElement("code");
  code.textContent = `width: ${inputElem.value}`;
  result.appendChild(code);
  resultsDiv.appendChild(result);

  inputElem.value = "";
```

```
  inputElem.focus();
});
```

<length-percentage> CSS type

The **`<length-percentage>`** CSS data type represents a value that can be either a `<length>` or a `<percentage>`.

Syntax

Refer to the documentation for `<length>` and `<percentage>` for details of the individual syntaxes allowed by this type.

Formal syntax

```
<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

length-percentage examples

This example demonstrates several properties that use `<length-percentage>` values.

HTML

```
<p>You can use percentages and lengths in so many places.</p>
```

CSS

```
p {
  /* length-percentage examples */
  width: 75%;
  height: 200px;
  margin: 3rem;
  padding: 1%;
  border-radius: 10px 10%;
  font-size: 250%;
  line-height: 1.5em;

  /* length examples */
  text-shadow: 1px 1px 1px red;
  border: 5px solid red;
  letter-spacing: 3px;

  /* percentage example */
  text-size-adjust: 20%;
}
```

Result

Use in calc()

Where a `<length-percentage>` is specified as an allowable type, this means that the percentage resolves to a length and therefore can be used in a `calc()` expression. Therefore, all of the following values are acceptable for `width`:

```
width: 200px;
width: 20%;
width: calc(100% - 200px);
```

<line-style> CSS type

The **`<line-style>`** enumerated value type represents keyword values that define the style of a line, or the lack of a line. The `<line-style>` keyword values are used in the following longhand and shorthand border and gap decoration properties:

- `border`, `border-style`
- `border-block`, `border-block-style`
- `border-block-end`, `border-block-end-style`
- `border-block-start`, `border-block-start-style`
- `border-bottom`, `border-bottom-style`
- `border-inline`, `border-inline-style`
- `border-inline-end`, `border-inline-end-style`
- `border-inline-start`, `border-inline-start-style`
- `border-left`, `border-left-style`
- `border-right`, `border-right-style`
- `border-top`, `border-top-style`
- `column-rule`, `column-rule-style`
- `row-rule`, `row-rule-style`

Syntax

Values

The `<line-style>` enumerated type is specified using one of the values listed below:

`none`

Displays no line. The used value of the line width is `0` even if a width value is specified. In the case of table cell and border collapsing, the `none` value has the *lowest* priority. If any other conflicting border is set, it will be displayed. The `none` value is similar to `hidden`.

`hidden`

Displays no line. The used value of the line width is `0` even if a width value is specified. In the case of table cell and border collapsing, the `hidden` value has the *highest* priority. If any other conflicting border is set, it won't be displayed. The `hidden` value is similar to `none`, but `hidden` is not a valid value for outline styles.

`dotted`

Displays a series of round dots. The radius of the dots is half the computed value of the line's width. The spacing of the dots is not defined by the specification and is implementation-specific.

`dashed`

Displays a series of short square-ended dashes or line segments. The exact size and length of the segments are not defined by the specification and are implementation-specific.

`solid`

Displays a single, straight solid line.

`double`

Displays two straight lines with some space between them. The length of the lines adds up to the pixel size defined by the line's width.

`groove`

Displays a border with a carved appearance. This value is the opposite of `ridge`.

`ridge`

Displays a border with an extruded appearance. This value is the opposite of `groove`.

`inset`

Displays a border that makes the element appear embedded. This value is the opposite of `outset`. When applied to a table cell border and `border-collapse` is set to `collapsed`, this value behaves like `groove`.

`outset`

Displays a border that makes the element appear embossed. This value is the opposite of `inset`. When applied to a table cell with `border-collapse` set to `collapsed`, this value behaves like `ridge`.

> **Note:** When `<outline-style>` is used as the value type for `outline` and `outline-style` properties, it is similar to `<line-style>`, but does not support `hidden` and includes the `auto` value. When `auto` is set, the user-agent defined `<line-style>` value is used.

Formal syntax

```
<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset
```

Examples

The first example demonstrates all the `<line-style>` keyword values. The second example demonstrates how some line style colors may display in unexpected ways.

Defining line styles

This example shows all the `<line-style>` values as values for the CSS `border-style` and `column-rule-style` properties.

HTML

This example uses multiple `<div>` elements, each with a class representing the `<line-style>` value that is being demonstrated.

```
<div class="{line-style}">
  <p>{line-style}</p>
  <p>a b c d e f g h i j k l m n o p q r s t u v w x y z</p>
</div>
```

```
<div class="none">
  <p>none</p>
  <p>a b c d e f g h i j k l m n o p q r s t u v w x y z</p>
</div>
<div class="hidden">
  <p>hidden</p>
  <p>a b c d e f g h i j k l m n o p q r s t u v w x y z</p>
</div>
<div class="dotted">
  <p>dotted</p>
  <p>a b c d e f g h i j k l m n o p q r s t u v w x y z</p>
</div>
<div class="dashed">
  <p>dashed</p>
  <p>a b c d e f g h i j k l m n o p q r s t u v w x y z</p>
</div>
<div class="solid">
  <p>solid</p>
  <p>a b c d e f g h i j k l m n o p q r s t u v w x y z</p>
```

```
</div>
<div class="double">
  <p>double</p>
  <p>a b c d e f g h i j k l m n o p q r s t u v w x y z</p>
</div>
<div class="groove">
  <p>groove</p>
  <p>a b c d e f g h i j k l m n o p q r s t u v w x y z</p>
</div>
<div class="ridge">
  <p>ridge</p>
  <p>a b c d e f g h i j k l m n o p q r s t u v w x y z</p>
</div>
<div class="inset">
  <p>inset</p>
  <p>a b c d e f g h i j k l m n o p q r s t u v w x y z</p>
</div>
<div class="outset">
  <p>outset</p>
  <p>a b c d e f g h i j k l m n o p q r s t u v w x y z</p>
</div>
```

CSS

In the CSS for this example, the border and the column-rule for all the `<p>` elements is defined to have a width of `7px` and the style value of `double`. For each paragraph, the `double` value is then overridden by specifying a different `<line-style>` value for the `border-style` and `column-rule-style` properties.

```
div {
  display: flex;
  gap: 1em;
  list-style: none;
  align-items: center;
}
div:first-of-type {
  display: none;
}

p:first-of-type {
  text-align: center;
  line-height: 5em;
}
p {
  width: 10em;
  height: 5em;
  background-color: palegoldenrod;
}
```

```
p {
  padding: 5px;
  border: double 7px #bada55;
}
p + p {
  columns: 3;
  column-gap: 20px;
  column-rule: double 7px;
  border-color: black;
}
.none p {
  border-style: none;
  column-rule-style: none;
}
.hidden p {
  border-style: hidden;
  column-rule-style: hidden;
}
.dotted p {
  border-style: dotted;
  column-rule-style: dotted;
}
.dashed p {
  border-style: dashed;
  column-rule-style: dashed;
}
.solid p {
  border-style: solid;
  column-rule-style: solid;
}
.double p {
  border-style: double;
  column-rule-style: double;
}
.groove p {
  border-style: groove;
  column-rule-style: groove;
}
.ridge p {
  border-style: ridge;
  column-rule-style: ridge;
}
.inset p {
  border-style: inset;
  column-rule-style: inset;
}
.outset p {
  border-style: outset;
  column-rule-style: outset;
}
```

Result

Notice that the black border is not always black.

Defining line styles and colors

This example demonstrates line-style and color choice. With some `<line-style>` keyword values, the color of the line may not be what you expect. To create the required "3D" effect of `groove`, `ridge`, `inset`, and `outset` styles when displaying these values in black or white, user agents use different color calculations than any other color-line combinations.

CSS

The four sides of each `<div>` have a different `<line-style>` value, and each list item has a different `<color>` value. We use generated content to display the CSS declared inline.

```
body {
  display: flex;
  flex-wrap: wrap;
  gap: 1em;
  text-transform: uppercase;
  font-family: monospace;
}
```

```
div {
  border-width: 10px;
  border-style: inset groove ridge outset;
  padding: 5px;
}
```

JavaScript

The JavaScript dynamically creates `<div>` elements, each with a different `border-color` set.

```
// prettier-ignore
const colors = [
  "#000000", "#000001", "#ffffff",
  "#ff00ff", "#ffff00", "#00ffff",
  "#cc33cc", "#cccc33", "#33cccc",
  "#ff0000", "#00ff00", "#0000ff",
  "#cc3333", "#33cc33", "#3333cc",
  "#993333", "#339933", "#333399",
];

for (const c of colors) {
  const div = document.createElement("div");
  div.style.borderColor = c;
  div.textContent = c;
  document.body.appendChild(div);
}
```

Result

Notice that the almost-black color of `#000001` may be different from the actual black, and the contrast between the dark and light edges is more noticeable when using lighter colors.

<line-width> CSS type

The **`<line-width>`** enumerated value type represents the length or keyword value that defines the width of a line, or the lack of a line. The `<line-width>` keyword values are used in the following longhand and shorthand properties:

- `border`, `border-width`
- `border-block`, `border-block-width`
- `border-block-end`, `border-block-end-width`
- `border-block-start`, `border-block-start-width`
- `border-bottom`, `border-bottom-width`
- `border-inline`, `border-inline-width`
- `border-inline-end`, `border-inline-end-width`
- `border-inline-start`, `border-inline-start-width`
- `border-left`, `border-left-width`
- `border-right`, `border-right-width`
- `border-top`, `border-top-width`
- `column-rule`, `column-rule-width`
- `row-rule`, `row-rule-width`
- `rule`, `rule-width`
- `outline`, `outline-width`

Syntax

Values

The `<line-width>` type is specified using either `<length>` or a keyword:

`<length>`

A non-negative `<length>`.

`hairline`

Represents a "just visible" line that is less than or equal to `1px`.

`thin`

Same as `1px`.

`medium`

Same as `3px`.

`thick`

Same as `5px`.

Formal syntax

```
<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

Examples

Defining a line width

This example demonstrates all the `<line-width>` keyword values, along with a `<length>` value.

HTML

We include five boxes within a `<section>` element.

```
<section>
  <div data-width="hairline">hairline</div>
  <div data-width="thin">thin</div>
  <div data-width="medium">medium</div>
  <div data-width="thick">thick</div>
  <div data-width="10px">10px</div>
</section>
```

CSS

We style all the elements to be identical, then set the `border-width` based on the element's `data-width` attribute.

```
section {
  display: flex;
  gap: 10px;
}
div {
  flex: 0 0 15%;
  border-style: solid;
  border-color: purple;
  text-align: center;
}
[data-width="hairline"] {
  border-width: hairline;
}

[data-width="thin"] {
  border-width: thin;
}

[data-width="medium"] {
  border-width: medium;
}

[data-width="thick"] {
  border-width: thick;
}

[data-width="10px"] {
  border-width: 10px;
}
```

```
@supports not (border-width: hairline) {
  body::before {
    content: "Your browser does not support the 'hairline' value.";
    color: black;
    background-color: #ffcd33;
    display: block;
    width: 100%;
    text-align: center;
  }
}
```

log() CSS function

The **`log()`** CSS function is an exponential function that returns the logarithm of a number.

Logarithm is the inverse of exponentiation. It is the number that a fixed base has to be raised to in order to yield the number passed as the first parameter.

In CSS, when a single parameter is passed, the natural logarithm `e`, or approximately `2.7182818`, is used, though the base can be set to any value with an optional second parameter.

Syntax

```
/* A <number> value */
width: calc(100px * log(7.389)); /* 200px */
```

```
width: calc(100px * log(8, 2)); /* 300px */
width: calc(100px * log(625, 5)); /* 400px */
```

Parameters

The `log(value [, base]?)` function accepts two comma-separated values as its parameters.

`value`

A calculation which resolves to a `<number>` greater than or equal to 0. Representing the value to be taken the log of.

`base`

Optional. A calculation which resolves to a `<number>` greater than or equal to 0. Representing the base of the logarithm. If not defined, the default logarithmic base `e` is used.

Return value

The logarithm of `value`, when `base` is defined.

The natural logarithm (base `e`) of `value`, when `base` is not defined.

Formal syntax

```
<log()> =
  log( <calc-sum> , <calc-sum>? )

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>       |
  <dimension>    |
  <percentage>   |
  <calc-keyword> |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using the <code>log()</code> function on a logarithmic scale

This example illustrates how the `log()` function can be used to visualize data values by using a logarithmic scale. The width of each bar in this example is relative to its data value on a logarithmic scale with base 10. On each element, its value is assigned to a CSS custom property named `--value`, which is then used by the `.bar` class to calculate its width.

HTML

```
<div class="bar" style="--value: 50">50</div>
<div class="bar" style="--value: 100">100</div>
<div class="bar" style="--value: 500">500</div>
<div class="bar" style="--value: 10000">10,000</div>
<div class="bar" style="--value: 2000000">2,000,000</div>
```

CSS

```
.bar {
  width: calc(log(var(--value), 10) * 2em);
}
```

```
.bar {
  height: 2em;
  background-color: tomato;
  color: white;
  display: flex;
  align-items: center;
  justify-content: center;
  margin: 0.25em 0;
}
```

Result

See also

- `sqrt()`
- `hypot()`
- `exp()`

max() CSS function

The **`max()`** CSS function lets you set the largest (most positive) value from a list of comma-separated expressions as the value of a CSS property value. The `max()` function can be used anywhere a `<length>`, `<frequency>`, `<angle>`, `<time>`, `<percentage>`, `<number>`, or `<integer>` is allowed.

Try it

```
width: max(20vw, 400px);
```

```
width: max(20vw, 100px);
```

```
width: max(5vw, 100px);
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    <img
      alt="Firefox logo"
      class="logo"
      src="/shared-assets/images/examples/firefox-logo.svg" />
  </div>
</section>
```

In the first example shown above, the width will be at least 400px, but will be wider if the viewport is more than 2000px wide (in which case 1vw would be 20px, so 20vw would be 400px). This technique uses an absolute unit to specify a fixed minimum value for the property, and a relative unit to allow the value to grow to suit larger viewports.

Syntax

```
max(1, 2, 3)
max(1px, 2px, 3px)
```

Parameters

The `max()` function takes one or more comma-separated expressions as its parameter, with the largest (most positive) expression value used as the value of the property to which it is assigned.

The expressions can be math expressions (using arithmetic operators), literal values, or other expressions, such as `attr()`, that evaluate to a valid argument type (like `<length>`), or nested `min()` and `max()` functions.

You can use different units for each value in your expression. You may also use parentheses to establish computation order when needed.

Notes

- Math expressions involving percentages for widths and heights on table columns, table column groups, table rows, table row groups, and table cells in both auto and fixed layout tables *may* be treated as if `auto` had been specified.
- It is permitted to nest `min()` and other `max()` functions as expression values. The expressions are full math expressions, so you can use direct addition, subtraction, multiplication and division without using the `calc()` function itself.
- The expression can be values combining the addition (`+`), subtraction (`-`), multiplication (`*`), and division (`/`) operators, using standard operator precedence rules. Make sure to put a space on each side of the `+` and `-` operands.
- You can (and often need to) combine `min()` and `max()` values, or use `max()` within a `clamp()` or `calc()` function.

Formal syntax

```
<max()> =
  max( <calc-sum># )

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Accessibility

When `max()` is used for controlling text size, make sure the text is always large enough to read. A suggestion is to use the `min()` function nested within a `max()` that has as its second value a relative length unit that is always large enough to read. For example:

```
small {
  font-size: max(min(0.5vw, 0.5em), 1rem);
}
```

This ensures a minimum size of *1rem*, with a text size that scales if the page is zoomed.

- MDN Understanding WCAG, Guideline 1.4 explanations Understanding Success Criterion 1.4.4: Resize Text | WAI | W3C

Examples

Setting a minimum size for a font

Another use case for `max()` is to allow a font size to grow while ensuring it is at least a minimum size, enabling responsive font sizes while ensuring legibility.

Let's look at some CSS:

```
h1 {
  font-size: 2rem;
}
h1.responsive {
  font-size: max(4vw, 2em, 2rem);
}
```

The font-size will at minimum be 2rems, or twice the default size of font for the page. This ensures that it is legible and accessible.

```
<h1>This text is always legible, but doesn't change size</h1>
<h1 class="responsive">
  This text is always legible, and is responsive, to a point
</h1>
```

Think of the `max()` function as finding the minimum value allowed for a property.

max-content CSS keyword

The `max-content` sizing keyword represents the maximum intrinsic size of an element. The keyword expands the element to the largest size needed to display its content without any soft wraps. For text content, this keyword does not wrap the content at all, even if it causes overflow.

The `interpolate-size` property and `calc-size()` function can be used to enable animations to and from `max-content`.

Syntax

```
/* Used as a length value */
width: max-content;
inline-size: max-content;
height: max-content;
block-size: max-content;

/* Used in grid tracks */
grid-template-columns: 200px 1fr max-content;
```

Examples

Sizing boxes with max-content

HTML

```
<div id="container">
  <div class="item">Item</div>
  <div class="item">
    Item with more text in it which will overflow the fixed width box.
  </div>
</div>
```

CSS

```
#container {
  background-color: #8cffa0;
  padding: 10px;
  width: 200px;
}

.item {
  width: max-content;
  background-color: #8ca0ff;
  padding: 5px;
  margin-bottom: 1em;
}
```

Result

Sizing grid columns with max-content

HTML

```
<div id="container">
  <div>Item</div>
  <div>Item with more text in it.</div>
  <div>Flexible item</div>
</div>
```

CSS

```
#container {
  display: grid;
  grid-template-columns: max-content max-content 1fr;
  grid-gap: 5px;
  box-sizing: border-box;
  height: 200px;
  width: 100%;
  background-color: #8cffa0;
  padding: 10px;
}

#container > div {
  background-color: #8ca0ff;
  padding: 5px;
}
```

Result

min() CSS function

The **`min()`** CSS function lets you set the smallest (most negative) value from a list of comma-separated expressions as the value of a CSS property value. The `min()` function can be used anywhere a `<length>`, `<frequency>`, `<angle>`, `<time>`, `<percentage>`, `<number>`, or `<integer>` is allowed.

Try it

```
width: min(50vw, 200px);
```

```
width: min(100vw, 4000px);
```

```
width: min(150vw, 100px);
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    <img
      alt="Firefox logo"
      class="logo"
      src="/shared-assets/images/examples/firefox-logo.svg" />
  </div>
</section>
```

In the first above example, the width will be at most 200px, but will be smaller if the viewport is less than 400px wide (in which case 1vw would be 4px, so 50vw would be 200px). This technique uses an absolute unit to specify a fixed maximum value for the property, and a relative unit to allow the value to shrink to suit smaller viewports.

Syntax

```
min(1, 2, 3)
min(1px, 2px, 3px)
```

Parameters

The `min()` function takes one or more comma-separated expressions as its parameter, with the smallest (most negative) expression value result used as the value.

The expressions can be math expressions (using arithmetic operators), literal values, or other expressions, such as `attr()`, that evaluate to a valid argument type (like `<length>`).

You can use different units for each value in your expression, if you wish. You may also use parentheses to establish computation order when needed.

Notes

- Math expressions involving percentages for widths and heights on table columns, table column groups, table rows, table row groups, and table cells in both auto and fixed layout tables *may* be treated as if `auto` had been specified.
- It is permitted to nest `max()` and other `min()` functions as expression values. The expressions are full math expressions, so you can use direct addition, subtraction, multiplication and division without using the `calc()` function itself.
- The expression can be values combining the addition (+), subtraction (-), multiplication (*), and division (/) operators, using standard operator precedence rules. Make sure to put a space on each side of the + and - operands.
- You can (and often need to) combine `min()` and `max()` values, or use `min()` within a `clamp()` or `calc()` function.
- You can provide more than two arguments, if you have multiple constraints to apply.

Formal syntax

```
<min()> =
  min( <calc-sum># )

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Accessibility

When using `min()` to set a maximum font size, ensure that the font can still be scaled at least 200% for readability (without assistive technology like a zoom function).

- MDN Understanding WCAG, Guideline 1.4 explanations Understanding Success Criterion 1.4.4: Resize Text | WAI | W3C

Examples

Setting a maximum size for a label and input

Another use case for `min()` is to set a maximum size on responsive form controls: enabling the width of labels and inputs to shrink as the width of their container shrinks.

Let's look at some CSS:

```
input,
label {
  padding: 2px;
  box-sizing: border-box;
  display: inline-block;
  width: min(40%, 400px);
  background-color: pink;
}

.container {
  margin: 4px;
  border: 1px solid black;
  padding: 4px;
}
```

Here, the container itself, along with the margin, border, and padding, will be 100% of its parent's width. We declare the input and label to be the lesser of 40% of the container width up to the padding or 400px wide, whichever is smaller. In other words, the widest that the label and input can be is 400px. The narrowest they will be is 40% of the container's width, which on a smartwatch's screen is very small.

```
<div class="container">
  <label for="misc">Type something:</label>
  <input type="text" id="misc" name="misc" />
</div>
```

min-content CSS keyword

The `min-content` sizing keyword represents the minimum intrinsic size of an element. The keyword shrinks the element to the smallest possible size without causing avoidable overflow of its content. For text content, this keyword causes the content to wrap at every opportunity (such as spaces between words), and the element will be only as wide as the longest word.

The `interpolate-size` property and `calc-size()` function can be used to enable animations to and from `min-content`.

Syntax

```
/* Used as a length value */
width: min-content;
inline-size: min-content;
height: min-content;
block-size: min-content;

/* Used in grid tracks */
grid-template-columns: 200px 1fr min-content;
```

Examples

Sizing boxes with min-content

HTML

```
<div class="item">Item</div>
<div class="item">Item with more text in it.</div>
```

CSS

```
.item {
  width: min-content;
  background-color: #8ca0ff;
  padding: 5px;
  margin-bottom: 1em;
}
```

Result

Sizing grid columns with min-content

HTML

```
<div id="container">
  <div>Item</div>
  <div>Item with more text in it.</div>
  <div>Flexible item</div>
</div>
```

CSS

```
#container {
  display: grid;
  grid-template-columns: min-content min-content 1fr;
  grid-gap: 5px;
  box-sizing: border-box;
  height: 200px;
  width: 100%;
  background-color: #8cffa0;
  padding: 10px;
}

#container > div {
  background-color: #8ca0ff;
  padding: 5px;
}
```

minmax() CSS function

The **`minmax()`** CSS function defines a size range greater than or equal to *min* and less than or equal to *max*. It is used with CSS grids.

Try it

```
grid-template-columns: minmax(20px, auto) 1fr 1fr;
```

```
grid-template-columns: minmax(0, 1fr) minmax(0, 1fr) minmax(0, 1fr);
```

```
grid-template-columns: minmax(2ch, 10ch) 1fr 1fr;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">
      <div>One. This column has more text in it.</div>
      <div>Two</div>
      <div>Three</div>
      <div>Four</div>
      <div>Five</div>
    </div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-gap: 10px;
  width: 250px;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
  text-align: left;
}
```

Syntax

```
/* <inflexible-breadth>, <track-breadth> values */
minmax(200px, 1fr)
minmax(400px, 50%)
minmax(30%, 300px)
minmax(100px, max-content)
minmax(min-content, 400px)
minmax(max-content, auto)
minmax(auto, 300px)
minmax(min-content, auto)

/* <fixed-breadth>, <track-breadth> values */
minmax(200px, 1fr)
minmax(30%, 300px)
minmax(400px, 50%)
minmax(50%, min-content)
minmax(300px, max-content)
minmax(200px, auto)

/* <inflexible-breadth>, <fixed-breadth> values */
minmax(400px, 50%)
minmax(30%, 300px)
minmax(min-content, 200px)
minmax(max-content, 200px)
minmax(auto, 300px)
```

A function taking two parameters, *min* and *max*.

Each parameter can be a `<length>`, a `<percentage>` or one of the keyword values `max-content`, `min-content`, or `auto`.

The second parameter *max* also accepts `<flex>` values. (this `fr` units can only be used for *max*, and are invalid for *min*.)

If *max* < *min*, then *max* is ignored and `minmax(min,max)` is treated as *min*.

Values

`<length>`

A non-negative length.

`<percentage>`

A non-negative percentage relative to the inline size of the grid container in column grid tracks, and the block size of the grid container in row grid tracks. If the size of the grid container depends on the size of its tracks, then the `<percentage>` must be treated as `auto`. The user agent may adjust the intrinsic size contributions of the track to the size of the grid container and increase the final size of the track by the minimum amount that would result in honoring the percentage.

`<flex>`

A non-negative dimension with the unit `fr` specifying the track's flex factor. Each `<flex>`-sized track takes a share of the remaining space in proportion to its flex factor.

`max-content`

Represents the largest max-content contribution of the grid items occupying the grid track.

`min-content`

Represents the largest min-content contribution of the grid items occupying the grid track.

`auto`

As `min`, it represents the largest minimum size (as specified by `min-width`/`min-height`) of the grid items occupying the grid track. As `max`, it is identical to `max-content`. However, unlike `max-content`, it allows expansion of the track by the `align-content` and `justify-content` property values like `normal` and `stretch`.

Formal syntax

```
<minmax()> =
  minmax( min , max )
```

This syntax reflects the latest standard as per CSS Grid Layout Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

CSS properties

`minmax()` function can be used within:

- `grid-template-columns`

- grid-template-rows
- grid-auto-columns
- grid-auto-rows

Examples

CSS

```
#container {
  display: grid;
  grid-template-columns: minmax(min-content, 300px) minmax(200px, 1fr) 150px;
  grid-gap: 5px;
  box-sizing: border-box;
  height: 200px;
  width: 100%;
  background-color: #8cffa0;
  padding: 10px;
}

#container > div {
  background-color: #8ca0ff;
  padding: 5px;
}
```

HTML

```
<div id="container">
  <div>Item as wide as the content, but at most 300 pixels.</div>
  <div>Item with flexible width but a minimum of 200 pixels.</div>
  <div>Inflexible item of 150 pixels width.</div>
</div>
```

mod() CSS function

The **`mod()`** CSS function returns a modulus left over when the first parameter is divided by the second parameter, similar to the JavaScript remainder operator (`%`). The modulus is the value left over when one operand, the dividend, is divided by a second operand, the divisor. It always takes the sign of the divisor.

The calculation is `a - (Math.floor(a / b) * b)`. For example, the CSS `mod(21, -4)` function returns the remainder of `-3`. The full calculation is `21 - (Math.floor(21 / -4) * -4)`. When dividing `21` by `-4`, the result is `-5.25`. This is floored to `-6`. Multiplying `-6` by `-4` is `24`. Subtracting this `24` from the original `21`, the remainder is -3.

Syntax

```
/* Unitless <number> */
line-height: mod(7, 2); /* 1 */
line-height: mod(14, 5); /* 4 */
line-height: mod(3.5, 2); /* 1.5 */

/* Unit based <percentage> and <dimension> */
margin: mod(15%, 2%); /* 1% */
margin: mod(18px, 4px); /* 2px */
margin: mod(19rem, 5rem); /* 4rem */
margin: mod(29vmin, 6vmin); /* 5vmin */
margin: mod(1000px, 29rem); /* 72px - if root font-size is 16px */

/* Negative/positive values */
rotate: mod(100deg, 30deg); /* 10deg */
rotate: mod(135deg, -90deg); /* -45deg */
rotate: mod(-70deg, 20deg); /* 10deg */
rotate: mod(-70deg, -15deg); /* -10deg */

/* Calculations */
scale: mod(10 * 2, 1.7); /* 1.3 */
rotate: mod(10turn, 18turn / 3); /* 4turn */
transition-duration: mod(20s / 2, 3000ms * 2); /* 4s */
```

Parameters

The `mod(dividend, divisor)` function accepts two comma-separated values as its parameters. Both parameters must have the same type, number, dimension, or `<percentage>`, for the function to be valid. While the units in the two parameters don't need to be the same, they do need of the same dimension type, such as `<length>`, `<angle>`, `<time>`, or `<frequency>` to be valid.

`dividend`

A calculation that resolves to a `<number>`, `<dimension>`, or `<percentage>` representing the dividend.

`divisor`

A calculation that resolves to a `<number>`, `<dimension>`, or `<percentage>` representing the divisor.

Return value

Returns a `<number>`, `<dimension>`, or `<percentage>` (corresponds to the parameters' type) representing the modulus, that is, the operation left over.

- If `divisor` is `0`, the result is `NaN`.
- If `dividend` is `infinite`, the result is `NaN`.
- If `divisor` is positive the result is positive (`0+`), and if `divisor` is negative the result is negative (`0-`).

Formal syntax

```
<mod()> =
  mod( <calc-sum> , <calc-sum> )

<calc-sum> =
```

```
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

<named-color> CSS type

The **<named-color>** CSS data type is the name of a color, such as red, blue, black, or lightseagreen. Syntactically, a <named-color> is an <ident>.

A <named-color> value can be used anywhere a <color> can be used.

Syntax

```
color: red;
color: orange;
color: tan;
color: rebeccapurple;
color: transparent;
```

Value

Named colors consists of standard colors, the transparent and currentColor keywords.

Standard colors

Basic colors have standard, memorable names:

Keyword	RGB hex value	Sample
black	#000000	
silver	#c0c0c0	
gray	#808080	
white	#ffffff	
maroon	#800000	
red	#ff0000	
purple	#800080	
fuchsia	#ff00ff	
green	#008000	
lime	#00ff00	
olive	#808000	
yellow	#ffff00	
navy	#000080	
blue	#0000ff	
teal	#008080	
aqua	#00ffff	

In addition to these 16 colors, about 150 other colors have a keyword associated to them:

Keyword	RGB hex value	Sample
aliceblue	#f0f8ff	
antiquewhite	#faebd7	
aqua	#00ffff	
aquamarine	#7fffd4	
azure	#f0ffff	
beige	#f5f5dc	
bisque	#ffe4c4	
black	#000000	
blanchedalmond	#ffebcd	
blue	#0000ff	
blueviolet	#8a2be2	
brown	#a52a2a	

Keyword	RGB hex value	Sample
burlywood	#deb887	
cadetblue	#5f9ea0	
chartreuse	#7fff00	
chocolate	#d2691e	
coral	#ff7f50	
cornflowerblue	#6495ed	
cornsilk	#fff8dc	
crimson	#dc143c	
cyan	#00ffff (synonym of aqua)	
darkblue	#00008b	
darkcyan	#008b8b	
darkgoldenrod	#b8860b	
darkgray	#a9a9a9	
darkgreen	#006400	
darkgrey	#a9a9a9	
darkkhaki	#bdb76b	
darkmagenta	#8b008b	
darkolivegreen	#556b2f	
darkorange	#ff8c00	
darkorchid	#9932cc	
darkred	#8b0000	
darksalmon	#e9967a	
darkseagreen	#8fbc8f	
darkslateblue	#483d8b	
darkslategray	#2f4f4f	
darkslategrey	#2f4f4f	
darkturquoise	#00ced1	
darkviolet	#9400d3	
deeppink	#ff1493	
deepskyblue	#00bfff	
dimgray	#696969	
dimgrey	#696969	
dodgerblue	#1e90ff	
firebrick	#b22222	
floralwhite	#fffaf0	
forestgreen	#228b22	
fuchsia	#ff00ff	
gainsboro	#dcdcdc	
ghostwhite	#f8f8ff	
gold	#ffd700	
goldenrod	#daa520	
gray	#808080	
green	#008000	
greenyellow	#adff2f	
grey	#808080 (synonym of gray)	
honeydew	#f0fff0	
hotpink	#ff69b4	
indianred	#cd5c5c	
indigo	#4b0082	
ivory	#fffff0	
khaki	#f0e68c	
lavender	#e6e6fa	
lavenderblush	#fff0f5	
lawngreen	#7cfc00	
lemonchiffon	#fffacd	
lightblue	#add8e6	
lightcoral	#f08080	
lightcyan	#e0ffff	
lightgoldenrodyellow	#fafad2	

Keyword	RGB hex value	Sample
lightgray	#d3d3d3	
lightgreen	#90ee90	
lightgrey	#d3d3d3

whitesmoke	#f5f5f5	
yellow	#ffff00	
yellowgreen	#9acd32	

Initially, in CSS Level 1, only 16 basic colors were defined, with `orange` added in CSS Level 2. Web designers found this list too short, and browser vendors added numerous names for colors based on the X11 color names. In SVG 1, then in CSS Colors Level 3, these names got standardized, formally defined, and made uniform (some had different spellings that are now aliases). They are called *extended color keywords*, *X11 colors*, or *SVG colors*.

In CSS Colors Level 4, an additional color, `rebeccapurple` was added to honor web pioneer Eric Meyer.

transparent

The `transparent` keyword represents a fully transparent color. This makes the background behind the colored item completely visible. Technically, `transparent` is a shortcut for `rgb(0 0 0 / 0%)`.

To prevent unexpected behavior, such as in a `<gradient>`, the current CSS spec states that `transparent` should be calculated in the alpha-premultiplied color space. However, be aware that older browsers may treat it as black with an alpha value of `0`.

The `transparent` keyword wasn't a true color in CSS Level 2 (Revision 1). It was a special keyword that could be used instead of a regular `<color>` value on two CSS properties: `background` and `border`. It was essentially added to allow developers to override an inherited solid color. With the advent of alpha channels in CSS Colors Level 3, `transparent` was redefined as a true color. It can now be used wherever a `<color>` value can be used.

Description

All names specify a color in the sRGB color space. Although the names more or less describe their respective colors, they are essentially artificial, without a strict rationale behind the terms used.

The color keywords all represent plain, solid colors without transparency.

Several keywords are aliases for each other:

- `aqua` / `cyan`
- `fuchsia` / `magenta`
- `darkgray` / `darkgrey`
- `darkslategray` / `darkslategrey`
- `dimgray` / `dimgrey`
- `lightgray` / `lightgrey`
- `lightslategray` / `lightslategrey`
- `gray` / `grey`
- `slategray` / `slategrey`

Though many keywords have been adapted from X11, their RGB values may differ from the corresponding color on X11 systems since manufacturers sometimes tailor X11 colors to their specific hardware.

Examples

Using named colors

HTML

```
<div id="container">
  <div id="one"></div>
  <div id="two"></div>
  <div id="three"></div>
</div>
```

CSS

```
#container {
  display: flex;
  justify-content: space-around;
  background-color: darkslateblue;
  padding: 20px;
}

#container > div {
  height: 100px;
  width: 100px;
  margin: 3px;
  border: 2px solid black;
}
```

```
#one {
  background-color: red;
}

#two {
  background-color: lavender;
}

#three {
  background-color: transparent;
}
```

- `<color>`: the data type of whose definition `<named-color>` is a constituent part.

<number> CSS type

The **`<number>`** CSS data type represents a number, being either an integer, a number with a fractional component, or a base-ten exponent in scientific notation.

Syntax

The syntax of `<number>` extends the syntax of `<integer>`. A fractional value is represented by a `.` followed by one or more decimal digits, and may be appended to an integer. A `<number>` can also end with the letter `e` or `E` followed by an integer, which indicates a base-ten exponent in scientific notation. There is no unit associated with numbers.

As with integers, the first character of the number can be immediately preceded by `-` or `+` to indicate the number's sign: whether the number is positive or negative.

Interpolation

When animated, values of the `<number>` CSS data type are interpolated as real, floating-point numbers. The speed of the interpolation is determined by the easing function associated with the animation.

Examples

Valid numbers

```
12          A raw <integer> is also a <number>.
4.01        Positive fraction
-456.8      Negative fraction
0.0         Zero
+0.0        Zero, with a leading +
-0.0        Zero, with a leading -
.60         Fractional number without a leading zero
10e3        Scientific notation
-3.4e-2     Complicated scientific notation
```

Invalid numbers

```
12.         Decimal points must be followed by at least one digit.
+-12.2      Only one leading +/- is allowed.
12.1.1      Only one decimal point is allowed.
```

- CSS values and units module

<overflow> CSS type

The **`<overflow>`** enumerated value type represents the keyword values for the `overflow-block`, `overflow-inline`, `overflow-x`, and `overflow-y` longhand properties and the `overflow` shorthand property. These properties apply to block containers, flex containers, and grid containers.

Syntax

```
<overflow> = visible | hidden | clip | scroll | auto
```

Values

The `<overflow>` enumerated value type is specified using one of the values listed below.

`visible`

> Overflow content is not clipped and may be visible outside the element's padding box. The element box is not a scroll container. This is the default value for all the properties that have the `<overflow>` enumerated value type.

`hidden`

> Overflow content is clipped at the element's padding box. There are no scroll bars, and the clipped content is not visible (i.e., clipped content is hidden), but the content still exists. User agents do not add scrollbars and also do not allow users to view the content outside the clipped region by actions such as dragging on a touch screen or using the scroll wheel on a mouse. The content *can* be scrolled programmatically (for example, by setting the value of the `scrollLeft` property or the `scrollTo()` method). The content can also be scrolled via keyboard interaction; arrows enable scrolling through the content and tabbing to a focusable element within the hidden content enables scrolling the focused element into view. The element box on which this value is set is a scroll container.

`clip`

> Overflow content is clipped at the element's *overflow clip edge* that is defined using the `overflow-clip-margin` property. As a result, content overflows the element's padding box by the `<length>` value of `overflow-clip-margin` or by `0px` if not set. Overflow content outside the clipped region is not visible, user agents do not add a scrollbar, and programmatic scrolling is also not supported. No new formatting context is created.

`scroll`

> Overflow content is clipped at the element's padding box, and overflow content can be scrolled into view using scrollbars. User agents display scrollbars in both horizontal and vertical directions if only one value is set, whether or not any content is overflowing or clipped. The use of this keyword value, therefore, can prevent scrollbars from appearing and disappearing as content changes. Printers may still print overflowing content. The element box on which this value is set is a scroll container.

`auto`

Overflow content is clipped at the element's padding box, and overflow content can be scrolled into view. Unlike `scroll`, user agents display scrollbars *only if* the content is overflowing and hide scrollbars by default. If content fits inside the element's padding box, it looks the same as with `visible` but still establishes a new formatting context. The element box on which this value is set is a scroll container.

> **Note:** The keyword value `overlay` is a legacy value alias for `auto`. With `overlay`, the scroll bars are drawn on top of the content instead of taking up space.

Examples

This example demos all the `<overflow>` enumerated values for the `overflow` property.

HTML

The HTML in this example contains some lyrics within the `<pre>` element. The HTML also contains a link text to enable testing the effects of keyboard focus on overflow and scroll behaviors. The same HTML code is repeated multiple times to show the effect of each `<overflow>` enumerated value.

```
<pre> 
Oh, Rubber Duckie, you're the one
You make bath time lots of fun
Rubber Duckie, I'm awfully fond of you

Rubber Duckie, joy of joys
When I squeeze you, you make noise
Rubber Duckie, you're my very best friend, it's true

Oh, every day when I make my way to the tubby
I find a little fella who's cute and yellow and chubby
Rub-a-dub-dubby

<a href="#">Rubber Duckie</a>, you're so fine
And I'm lucky that you're mine
Rubber Duckie, I'm awfully fond of you
</pre>
```

```
<pre> 
Oh, Rubber Duckie, you're the one
You make bath time lots of fun
Rubber Duckie, I'm awfully fond of you

Rubber Duckie, joy of joys
When I squeeze you, you make noise
Rubber Duckie, you're my very best friend, it's true

Oh, every day when I make my way to the tubby
I find a little fella who's cute and yellow and chubby
Rub-a-dub-dubby

<a href="#">Rubber Duckie</a>, you're so fine
And I'm lucky that you're mine
Rubber Duckie, I'm awfully fond of you
</pre>

<pre> 
Oh, Rubber Duckie, you're the one
You make bath time lots of fun
Rubber Duckie, I'm awfully fond of you

Rubber Duckie, joy of joys
When I squeeze you, you make noise
Rubber Duckie, you're my very best friend, it's true

Oh, every day when I make my way to the tubby
I find a little fella who's cute and yellow and chubby
Rub-a-dub-dubby

<a href="#">Rubber Duckie</a>, you're so fine
And I'm lucky that you're mine
Rubber Duckie, I'm awfully fond of you
</pre>

Rub-a-dub-dubby

<a href="#">Rubber Duckie</a>, you're so fine
And I'm lucky that you're mine
Rubber Duckie, I'm awfully fond of you
</pre>
```

CSS

For the purpose of demonstration, the size of the `<pre>` element box has been defined to ensure that the content overflows its container in both the inline and block directions. A different `<overflow>` value is set for each of the repeating `<pre>` elements. For the `clip` value demonstration, an `overflow-clip-margin` has been added.

```
pre {
  border: 2px dashed red;
  margin-bottom: 3em;
}

::before {
  font-weight: bold;
  color: white;
  background: crimson;
  display: inline-block;
  width: 100%;
  padding: 3px 5px;
  box-sizing: border-box;
}
```

```
pre {
  block-size: 100px;
  inline-size: 295px;
}

pre:nth-of-type(1) {
  overflow: hidden;
}
pre:nth-of-type(1)::before {
  content: "hidden: ";
}

pre:nth-of-type(2) {
  overflow: clip;
  overflow-clip-margin: 1em;
}
pre:nth-of-type(2)::before {
  content: "clip: ";
}

pre:nth-of-type(3) {
  overflow: scroll;
}
pre:nth-of-type(3)::before {
  content: "scroll: ";
}

pre:nth-of-type(4) {
  overflow: auto;
}
pre:nth-of-type(4)::before {
  content: "auto: ";
}

pre:nth-of-type(5) {
  overflow: clip;
  overflow: overlay;
  overflow-clip-margin: 3em;
}
pre:nth-of-type(5)::before {
  content: "overlay (or clip if not supported): ";
}

pre:nth-of-type(6) {
  overflow: visible;
}
pre:nth-of-type(6)::before {
  content: "visible: ";
}
```

Result

To see the effect of keyboard focus on overflow and scroll behaviors, try tabbing through all the links in the example. Notice that the `clip` box does not create a scroll container, and the link does not come into view when the link is focused. The `visible` value, which has the link always in view, is also not a scroll container.

- CSS overflow module

<overflow-position> CSS type

The **`<overflow-position>`** enumerated value type defines how an alignment subject that is larger than its alignment container will overflow that container. For example, if centered items are wider than their container, the overflow may be displayed beyond the viewport's start edge, which can't be scrolled to. The `<overflow-position>` value defines whether the alignment mode should be overridden to ensure the content is visible (`safe`) or if the alignment mode must be adhered to (`unsafe`).

This data type is valid for the `align-content`, `align-items`, `align-self`, `justify-items` and `justify-self` properties as well as the `place-content`, `place-items`, and `place-self` shorthand properties. If omitted, the default overflow alignment is a blend of `safe` and `unsafe`.

Syntax

```
<overflow-position> = unsafe | safe
```

Values

The following keyword values are represented by the `<overflow-position>` grammar term:

`safe`

If the size of the alignment subject overflows the alignment container, the alignment subject is instead aligned as if the alignment mode were `start`.

`unsafe`

Regardless of the relative sizes of the alignment subject and alignment container, the given alignment value is honored.

param() CSS function

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`param()`** CSS function is used to set link parameters. This can be done using the `link-parameters` CSS function, in the fragment URL of an external resource, or in the `<url-modifier>` of the `url()` CSS function.

Syntax

```
/* a single value */
param(--color, red);

/* multiple values */
param(--color1, red),
param(--color2, blue),
param(--color3, green);
```

Values

`<dashed-ident>`

A `<dashed-ident>` is a user-defined variable that is used as an identifier in the `env()` CSS function to update the value.

`<declaration_value>` Optional

A `<declaration_value>` is the value of the attribute being updated. If the `<declaration-value>` is omitted, it represents an empty value.

Formal syntax

```
<param()> =
  param( <param-spec> , <declaration-value>? )

<param-spec> =
  color                          |
  accent-color                   |
  [ <dashed-ident> <css-type>? ]

<css-type> =
  <syntax-component>  |
  <type()>

<syntax-component> =
  <syntax-single-component> <syntax-multiplier>?  |
  '<' transform-list '>'

<type()> =
  type( <string> )

<syntax-single-component> =
  '<' <syntax-type-name> '>'  |
  <ident>

<syntax-multiplier> =
  '#'  |
  '+'

<syntax-type-name> =
  angle              |
  color              |
  custom-ident       |
  image              |
  integer            |
  length             |
  length-percentage  |
  number             |
  percentage         |
  resolution         |
  string             |
```

```
  time               |
  url                |
  transform-function
```

This syntax reflects the latest standard as per CSS Functions and Mixins Module, CSS Images Module Level 4, CSS Linked Parameters Module Level 1, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

All of the following examples use the same SVG file, which has attributes set with `env()` CSS function.

```
<!-- example of the code in the external SVG file -->
<svg viewBox="0 0 100 100" xmlns="http://www.w3.org/2000/svg">
  <rect
    width="100"
    height="100"
    stroke="env(--color1, chartreuse)"
    stroke-width="10"
    fill="env(--color2, darkgreen)"
   />
</svg>
```

Using <code>link-parameters</code> property

In this example the SVG attributes are updated with the `link-parameters` CSS property and `param()` function.

```
<div class="squares">
  <img
    class="original"
    src="square.svg"
    alt="A square with a chartreuse border and a dark green fill." />
  <img
    class="greyscale"
    src="square.svg"
    alt="A square with a slate grey border and a light grey fill." />
  <img
    class="high-contrast"
    src="square.svg"
    alt="A square with a fuchsia border and a yellow fill." />
</div>
```

```
.squares {
  height: 200px;
  display: flex;
  flex-direction: row;
  justify-content: space-between;
}
img {
  height: 100%;
}
```

```
.greyscale {
  link-parameters:
    param(--color1, slategrey),
    param(--color2, lightgrey);
  &:hover {
    link-parameters:
      param(--color1, lightgrey),
      param(--color2, slategrey);
  }
}
.high-contrast {
  link-parameters:
    param(--color1, fuchsia),
    param(--color2, yellow);
  &:hover {
    link-parameters:
      param(--color1, yellow),
      param(--color2, fuchsia);
  }
}
```

Passing <code>param()</code> into URL modifier

In this example the SVG attributes are updated by passing the `param()` function into the URL fragment of the `src` attribute of the `<img>` HTML element.

```
<img
  src="square.svg#param(--color1, slategrey)&param(--color2, lightgrey)"
  alt="A square with a slate grey border and a light grey fill."
/>
```

Using <code>param()</code> with <code>background-image</code> property

In this example the SVG attributes are updated by passing the `param()` function into the `url()` data type of the `background-image` CSS property.

```
.foo {
  background-image: url(
    "square.svg"
    param(--color1, slategrey)
    param(--color2, lightgrey)
  );
}
```

- `link-parameters`
- `env()`

<percentage> CSS type

The **`<percentage>`** CSS data type represents a percentage value. It is often used to define a size as relative to an element's parent object. Numerous properties can use percentages, such as `width`, `height`, `margin`, `padding`, and `font-size`.

> **Note:** Only calculated values can be inherited. Thus, even if a percentage value is used on the parent property, a real value (such as a width in pixels for a `<length>` value) will be accessible on the inherited property, not the percentage value.

Syntax

The `<percentage>` data type consists of a `<number>` followed by the percentage sign (`%`). Optionally, it may be preceded by a single `+` or `-` sign, although negative values are not valid for all properties. As with all CSS dimensions, there is no space between the symbol and the number.

Interpolation

When animated, values of the `<percentage>` data type are interpolated as real, floating-point numbers. The speed of the interpolation is determined by the easing function associated with the animation.

Examples

Width and margin-left

```
<div class="container">
  <div class="box1">Width: 50%, Left margin: 20%</div>
  <div class="box2">Width: 30%, Left margin: 60%</div>
</div>
```

```
.container {
  background-color: navy;
}

.box1 {
  width: 50%;
  margin-left: 20%;
  background-color: chartreuse;
}

.box2 {
  width: 30%;
  margin-left: 60%;
  background-color: pink;
}
```

Font-size

```
<div class="container">
  <p>Full-size text (18px)</p>
  <p><span class="half">50% (9px)</span></p>
  <p><span class="double">200% (36px)</span></p>
</div>
```

```
.container {
  font-size: 18px;
}

.half {
  font-size: 50%;
}

.double {
  font-size: 200%;
}
```

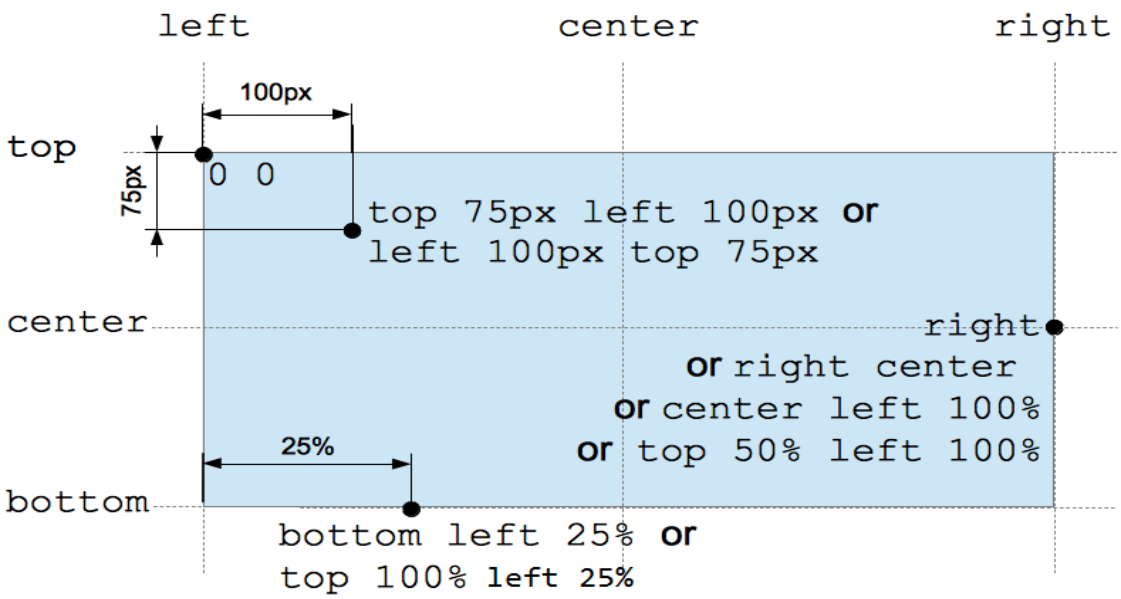
<position> CSS type

The **`<position>`** CSS data type denotes a two-dimensional coordinate used to set a location relative to an element box. It is used in the `background-position`, `object-position`, `mask-position` `offset-position`, `offset-anchor` and `transform-origin` properties.

> **Note:** The final position described by the `<position>` value does not need to be inside the element's box.

Syntax



The `<position>` data type is specified with one or two keywords, with optional offsets.

The keyword values are `center`, `top`, `right`, `bottom`, and `left`. Each keyword represents either an edge of the element's box or the center line between two edges. Depending on the context, `center` represents either the center between the left and right edges, or the center between the top and bottom edges.

If specified, an offset can be either a relative `<percentage>` value or an absolute `<length>` value. Positive values are offset towards the right or the bottom, whichever is appropriate. Negative values are offset in the opposite directions.

If only a single offset value is specified, it defines the x-coordinate, with the value for the other axis defaulting to `center`.

```
/* 1-value syntax */
keyword                 /* Either the horizontal or vertical position; the other axis defaults to center */
value                   /* The position on the x-axis; the y-axis defaults to 50% */

/* 2-value syntax */
keyword keyword         /* A keyword for each direction (the order is irrelevant) */
keyword value           /* A keyword for horizontal position, value for vertical position */
value keyword           /* A value for horizontal position, keyword for vertical position */
value value             /* A value for each direction (horizontal then vertical) */

/* 4-value syntax */
keyword value keyword value /* Each value is an offset from the keyword that precedes it */
```

> **Note:** The `background-position` property also accepts a three-value syntax. This is not allowed in other properties that use `<position>`.

Interpolation

When animated, a point's abscissa and ordinate values are interpolated independently. However, because the speed of the interpolation is determined by a single easing function for both coordinates, the point will move in a straight line.

Formal syntax

```
<position> =
  <position-one>   |
  <position-two>   |
  <position-four>

<position-one> =
  left             |
  center           |
  right            |
  top              |
  bottom           |
  x-start          |
  x-end            |
  y-start          |
  y-end            |
  block-start      |
  block-end        |
  inline-start     |
  inline-end       |
  <length-percentage>

<position-two> =
  [ left | center | right | x-start | x-end ] && [ top | center | bottom | y-start | y-end ]  |
  [ left | center | right | x-start | x-end | <length-percentage> ] [ top | center | bottom | y-start | y-end | <length-percentage> ]  |
  [ block-start | center | block-end ] && [ inline-start | center | inline-end ]  |
  [ start | center | end ]{2}

<position-four> =
  [ [ left | right | x-start | x-end ] <length-percentage> ] && [ [ top | bottom | y-start | y-end ] <length-percentage> ]  |
  [ [ block-start | block-end ] <length-percentage> ] && [ [ inline-start | inline-end ] <length-percentage> ]  |
  [ [ start | end ] <length-percentage> ]{2}

<length-percentage> =
```

```
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Valid positions

```
center
left
center top

right 8.5%
bottom 12vmin right -6px

10% 20%
8rem 14px
```

Invalid positions

```
left right
bottom top
10px 15px 20px 15px
```

<position-area> CSS type

The **`<position-area>`** CSS data type defines the cell or spanned cells of a **position-area grid**, a 3x3 grid whose center cell is an anchor element.

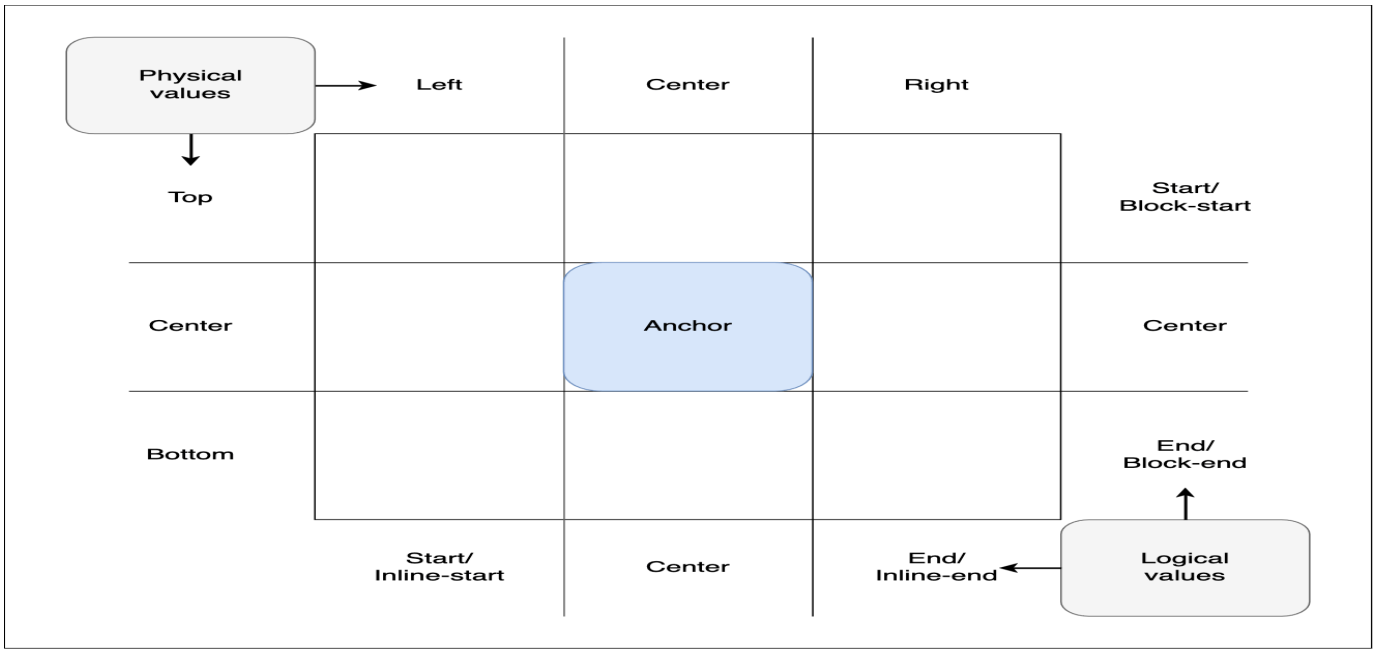
The `<position-area>` keyword values can be set as the value of the `position-area` property to place an anchor-positioned element in a specific location relative to its associated anchor element.

Syntax

```
<position-area> = [
  [ left | center | right | span-left | span-right | x-start | x-end | span-x-start | span-x-end | self-x-start | self-x-end | span-self-x-start | span-self-x-end | span-all ]
||
  [ top | center | bottom | span-top | span-bottom | y-start | y-end | span-y-start | span-y-end | self-y-start | self-y-end | span-self-y-start | span-self-y-end | span-all ]
|
  [ block-start | center | block-end | span-block-start | span-block-end | span-all ]
||
  [ inline-start | center | inline-end | span-inline-start | span-inline-end | span-all ]
|
  [ self-block-start | self-block-end | span-self-block-start | span-self-block-end | span-all ]
||
  [ self-inline-start | self-inline-end | span-self-inline-start | span-self-inline-end | span-all ]
|
  [ start | center | end | span-start | span-end | span-all ]{1,2}
|
  [ self-start | center | self-end | span-self-start | span-self-end | span-all ]{1,2}
]
```

Description

Position areas work on the concept of a **position-area grid**, a 3x3 grid of tiles composed of four grid lines, two on each axis, with an anchor element being the center tile:



When used as the value of a positioned element's `position-area` property, the dimensions of the center tile are defined by the containing block of the element's default anchor element. The dimensions of the grid's outer edge are defined by the positioned element's containing block. Logical keyterms are generally based on the writing mode and direction of the containing block, except for the `self-*` keyterms, which

are calculated from the writing mode of the anchor-positioned element.

The grid tiles are broken up into rows and columns:

- The three rows are represented by the physical values `top`, `center`, and `bottom`. They also have logical equivalents such as `block-start`, `center`, and `block-end`, and coordinate equivalents — `y-start`, `center`, and `y-end`.
- The three columns are represented by the physical values `left`, `center`, and `right`. They also have logical equivalents such as `inline-start`, `center`, and `inline-end`, and coordinate equivalents — `x-start`, `center`, and `x-end`.

`<position-area>` values contain one or two keywords defining a specific area of the position-area grid. Setting a `position-area` value on a positioned element places its containing block in the specified grid area:

```
/* Examples: Two keywords to place the element in a single specific tile */
position-area: top left;
position-area: bottom right;
position-area: start end;
position-area: center end;
position-area: block-start center;
position-area: inline-start block-end;
position-area: x-start y-end;
position-area: center self-y-end;

/* Examples: Two keywords to span the element across two tiles */
position-area: top span-left;
position-area: span-bottom right;
position-area: center span-start;
position-area: inline-start span-block-end;
position-area: y-start span-x-end;

/* Examples: Two keywords to span the element across three tiles */
position-area: top span-all;
position-area: block-end span-all;
position-area: self-x-start span-all;

/* Examples: One keyword with an implicit second keyword  */
position-area: top; /* equiv: top span-all */
position-area: inline-start; /* equiv: inline-start span-all */
position-area: center; /* equiv: center center */
position-area: span-all; /* equiv: span-all span-all */
position-area: start; /* equiv: start start */
position-area: end; /* equiv: end end */
```

The different types of keywords that can be used include:

- Physical grid keywords
- Generic logical row and column keywords
- Explicit inline and block logical keywords
- Coordinate grid keywords

> **Note:** Generally, you can't mix different types in one value, e.g., physical and logical. To do so results in invalid values. For example, `position-area: bottom inline-end` is not a valid value because it mixes physical and logical keywords.

Physical grid keywords

The physical grid keywords specify a cell or section of the `position-area` grid using physical values. These values are not affected by `writing-mode` or `direction` settings.

With physical row and column keywords, you can specify one keyword from each of the two lists below to select a single specific grid tile:

- `top`, `center`, or `bottom`: The top, center, or bottom row of the grid.
- `left`, `center`, or `right`: The left-hand, center, or right-hand column of the grid.

For example, `top left` selects the top left tile, while `center right` selects the center tile of the right-hand column.

Physical spanning grid keywords

The physical spanning keywords — when combined with a physical row or column keyword — specify a second grid tile for the position area to expand into. When such a combination is set as a `position-area` property value, a selected element is initially placed in the center of the specified row or column; it then spans in the direction specified in the spanning keyword, spanning two grid tiles:

`span-left`

Span the center column and the left-hand column of the grid.

`span-right`

Span the center column and the right-hand column of the grid.

`span-top`

Span the center row and the top row of the grid.

`span-bottom`

Span the center row and the bottom row of the grid.

`span-all`

Valid with all the keyword types, spans the cell listed as well as the adjacent cells in the same row or column. See `span-all` below.

For example, `top span-left` spans the top-center and top-left grid cells.

> **Note:** Trying to pair a row or column keyword with an inappropriate spanning keyword will result in an invalid value. For example, `right span-right` is invalid — you can't select the center-right grid tile and then try to span further to the right.

Physical grid keyword defaults

If only a single physical keyword is specified in the `position-area` value, the other value is implied as follows:

`left`, `right`, `top`, or `bottom`

The other value defaults to `span-all`, causing the element to span all three tiles of the column or row it was initially placed in. For example, `left` is equivalent to `left span-all`.

`span-left`, `span-right`, `span-top`, or `span-bottom`

The other value defaults to `span-all`. For example, `span-left` is equivalent to `span-left span-all`.

`center` or `span-all`

The other value defaults to the same as the first value. For example, `center` is equivalent to `center center` and `span-all` is equivalent to `span-all span-all`.

Logical grid keywords

The logical grid keywords specify an area of the position area grid using logical values. With these values, the position and direction are affected by `writing-mode` and `direction` settings on either the element's containing block or, in the case of the `self` keywords, the positioned element itself. There are two types of logical keywords; generic and explicit.

Generic logical row and column keywords

The generic logical keywords use the same terms for the inline and block directions, with the direction determined by the position of the keyterm within a pair of `<position-area>` values. The first value defines the block direction position and the second value defines the inline value. You can specify one or two keyterms from the following list. Specifying two from this list defines a single specific grid tile. The keyword position or direction is:

`start`

The start of the grid's block or inline direction, calculated from the containing block's writing mode.

`end`

The end of the grid's block or inline direction, calculated from the containing block's writing mode.

`self-start`

The start of the grid's block or inline direction, calculated from the element's own writing mode.

`self-end`

The end of the grid's block or inline direction, calculated from the element's own writing mode.

`center`

The center of the grid's block direction (if this keyword is specified first) or inline direction (if this keyword is specified second).

For example, `start end` and `self-start self-end` both describe the position at the start of the block direction and the end of the inline direction. With `writing-mode: horizontal-tb` set, this is the top right of the anchor element, whereas with `writing-mode: vertical-rl` it is the bottom right of the anchor.

Generic logical spanning row and column keywords

The generic logical spanning keywords — when combined with a logical row or column keyword — specify a second grid tile for the position area to expand into. When such a combination is set as a `position-area` property value, a selected element is initially placed in the center of the specified row or column, and it then spans in the direction specified in the spanning keyword, spanning two grid tiles:

`span-start`

Span the center tile and the start tile of the grid row/column, with the direction referring to the writing mode of the element's containing block.

`span-end`

Span the center tile and the end tile of the grid row/column, with the direction referring to the writing mode of the element's containing block.

`span-self-start`

Span the center tile and the start tile of the grid row/column for the positioned element's own writing mode.

`span-self-end`

Span the center tile and the end tile of the grid row/column, calculated from the element's own writing mode.

For example, `start span-end` and `self-start span-self-end` both specify a grid position area that starts in the center of the start block row, and spans across the tiles in that row that sit in the inline center and end columns. With `writing-mode: horizontal-tb` set, this would span over the top center and top right of the anchor, whereas with `writing-mode: vertical-rl` set it would span the element over the right center and bottom right.

Explicit inline and block logical keywords

The explicit inline and block logical row and column keywords refer explicitly to a block (row) or inline (column) position. You can specify one keyword for the block direction and one for the inline direction to select a single specific grid tile. Unlike with generic logical keyword values, the keyword order doesn't matter. However, declaring two keywords in the same axis invalidates the value.

`block-start`

The start of the grid's block direction calculated from the containing block's writing mode.

`block-end`

The end of the grid's block direction calculated from the containing block's writing mode.

`inline-start`

The start of the grid's inline direction calculated from the containing block's writing mode.

`inline-end`

The end of the grid's inline direction calculated from the containing block's writing mode.

For example, `block-start inline-end` specifies the tile at the start of the block direction and the end of the inline direction. With `writing-mode: horizontal-tb` set, this would be the tile at the top-right of the anchor, whereas with `writing-mode: vertical-rl` set this would be the tile at the bottom-right.

> **Note:** The specification defines `self` equivalents of these keywords — `block-self-start`, `block-self-end`, `inline-self-start`, and `inline-self-end`. However, these are not currently supported in any browser.

Explicit inline and block logical spanning keywords

The explicit logical spanning keywords — when combined with a logical row or column keyword — specify a second grid tile for the position area to expand into. When such a combination is set as a `position-area` property value, a selected element is initially placed in the center of the specified row or column, based on the containing block's writing mode, and it then spans in the direction specified in the spanning keyword, spanning two grid tiles:

`span-block-start`

Span the center tile and the block-start tile of the specified inline column.

`span-block-end`

Span the center tile and the block-end tile of the specified inline column.

`span-inline-start`

Span the center tile and the inline-start tile of the specified block row.

`span-inline-end`

Span the center tile and the inline-end tile of the specified block row.

For example, `block-end span-inline-start` selects the center tile of the end block row and spans across the tiles in that row that sit in the inline center and start columns. With `writing-mode: horizontal-tb` set, this would span the bottom-center and bottom-left grid tiles, whereas with `writing-mode: vertical-rl` set it would span the left-center and top-left grid tiles.

> **Note:** The specification defines `self` equivalents of these keywords, for example — `span-self-block-start`, `span-self-block-end`, `span-self-inline-start`, and `span-self-inline-end`. However, these are not currently supported in any browser.

> **Note:** Trying to pair a row or column keyword with an inappropriate spanning keyword will result in an invalid property value. For example, `block-end span-block-end` is invalid — you can't select the center block-end row and then try to span one tile further past the block end direction.

Logical grid keyword defaults

If only a single logical `<position-area>` keyword is specified, the other value is implied as follows:

`start`, `end`, `self-start`, or `self-end`

The other value defaults to the same as the first value, selecting the grid cell at the start row and column, or the end row and column.

`span-start`, `span-self-start`, `span-end`, `span-self-end`

The other value defaults to the same as the first value. For example, `span-start` is equivalent to `span-start span-start`.

`block-start`, `block-end`, `inline-start`, `inline-end`

The other value defaults to `span-all`, spanning all three tiles of the column or row set. For example, `block-start` is equivalent to `block-start span-all`.

`span-block-start`, `span-block-end`, `span-inline-start`, `span-inline-end`

The other value defaults to `span-all`. For example, `span-inline-start` is equivalent to `span-inline-start span-all`.

Coordinate grid keywords

These keywords specify the cells of the `position-area` grid using x- and y-coordinate values. Its position/direction will be affected by `writing-mode` and/or `direction` settings on either an element's containing block or, in the case of the `self` keywords, the element itself.

However, the grid cells are defined according to physical axes rather than block/inline directions:

- For `writing-mode: horizontal-tb` and `vertical-lr`, the x-axis runs left-to-right and the y-axis runs top-to-bottom.
- For `writing-mode: horizontal-tb; direction: rtl` and `writing-mode: vertical-rl`, the x-axis runs right-to-left and the y-axis runs top-to-bottom.

With coordinate row and column keywords, you can specify one keyword from the x-axis and one from the y-axis to define a single specific grid tile.

The x-axis keywords include:

`x-start`

The start tile along the grid's x-axis, calculated from the containing block's writing mode.

`x-end`

The end tile along the grid's x-axis, calculated from the containing block's writing mode.

`self-x-start`

The start tile along the grid's x-axis, calculated from the element's own writing mode.

`self-x-end`

The end tile along the grid's x-axis, calculated from the element's own writing mode.

`center`

The center of the grid's x-axis, calculated from the element's own writing mode.

The y-axis keywords include:

`y-start`

The start tile along the grid's y-axis, calculated from the containing block's writing mode.

`y-end`

The end tile along the grid's y-axis, calculated from the containing block's writing mode.

`self-y-start`

The start tile along the grid's y-axis, calculated from the element's own writing mode.

`self-y-end`

The end tile along the grid's y-axis, calculated from the element's own writing mode.

`center`

The center of the grid's y-axis, calculated from the element's own writing mode.

For example, `x-end y-start` and `self-x-end self-y-start` both select the grid cell at end of the x-axis and the start of the y-axis. With `writing-mode: horizontal-tb` set, this would be the cell to the top right of the anchor, whereas with `writing-mode: vertical-rl` is at the top left.

Coordinate spanning keywords

When combined with a coordinate row or column keyword, the coordinate-spanning keywords specify a second grid tile for the position area to expand into. When such a combination is set as a `position-area` property value, a selected element is initially placed in the center of the specified row or column, and it then spans in the direction specified in the spanning keyword, spanning two grid tiles:

`span-x-start`

: Span the center tile and the x-start tile of the specified y-axis row.

`span-x-end`

: Span the center tile and the x-end tile of the specified y-axis row.

`span-y-start`

: Span the center tile and the y-start tile of the specified x-axis column.

`span-y-end`

: Span the center tile and the y-end tile of the specified x-axis column.

For example, `y-end span-x-end` selects the tile at the center of the end y-row, and spans across the tiles in that row that sit in the x-center and x-end columns. With `writing-mode: horizontal-tb` set, the position grid area would span the grid tiles at the bottom-center and bottom-right, whereas with `writing-mode: vertical-rl` set it would span the bottom-center and bottom-left tiles.

> **Note:** The specification doesn't define separate coordinate `self` spanning keywords, but these are not needed — the spanning keywords can be used with both coordinate row and column keywords.

Coordinate grid keyword defaults

If only a single coordinate grid `<position-area>` keyword is specified, the other value is implied as follows:

`x-start`, `self-x-start`, `x-end`, `self-x-end`, `y-start`, `self-y-start`, `y-end`, or `self-y-end`

: The other value defaults to `span-all`, selecting the grid tiles spanning all three tiles of the column or row it was initially placed in. For example, `x-start` is equivalent to `x-start span-all`.

`span-x-start`, `span-x-end`, `span-y-start`, `span-y-end`, `span-self-x-start`, `span-self-x-end`, `span-self-y-end`, or `span-self-y-start`

: The other value defaults to `span-all`. For example, `span-x-start` is equivalent to `span-x-start span-all`.

<code>span-all</code>

`span-all` is a special keyword usable with all of the row and column keywords listed in the sections above. When you specify two values — a row/column keyword and `span-all`, the element is placed in the specified row or column, and it then spans all of the tiles in that row or column.

Examples

See the `position-area` property page.

For detailed information on anchor features and usage, see the CSS anchor positioning module and the Using CSS anchor positioning guide.

pow() CSS function

The **`pow()`** CSS function is an exponential function that returns the value of a base raised to the power of a number.

The `exp()` function is a special case of `pow()` where the value of the base is the mathematical constant e.

Syntax

```
/* A <number> value */
width: calc(10px * pow(5, 2)); /* 10px * 25 = 250px */
width: calc(10px * pow(5, 3)); /* 10px * 125 = 1250px */
width: calc(10px * pow(2, 10)); /* 10px * 1024 = 10240px */
```

Parameters

The `pow(base, number)` function accepts two comma-separated values as its parameters.

`base`

: A calculation that resolves to a `<number>`, representing the base.

`number`

: A calculation that resolves to a `<number>`, representing the exponent.

Return value

Returns a `<number>` representing $base^{number}$, that is, `base` raised to the power of `number`.

Formal syntax

```
<pow()> =
  pow( <calc-sum> , <calc-sum> )

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*
```

```
<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Scale headings by fixed ratio

The `pow()` function can be useful for strategies like CSS Modular Scale, which relates all the font-sizes on a page to each other by a fixed ratio.

HTML

```
<h1>Heading 1</h1>
<h2>Heading 2</h2>
<h3>Heading 3</h3>
<h4>Heading 4</h4>
<h5>Heading 5</h5>
<h6>Heading 6</h6>
```

CSS

```
h1 {
  font-size: calc(1rem * pow(1.5, 4));
}
h2 {
  font-size: calc(1rem * pow(1.5, 3));
}
h3 {
  font-size: calc(1rem * pow(1.5, 2));
}
h4 {
  font-size: calc(1rem * pow(1.5, 1));
}
h5 {
  font-size: calc(1rem * pow(1.5, 0));
}
h6 {
  font-size: calc(1rem * pow(1.5, -1));
}
```

progress() CSS function

The **`progress()`** CSS function returns a `<number>` value representing the position of one value (the progress value) relative to two other values (the progress start and end values).

Syntax

```
/* With fixed progress value */
progress(300, 0, 1000)
progress(50px, 0px, 100px)
progress(50%, 30%, 80%)

/* Unclamped return value */
progress(no-clamp 300, 0, 100)
progress(no-clamp 50px, 0px, 100px)

/* With custom property */
progress(var(--container-width), 320, 1200)

/* Inside math function */
calc((progress(var(--container-width), 20%, 80%) / 2) + 0.5)

/* Inside non-math function */
rgb(
  calc(255 * progress(var(--container-width), 320px, 1200px))
  calc(255 * progress(var(--container-width), 320px, 1200px)) 255 / 0.5
);

/* Math function inside progress() */
progress(calc(20 + 30), 0, 100)
```

Parameters

The `progress()` function takes an optional keyword followed by three comma-separated `<calc-sum>` expressions as parameters:

```
progress(no-clamp? <calc-sum>, <calc-sum>, <calc-sum>)
```

These are:

`no-clamp` Optional

A keyword that stops the return value from being clamped to the range `0` to `1`. It is written before the progress value, and is not followed by a comma. See Clamping the return value.

Progress

The value to calculate the position of relative to the other two values.

Progress start

The lower progress bound.

Progress end

The upper progress bound.

Return value

A `<number>` representing the position of the progress value relative to the other two values. This is calculated as follows:

```
(progress - progress start) / (progress end - progress start)
```

If the progress value is in between the progress start and progress end values, the return value will be between `0` and `1`, representing a percentage.

If the `no-clamp` keyword is included, then the return value can be any number. Otherwise, the return value is clamped to the range `0` to `1`.

Description

The CSS `progress()` function provides a way to calculate a progress ratio, which is useful for creating use cases such as progress bar animations, or boxes that fade in as they become wider to reveal their contents.

The simplest possible use might look like this:

```
opacity: progress(5, 0, 10);
```

In this case, the computed value of `opacity` would be `0.5`, as 5 is mid-way between `0` and `10`.

Clamping the return value

By default, the return value is clamped to the range `0` to `1`, so a progress value outside the progress start and end bounds returns the nearest bound:

```
/* Computes to 1, not 1.5 */
scale: progress(15, 0, 10);

/* Computes to 0, not -0.5 */
scale: progress(-5, 0, 10);
```

Including the `no-clamp` keyword before the progress value removes this restriction, so the function extrapolates beyond the bounds instead of stopping at them:

```
/* Computes to 1.5 */
scale: progress(no-clamp 15, 0, 10);

/* Computes to -0.5 */
scale: progress(no-clamp -5, 0, 10);
```

Note that `no-clamp` is a keyword rather than a separate parameter, so it is not followed by a comma.

Permitted unit types

The parameters of a `progress()` function can be mathematical expressions or simple values. The values (or expression results) can be any `<number>`, `<dimension>`, or `<percentage>` value. They can have different units, but they must all be of the same type, or else the function is invalid.

The example we saw previously is valid — all of its parameters are unitless `<number>` values:

```
progress(5, 0, 10)
```

The next example is also valid — all of its parameters have `<length>` units. Behind the scenes, the computed values are used for the calculation. Provided the `font-size` is `16px` at the point of calculation, `3em` will resolve to `48px`, which is `48%` of the way between `0px` and `100px`, so the return value will be `0.48`.

```
progress(3em, 0px, 100px)
```

The final couple of examples in this section is not valid, however. The types do not match, so the resulting calculations do not make sense.

```
progress(3s, 0px, 100px)
progress(3em, 0, 100)
```

Creating unitless values

The `progress()` function outputs unitless values, therefore it can be used for the purpose of removing units from values in the same manner as the `tan(atan2())` hack. Note however that, due to the updates in behavior around CSS typed arithmetic, this can also be achieved via simple division.

Combining <code>progress()</code> with other functions and custom properties

Because `progress()` only ever returns a unitless value, it is common to combine it with another math function such as `calc()` to output the value and units you want. You can also use CSS custom properties inside `progress()` functions — this makes sense, as you'll often want to set the same values in multiple places, and/or base them on custom properties set via JavaScript.

The following example calculates what percentage the viewport width is between a minimum width of `320px` and a maximum width of `1200px`. The `calc()` function is used to multiply the `progress()` return value by `600px` to convert it into a pixel value that will half of the viewport width's progress value between `320px` and `1200px`.

```
width: calc(progress(100vw, 320px, 1200px) * 600px);
```

For example, if the viewport width is `700px`, the progress value will be calculated as `((700 - 320) / (1200 - 320))` = `0.431818`. The width will then be calculated as `0.431818 * 600px`, which equals `259.1px`.

The next example is an update of the previous one, in which we've used custom properties for the progress, progress start, and progress end values.

```
width: calc(
  progress(
      var(--container-width),
      var(--custom-min-width),
      var(--custom-max-width)
    ) *
    var(--custom-max-width)
);
```

It is possible to use `progress()` functions to calculate individual values inside other functions and component values inside shorthand property values, provided your functions return valid types for those values.

This can result in some complex expressions. For example, here we are calculating the first two channels of an `rgb()` color proportionate to the same width proportion as before:

```
background-color: rgb(
  calc(
      255 *
        progress(
          var(--container-width),
          var(--custom-min-width),
          var(--custom-max-width)
        )
    )
    calc(
      255 *
        progress(
          var(--container-width),
          var(--custom-min-width),
          var(--custom-max-width)
        )
    )
    255 / 0.5
);
```

Formal syntax

```
<progress()> =
  progress( no-clamp? <calc-sum> , <calc-sum> , <calc-sum> )

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic <code>progress()</code> usage

In this example, we'll show basic usage of the `progress()` function to set a progress bar `width` as a percentage equal to the progress ratio of its parent's `width` between its `min-width` and `max-width`.

HTML

Our HTML features a `<section>` element representing our content, and a `<div>` element representing the width progress bar.

```
<section>
  <div class="progress"></div>
</section>
```

CSS

In our CSS, we first set some custom properties on our `<section>` element to represent its `min-width`, `max-width`, and `width`. We then set those properties to the appropriate custom property values, then give our `<section>` a solid `background-color` so it is visible.

```
html {
  height: 100%;
  font-family: sans-serif;
}

body,
section {
  height: inherit;
}
```

```
section {
  --custom-min-width: 300px;
  --custom-max-width: 700px;
  --custom-width: 600px;

  min-width: var(--custom-min-width);
  max-width: var(--custom-max-width);
  width: var(--custom-width);

  background-color: cyan;
}
```

Now onto our `<div>` — we first give it a `height` and a dark `background-color` so it stands out against our `<section>` element. We then calculate its `width` by using a `progress()` function to calculate the progress ratio of the width between the minimum and maximum width, then using a `calc()` function to multiply the `progress()` return value by `100%` to return a percentage.

```
.progress {
  height: 4px;
  background-color: red;

  width: calc(
    progress(
        var(--custom-width),
        var(--custom-min-width),
        var(--custom-max-width)
      ) *
      100%
  );
}
```

Result

This demo will render as follows:

The width of the `<div>` is `75%` of the `<section>` width, as the `min-width` is `400px`, the `max-width` is `700px`, and the `width` is `600px`, which is `75%` of the distance between the previous two values.

Resize effects on a container

This example shows off some more involved uses of the `progress()` function, resulting in some fun effects as the browser window is resized.

This example works much better when rendered full-size in a desktop browser tab. Therefore, we have not rendered it in an embedded live sample in this page. Instead, you can find it running live at CSS `progress()` function demo (also see the source code).

Open the live example in a separate tab, and try increasing and decreasing the browser window width to see the effect. Keep this open so you can refer back to it as you read the explanation below.

HTML

Our HTML features an `<article>` element that contains the rest of our content, and two `<section>` elements — one to hang a background image off, and the other one to contain our content. The `<section class="content">` also contains a `<div class="progress">` representing a width progress bar, the same as the one in our previous demo. We have omitted the rest of the content for brevity.

```
<article>
  <section class="background"></section>
  <section class="content">
    <div class="progress"></div>
    <!-- Content here -->
  </section>
</article>
```

JavaScript

In our script, we first grab a reference to our `<article>` element. We then define a function called `setContainerWidth()`, which grabs the `<article>`'s client width via `Element.getBoundingClientRect()`, and sets a custom property on it called `--container-width`, which is equal to the client width rounded down, with `px` appended to it.

We then set a `resize` event listener on the `Window` object, which runs `setContainerWidth()` when the browser window is resized. We also run it once to set the `--container-width` custom property on the `<article>` element once the page loads.

```
const articleElem = document.querySelector("article");

function setContainerWidth() {
  const clientWidth = articleElem.getBoundingClientRect().width;
  articleElem.style.setProperty(
    "--container-width",
    `${Math.floor(clientWidth)}px`,
  );
}

window.addEventListener("resize", setContainerWidth);

setContainerWidth();
```

With this set up, we can now set some property values based on the `--container-width`, so that parts of our design will dynamically change as the window resizes.

CSS

The following section explains just the CSS relevant to how we've used the `progress()` function in the demo. For the full CSS, see the CSS source.

We first center the `<article>` inside the `<body>` using flexbox, then set some custom properties on it to represent the `min-width` and `max-width` values we will use elsewhere. We then target the `<article>` element, giving it `min-width` and `max-width` values equal to the custom properties we set earlier. We set its `position` to `relative` so we can position its content relative to it, then give it a percentage `width`, fixed `height`, and `border`.

```
body {
  height: inherit;
  display: flex;
  justify-content: center;
  align-items: center;
  --custom-min-width: 320px;
  --custom-max-width: 1200px;
}

article {
  min-width: var(--custom-min-width);
  max-width: var(--custom-max-width);
  position: relative;
  width: 70%;
  height: 600px;
  border: 3px solid black;
}
```

Now on to our `progress` `<div>`. We set its `width` equal to a percentage based on the progress ratio of the `--container-width` custom property set on the `<article>` element via JavaScript between its `min-width` and `max-width` (we use the same custom properties here for the second and third `progress()` parameters as we did for the `<article>` `min-width` and `max-width`).

We also give it a `height` and `background-color`, then absolutely position it at the top and left corner of the `<article>`.

```
.progress {
  width: calc(
    progress(
        var(--container-width),
        var(--custom-min-width),
        var(--custom-max-width)
      ) *
      100%
  );
  height: 4px;
  background-color: red;
  position: absolute;
  top: 0;
  left: 0;
}
```

Next, we'll look at our `background` `<section>`. We absolutely position it relative to our `<article>`, setting `inset: 0` on it so that it adopts the same size and sits over the top of it. We then set a rather wide `background-image` on it, and position the background image by giving the `background-position-x` property the same value as we gave the progress bar's `width` property. This has the effect that, when you increase the browser window width, the background image is moved over to the left, creating a nice image scrolling effect.

```
.background {
  position: absolute;
  inset: 0;
  background-image: url("https://mdn.github.io/shared-assets/images/examples/wide-background.jpg");
  background-position-x: calc(
    progress(
        var(--container-width),
        var(--custom-min-width),
        var(--custom-max-width)
      ) *
      100%
  );
}
```

We position the `content` `<section>` absolutely so it sits over the top of the `background` `<section>`, then give it some `padding`. We then vary two property values as the browser window is resized, using the same progress ratio as before:

- We vary the R and G components of the `background-color`, multiplying the progress ratio by 255 in each case to get a proportionate channel value. As the window gets wider, the background color gets less blue and more white, making the scene look as it is going from night to day (the color value has an opacity of `0.5`, so it acts like a tint for the underlying image).
- We vary the `opacity` so that the content fades in a bit when the window gets wider.

```
.content {
  position: absolute;
  inset: 0;
  padding: 20px;
  background-color: rgb(
    calc(
        255 *
          progress(
            var(--container-width),
            var(--custom-min-width),
            var(--custom-max-width)
          )
      )
      calc(
        255 *
          progress(
            var(--container-width),
            var(--custom-min-width),
            var(--custom-max-width)
          )
      )
      255 / 0.5
  );
  opacity: calc(
    (
        progress(
            var(--container-width),
            var(--custom-min-width),
            var(--custom-max-width)
          ) /
          2
      ) +
      0.5
  );
}
```

random() CSS function

The **`random()`** CSS function generates a random value within a specified range, optionally limiting the possible values to step size intervals between those limits. It can be used when specifying a `<length>`, `<frequency>`, `<angle>`, `<time>`, `<resolution>`, `<percentage>`, `<number>`, or `<integer>` within a property value.

Try it

```
<div class="box"></div>
```

```
.box {
  rotate: random(property-scoped, 0deg, 360deg);
  width: random(property-scoped, 50px, 300px);
  background-color: hsl(random(property-scoped, 0, 360) 50% 50%);
  height: random(property-scoped, 50px, 300px);
```

```
}

@supports not (order: random(1, 2)) {
  body::before {
    content: "Your browser doesn't support the random() function.";
  }
}
```

Syntax

```
/* Basic usage */
random(0, 100)
random(10px, 500px)
random(0deg, 360deg)

/* With step interval */
random(0, 100, 10)
random(0rad, 1turn, 30deg)

/* With <random-key> */
random(auto, 0, 360)
random(element-scoped, 0s, 5s)
random(property-scoped, 0s, 5s)
random(property-index-scoped, 0s, 5s)
random(--unique-base, 400px, 100px)
random(fixed 0.5, 1em, 40vw)
random(--unique-base property-scoped, 100dpi, 300dpi)

/* With <random-key> and step interval */
random(property-scoped, 0deg, 360deg, 45deg)
random(--my-base, 1em, 3rem, 2px)
```

Parameters

The `random(seed, min, max, step)` function accepts two to four comma-separated expressions as its parameters.

`<random-key>` Optional

Controls which `random()` functions in the document will share a random base value, or *seed*, and which will get distinct values. Specified as one of the following values:

`auto`

The `auto` value is the default and is what is applied if the `<random-key>` is excluded. This random function generates independent random values. The random cache name, and thus the result, varies across every `random()` instance in a multi-component value, across different properties, and across different elements. This is equivalent to specifying `element-scoped property-index-scoped`.

`element-scoped`

Adds an element-specific identifier to the random cache name, so if applied over multiple properties (e.g., `width` and `height`) both properties use the same value, but each element (e.g., `<div>`) gets a different random values.

`property-scoped`

Adds the property name to the random cache name, so if applied over multiple properties (e.g., `width` and `height`) both properties gets a different random value, but each element (e.g., `<div>`) uses the same random values.

`property-index-scoped`

Adds the property name and the index of the `random()` function among all random functions used in the same property value to the random cache name, so multiple instances in the same declaration each get different random values.

`<dashed-ident>`

A custom name for the random cache key (e.g., `--my-random-key`). When used alone, the same random base value is shared across all elements and properties that use the same identifier. When combined with a `*-scoped` keyword, the sharing behavior is determined by the keyword.

`fixed <number>`

Bypasses the random cache name and uses the `<number>` — between `0` and `1`, inclusive of 0, exclusive of 1 — as the seed's value.

`<calc-sum>, <calc-sum>`

Specified as `<number>`, `<dimension>`, or `<percentage>` values, or calculations resolving to one of these types, defining the minimum and maximum values, respectively. Both values must be resolvable to the same data type. If the maximum is less than the minimum, the function will return the first `<calc-sum>` value.

`<calc-sum>` Optional

Specifies the step interval. If present and of the same data type as the minimum and maximum `<calc-sum>` values, it defines the return value to be the minimum value or at increments of the step value from the minimum value, up to the maximum value.

Return value

Returns a random `<number>`, `<dimension>`, or `<percentage>` between the minimum and maximum range values, inclusive, in the same type as the `<calc-sum>` parameters.

Description

The `random(SEED, MIN, MAX, STEP)` function specifies the minimum and maximum values and optional step increments, starting at the minimum value. The function generates a random result within the range specified. The seed, an optional `<random-key>` parameter, enables sharing or varying random base values across different properties and elements.

The minimum, maximum and step values specified must be of the same data type for the function to be valid. While the units in the two to three `<calc-sum>` parameters don't need to be the same, they do need to be of the same data type, such as `<number>`, `<percentage>`, `<length>`, `<angle>`, `<time>`, or `<frequency>`, to be valid.

Random base value

The random base value works like a seed for randomness. It's a starting number that is used to generate the final random result. When two `random()` functions share the same base value, their results vary together in a predictable pattern. When they have different base values, their results are completely independent of each other.

The optional first `<random-key>` parameter controls how the random base value is shared. It can be `auto`, a scope keyword (`element-scoped`, `property-scoped`, or `property-index-scoped`), a custom `<dashed-ident>`, `fixed <number>`, or a `<dashed-ident>` paired with a scope keyword.

Scope keywords

Used on their own, the scope keywords control sharing without a custom name:

- `property-scoped` shares a base value across all elements, per property.
- `element-scoped` gives each element its own base value, per property.
- `property-index-scoped` works like `property-scoped`, but also separates `random()` calls by position within a shorthand.

The `property-scoped` keyword makes `.a`, `.b`, and `.c` identical rectangles, since every element gets the same `width` value and the same `height` value:

```
.a,
.b,
.c {
  width: random(property-scoped, 10px, 200px);
  height: random(property-scoped, 10px, 200px);
}
```

The `element-scoped` values would give each element its own independently sized `width` value and `height` value.

The `property-index-scoped` keyword is useful in shorthands, where each position needs its own shared value:

```
.a,
.b,
.c {
  margin: random(property-index-scoped, 5px, 40px)
    random(property-index-scoped, 5px, 40px)
    random(property-index-scoped, 5px, 40px)
    random(property-index-scoped, 5px, 40px);
}
```

All three elements get the same top margin, the same right margin, and so on, but the four margin values differ from each other.

Custom names

A `<dashed-ident>` (e.g., `--custom-name`) used alone shares its base value globally: any `random()` call anywhere in the document with the same identifier gets the same result. This makes `.a`, `.b`, and `.c` identical squares, since every `width` and `height` resolves to the same value:

```
.a,
.b,
.c {
  width: random(--custom-name, 10px, 200px);
  height: random(--custom-name, 10px, 200px);
}
```

Pair a `<dashed-ident>` with a scope keyword to narrow that sharing. `property-scoped` keeps it global across elements but separates it by property:

```
.a,
.b,
.c {
  width: random(--custom-name property-scoped, 10px, 200px);
  height: random(--custom-name property-scoped, 10px, 200px);
}
```

`element-scoped` instead keeps `width` and `height` linked within each element, but gives each element its own value, so `.a`, `.b`, and `.c` become squares of different sizes:

```
.a,
.b,
.c {
  width: random(--custom-name element-shared, 10px, 200px);
  height: random(--custom-name element-shared, 10px, 200px);
}
```

Automatic behavior

When the first parameter is omitted, or explicitly set to `auto`, an ident is auto-generated from the property name and position. This behavior can cause some unexpected random base value sharing.

```
.foo {
  width: random(100px, 200px);
}
.foo:hover {
  width: random(100px, 200px);
}
.bar {
  margin: random(1px, 100px) random(1px, 100px);
}
.bar:hover {
  margin: random(1px, 100px) random(1px, 100px) random(1px, 100px)
    random(1px, 100px);
}
```

When the `<random-key>` defaults or is explicitly set to `auto`, the user agent auto-generates a seed name, or *generated value sharing identifier*, following consistent rules based on property name and order. Because of this, `random()` functions can end up with the same seed name and, therefore, the same random base value. In this example, the generated value sharing identifier for the `random()` function in the `width` property value is the same for `.foo` as for `.foo:hover`, so the value won't change between states. Similarly, the first two `random()` functions in both `margin` declarations have the same generated value sharing identifier, meaning the first two values in the `margin` shorthand will be unchanged when hovered; on hover, `bar`'s top and right margins will remain the same, but the bottom and left margins will get independent random values. To get an independent value for each `random()` function, provide a unique `<dashed-ident>`.

Custom properties

As with all CSS functions, when a `random()` function is included within a custom property value, the value remains a function; behaving like a text replacement mechanism, not storing a single return value.

```
--random-size: random(1px, 100px);
```

In this example, the `--random-size` custom property does not "store" the randomly generated result. When `var(--random-size)` is parsed it is effectively replaced with `random(1px, 100px)`, meaning each use creates a new `random()` function call with its own base value depending on the context in which its used.

This is not true in the case of using `random()` when registering a custom property with `@property`. Registered custom properties compute random values and store them.

In this example, as `--defaultSize` is registered, `.a`, `.b`, and `.c` will be squares of equal size, but their colors will be random, as `--random-angle` was not registered:

```
@property --defaultSize {
  syntax: "<length> | <percentage>";
  inherits: true;
  initial-value: random(100px, 200px);
}
:root {
  --random-angle: random(0deg, 360deg);
}
.a,
.b,
.c {
  background-color: hsl(var(--random-angle) 100% 50%);
  height: var(--defaultSize);
  width: var(--defaultSize);
}
```

Accessibility

Because `random()` can generate an unknown value within a range, you don't have full control over what you get. This can lead to inaccessible results. For example, if you use `random()` to generate text color, you could end up with a value that has low contrast with its background. It is important to be mindful of the context in which `random()` is used, ensuring your results are always accessible.

Formal syntax

```
<random()> =
  random( <random-key>? , <calc-sum> , <calc-sum> , <calc-sum>? )

<random-key> =
  auto                  |
  <random-cache-key>    |
  fixed <number [0,1]>

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<random-cache-key> =
  <dashed-ident>                                  ||
  element-scoped                                  ||
  [ property-scoped | property-index-scoped | <random-ua-ident> ]

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<random-ua-ident> =
  <custom-ident>

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic Usage

In this example, we'll generate random colors for some circular badges to demonstrate the basic usage of the `random()` function.

HTML

We include five badges, one using the `desaturated` class and two using the `unique` class.

```
<div class="badge"></div>
<div class="badge"></div>
<div class="badge desaturated"></div>
<div class="badge unique"></div>
<div class="badge unique"></div>
```

CSS

We render the five badges as circles. We use the `random()` function within an `hsl()` color function to define the `<angle>` of the `<hue>`. We set `property-scoped` to share the random base value between the default `badge` and the `desaturated` one, so it is a less saturated version of the same `<hue>`. We then override the `unique` badges to have a truly random `hue` by letting the base value sharing parameter default to `auto`.

```
.badge {
  display: inline-block;
  width: 5em;
  aspect-ratio: 1/1;
  border-radius: 50%;
  background: hsl(random(property-scoped, 0, 360) 50% 50%);
}
.badge.desaturated {
  background: hsl(random(property-scoped, 0, 360) 10% 50%);
}
.badge.unique {
  background: hsl(random(0, 360) 50% 50%);
}
```

```
@supports not (order: random(1, 2)) {
  body::before {
    content: "Your browser doesn't support the random() function.";
```

```
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

Result

Random value sharing between properties

In this example, we create a starry backdrop to demonstrate combining a `<dashed-ident>` with `element-scoped` to share a random base value between properties within each individual element, without sharing it across elements.

HTML

We include five particles, all sharing the same class name.

```
<div class="particle"></div>
<div class="particle"></div>
<div class="particle"></div>
<div class="particle"></div>
<div class="particle"></div>
```

CSS

Every particle has the same styles. We use the `random()` function for the `height`, `width`, `top`, and `left` values to randomly size and position each particle. We pair a `<dashed-ident>` with `element-scoped` for `height` and `width`, so each particle is a circle (its height matches its width) but sized independently of the others. `top` and `left` are left at the default `auto`, so each axis is positioned independently.

```
body {
  background: black;
}

.particle {
  border-radius: 50%;
  background: white;
  position: fixed;
  width: random(--particle-size element-scoped, 0.25em, 1em);
  height: random(--particle-size element-scoped, 0.25em, 1em);
  top: random(0%, 100%);
  left: random(0%, 100%);
  animation: move 1s alternate-reverse infinite;
}
```

```
@supports not (order: random(1, 2)) {
  body::before {
    content: "Your browser doesn't support the random() function.";
    color: white;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

Result

<ratio> CSS type

The **`<ratio>`** CSS data type describes the proportional relationship between two values. It mostly represents the aspect ratio, which relates width to height. For example, the `<ratio>` is used as a value for the `aspect-ratio` media feature in `@media` media queries, the `aspect-ratio` size feature in `@container` container queries, and as a value for the CSS `aspect-ratio` property.

Syntax

The `<ratio>` data type is a `<number>` followed by a forward slash ('/', Unicode `U+002F SOLIDUS`) and a second `<number>`. Both numbers must be positive. Spaces before and after the slash are optional. The first number represents the width, while the second represents the height. In addition a single `<number>` as a value is allowable.

Two ratios are compared using the quotients' numeric values. For example, 16/16 is less than 16/9 because it resolves to 1 while the second resolves to 1.7. This means a tall screen's aspect ratio is smaller than a wide screen's, and portrait images have smaller aspect ratios than landscape images.

Common aspect ratios

Ratio		Usage
`4/3` or `1.33333`		Traditional TV format in the twentieth century.

Ratio		Usage
`16/9` or `1.7777778`		Modern "widescreen" TV format.
`185/100` or `1.85`		The most common movie format since the 1960s.
`239/100` or `2.39`		"Widescreen," anamorphic movie format.

Formal syntax

```
<ratio> =
  <number [0,∞]> [ / <number [0,∞]> ]?
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Use in a media query

```
@media screen and (aspect-ratio >= 16/9) {
  /* … */
}
```

Use in a @container size query

```
@container (aspect-ratio > 1) and (width < 20em) {
  /* … */
}
```

Use as a CSS property value

```
.square {
  aspect-ratio: 1 / 1;
}
.circle {
  aspect-ratio: 1;
  border-radius: 50%;
}
.portrait {
  aspect-ratio: 5 / 7;
}
```

ray() CSS function

The **`ray()`** CSS function defines the `offset-path` line segment that an animated element can follow. The line segment is referred to as "ray". The ray begins from an `offset-position` and extends in the direction of the specified angle. The length of a ray can be constrained by specifying a size and using the `contain` keyword.

Syntax

```
/* all parameters specified */
offset-path: ray(50deg closest-corner contain at 100px 20px);

/* two parameters specified, order does not matter */
offset-path: ray(contain 200deg);

/* only one parameter specified */
offset-path: ray(45deg);
```

Parameters

The parameters can be specified in any order.

`<angle>`

Specifies the direction in which the line segment extends from the offset starting position. The angle `0deg` lies on the y-axis pointing up, and positive angles increase in the clockwise direction.

`<size>`

Specifies the length of the line segment, which is the distance between `offset-distance` `0%` and `100%`, relative to the containing box. This is an optional parameter (`closest-side` is used if no `<size>` is specified). It accepts one of the following keyword values:

`closest-side`: Distance between the ray's starting point and the closest side of the containing block of the element. If the ray's starting point lies on an edge of the containing block, the length of the line segment is zero. If the ray's starting point is outside the containing block, the edge of the containing block is considered to extend to infinity. This is the default value.

`closest-corner`: Distance between the ray's starting point and the closest corner in the element's containing block. If the ray's starting point lies on a corner of the containing block, the length of the line segment is zero.

`farthest-side`: Distance between the ray's starting point and the farthest side of the containing block of the element. If the ray's starting point is outside the containing block, the edge of the containing block is considered to extend to infinity.

`farthest-corner`: Distance between the ray's starting point and the farthest corner in the element's containing block.

`sides`: Distance between the ray's starting point and the point where the line segment intersects the containing block's boundary. If the starting point is on or outside the containing block's boundary, the length of the line segment is zero.

`contain`

Reduces the length of the line segment so that the element stays within the containing block even at `offset-distance: 100%`. Specifically, the segment's length is reduced by half the width or half the height of the element's border box, whichever is greater, and never less than zero. This is an optional parameter.

`at <position>`

Specifies the point where the ray begins and where the element is placed in its containing block. This is an optional parameter. If included, the `<position>` value must be preceded by the `at` keyword. If omitted, the value used is the `offset-position` value of the element. If omitted and the element doesn't have an `offset-position` value, the value used for the ray's starting position is `offset-position: normal`, which places the element at the center (or `50% 50%`) of the containing block.

Description

The `ray()` function positions an element along a path by specifying its location in a two-dimensional space through an angle and a distance from a reference point (polar coordinates). This feature makes the `ray()` function useful for creating 2D spatial transitions. For comparison, this approach differs from the method of specifying a point by its horizontal and vertical distances from a fixed origin (rectangular coordinates), which is used by the `translate()` function, and from moving an element along a defined path through animation.

As `ray()` works in 2D space, it's important to consider both the initial position and orientation of the element. When the `ray()` function is applied as the `offset-path` value on an element, here's how you can control these aspects:

- The element is initially positioned by moving the element's `offset-anchor` point to the element's offset starting position. By default, the ray's starting position is determined by the `offset-position` value. If `offset-position` is explicitly specified as `normal` (or omitted and allowed to default to `normal`), the element is positioned at the `center` (or `50% 50%`) of its containing block. Specifying `offset-position: auto` sets the starting position at the `top left` corner (or `0 0`) of the element's position.
- The element is initially rotated such that its inline axis — its direction of text flow — aligns with the angle specified by `ray()`. For example, with the `ray()` angle of `0deg`, which lies on the y-axis pointing up, the element's inline axis is rotated to be vertical to match the ray's angle. The element maintains this rotation throughout its path. To customize this behavior, use the `offset-rotate` property, which allows you to specify a different rotation angle or direction for the element, enabling more precise control over its appearance as it follows the path. For example, setting `offset-rotate: 0deg` will remove any rotation applied by `ray()`, aligning back the element's inline axis with the direction of text flow.

Formal syntax

```
<ray()> =
  ray( <angle>          &&
  <ray-size>?           &&
  contain?              &&
  [ at <position> ]? )

<ray-size> =
  <radial-extent>  |
  sides

<position> =
  <position-one>   |
  <position-two>   |
  <position-four>

<radial-extent> =
  closest-corner   |
  closest-side     |
  farthest-corner  |
  farthest-side

<position-one> =
  left               |
  center             |
  right              |
  top                |
  bottom             |
  x-start            |
  x-end              |
  y-start            |
  y-end              |
  block-start        |
  block-end          |
  inline-start       |
```

```
  inline-end           |
  <length-percentage>

<position-two> =
  [ left | center | right | x-start | x-end ] && [ top | center | bottom | y-start | y-end ]  |
  [ left | center | right | x-start | x-end | <length-percentage> ] [ top | center | bottom | y-start | y-end | <length-percentage> ]  |
  [ block-start | center | block-end ] && [ inline-start | center | inline-end ]  |
  [ start | center | end ]{2}

<position-four> =
  [ [ left | right | x-start | x-end ] <length-percentage> ] && [ [ top | bottom | y-start | y-end ] <length-percentage> ]  |
  [ [ block-start | block-end ] <length-percentage> ] && [ [ inline-start | inline-end ] <length-percentage> ]  |
  [ [ start | end ] <length-percentage> ]{2}

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Images Module Level 3, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5, Motion Path Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Defining the angle and starting position for a ray

This example shows how to work with an element's starting position and how the element's orientation is impacted by the specified ray angle.

CSS

```
body {
  width: fit-content;
  height: fit-content;
}

.container {
  width: 80vw;
  height: 100px;
  border: 1px dashed black;
  margin: 0 0.5em 2em 2em;
  text-align: center;
}

pre {
  font-size: 1em;
  text-align: right;
  padding-right: 10px;
  line-height: 1em;
}

.box {
  display: flex;
  justify-content: center;
  align-items: center;
  width: 50px;
  height: 50px;
}

.box + .box {
  opacity: 1;
}
```

```
.box {
  background-color: palegreen;
  border-top: 4px solid black;
  opacity: 20%;
}

.box:first-of-type {
  position: absolute;
}

.box1 {
  offset-path: ray(0deg);
}

.box2 {
  offset-path: ray(150deg);
}

.box3 {
  offset-rotate: 0deg;
  offset-position: 20% 40%;
  offset-path: ray(150deg);
}

.box4 {
  offset-position: 0 0;
  offset-path: ray(0deg);
}

.box5 {
  offset-path: ray(60deg closest-side at bottom right);
}
```

```
<pre>/* original */</pre>
<div class="container">
  <div class="box">0</div>
  <div class="box box0">0</div>
</div>

<pre>
  offset-path: ray(0deg);
  /* Default offset starting position is 50% 50% */
```

```
</pre>
<div class="container">
  <div class="box">0</div>
  <div class="box box1">1</div>
</div>

<pre>
  offset-path: ray(150deg);
</pre>
<div class="container">
  <div class="box">0</div>
  <div class="box box2">2</div>
</div>

<pre>
  offset-rotate: 0deg;
  offset-position: 20% 40%;
  offset-path: ray(150deg);
</pre>
<div class="container">
  <div class="box">0</div>
  <div class="box box3">3</div>
</div>

<pre>
  offset-position: 0 0;
  offset-path: ray(0deg);
</pre>
<div class="container">
  <div class="box">0</div>
  <div class="box box4">4</div>
</div>

<pre>
  offset-path: ray(60deg closest-side at bottom right);
</pre>
<div class="container">
  <div class="box">0</div>
  <div class="box box5">5</div>
</div>
```

Similar to `transform-origin`, the default anchor point is at the center of an element. This anchor point can be modified using the `offset-anchor` property.

In this example, various `offset-path: ray()` values are applied to the boxes numbered `1` to `5`. The "containing block" of each box is depicted with a dashed border. A faded box in the upper left corner shows each box's default position without any `offset-position` or `offset-path` applied, allowing for a side-by-side comparison. The top of each box is highlighted with a `solid` border to illustrate variations in ray starting points and orientations. After positioning at the ray's starting point, a box aligns with the direction of the specified ray angle. If `offset-position` is not specified, the default offset starting position of the ray is the center (or `50% 50%`) of the box's containing block.

Result

- `box1` gets initially positioned such that its anchor point (its center) is at the default offset starting position (`50% 50%` of the containing block). `box1` is also rotated to orient it towards the `0deg` angle of the ray. This will now be the starting point of the path. You can observe the change in position and rotation of the box by comparing it to the faded `box0` on the left. The box is rotated to match the `0deg` angle along y-axis, pointing up. The box rotation is evident from the orientation of the number inside the box.
- In `box2`, a greater positive angle of `150deg` is applied to the ray to show how the ray angle works. Starting from the top-left corner, the box is rotated in a clockwise direction to reach the specified angle of `150deg`.
- `box2` and `box3` have the same `offset-path` values. In `box3`, an `offset-rotate` of `0deg` is also applied to the element. As a result, the element will remain rotated at this specific angle all along the ray's path, and the element will not rotate in the direction of the path. Notice in `box3` that the ray path is at `150deg`, but the box orientation will not change along the path because of `offset-rotate`. Also note that the `offset-path` property of `box3` does not specify a starting `<position>`, so the ray's starting position is derived from the element's `offset-position`, which in this case is `top 20% left 40%`.
- The `offset-position` of `box4` is set to top-left corner (`0 0`) of the containing block, and as a result, the element's anchor point and the offset starting position coincide. The ray angle of `0deg` is applied to the element at this starting point.
- In `box5`, the `offset-path` property specifies the `at <position>` value, which places the box at the `bottom` and `right` edge of the element's containing block and `60deg` is applied to the ray's angle.

Animating an element along the ray

In this example, the first shape is shown as a reference for its position and orientation. A ray motion path is applied on the other shapes.

CSS

```
body {
  display: grid;
  grid-template-columns: 200px 100px;
  gap: 40px;
  margin-left: 40px;
}

.container {
  transform-style: preserve-3d;
  width: 150px;
  height: 100px;
  border: 2px dotted green;
}

.shape {
  width: 40px;
  height: 40px;
  background: #2bc4a2;
  margin: 5px;
  text-align: center;
  line-height: 40px;
  clip-path: polygon(0% 0%, 70% 0%, 100% 50%, 70% 100%, 0% 100%, 30% 50%);
  animation: move 5000ms infinite alternate ease-in-out;
}

.shape2 {
  offset-path: ray(120deg sides contain);
}
```

```
.shape3 {
  offset-rotate: 0deg;
  offset-path: ray(120deg sides contain);
}

.shape4 {
  offset-position: auto;
  offset-path: ray(120deg closest-corner);
}

.shape5 {
  offset-position: auto;
  offset-path: ray(120deg farthest-corner);
}

@keyframes move {
  0%,
  20% {
    offset-distance: 0%;
  }
  80%,
  100% {
    offset-distance: 100%;
  }
}
```

```
<div>
  <div class="container">
    <div class="shape shape1">&mdash;</div>
  </div>
</div>

<pre>/* no offset-path applied */</pre>

<div>
  <div class="container">
    <div class="shape shape2">&mdash;</div>
  </div>
</div>

<pre>offset-path: ray(120deg sides contain);</pre>

<div>
  <div class="container">
    <div class="shape shape3">&mdash;</div>
  </div>
</div>

<pre>
offset-path: ray(120deg sides contain);
offset-rotate: 0deg;
</pre>

<div>
  <div class="container">
    <div class="shape shape4">&mdash;</div>
  </div>
</div>

<pre>
  offset-position: auto;
  offset-path: ray(120deg closest-corner);
</pre>

<div>
  <div class="container">
    <div class="shape shape5">&mdash;</div>
  </div>
</div>

<pre>
  offset-position: auto;
  offset-path: ray(120deg farthest-corner);
</pre>
```

Result

In the first two samples where `offset-path` is applied, notice the orientation of the shape without `offset-rotate` and with `offset-rotate`. Both these samples use the default `offset-position` value `normal`, and therefore, the path motion starts from `50% 50%`. The last two `offset-path` samples show the impact of corner `<size>` values: `closest-corner` and `farthest-corner`. The `closest-corner` value creates a very short offset-path because the shape is already at the corner (`offset-position: auto`). The `farthest-corner` value creates the longest offset-path, going from the top-left corner of the containing block to the bottom-right corner.

<relative-size> CSS type

The **`<relative-size>`** CSS data type describes relative size keywords. The `<relative-size>` keywords define a size relative to the computed size of the parent element. This data type is used in the `font` shorthand and `font-size` properties.

Syntax

```
<relative-size> = smaller | larger
```

Values

The `<relative-size>` data type is defined using a keyword value chosen from the list below.

`smaller`

A relative size one size smaller than the inherited size.

`larger`

A relative size one size larger than the inherited size.

Description

The `<relative-size>` keywords are relative to the current size of the element. If the inherited size is defined using an `<absolute-size>` keyword, the `<relative-size>` value equates to the adjacent size in the `<absolute-size>` table. Otherwise, the relative increase or decrease in size is between 120% and 150%.

Examples

Comparing the keyword values

```
<ul>
  <li class="smaller">font-size: smaller;</li>
  <li>font-size is not specified</li>
  <li class="larger">font-size: larger;</li>
</ul>
```

```
li {
  margin-bottom: 0.3em;
}
.smaller {
  font-size: smaller;
}
.larger {
  font-size: larger;
}
```

rem() CSS function

The **`rem()`** CSS function returns a remainder left over when the first parameter is divided by the second parameter, similar to the JavaScript remainder operator (%). The remainder is the value left over when one operand, the dividend, is divided by a second operand, the divisor. It always takes the sign of the dividend.

> **Note:** To read about the unit `rem`, see the `<length>` page.

For example, the CSS `rem(27, 5)` function returns the remainder of `2`. When dividing 27 by 5, the result is 5 with a remainder of 2. The full calculation is `27 / 5 = 5 * 5 + 2`.

Syntax

```
/* Unitless <number> */
line-height: rem(21, 2); /* 1 */
line-height: rem(14, 5); /* 4 */
line-height: rem(5.5, 2); /* 1.5 */

/* Unit based <percentage> and <dimension> */
margin: rem(14%, 3%); /* 2% */
margin: rem(18px, 5px); /* 3px */
margin: rem(10rem, 6rem); /* 4rem */
margin: rem(26vmin, 7vmin); /* 5vmin */
margin: rem(1000px, 29rem); /* 72px - if root font-size is 16px */

/* Negative/positive values */
rotate: rem(200deg, 30deg); /* 20deg */
rotate: rem(140deg, -90deg); /* 50deg */
rotate: rem(-90deg, 20deg); /* -10deg */
rotate: rem(-55deg, -15deg); /* -10deg */

/* Calculations */
scale: rem(10 * 2, 1.7); /* 1.3 */
rotate: rem(10turn, 18turn / 3); /* 4turn */
transition-duration: rem(20s / 2, 3000ms * 2); /* 4s */
```

Parameters

The `rem(dividend, divisor)` function accepts two comma-separated values as its parameters. Both parameters must have the same type, number, dimension, or `<percentage>`, for the function to be valid. While the units in the two parameters don't need to be the same, they do need of the same dimension type, such as `<length>`, `<angle>`, `<time>`, or `<frequency>` to be valid.

`dividend`

A calculation that resolves to a `<number>`, `<dimension>`, or `<percentage>` representing the dividend.

`divisor`

A calculation that resolves to a `<number>`, `<dimension>`, or `<percentage>` representing the divisor.

Return value

Returns a `<number>`, `<dimension>`, or `<percentage>` (corresponds to the parameters' type) representing the remainder, that is, the operation left over.

- If `divisor` is `0`, the result is `NaN`.
- If `dividend` is `infinite`, the result is `NaN`.
- If `dividend` is positive the result is positive (`0+`), and if `dividend` is negative the result is negative (`0-`).

Formal syntax

```
<rem()> =
  rem( <calc-sum> , <calc-sum> )

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>       |
  <dimension>    |
  <percentage>   |
  <calc-keyword> |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

repeat() CSS function

The **repeat()** CSS function represents a repeated fragment of the track list or rule-line list. It allows repeated patterns of columns, rows, and their gap decorations, to be written in a compact form.

Try it

```
grid-template-columns: repeat(2, 60px);
rule-color: repeat(2, green, orange), yellow;
```

```
grid-template-columns: 1fr repeat(2, 60px);
rule-color: repeat(2, green), repeat(2, yellow);
```

```
grid-template-columns: repeat(2, 20px 1fr);
rule-color: repeat(auto, green), repeat(2, yellow);
```

```
grid-template-columns: repeat(auto-fill, 40px);
rule-color: repeat(2, orange, yellow), repeat(auto, green);
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-auto-rows: 40px;
  grid-gap: 10px;
  width: 220px;
  rule: solid 4px;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}
```

This function can be used with the following features:

CSS grid properties:

- grid-template-columns
- grid-template-rows

CSS gap properties:

- column-rule-color
- row-rule-color
- rule-color shorthand
- column-rule-style
- row-rule-style

- `rule-style` shorthand
- `column-rule-width`
- `row-rule-width`
- `rule-width` shorthand
- `column-rule` shorthand
- `row-rule` shorthand
- `rule` shorthand

Syntax

```
/* <track-repeat> values */
repeat(4, 1fr)
repeat(4, [col-start] 250px [col-end])
repeat(4, [col-start] 60% [col-end])
repeat(4, [col-start] 1fr [col-end])
repeat(4, [col-start] min-content [col-end])
repeat(4, [col-start] max-content [col-end])
repeat(4, [col-start] auto [col-end])
repeat(4, [col-start] minmax(100px, 1fr) [col-end])
repeat(4, [col-start] fit-content(200px) [col-end])
repeat(4, 10px [col-start] 30% [col-middle] auto [col-end])
repeat(4, [col-start] min-content [col-middle] max-content [col-end])

/* <auto-repeat> values */
repeat(auto-fill, 250px)
repeat(auto-fit, 250px)
repeat(auto-fill, [col-start] 250px [col-end])
repeat(auto-fit, [col-start] 250px [col-end])
repeat(auto-fill, [col-start] minmax(100px, 1fr) [col-end])
repeat(auto-fill, 10px [col-start] 30% [col-middle] 400px [col-end])

/* <fixed-repeat> values */
repeat(4, 250px)
repeat(4, [col-start] 250px [col-end])
repeat(4, [col-start] 60% [col-end])
repeat(4, [col-start] minmax(100px, 1fr) [col-end])
repeat(4, [col-start] fit-content(200px) [col-end])
repeat(4, 10px [col-start] 30% [col-middle] 400px [col-end])

/* <name-repeat> values */
repeat(5, [footer])
repeat(auto-fill, [header])
repeat(2, [header footer])

/* <repeat-line> */
repeat(4, dashed)
repeat(2, solid, dotted, inset)
repeat(3, medium)
repeat(4, red)
repeat(3, green medium outset)

/* <auto-repeat-line> */
repeat(auto, dotted)
repeat(auto, 10px)
repeat(auto, currentcolor)
repeat(auto, red, blue, green)
repeat(auto, var(--lineColor) var(--lineSize) solid)
```

Values

The `repeat()` function takes two arguments: The first argument specifies **repeat count**, and the second specifies the **repeated values list** (the list of values to be repeated).

Repeat count values

`<integer>`

A positive integer greater than or equal to `1` specifying the number of times the feature list in the second parameter will be repeated.

`auto-fill`

Specifies an auto repeater that repeats to fill a space. Resolves to the largest number of repetitions that does not cause overflow of a constrained (has a maximum size) content box. Otherwise, if the content box has a minimum size, the fewest number of repetitions that meets the minimum size. If there is neither a minimum nor a maximum size, resolves to `1`. When used with subgrid, the second parameter must be a list of line names.

`auto-fit`

Behaves as `auto-fill`, except that after placing grid items, any empty repeated tracks are collapsed.

`auto`

Specifies an auto repeater. Once the values from other components of the property value have been applied, the values from the second parameter are repeated as many times as needed, filling any missing values.

Repeated values list

A list from one of the following track list types. Whether the components of the list are comma- or space-separated, depends on which separator is expected for that property value list type.

`<line-names>`

To add line names to subgrids, each `<line-names>` is zero or more `<custom-ident>` values, space-separated and enclosed in square brackets, such as `[start header-start]`.

`<track-size>`

Each `<track-size>` is a positive `<length-percentage>`, a `minmax()` function with the first parameter being the keyword `min-content`, `max-content`, or `auto`, or a positive `<length-percentage>`, or a `fit-content()` function.

`<fixed-size>`

Each `<fixed-size>` is either a positive `<length-percentage>`, or a `minmax()` function whose first parameter is a positive `<length-percentage>` and whose second parameter is a non-negative dimension with the unit `fr` specifying the track's flex factor or the keyword `min-content`, `max-content`, or `auto`, or a `minmax()` function whose first parameter is a positive `<length-percentage>` or the keyword `min-content`, `max-content`, or `auto`, and whose second parameter is a positive `<length-percentage>`.

`<value>`

For defining gap rules, each `<value>` is a value that would be accepted by the property in which the `repeat()` appears, such as a `<line-style>`, `<line-width>`, `<color>`, or all three as a `<gap-rule>`.

Description

The `repeat()` function represents a repeated fragment within a comma- or space-separated values list, that allows a recurring pattern to be written in a more compact form that can be repeated a specified number of times or can be auto-repeated.

The generic form of the `repeat()` syntax is, approximately,

```
repeat( <repeat-count>, <values-list> )
```

The first argument, the **repeat count**, specifies the number of repetitions. It defines the number of times the list of values defined in the second parameter should be repeated. It is specified either as an integer value of `1` or more or as the keyword `auto-fill`, `auto-fit`, or `auto`.

The second argument is a comma- or space-separated list of values that are valid for the property in which the `repeat()` appears. It specifies the **repeated value type**, which is generally the *tracks* or *rule feature(s)* to be repeated.

tracks:

Specifies the set of tracks that will be repeated. Fundamentally this consists of one or more space-separated values, where each value represents the size of that track. Each size is specified using either a `<track-size>` value or a `<fixed-size>` value. You can also specify one or more line names before or after each track, by providing `<line-names>` values before and/or after the track size.

rule feature:

Specifies the rule feature that will be repeated. This is either a comma separated list of `<color>`, `<line-width>`, or `<line-style>` values, or a comma-separated list of shorthand declarations setting the line's color, width, and style.

Syntax forms

The syntax of the `repeat()` function has several forms:

`<track-repeat> = repeat( <integer>, [ <line-names>? <track-size> ]+ <line-names>? )`

The `<integer>` sets the repeat count.

The `<track-size>` values set the track size. A `<track-size>` is either a `<length-percentage>`, a `<flex>` value (a positive `fr` unit value), or the keyword `min-content`, `max-content`, or `auto`, a `fit-content()` function with a `<length-percentage>` parameter, or a `minmax()` function. For `minmax()` track values, the `min` is either a `<length-percentage>`, or the `min-content`, `max-content`, or `auto` keyword while the `max` can be any of those, or a `<flex>` value.

Each `<track-size>` is optionally preceded by `<line-names>`, which are zero or more space-separated `<custom-ident>` values enclosed in square brackets.

An ending `<line-names>` is optional.

`<auto-repeat> = repeat( auto-fill | auto-fit, [ <line-names>? <fixed-size> ]+ <line-names>? )`

The `auto-fill` or `auto-fit` keyword sets the repeat count

The `<fixed-size>` sets the track size. A `<fixed-size>` is either a `<length-percentage>` value, or a `minmax()` function with either the `min` or the `max` being a `<length-percentage>` and the other value also being a `<length-percentage>`, or set to the keyword `min-content`, `max-content`, or `auto`.

Each `<fixed-size>` is optionally preceded by `<line-names>`.

The ending `<line-names>` is optional.

`<fixed-repeat> = repeat( <integer>, [ <line-names>? <fixed-size> ]+ <line-names>? )`

Same as `<auto-repeat>`, except the `<integer>` sets the repeat count, so there is no auto-repeating.

`<name-repeat> = repeat( [ <integer> | auto-fill ], <line-names>+)`

The integer or `auto-fill` keyword sets the repeat count

The `<line-names>` are one or more space-separated `<custom-ident>` values enclosed in square brackets.

These line names (rather than track sizes) are relevant for `subgrid`.

`<repeat-value-type> = repeat( <integer> , <value># )`

The `<integer>` sets the repeat count.

The `<value>` is one or more comma-separated valid values for the property on which the `repeat()` function is applied.

Multiple `repeat()` functions of the `<repeat-value-type>` may be used within a single value declaration.

`<auto-repeat-value-type> = repeat( auto , <value># )`

The `auto` keyword specifies an auto repeater. An auto repeater will be used to fill in values for gaps that would not otherwise receive values from other parts of the list.

The `<value>` is one or more comma-separated valid values for the property on which the `repeat()` function is applied.

At most one `repeat()` in a given list of values may be an auto repeater.

Auto-fit versus auto-fill

When the first parameter of the `repeat()` function is a keyword, either `auto-fill`, `auto-fit`, or `auto`, rather than an integer, it creates an auto-repeater. An auto-repeating `repeat()` function repeats the values provided as the second parameter as many times as necessary.

With `auto-fill`, if the container has a definite or maximum size set in the relevant axis, the number of repetitions is the largest possible positive integer that does not cause the content to overflow its container. Treating each track as its maximal track sizing function (each independent value used to define `grid-template-rows` or `grid-template-columns`), if that is definite. Otherwise, if there is no definite or maximum size defined, the `repeat()` function is a minimum track sizing function. If any number of repetitions would overflow, the repetition is `1`. Otherwise, if the grid container has a definite minimal size in the relevant axis, the number of repetitions is the smallest possible positive integer that fulfills that minimum requirement. Otherwise, the specified track list repeats only once.

The `auto-fit` value behaves the same as `auto-fill`, except that after placing the grid items any empty repeated tracks are collapsed. An empty track is one with no in-flow grid items placed into or spanning across it. (This can result in all tracks being collapsed, if they're all empty.)

A collapsed track is treated as having a single fixed track sizing function of `0px`, and the gutters on either side of it collapse.

For the purpose of finding the number of auto-repeated tracks, the user agent floors the track size to a user agent specified value (e.g., `1px`), to avoid dividing by zero.

Use exceptions and rules

There are some rules and restrictions when using `repeat()`:

A property value can contain multiple `repeat()` functions.

```
.wrapper {
  grid-template-columns:
    repeat(2, 10px)
    repeat(2, minmax(min-content, max-content));
}
```

A property value can contain, at most, one auto-repeat `repeat()` function.

```
.wrapper {
  row-rule:
    repeat(auto, yellow 3px solid, red 1px dashed),
    repeat(auto, green 5px dotted);
}
```

If a property declaration uses `<auto-repeat>`, it is only allowed to use `<fixed-repeat>` for any additional `repeat()` calls. Automatic repetitions (`auto-fill` or `auto-fit`) cannot be combined with fully intrinsic or flexible sizes. For example, this is invalid, because it combines the `<auto-repeat>` form with the `<track-repeat>` form:

```
.wrapper {
  grid-template-columns:
    repeat(auto-fill, 10px)
    repeat(2, minmax(min-content, max-content));
}
```

The `repeat()` notation cannot be nested within another `repeat()` function.

```
.wrapper {
  grid-template-columns: repeat(
    2,
    minmax(min-content, max-content),
    repeat(3, 10px)
  );
  column-rule: repeat(
    auto,
    yellow 3px solid,
    repeat(5, green 5px dotted),
    red 1px dashed
  );
}
```

Formal syntax

```
<track-repeat> =
  repeat( [ <integer [1,∞]> ] , [ <line-names>? <track-size> ]+ <line-names>? )

<auto-repeat> =
  repeat( [ auto-fill | auto-fit ] , [ <line-names>? <track-size> ]+ <line-names>? )

<fixed-repeat> =
  repeat( [ <integer [1,∞]> ] , [ <line-names>? <fixed-size> ]+ <line-names>? )

<name-repeat> =
  repeat( [ <integer [1,∞]> | auto-fill ] , <line-names>+ )

<integer> =
  <number-token>

<line-names> =
  '[' <custom-ident>* ']'

<track-size> =
  <track-breadth>                              |
  minmax( <inflexible-breadth> , <track-breadth> )  |
  fit-content( <length-percentage [0,∞]> )

<fixed-size> =
  <fixed-breadth>                              |
  minmax( <fixed-breadth> , <track-breadth> )       |
  minmax( <inflexible-breadth> , <fixed-breadth> )

<track-breadth> =
  <length-percentage [0,∞]>  |
  <flex [0,∞]>               |
  min-content                |
  max-content                |
  auto

<inflexible-breadth> =
  <length-percentage [0,∞]>  |
  min-content                |
  max-content                |
  auto

<length-percentage> =
  <length>      |
  <percentage>

<fixed-breadth> =
  <length-percentage [0,∞]>
```

This syntax reflects the latest standard as per CSS Grid Layout Module Level 2, CSS Grid Layout Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Specifying grid columns using repeat()

HTML

```
<div id="container">
  <div>This item is 50 pixels wide.</div>
  <div>Item with flexible width.</div>
  <div>This item is 50 pixels wide.</div>
  <div>Item with flexible width.</div>
  <div>Inflexible item of 100 pixels width.</div>
</div>
```

CSS

```
#container {
  display: grid;
  grid-template-columns: repeat(2, 50px 1fr) 100px;
  grid-gap: 5px;
  box-sizing: border-box;
  height: 200px;
  width: 100%;
  background-color: #8cffa0;
  padding: 10px;
}

#container > div {
  background-color: #8ca0ff;
  padding: 5px;
}
```

<resolution> CSS type

The **`<resolution>`** CSS data type, used for describing resolutions in media queries, denotes the pixel density of an output device, i.e., its resolution.

On screens, the units are related to *CSS* inches, centimeters, or pixels, not physical values.

Syntax

The `<resolution>` data type consists of a strictly positive `<number>` followed by one of the units listed below. As with all CSS dimensions, there is no space between the unit literal and the number.

Units

`dpi`

Represents the number of dots per inch. Screens typically contains 72 or 96 dots per inch, but the dpi for printed documents is usually much greater. As 1 inch is 2.54 cm, `1dpi = 0.39dpcm`.

`dpcm`

Represents the number of dots per centimeter. As 1 inch is 2.54 cm, `1dpcm = 2.54dpi`.

`dppx`

Represents the number of dots per `px` unit. Due to the 1:96 fixed ratio of CSS `in` to CSS `px`, `1dppx` is equivalent to `96dpi`, which corresponds to the default resolution of images displayed in CSS as defined by `image-resolution`.

`x`

Alias for `dppx`.

> **Note:** Although the number `0` is always the same regardless of unit, the unit may not be omitted. In other words, `0` is invalid and does not represent `0dpi`, `0dpcm`, or `0dppx`.

Examples

Use in a media query

```
@media print and (resolution >= 300dpi) {
  /* … */
}

@media (resolution: 120dpcm) {
  /* … */
}

@media (resolution >= 2dppx) {
  /* … */
}

@media (resolution: 1x) {
```

```
  /* … */
}
```

Valid resolutions

```
96dpi
50.82dpcm
3dppx
```

Invalid resolutions

```
72 dpi     Spaces are not allowed between the number and the unit.
ten dpi    The number must use digits only.
0          The unit is required.
```

revert CSS keyword

The **`revert`** CSS keyword reverts the cascaded value of the property from its current value to the value the property would have had if no changes had been made by the current **style origin** to the current element. Thus, it resets the property either to user agent set value, to user set value, to its inherited value (if it is inheritable), or to initial value. It can be applied to any CSS property, including the CSS shorthand property `all`.

This keyword removes from the cascade all of the styles that have been overridden until the style being rolled back to is reached.

- If used by a site's own styles (the author origin), `revert` rolls back the property's cascaded value to the user's custom style, if one exists; otherwise, it rolls the style back to the user agent's default style.
- If used in a user's custom stylesheet, or if the style was applied by the user (the user origin), `revert` rolls back the cascaded value to the user agent's default style.
- If used within the user agent's default styles, this keyword is functionally equivalent to `unset`.

The `revert` keyword works exactly the same as `unset` in many cases. The only difference is for properties that have values set by the browser or by custom stylesheets created by users (set on the browser side).

Revert will not affect rules applied to children of an element you reset (but will remove effects of a parent rule on a child). So if you have a `color: green` for all sections and `all: revert` on a specific section, the color of the section will be black. But if you have a rule to make all paragraphs red, then all paragraphs will still be red in all sections.

> **Note:** Revert is just a value. It is still possible to override the `revert` value using specificity.

> **Note:** The `revert` keyword is different from and should not be confused with the `initial` keyword, which uses the initial value defined on a per-property basis by the CSS specifications. In contrast, user-agent stylesheets set default values on the basis of CSS selectors.
>
> For example, the initial value for the `display` property is `inline`, whereas a normal user-agent stylesheet sets the default `display` value of `<div>`s to `block`, of `<table>`s to `table`, etc.

Examples

Revert vs. unset

Although `revert` and `unset` are similar, they differ for some properties for some elements.

So in the below example, we set custom `font-weight`, but then try to `revert` and `unset` it inline in the HTML document. The `revert` keyword will revert the text to bold because that is the default value for headers in most browsers. The `unset` keyword will keep the text normal because, as an inherited property, the `font-weight` would then inherit its value from the body.

HTML

```
<h3 style="font-weight: revert; color: revert;">
  This should have its original font-weight (bold) and color: black
</h3>
<p>Just some text</p>
<h3 style="font-weight: unset; color: unset;">
  This will still have font-weight: normal, but color: black
</h3>
<p>Just some text</p>
```

CSS

```
h3 {
  font-weight: normal;
  color: blue;
}
```

Result

Revert all

Reverting all values is useful in a situation where you've made several style changes and then you want to revert to the browser default values. So in the above example, instead of reverting `font-weight` and `color` separately, you could just revert all of them at once - by applying the `revert` keyword on `all`.

HTML

```
<h3>This will have custom styles</h3>
<p>Just some text</p>
<h3 style="all: revert">This should be reverted to browser/user defaults.</h3>
<p>Just some text</p>
```

CSS

```
h3 {
  font-weight: normal;
  color: blue;
  border-bottom: 1px solid grey;
}
```

Result

Revert on a parent

Reverting effectively removes the value for the element you select with some rule and this happens only for that element. To illustrate this, we will set a green color on a section and red color on a paragraph.

HTML

```
<main>
  <section>
    <h3>This h3 will be dark green</h3>
    <p>Text in paragraph will be red.</p>
    This stray text will also be dark green.
  </section>
  <section class="with-revert">
    <h3>This h3 will be steelblue</h3>
    <p>Text in paragraph will be red.</p>
    This stray text will also be steelblue.
  </section>
</main>
```

CSS

```
main {
  border: 3px solid steelblue;
}

section {
  margin: 0.5rem;
  border: 2px dashed darkgreen;
}
```

```
main {
  color: steelblue;
}
section {
  color: darkgreen;
}
p {
  color: red;
}
section.with-revert {
  color: revert;
}
```

Result

Notice how the paragraph is still red even though a `color` property for the section was reverted. Also, note that both the header and plain text node are `steelblue`. The result of reverting makes it as if `section { color: darkgreen; }` did not exist for the section with `color: revert` applied.

Also, if neither the user agent nor the user override the `<h3>` or `<section>` color values, then the `steelblue` color is inherited from `<main>`, as the `color` property is an inherited property.

See also

- Use the `initial` keyword to set a property to its initial value.
- Use the `inherit` keyword to make an element's property the same as its parent.
- Use the `revert-layer` keyword to reset a property to the value established in a previous cascade layer.
- Use the `revert-rule` keyword to reset a property to the value of an earlier matching style rule.
- Use the `unset` keyword to set a property to its inherited value if it inherits or to its initial value if not.
- The `all` property lets you reset all properties to their initial, inherited, reverted, or unset state at once.

revert-layer CSS keyword

The **`revert-layer`** CSS-wide keyword rolls back the value of a property in a cascade layer to the value of the property in a CSS rule matching the element in a previous cascade layer. The value of a property with this keyword is recalculated as if no rules were specified on the target element in the current cascade layer.

If there is no other cascade layer to revert to for the matching CSS rule, the property value rolls back to the computed value derived from the current layer. Furthermore, if there is no matching CSS rule in the current layer, the property value for the element rolls back to the style defined in a previous style origin.

This keyword can be applied to any CSS property, including the CSS shorthand property `all`.

Revert-layer vs. revert

The `revert-layer` keyword lets you rollback styles to those specified in previous cascade layers within the author origin. The `revert` keyword, in comparison, lets you roll back styles applied in the author origin to those specified in the user origin or user-agent origin.

The `revert-layer` keyword is ideally meant to be applied to properties within a cascade layer. However, if applied to properties outside a cascade layer, it rolls back property values to any values set by presentational hints (such as `width` and `height` attributes or the `<s>` element in HTML), defaulting to the values established by the user agent's stylesheet or user styles. Unlike the `revert` keyword, which considers presentational hints as part of the author origin and reverts them as well, the `revert-layer` keyword ignores presentational hints outside the cascade layer, so it does not revert them.

Examples

Default cascade layer behavior

In the example below, two cascade layers are defined in the CSS, `base` and `special`. By default, rules in the `special` layer will override competing rules in the `base` layer because `special` is listed after `base` in the `@layer` declaration statement.

HTML

```
<p>This example contains a list.</p>

<ul>
  <li class="item feature">Item one</li>
  <li class="item">Item two</li>
  <li class="item">Item three</li>
</ul>
```

CSS

```
@layer base, special;

@layer special {
  .item {
    color: red;
  }
}

@layer base {
  .item {
    color: blue;
  }
  .feature {
    color: green;
  }
}
```

Result

All the `<li>` elements match the `item` rule in the `special` layer and are red. This is the default cascade layer behavior, where rules in the `special` layer take precedence over rules in the `base` layer.

Revert to style in previous cascade layer

Let's examine how the `revert-layer` keyword changes the default cascade layer behavior. For this example, the `special` layer contains an additional `feature` rule targeting the first `<li>` element. The `color` property in this rule is set to `revert-layer`.

HTML

```
<p>This example contains a list.</p>

<ul>
  <li class="item feature">Item one</li>
  <li class="item">Item two</li>
  <li class="item">Item three</li>
</ul>
```

CSS

```
@layer base, special;

@layer special {
  .item {
    color: red;
  }
  .feature {
    color: revert-layer;
  }
}

@layer base {
  .item {
    color: blue;
  }
  .feature {
    color: green;
  }
}
```

Result

With `color` set to `revert-layer`, the `color` property value rolls back to the value in the matching `feature` rule in the previous layer `base`, and so 'Item one' is now green.

Revert to style in previous origin

This example shows the `revert-layer` keyword behavior when there is no cascade layer to revert to *and* there is no matching CSS rule in the current layer to inherit the property value.

HTML

```
<p>This example contains a list.</p>

<ul>
  <li class="item feature">Item one</li>
  <li class="item">Item two</li>
  <li class="item">Item three</li>
</ul>
```

CSS

```
@layer base {
  .item {
    color: revert-layer;
  }
}
```

Result

The style for all `<li>` elements rolls back to the defaults in the user-agent origin.

- `revert`
- `revert-rule`
- `unset`
- `all`
- CSS cascading and inheritance module

revert-rule CSS keyword

The **`revert-rule`** CSS-wide keyword rolls back the cascaded value of a property to the value it would have had if the current style rule had not been present. The cascade then determines the value from the remaining declarations — this could be another rule in the same cascade layer, a rule in a different layer, a different style origin, or a default value (`inherited` or `initial`).

When used inside a CSS animation (the animation origin), the `revert-rule` keyword behaves like `revert-layer`.

This keyword can be applied to any CSS property, including the CSS shorthand property `all`.

Revert-rule vs. revert-layer vs. revert

The `revert-rule`, `revert-layer`, and `revert` keywords each roll back the cascade, but at different levels of granularity:

- `revert` removes all declarations from the current style origin, rolling back to the previous origin (for example, from author styles to user-agent styles).
- `revert-layer` removes all declarations from the current cascade layer, rolling back to the previous layer within the same origin.
- `revert-rule` removes only the declarations from the current style rule. Other rules in the same cascade layer still apply.

This makes `revert-rule` useful for conditionally ignoring specific declarations within a rule while still respecting declarations from other rules in the same layer.

Examples

Rolling back to the previous rule

In this example, two rules target the same element. The second rule uses `revert-rule` on the `color` property, which causes the cascade to determine the value as if the `p.special` rule were not present, falling back to the value established by the first rule.

HTML

```
<p class="special">This paragraph has special styling.</p>
```

CSS

```
body {
  font-family: system-ui;
}

@supports not (color: revert-rule) {
  body::before {
    content: "Your browser doesn't support the revert-rule keyword yet.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1em;
  }
}
```

```
p {
  color: blue;
  font-weight: bold;
}

p.special {
  color: revert-rule;
  border: 1px solid currentColor;
}
```

Result

The paragraph text is blue from the `p` rule because `color: revert-rule` causes the `color` declaration in `p.special` to be ignored. The `font-weight` and `border` declarations are unaffected.

Reverting from a style attribute

When `revert-rule` is used in a style attribute, it causes the cascade to act as if the style attribute were not present. This works because the style attribute is treated as its own style rule.

HTML

```
<p style="color: revert-rule">This text uses the stylesheet color.</p>
```

CSS

```
body {
  font-family: system-ui;
}

@supports not (color: revert-rule) {
  body::before {
    content: "Your browser doesn't support the revert-rule keyword yet.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1em;
  }
}
```

```
p {
  color: green;
}
```

Result

The paragraph text is green because `revert-rule` causes the cascade to ignore the style attribute's declaration, and the `p` rule takes effect.

Chaining multiple <code>revert-rule</code> values

If multiple rules use `revert-rule` for the same property, the cascade ignores each of them in turn, continuing back through earlier rules until it finds a concrete value.

HTML

```
<p class="a b">This text is styled by a chain of revert-rule values.</p>
```

CSS

```
body {
  font-family: system-ui;
}

@supports not (color: revert-rule) {
  body::before {
    content: "Your browser doesn't support the revert-rule keyword yet.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1em;
  }
}
```

```
p {
  color: red;
}
p.a {
  color: revert-rule;
}
p.b {
  color: revert-rule;
}
```

Result

Both the `p.b` and `p.a` rules are ignored by `revert-rule`. The cascade falls through to the `p` rule, so the text is red.

- CSS cascading and inheritance module

round() CSS function

The **`round()`** CSS function returns a rounded number based on a selected rounding strategy.

Authors should use a custom CSS property (e.g., `--my-property`) for the rounding value, interval, or both; using the `round()` function is redundant if these have known values.

Syntax

```
width: round(var(--width), 50px);
width: round(up, 101px, var(--interval));
width: round(down, var(--height), var(--interval));
margin: round(to-zero, -105px, 10px);
```

Parameters

The `round(<rounding-strategy>, valueToRound, roundingInterval)` function specifies an optional rounding strategy, a value (or mathematical expression) to be rounded and a rounding interval (or mathematical expression). The `valueToRound` is rounded according to the rounding strategy, to the nearest integer multiple of `roundingInterval`.

`<rounding-strategy>`

The rounding strategy. This may be one of the following values:

`up`

Round `valueToRound` up to the nearest integer multiple of `roundingInterval` (if the value is negative, it will become "more positive"). This is equivalent to the JavaScript `Math.ceil()` method.

`down`

Round `valueToRound` down to the nearest integer multiple of `roundingInterval` (if the value is negative, it will become "more negative"). This is equivalent to the JavaScript `Math.floor()` method.

`nearest` (default)

Round `valueToRound` to the nearest integer multiple of `roundingInterval`, which may be either above or below the value. If the `valueToRound` is half way between the rounding targets above and below (neither is "nearest"), it will be rounded up. Equivalent to JavaScript `Math.round()`.

`to-zero`

Round `valueToRound` to the nearest integer multiple of `roundingInterval` closer to/towards zero (a positive number will decrease, while a negative value will become "less negative"). This is equivalent to the JavaScript `Math.trunc()` method.

`valueToRound`

The value to be rounded. This must be a `<number>`, `<dimension>`, or `<percentage>`, or a mathematical expression that resolves to one of those values.

`roundingInterval`

The rounding interval. This is a `<number>`, `<dimension>`, or `<percentage>`, or a mathematical expression that resolves to one of those values. If `valueToRound` is a `<number>`, `roundingInterval` may be omitted and defaults to `1`. Otherwise, omitting it results in an invalid expression.

Return value

The value of `valueToRound`, rounded to the nearest lower or higher integer multiple of `roundingInterval`, depending on the `rounding strategy`.

- If `roundingInterval` is 0, the result is `NaN`.
- If `valueToRound` and `roundingInterval` are both `infinite`, the result is `NaN`.
- If `valueToRound` is infinite but `roundingInterval` is finite, the result is the same `infinity`.
- If `valueToRound` is finite but `roundingInterval` is infinite, the result depends on the rounding strategy and the sign of `A`:

    - `up` - If `valueToRound` is positive (not zero), return `+∞`. If `valueToRound` is `0+`, return `0+`. Otherwise, return `0-`.
    - `down` - If `valueToRound` is negative (not zero), return `-∞`. If `valueToRound` is `0-`, return `0-`. Otherwise, return `0+`.
    - `nearest`, `to-zero` - If `valueToRound` is positive or `0+`, return `0+`. Otherwise, return `0-`.
- The argument calculations can resolve to `<number>`, `<dimension>`, or `<percentage>`, but must have the same type, or else the function is invalid; the result will have the same type as the arguments.
- If `valueToRound` is exactly equal to an integer multiple of `roundingInterval`, `round()` resolves to `valueToRound` exactly (preserving whether `valueToRound` is `0-` or `0+`, if relevant). Otherwise, there are two integer multiples of `roundingInterval` that are potentially "closest" to `valueToRound`, lower `roundingInterval` which is closer to `-∞` and upper `roundingInterval` which is closer to `+∞`.

Formal syntax

```
<round()> =
  round( <rounding-strategy>? , <calc-sum> , <calc-sum>? )

<rounding-strategy> =
  nearest     |
  up          |
  down        |
  to-zero     |
  line-width

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Round positive values

This example demonstrates how the `round()` function's rounding strategies work for positive values.

Of the five boxes below, the `round()` function is used to set the height of the last four. The value to be rounded is between 100 px and 125 px in each case, and the rounding value is 25px in all cases. The height of the boxes is therefore either rounded up to 125 px or down to 100 px.

HTML

The HTML defines 5 `div` elements that will be rendered as boxes by the CSS. The elements contain text indicating the rounding strategy, initial value, and expected final height of the box (in parentheses).

```
<div class="box box-1">height: 100px</div>
<div class="box box-2">up 101px (125px)</div>
<div class="box box-3">down 122px (100px)</div>
<div class="box box-4">to-zero 120px (100px)</div>
<div class="box box-5">nearest 117px (125px)</div>
```

CSS

```
body {
  height: 100vh;
  display: flex;
  justify-content: center;
  align-items: center;
  gap: 50px;
}
```

The CSS that is applied to all boxes is shown below. Note that we apply a custom CSS property named `--rounding-interval`, that we will use for the rounding interval.

```
div.box {
  width: 100px;
  height: 100px;
  background: lightblue;
  --rounding-interval: 25px;
}
```

The first `div` from the left isn't targeted with specific CSS rules, so it will have a default height of 100px. The CSS for `div` two, three, and four is shown below, which round, up, down, and to-zero, respectively.

```
div.box-2 {
  height: round(up, 101px, var(--rounding-interval));
}
div.box-3 {
  height: round(down, 122px, var(--rounding-interval));
}
div.box-4 {
  height: round(to-zero, 120px, var(--rounding-interval));
}
```

Notice how above we indicate the rounding interval using `var()` and the custom CSS property `--rounding-interval`.

The last box is set without specifying a rounding strategy, and hence defaults to `nearest`. In this case, the nearest interval to 117 px is 125px, so it will round up. Just for contrast, here we specified hardcoded values for both the rounding value and interval. While this is allowed, you wouldn't do this normally because there is no point rounding a number when you already know what the result must be.

```
div.box-5 {
  height: round(117px, 25px);
```

```
}
```

Result

If the browser supports the CSS `round()` function, you should see five columns with heights that are rounded as indicated by their contained text.

- `rem()`

<rule-list> CSS type

The **`<rule-list>`** CSS data type represents a sequence of **zero or more CSS rules**. It is used to define places in CSS where multiple rules may appear, such as the top level of a stylesheet or inside grouping at-rules like `@media` or `@supports`.

A `<rule-list>` is not written directly. Instead, it describes how the CSS parser collects and interprets rules inside a block or stylesheet.

Syntax

A `<rule-list>` is defined as a sequence of **zero or more**:

- **Style rules** (e.g., `p { color: red; }`).
- **Qualified at-rules** (e.g., `@media (width < 600px) { ... }`).
- **Ignored statements** (e.g., parse errors handled by the parser, which the parser automatically skips).

All whitespace, comments, and invalid or malformed constructs are handled according to the CSS parser rules.

Description

The `<rule-list>` type appears in the specification anywhere CSS is defined to contain a "list of rules."

Examples include:

- The **top level** of a stylesheet.
- The body of **grouping at-rules** like `@media`, `@custom-media`, `@supports`, `@layer`, `@container`.
- The contents of **nesting selectors** (CSS Nesting).

Although authors cannot explicitly write `<rule-list>`, understanding it is crucial when interpreting how CSS parses nested structures, how invalid rules are dropped, and how the cascade forms within conditional blocks.

Examples

A <code><rule-list></code> in a stylesheet

The following stylesheet is treated as a `<rule-list>` containing two style rules and an at-rule.

```
p {
  margin: 0;
}

h1 {
  font-size: 2rem;
}

@media (width < 600px) {
  body {
    background: lightgray;
  }
}
```

A <code><rule-list></code> inside <code>@media</code> at-rule

The block contained inside an `@media` at-rule is a `<rule-list>` containing one or more style rules. The following example contains two style rules.

```
@media (prefers-color-scheme: dark) {
  main {
    background: black;
    color: white;
  }

  a {
    color: skyblue;
  }
}
```

Invalid rules inside a <code><rule-list></code>

The invalid token sequence (`!invalid-rule`) is ignored by the parser. The rest of the rules form a valid `<rule-list>`.

```
body {
  color: black;
}

!invalid-rule

@supports (display: grid) {
  section {
    display: grid;
  }
}
```

<self-position> CSS type

The **`<self-position>`** enumerated value data type is used by the `justify-self` and `align-self` properties, and the `place-self` shorthand, to align the box within its alignment container. It is also used by the `justify-items` and `align-items` properties, and the `place-items` shorthand, to specify default values for `justify-self` and `align-self`.

Syntax

```
<self-position> = center | start | end | self-start | self-end | flex-start | flex-end
```

Values

The following keyword values are represented by the `<self-position>` grammar term:

`center`

Centers the alignment subject within its alignment container.

`start`

Aligns the alignment subject flush with the alignment container's start edge.

`end`

Aligns the alignment subject flush with the alignment container's end edge.

`self-start`

Aligns the alignment subject flush with the edge of the alignment container corresponding to the alignment subject's start side.

`self-end`

Aligns the alignment subject flush with the edge of the alignment container corresponding to the alignment subject's end side.

`flex-start`

In flex layout, aligns the alignment subject flush with the edge of the alignment container corresponding to the flex container's main-start or cross-start side, as appropriate. It is identical to `start` for layout modes other than flex layout.

`flex-end`

In flex layout, aligns the alignment subject flush with the edge of the alignment container corresponding to the flex container's main-end or cross-end side, as appropriate. Identical to `end` for layout modes other than flex layout.

> **Note:** The `left` and `right` keywords are excluded from `<self-position>`, despite being valid positional alignment values for the `justify-*` properties (`justify-content`, `justify-self`, and `justify-items`), because they are not allowed in the `align-*` properties (`align-content`, `align-self`, and `align-items`). They are instead explicitly included in the `justify-*` properties' grammars.

See also

- Properties that use this data type: `align-self`, `justify-self`, `place-self`, `align-items`, `justify-items`, `place-items`
- Other box alignment data types: `<baseline-position>`, `<content-distribution>`, `<overflow-position>`, and `<content-position>`
- CSS box alignment module
- CSS flexible box layout module
- CSS grid layout module

<shape> CSS type

The **`<shape>`** CSS data type defines the specific form (shape) of a region. The region represents the part of an element to which the `clip` property applies.

> **Note:** `<shape>` and `rect()` work in conjunction with `clip`, which has been deprecated in favor of `clip-path`. When possible, use `clip-path` and the `<basic-shape>` data type instead.

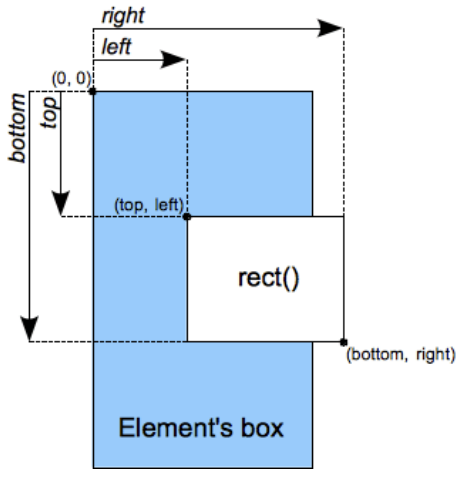
Syntax

The `<shape>` data type is specified using the `rect()` function, which produces a region in the form of a rectangle.

`rect()`

```
rect(top, right, bottom, left)
```

Values



top

Is a `<length>` representing the offset for the top of the rectangle relative to the top border of the element's box.

right

Is a `<length>` representing the offset for the right of the rectangle relative to the left border of the element's box.

bottom

Is a `<length>` representing the offset for the bottom of the rectangle relative to the top border of the element's box.

left

Is a `<length>` representing the offset for the left of the rectangle relative to the left border of the element's box.

Interpolation

When animated, values of the `<shape>` data type are interpolated over their `top`, `right`, `bottom`, and `left` components, each treated as a real, floating-point number. The speed of the interpolation is determined by the easing function associated with the animation.

Example

Example demonstrating correct use of the rect() function

```
img.clip04 {
  clip: rect(10px, 20px, 20px, 10px);
}
```

See also

- Related CSS property: `clip`

sibling-count() CSS function

The **`sibling-count()`** CSS function returns an integer representing the total number of sibling DOM elements (direct children of the parent) of the element on which it is used, including itself.

> **Note:** The `counter()` function provides a similar result but it returns a `<string>` (which is more suitable for generated content, while `sibling-count()` returns an `<integer>` (which can be used for calculations).

Syntax

```
sibling-count()
```

Parameters

The `sibling-count()` function doesn't accept parameters.

Return value

An integer; the total number of sibling DOM elements including the element itself.

Examples

Dynamic column count

This example demonstrates setting the width of each item in a list based on the number of items, enabling placing each child in its own column.

HTML

We include a `<ul>` container and several `<li>` elements children.

```
<ul>
  <li>One</li>
  <li>Two</li>
  <li>Three</li>
  <li>Four</li>
  <li>Five</li>
</ul>
```

CSS

We divide the `width` of each list item by the number of direct children the list contains. We also set every odd element to have a `background-color` to better demonstrate the resulting effect.

```
ul {
  list-style-type: none;
  padding: 0;
  margin: 0;
  text-align: center;
  display: flex;
}

li {
  width: calc(100% / sibling-count());
}

li:nth-of-type(odd) {
  background-color: rgb(0 0 0 / 0.05);
}
```

Results

See also

- `sibling-index()`
- `calc()`

sibling-index() CSS function

The **`sibling-index()`** CSS function returns an integer representing the position of the current element in the DOM tree relative to all its sibling elements. The returned value is the index number of the contextual child's position among all the sibling elements within a parent element, with the first child returning `1` and the last child, returning the `length` of `Element.children`.

> **Note:** Like the `:nth-child()` pseudo-class, `sibling-index()` starts from 1, not 0.

> **Note:** The `counter()` function provides a similar result but it returns a `<string>` (which is more suitable for generated content, while `sibling-index()` returns an `<integer>` (which can be used for calculations).

Try it

```
--width: calc(sibling-index() * 30px);
```

```
--width: calc(sibling-index() * 20px);
```

```
--width: calc(sibling-index() * 10px);
```

```
--width: 100px;
```

```
<ul id="example-element">
  <li>1</li>
  <li>2</li>
  <li>3</li>
  <li>4</li>
  <li>5</li>
  <li>6</li>
  <li>7</li>
  <li>8</li>
  <li>9</li>
  <li>10</li>
</ul>
```

```
#example-element {
  list-style-type: none;
  padding: 0;
  margin: 0 auto;
  display: flex;
  flex-direction: column;
  align-items: center;
  gap: 4px;
}

#example-element > li {
  text-align: center;
  padding: 2px;
  border-radius: 8px;
  width: var(--width, calc(sibling-index() * 30px));
  color: white;
  background-color: hsl(
    calc(360deg / sibling-count() * sibling-index()) 50% 50%
  );
}
```

Syntax

```
sibling-index()
```

Parameters

The `sibling-index()` function doesn't accept parameters.

Return value

An integer; the position of the current element in the DOM tree's sibling order.

Examples

Dynamic list width

This example demonstrates how to dynamically increase the width of each `<li>` item in the `<ul>` by `50px`.

HTML

```
<ul>
  <li>One</li>
  <li>Two</li>
  <li>Three</li>
  <li>Four</li>
</ul>
```

CSS

```
li {
  width: calc(sibling-index() * 50px);
  background-color: #ffaaaa;
}
```

Results

Sequential animations

Combining `sibling-index()` with CSS animations opens new possibilities. In this example, the opacity of elements in sequential order by setting an `animation-delay` based on their order in the DOM.

HTML

We include a container element with four children:

```
<ul>
  <li>One</li>
  <li>Two</li>
```

```
  <li>Three</li>
  <li>Four</li>
</ul>
```

CSS

We apply the `fade-in` animation to each element. We use the `sibling-index()` function within a `calc()` function to set the duration of the `animation-delay` based on the source element's position in the source order. The `animation-fill-mode` applies the animation's `0%` keyframe until the `animation-duration` expires.

```
ul {
  list-style-type: none;
  padding: 0;
  margin: 0;
}

li {
  animation-name: fade-in;
  animation-duration: 1s;
  animation-iteration-count: 1;
  animation-timing-function: linear;
  animation-fill-mode: backwards;
  animation-delay: calc(1s * sibling-index());
}

@keyframes fade-in {
  from {
    opacity: 0;
  }
  to {
    opacity: 1;
  }
}
```

sign() CSS function

The **`sign()`** CSS function contains one calculation, and returns `-1` if the numeric value of the argument is negative, `+1` if the numeric value of the argument is positive, `0`⁺ if the numeric value of the argument is 0^+, and `0`⁻ if the numeric value of the argument is 0^-.

> **Note:** While `abs()` returns the absolute value of the argument, `sign()` returns the sign of the argument.

Syntax

```
/* property: sign( expression ) */
top: sign(20vh - 100px);
```

Parameters

The `sign(x)` function accepts only one value as its parameter.

`x`

A calculation which resolves to a number.

Return value

A number representing the sign of `A`:

- If `x` is positive, returns `1`.
- If `x` is negative, returns `-1`.
- If `x` is positive zero, returns `0`.
- If `x` is negative zero, returns `-0`.
- Otherwise, returns `NaN`.

Formal syntax

```
<sign()> =
  sign( <calc-sum> )

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Background image position

For example, in `background-position` positive percentages resolve to a negative length, and vice versa, if the background image is larger than the background area. Thus `sign(10%)` might return `1` or `-1`, depending on how the percentage is resolved! (Or even `0`, if it's resolved against a zero length.)

```
div {
  background-position: calc(sign(10%) * 1px);
}
```

Position direction

Another use case is to control the `position` of the element. Either a positive or a negative value.

```
div {
  position: absolute;
  top: calc(100px * sign(var(--value)));
}
```

See also

- `abs()`
- Using CSS typed arithmetic

sin() CSS function

The **`sin()`** CSS function is a trigonometric function that returns the sine of a number, which is a value between `-1` and `1`. The function contains a single calculation that must resolve to either a `<number>` or an `<angle>` by interpreting the result of the argument as radians. That is, `sin(45deg)`, `sin(0.125turn)`, and `sin(3.14159 / 4)` all represent the same value, approximately `0.707`.

Try it

```
transform: translateX(calc(cos(0deg) * 140px))
  translateY(calc(sin(0deg) * -140px));
```

```
transform: translateX(calc(cos(90deg) * 140px))
  translateY(calc(sin(90deg) * -140px));
```

```
transform: translateX(calc(cos(135deg) * 140px))
  translateY(calc(sin(135deg) * -140px));
```

```
transform: translateX(calc(cos(180deg) * 140px))
  translateY(calc(sin(180deg) * -140px));
```

```
transform: translateX(calc(cos(-45deg) * 140px))
  translateY(calc(sin(-45deg) * -140px));
```

```
<div class="circle">
  <span class="dot" id="example-element"></span>
</div>
```

```
:root {
  --radius: 140px;
  --dot-size: 10px;
}
.circle {
  display: grid;
  place-content: center;
  margin: 0 auto;
  width: calc(var(--radius) * 2);
  aspect-ratio: 1;
  border-radius: 50%;
  border: 2px solid #666666;
  background-image:
    radial-gradient(black var(--dot-size), transparent var(--dot-size)),
    linear-gradient(135deg, blue, deepskyblue, lightgreen, lavender, honeydew);
}
.dot {
  display: block;
  width: var(--dot-size);
  aspect-ratio: 1;
  border-radius: 50%;
  border: 2px solid #666666;
  background-color: #ff6666;
  transform: translateX(calc(cos(0deg) * var(--radius)))
    translateY(calc(sin(0deg) * var(--radius) * -1));
}
```

Syntax

```
/* Single <angle> values */
width: calc(100px * sin(45deg));
width: calc(100px * sin(0.25turn));
width: calc(100px * sin(1.0471967rad));

/* Single <number> values */
width: calc(100px * sin(63.673));
width: calc(100px * sin(2 * 0.125));

/* Other values */
width: calc(100px * sin(pi / 2));
width: calc(100px * sin(e / 4));
```

Parameters

The `sin(angle)` function accepts only one value as its parameter.

`angle`

A calculation which resolves to a `<number>` or an `<angle>`. When specifying unitless numbers they are interpreted as a number of radians, representing an `<angle>`

Return value

The sine of an `angle` will always return a number between `-1` and `1`.

- If `angle` is `infinity`, `-infinity`, or `NaN`, the result is `NaN`.
- If `angle` is `0`⁻, the result is `0`⁻.

Formal syntax

```
<sin()> =
  sin( <calc-sum> )

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Changing box sizes

In this example, `sin(30deg)` will return `0.5`, making the box have a `50px` width and a `50px` height.

```
div {
  background-color: red;
  width: calc(sin(30deg) * 100px);
  height: calc(sin(30deg) * 100px);
}
```

Controlling animation duration

Another use case is to control the `animation-duration`, reducing the duration based on the sine value. In this case, the animation duration will be `1s`.

```
div {
  animation-name: myAnimation;
  animation-duration: calc(sin(0.25turn) * 1s);
}
```

sqrt() CSS function

The **`sqrt()`** CSS function is an exponential function that returns the square root of a number.

The function `pow(x, 0.5)` is equivalent to `sqrt(x)`.

Syntax

```
/* A <number> value */
width: calc(100px * sqrt(9)); /*  300px */
width: calc(100px * sqrt(25)); /*  500px */
width: calc(100px * sqrt(100)); /* 1000px */
```

Parameters

The `sqrt(x)` function accepts only one value as its parameter.

`x`

A calculation which resolves to a `<number>` greater than or equal to 0.

Return value

Returns a `<number>` which is the square root of `x`.

- if `x` is `+∞`, the result is `+∞`.
- If `x` is `0`⁻, the result is `0`⁻.
- If `x` is less than `0`, the result is `NaN`.

Formal syntax

```
<sqrt()> =
  sqrt( <calc-sum> )

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Scale sizes based on square root

This example shows how you can use the `sqrt()` function to calculate sizes.

HTML

```
<div class="boxes">
  <div class="box">50px</div>
  <div class="box one">100px</div>
  <div class="box two">150px</div>
  <div class="box three">200px</div>
</div>
```

CSS

Here we are using CSS custom properties to define the sizes to be used. First, we declare the first size (`--size-0`), which is then used to calculate the other sizes.

- `--size-1` is calculated by multiplying the value of `--size-0` (50px) by the square root of 4 (2), which results in 100px.
- `--size-2` is calculated by multiplying the value of `--size-0` (50px) by the square root of 9 (3), which results in 150px.
- `--size-3` is calculated by multiplying the value of `--size-0` (50px) by the square root of 16 (4), which results in 200px.

```
:root {
  --size-0: 50px;
  --size-1: calc(var(--size-0) * sqrt(4)); /*  100px */
  --size-2: calc(var(--size-0) * sqrt(9)); /*  150px */
  --size-3: calc(var(--size-0) * sqrt(16)); /*  200px */
}
```

```
.boxes {
  display: flex;
  flex-wrap: wrap;
  justify-content: space-around;
}

.box {
  width: var(--size-0);
  height: var(--size-0);
  background-color: tomato;
  color: white;
  display: flex;
  align-items: center;
  justify-content: center;
}
```

The sizes are then applied as the `width` and `height` values of the selectors.

```
.one {
  width: var(--size-1);
  height: var(--size-1);
}
.two {
  width: var(--size-2);
  height: var(--size-2);
}
.three {
  width: var(--size-3);
  height: var(--size-3);
}
```

<string> CSS type

The **`<string>`** CSS data type represents a sequence of characters. Strings are used in numerous CSS properties, such as `content`, `font-family`, and `quotes`.

Syntax

The `<string>` data type is composed of any number of Unicode characters surrounded by either double (`"`) or single (`'`) quotes.

Most characters can be represented literally. All characters can also be represented with their respective Unicode code points in hexadecimal, in which case they are preceded by a backslash (`\`). For example, `\22` represents a double quote, `\27` a single quote (`'`), and `\A9` the copyright symbol (©).

Importantly, certain characters which would otherwise be invalid can be escaped with a backslash. These include double quotes when used inside a double-quoted string, single quotes when used inside a single-quoted string, and the backslash itself. For example, `\\` will create a single backslash.

To output new lines, you must escape them with a line feed character such as `\A` or `\00000A`. In your code, however, strings can span multiple lines, in which case each new line must be escaped with a `\` as the last character of the line.

However, to get new lines, you must also set the `white-space` property to appropriate value.

> **Note:** Character references (such as ` ` or `—`) cannot be used in a CSS `<string>`.

Examples

Examples of valid strings

```
/* Basic strings */
"This string is demarcated by double quotes."
'This string is demarcated by single quotes.'

/* Character escaping */
"This is a string with \" an escaped double quote."
"This string also has \22 an escaped double quote."
'This is a string with \' an escaped single quote.'
'This string also has \27 an escaped single quote.'
"This is a string with \\ an escaped backslash."

/* New line in a string */
"This string has a \Aline break in it."

/* String spanning two lines of code (these two strings will have identical output) */
"A really long \
awesome string"
"A really long awesome string"
```

superellipse() CSS function

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`superellipse()`** CSS function defines the curvature of an ellipse, and is used to specify corner shapes either directly, or via `<corner-shape-value>` keywords.

Syntax

```
superellipse(infinity)
superellipse(4)
superellipse(1.7)
superellipse(0)
superellipse(-2.8)
superellipse(-3)
superellipse(-infinity)
```

Parameters

`<number>`

A number in the range of `-infinity` to `infinity`, inclusive.

Return value

A superellipse shape.

Description

The `superellipse()` function returns a superellipse shape, which is used to specify `corner-shape` values. A superellipse is a closed curve symmetric shape between a rectangle and an ellipse. It resembles an ellipse that retains the geometric features of its two axes.

The superellipse shape is calculated using a modified version of an ellipse. The following equation defines an ellipse centered at the origin:

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$$

The `a` and `b` variables refer to the radii of the ellipse, while the `x` and `y` coordinates are points on the ellipse's circumference.

A circle is an ellipse where the radii, the `a` and `b` in the previous equation, are the same length. With `a` and `b` both equal to `r`, the equation for a circle can be written as:

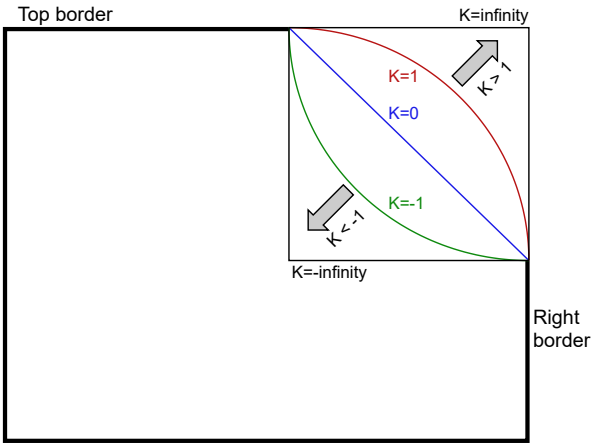
$$x^2 + y^2 = r^2$$

In this equation, the `x` and `y` are coordinates of points on the circle's circumference, and the `r` is the radius of the circle, with the center of the circle being `(0, 0)`. The ellipse is produced by scaling a circle shape along the `x` and/or `y` axis.

A superellipse shape is created by replacing the `2` exponent in each case with 2^K, `K` being the argument passed to the `superellipse()` function, which modifies the curvature of the ellipse:

$$x^{2^K} + y^{2^K} = 1$$

The following diagram illustrates different `superellipse()` values for the top right corner of a container: `infinity`, `1`, `0`, `-1`, and `-infinity`:



- A `κ` value of `0` creates a straight line. This value can be used to create beveled corners and corresponds to the `<corner-shape-value>` `bevel` keyword.
- A `κ` value of `1` creates an ordinary ellipse, corresponding to the `round` keyword.
- A `κ` value of `>1` makes the ellipse shape more square; `2` corresponds to the `squircle` keyword.
- A `κ` value of `infinity` creates a perfect square (corresponding to the `square` keyword), although `κ` values of `10` or more are virtually indistinguishable from a square.
- Negative `κ` values result in a concave curve, resulting in corner shapes that are curved inward, or "scooped out". A `κ` value of `-1` corresponds to the `scoop` keyword and `-infinity` corresponds to the `notch` keyword.

A negative or positive superellipse would appear symmetrical to a superellipse with its inverse value.

> **Note:** For any `κ` parameter value passed, the `superellipse()` function's return value will always be the same for that `κ` value. When that value is applied to two elements, the appearance of the corner shape may differ if the box size or `border-radius` values differ.

Formal syntax

```
<superellipse()> =
  superellipse( <number>  |
  infinity                |
  -infinity )
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

<code>superellipse()</code> value comparison

In this example, two `<input type="range">` sliders allow you to cycle through many different `corner-shape` `superellipse()` values and `border-radius` values enabling you to compare the effects of each on a container. The code is hidden for brevity, but the full explanation of the superellipse value comparison is provided on the `corner-shape` reference page.

```
<form>
  <div>
    <label for="superellipse-slider">Choose a superellipse() value:</label>
    <input
      type="range"
      id="superellipse-slider"
      min="-5"
      value="0"
      max="5"
      step="0.1" />
  </div>
  <div>
    <label for="radius-slider">Choose a border-radius value:</label>
    <input type="range" id="radius-slider" min="0" value="45" max="90" />
  </div>
</form>
<section></section>
```

```
html {
  font-family: "Helvetica", "Arial", sans-serif;
}

body {
  width: fit-content;
  margin: 20px auto;
}

section {
  display: flex;
  justify-content: center;
  align-items: center;
  flex: 100%;
  margin-top: 20px;
}

form div {
  margin-top: 5px;
  display: flex;
}

section {
  width: 100%;
  height: 180px;
  background-color: orange;
```

```
  background-image: linear-gradient(
    to bottom,
    rgb(255 255 255 / 0),
    rgb(255 255 255 / 0.5)
  );
}

section {
  box-shadow: 1px 1px 3px gray;
}
```

```
const rectangle = document.querySelector("section");
const superEllipseRange = document.getElementById("superellipse-slider");
const borderRadiusRange = document.getElementById("radius-slider");

function setCorners() {
  const seValue = `superellipse(${superEllipseRange.value})`;
  rectangle.style.cornerShape = seValue;
  const brValue = `${borderRadiusRange.value}px`;
  rectangle.style.borderRadius = brValue;
  rectangle.innerHTML = `<div><code>corner-shape: ${seValue};</code><br><code>border-radius: ${brValue};</code></div>`;
}

superEllipseRange.addEventListener("input", setCorners);
borderRadiusRange.addEventListener("input", setCorners);
setCorners();
```

> **Note:** See also the `<corner-shape-value>` value comparison example.

symbols() CSS function

The **`symbols()`** CSS function enables defining counter styles inline, directly as a value of properties such as `list-style`, providing a less powerful but simpler alternative to the `@counter-style` method of defining a counter style.

Unlike `@counter-style`, which defines a reusable counter style, `symbols()` is *anonymous* (i.e., it can only be used once). This function accepts strings and images as values. In comparison, the `@counter-style`'s `symbols` descriptor also accepts identifiers.

Syntax

```
symbols() = symbols( <symbols-type>? [ <string> | <image> ]+ );
```

`<symbols-type>` can be one of the following:

- `cyclic`: The system cycles through the given values in the order of their definition, and returns to the start when it reaches the end.
- `numeric`: The system interprets the given values as the successive units of a place-value numbering system.
- `alphabetic`: The system interprets the given values as the digits of an alphabetic numbering system, like a place-value numbering system but without `0`.
- `symbolic`: The system cycles through the values, printing them an additional time at each cycle (one time for the first cycle, two times for the second, etc.).
- `fixed`: The system cycles through the given values once, then falls back to Arabic numerals.

Formal syntax

```
<symbols()> =
  symbols( <symbols-type>? [ <string> | <image> ]+ )

<symbols-type> =
  cyclic      |
  numeric     |
  alphabetic  |
  symbolic    |
  fixed

<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
  <gradient>

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-set()> =
  image-set( <image-set-option># )

<cross-fade()> =
  cross-fade( <cf-image># )

<element()> =
  element( <id-selector> )

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
```

```
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Counter Styles Level 3, CSS Images Module Level 4, CSS Images Module Level 5, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<ol>
  <li>One</li>
  <li>Two</li>
  <li>Three</li>
  <li>Four</li>
  <li>Five</li>
</ol>
```

CSS

```
ol {
  list-style: symbols(cyclic "*" "†" "‡");
}
```

Result

<system-color> CSS type

The **`<system-color>`** CSS data type usually reflects the default color choices used for the different parts of a web page.

However, user agents can provide an accessibility feature called *forced colors mode*, in which colors are restricted into a user- and user agent-defined palette, overriding the author's choice of colors in certain properties. In forced colors mode, `<system-color>` exposes the chosen colors, so that the rest of the page can integrate with them. An example of forced colors mode is high contrast mode on Windows.

In forced colors mode, authors should use colors from the `<system-color>` type for all properties that are *not* in the set of properties whose colors are overridden. This ensures that the page consistently uses the same color palette across all properties.

Authors can detect forced colors mode using the `forced-colors` media feature.

A `<system-color>` value can be used anywhere a `<color>` can be used.

Syntax

Note that these keywords are *case insensitive*, but are listed here with mixed case for readability.

Depending on your settings, the sample colors displayed in the table may change. You can also view this page with different browsers, operating systems, and system settings, to check the differences.

Keyword	Description	Sample
`AccentColor`	Background of accented user interface controls.	
`AccentColorText`	Text of accented user interface controls.	
`ActiveText`	Text of active links.	
`ButtonBorder`	Base border color of controls.	
`ButtonFace`	Background color of controls.	
`ButtonText`	Text color of controls.	
`Canvas`	Background of application content or documents.	
`CanvasText`	Text color in application content or documents.	
`Field`	Background of input fields.	
`FieldText`	Text in input fields.	
`GrayText`	Text color for disabled items (for example, a disabled control).	
`Highlight`	Background of selected items.	
`HighlightText`	Text color of selected items.	
`LinkText`	Text of non-active, non-visited links.	
`Mark`	Background of text that has been specially marked (such as by the HTML `mark` element).	
`MarkText`	Text that has been specially marked (such as by the HTML `mark` element).	
`SelectedItem`	Background of selected items, for example, a selected checkbox.	
`SelectedItemText`	Text of selected items.	
`VisitedText`	Text of visited links.	

> **Note:** To reduce the risk of fingerprinting, some browsers return a fixed value for `AccentColor` and `AccentColorText` unless they are used in certain restricted circumstances. See browser compatibility for details.

Deprecated system color keywords

The following keywords were defined in earlier versions of the CSS Color Module. They are now deprecated for use on public web pages.

Keyword	Description	Replacement	Sample
`ActiveBorder`	Active window border	`ButtonBorder`	
`ActiveCaption`	Active window caption. Should be used with `CaptionText` as foreground color.	`Canvas`	
`AppWorkspace`	Background color of multiple document interface.	`Canvas`	
`Background`	Desktop background.	`Canvas`	
`ButtonHighlight`	The color of the border facing the light source for 3-D elements that appear 3-D due to that layer of surrounding border.	`ButtonFace`	
`ButtonShadow`	The color of the border away from the light source for 3-D elements that appear 3-D due to that layer of surrounding border.	`ButtonFace`	
`CaptionText`	Text in caption, size box, and scrollbar arrow box. Should be used with the `ActiveCaption` background color.	`CanvasText`	
`InactiveBorder`	Inactive window border.	`ButtonBorder`	
`InactiveCaption`	Inactive window caption. Should be used with the `InactiveCaptionText` foreground color.	`Canvas`	
`InactiveCaptionText`	Color of text in an inactive caption. Should be used with the `InactiveCaption` background color.	`GrayText`	
`InfoBackground`	Background color for tooltip controls. Should be used with the `InfoText` foreground color.	`Canvas`	
`InfoText`	Text color for tooltip controls. Should be used with the `InfoBackground` background color.	`CanvasText`	
`Menu`	Menu background. Should be used with the `MenuText` or `-moz-MenuBarText` foreground color.	`Canvas`	
`MenuText`	Text in menus. Should be used with the `Menu` background color.	`CanvasText`	
`Scrollbar`	Background color of scroll bars.	`Canvas`	
`ThreeDDarkShadow`	The color of the darker (generally outer) of the two borders away from the light source for 3-D elements that appear 3-D due to two concentric layers of surrounding border.	`ButtonBorder`	
`ThreeDFace`	The face background color for 3-D elements that appear 3-D due to two concentric layers of surrounding border. Should be used with the `ButtonText` foreground color.	`ButtonFace`	
`ThreeDHighlight`	The color of the lighter (generally outer) of the two borders facing the light source for 3-D elements that appear 3-D due to two concentric layers of surrounding border.	`ButtonBorder`	
`ThreeDLightShadow`	The color of the darker (generally inner) of the two borders facing the light source for 3-D elements that appear 3-D due to two concentric layers of surrounding border.	`ButtonBorder`	
`ThreeDShadow`	The color of the lighter (generally inner) of the two borders away from the light source for 3-D elements that appear 3-D due to two concentric layers of surrounding border.	`ButtonBorder`	
`Window`	Window background. Should be used with the `WindowText` foreground color.	`Canvas`	
`WindowFrame`	Window frame.	`ButtonBorder`	
`WindowText`	Text in windows. Should be used with the `Window` background color.	`CanvasText`	

Examples

Using system colors

In this example we have a button that normally gets its contrast using the `box-shadow` property. In forced colors mode, `box-shadow` is forced to `none`, so the example uses the `forced-colors` media feature to ensure there is a border of the appropriate color (`ButtonBorder` in this case).

HTML

```
<button class="button">Press me!</button>
```

CSS

```
.button {
  border: 0;
  padding: 10px;
  box-shadow:
    -2px -2px 5px gray,
    2px 2px 5px gray;
}

@media (forced-colors: active) {
  .button {
    /* Use a border instead, since box-shadow
    is forced to 'none' in forced-colors mode */
    border: 2px ButtonBorder solid;
  }
}
```

tan() CSS function

The **`tan()`** CSS function is a trigonometric function that returns the tangent of a number, which is a value between `-infinity` and `infinity`. The function contains a single calculation that must resolve to either a `<number>` or an `<angle>` by interpreting the result of the argument as radians.

Syntax

```
/* Single <angle> values */
width: calc(100px * tan(45deg));
width: calc(100px * tan(0.125turn));
width: calc(100px * tan(0.785398163rad));

/* Single <number> values */
width: calc(100px * tan(0.5773502));
width: calc(100px * tan(1.732 - 1));

/* Other values */
```

```
width: calc(100px * tan(pi / 3));
width: calc(100px * tan(e));
```

Parameters

The `tan(angle)` function accepts only one value as its parameter.

`angle`

A calculation which resolves to a `<number>` or an `<angle>`. When specifying unitless numbers they are interpreted as a number of radians, representing an `<angle>`.

Return value

The tangent of an `angle` will always return a number between −∞ and +∞.

- If `angle` is `infinity`, `-infinity`, or `NaN`, the result is `NaN`.
- If `angle` is `0`−, the result is `0`−.
- If `angle` is one of the asymptote values (such as `90deg`, `270deg`, etc.), the result is *explicitly undefined*. Authors *must not* rely on `tan()` returning any particular value for these inputs.

Formal syntax

```
<tan()> =
  tan( <calc-sum> )

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Drawing parallelograms

The `tan()` function can be used to draw a parallelogram with a given bounding box.

HTML

```
<div class="parallelogram"></div>
```

CSS

```
body {
  height: 100vh;
  display: flex;
  justify-content: center;
  align-items: center;
}
```

```
.parallelogram {
  --w: 400;
  --h: 200;
  --angle: 30deg;
  position: relative;
  width: calc(1px * var(--w));
  height: calc(1px * var(--h));
}
.parallelogram::before {
  content: "";
  position: absolute;
  width: calc(100% - 100% * var(--h) / var(--w) * tan(var(--angle)));
  height: 100%;
  transform-origin: 0 100%;
  transform: skewX(calc(0deg - var(--angle)));
  background-color: red;
}
```

<text-edge> CSS type

The **`<text-edge>`** enumerated data type defines keywords that specify font metrics representing specific regions on a font's block-start edge and block-end edge. Each keyword specifies a position of a font's over and/or under edge.

The `<text-edge>` values are used in the `text-box-edge` property to specify an amount of space to trim from the block-start and block-end edge of a text element's block container.

Syntax

The `<text-edge>` data type is composed of one or two keywords representing specific regions on a font's block-start (over) edge and/or block-end (under) edge:

- When one value is specified, the position of the font's over edge and under edge are specified using that same keyword.
- When two values are specified, the first value specifies the position of the font's over edge, and the second value specifies the position of the font's under edge.

Values

Single keyword values

`text`

The font's over and under edges are its text-over baseline/text-under baseline: this includes the font's ascenders and descenders but excludes the half-leading set on the text.

> **Note:** The amount of half-leading included on a text element can be controlled using the `line-height` property.

> **Note:** The `ideographic` and `ideographic-ink` keywords are intended to specify over and under edge positions specific to CJK language characters. Currently their exact behavior is being debated and they are not supported by any browser.

Two keyword values

`alphabetic`

The font's under edge is its alphabetic baseline, which is the bottom of its short lower-case letters (for example, "m", "n", and "o") or capital letters.

`cap`

The font's over edge is its cap-height baseline, which is the top of its capital letters.

`ex`

The font's over edge is its x-height baseline, which is the top of its short lower-case letters.

`text`

The font's over edge is its text-over baseline (includes the font's ascenders but excludes the over edge half-leading), or its under edge is its text-under baseline (includes the font's descenders but excludes the under edge half-leading), depending on which edge the value is set for.

Formal syntax

```
<text-edge> =
  [ text | ideographic | ideographic-ink ]           |
  [ text | ideographic | ideographic-ink | cap | ex ] [ text | ideographic | ideographic-ink | alphabetic ]
```

Examples

See `text-box-edge` examples

- CSS inline layout module

<time> CSS type

The **`<time>`** CSS data type represents a time value expressed in seconds or milliseconds. It is used in `animation`, `transition`, and related properties.

Syntax

The `<time>` data type consists of a `<number>` followed by one of the units listed below. Optionally, it may be preceded by a single `+` or `-` sign. As with all dimensions, there is no space between the unit literal and the number.

> **Note:** Although the number `0` is always the same regardless of unit, the unit may not be omitted. In other words, `0` is invalid and does not represent `0s` or `0ms`.

Units

`s`

Represents a time in seconds. Examples: `0s`, `1.5s`, `-60s`.

`ms`

Represents a time in milliseconds. Examples: `0ms`, `150.25ms`, `-60000ms`.

> **Note:** Conversion between `s` and `ms` follows the logical `1s = 1000ms`.

Examples

Valid times

```
12s         Positive integer
-456ms      Negative integer
4.3ms       Non-integer
14mS        The unit is case-insensitive, although capital letters are not recommended.
+0s         Zero with a leading + and a unit
-0ms        Zero with a leading - and a unit
```

Invalid times

```
0           Although unitless zero is allowed for <length>s, it's invalid for <time>s.
12.0        This is a <number>, not a <time>, because it's missing a unit.
7 ms        No space is allowed between the number and the unit.
```

See also

- `<time-percentage>`
- CSS values and units module

<time-percentage> CSS type

The **`<time-percentage>`** CSS data type represents a value that can be either a `<time>` or a `<percentage>`.

Syntax

Refer to the documentation for `<time>` and `<percentage>` for details of the individual syntaxes allowed by this type.

Formal syntax

```
<time-percentage> =
  <time>       |
  <percentage>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Use in calc()

Where a `<time-percentage>` is specified as an allowable type, this means that the percentage resolves to a time and therefore can be used in a `calc()` expression.

Valid percentages

```
50%
+50%       Optional plus sign
-50%       Negative percentages are not valid for all properties that accept percentages
```

Invalid percentages

```
50 %       Space not allowed between the number and the percentage sign
```

Valid times

```
12s        Positive integer
-456ms     Negative integer
4.3ms      Non-integer
14mS       The unit is case-insensitive, although capital letters are not recommended.
+0s        Zero with a leading + and a unit
-0ms       Zero with a leading - and a unit
```

Invalid times

```
0          Although unitless zero is allowed for <length>s, it's invalid for <time>s.
12.0       This is a <number>, not a <time>, because it's missing a unit.
7 ms       No space is allowed between the number and the unit.
```

- `<time>`
- CSS values and units module

<timeline-range-name> CSS type

The **`<timeline-range-name>`** enumerated data type is a CSS identifier representing one of the predefined named timeline ranges inside a view progress timeline.

The `<timeline-range-name>` keyword values are used in keyframe selectors and the following longhand and shorthand properties:

- `animation-range-end`
- `animation-range-start`
- `animation-range` shorthand
- `timeline-trigger-activation-range-end`
- `timeline-trigger-activation-range-start`
- `timeline-trigger-activation-range` shorthand
- `timeline-trigger-active-range-end`
- `timeline-trigger-active-range-start`
- `timeline-trigger-active-range` shorthand

Syntax

Valid `<timeline-range-name>` values:

`cover`

> Represents the full range of a view progress timeline, from the point where the subject element's start border edge first enters the scrollport's view progress visibility range (`0%` progress) to the point where the end border edge has completely left it (`100%` progress). This is the default range for view progress timelines.

`contain`

> Represents the range of a view progress timeline where the subject element is fully contained by, or fully contains, the view progress visibility range within the scrollport
>
> - If the subject element is smaller than the scrollport, it ranges from the point where the subject element is first completely contained by the scroll port (`0%` progress), to the point where it is no longer completely contained by the scroll port (`100%` progress).
> - If the subject element is larger than the scrollport, it ranges from the point where the subject element first completely covers the scroll port (`0%` progress), to the point where it no longer completely covers the scrollport (`100%` progress).

`entry`

> Represents the range of a view progress timeline from the point where the subject element first starts to enter the scroll port, to the point where it has completely entered the scrollport. `0%` is equivalent to `0%` of the `cover` range. `100%` is equivalent to `0%` of the `contain` range.

`exit`

Represents the range of a view progress timeline from the point where the subject element first starts to exit the scroll port, to the point where it has completely exited the scrollport. `0%` is equivalent to `100%` of the `contain` range. `100%` is equivalent to `100%` of the `cover` range.

`entry-crossing`

Represents the range during which the principal box crosses the end border edge. The start (0% progress) of the range occurs when the start border edge of the element's principal box coincides with the end edge of its view progress visibility range. The end (100%) of the range is the point at which the end border edge of the element's principal box coincides with the end edge of its view progress visibility range. The size of the range is the size of the element's principal box in the scroll direction.

`exit-crossing`

Represents the range where the principal box crosses the start border edge. The range start (0% progress) occurs when the start border edge of the element's principal box coincides with the start edge of its view progress visibility range. The range end (100% progress) is the point at which the end border edge of the element's principal box coincides with the start edge of its view progress visibility range. The size of the range is the size of the element's principal box in the scroll direction.

`scroll`

Represents the full range of the scroll container on which the view progress timeline is defined. The range start (0% progress) and end (100% progress) occur at the very start and end positions of the scroll container underlying the view progress timeline. This is the default range for scroll progress timelines.

Formal syntax

```
<timeline-range-name> =
  cover           |
  contain         |
  entry           |
  exit            |
  entry-crossing  |
  exit-crossing   |
  scroll
```

Examples

<transform-function> CSS type

The **`<transform-function>`** CSS data type represents a transformation that affects an element's appearance. Transformation functions can rotate, resize, distort, or move an element in 2D or 3D space. It is used in the `transform` property.

Syntax

The `<transform-function>` data type is specified using one of the transformation functions listed below. Each function applies a geometric operation in either 2D or 3D.

Matrix transformation

`matrix()`

Describes a homogeneous 2D transformation matrix.

`matrix3d()`

Describes a 3D transformation as a 4×4 homogeneous matrix.

Perspective

`perspective()`

Sets the distance between the user and the z=0 plane.

Rotation

`rotate()`

Rotates an element around a fixed point on the 2D plane.

`rotate3d()`

Rotates an element around a fixed axis in 3D space.

`rotateX()`

Rotates an element around the horizontal axis.

`rotateY()`

Rotates an element around the vertical axis.

`rotateZ()`

Rotates an element around the z-axis.

Scaling (resizing)

`scale()`

Scales an element up or down on the 2D plane.

`scale3d()`

Scales an element up or down in 3D space.

`scaleX()`

Scales an element up or down horizontally.

`scaleY()`

Scales an element up or down vertically.

`scaleZ()`

Scales an element up or down along the z-axis.

Skewing (distortion)

`skew()`

Skews an element on the 2D plane.

`skewX()`

Skews an element in the horizontal direction.

`skewY()`

Skews an element in the vertical direction.

Translation (moving)

`translate()`

Translates an element on the 2D plane.

`translate3d()`

Translates an element in 3D space.

`translateX()`

Translates an element horizontally.

`translateY()`

Translates an element vertically.

`translateZ()`

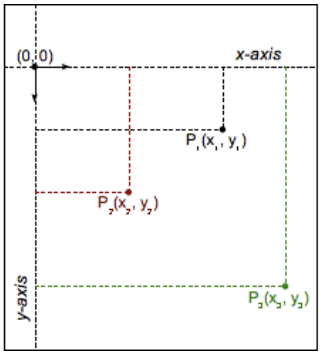
Translates an element along the z-axis.

Description

Various coordinate models can be used to describe an HTML element's size and shape, as well as any transformations applied to it. The most common is the Cartesian coordinate system, although homogeneous coordinates are also sometimes used.

Cartesian coordinates

In the Cartesian coordinate system, a two-dimensional point is described using two values: an x coordinate (abscissa) and a y coordinate (ordinate). This is represented by the vector notation `(x, y)`.



In CSS (and most computer graphics), the origin `(0, 0)` represents the *top-left* corner of any element. Positive coordinates are down and to the right of the origin, while negative ones are up and to the left. Thus, a point that's 2 units to the right and 5 units down would be `(2, 5)`, while a point 3 units to the left and 12 units up would be `(-3, -12)`.

Transformation functions

Transformation functions alter the appearance of an element by manipulating the values of its coordinates. A linear transformation function is described using a 2×2 matrix, like this:

$$\begin{pmatrix} a & c \\ b & d \end{pmatrix}$$

The function is applied to an element by using matrix multiplication. Thus, each coordinate changes based on the values in the matrix:

$$\begin{pmatrix} a & c \\ b & d \end{pmatrix}\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} ax + cy \\ bx + dy \end{pmatrix}$$

It is even possible to apply several transformations in a row:

$$\begin{pmatrix} a_1 & c_1 \\ b_1 & d_1 \end{pmatrix}\begin{pmatrix} a_2 & c_2 \\ b_2 & d_2 \end{pmatrix} = \begin{pmatrix} a_1a_2 + c_1b_2 & a_1c_2 + c_1d_2 \\ b_1a_2 + d_1b_2 & b_1c_2 + d_1d_2 \end{pmatrix}$$

With this notation, it is possible to describe, and therefore compose, most common transformations: rotations, scaling, or skewing. (In fact, all transformations that are linear functions can be described.) Composite transformations are effectively applied in order from right to left.

However, one major transformation is not linear, and therefore must be special-cased when using this notation: translation. The translation vector `(tx, ty)` must be expressed separately, as two additional parameters.

> **Note:** Though trickier than Cartesian coordinates, homogeneous coordinates in projective geometry lead to 3×3 transformation matrices, and can express translations as linear functions.

> **Note:** Transform functions are used with the `transform` property but not with individual transform properties-`translate`, `scale`, and `rotate`.

Examples

Transform function comparison

The following example provides a 3D cube created from DOM elements and transforms, and a select menu allowing you to choose different transform functions to transform the cube with, so you can compare the effects of the different types.

Choose one, and the transform is applied to the cube; after 2 seconds, the cube reverts to its starting state. The cube's starting state is slightly rotated using `transform3d()`, to allow you to see the effect of all the transforms.

HTML

```
<main>
  <section id="example-element">
    <div class="face front">1</div>
    <div class="face back">2</div>
    <div class="face right">3</div>
    <div class="face left">4</div>
    <div class="face top">5</div>
    <div class="face bottom">6</div>
  </section>

  <div class="select-form">
    <label for="transfunction">Select a transform function</label>
    <select id="transfunction">
      <option selected>Choose a function</option>
      <option>rotate(360deg)</option>
      <option>rotateX(360deg)</option>
      <option>rotateY(360deg)</option>
      <option>rotateZ(360deg)</option>
      <option>rotate3d(1, 1, 1, 90deg)</option>
      <option>scale(1.5)</option>
      <option>scaleX(1.5)</option>
      <option>scaleY(1.5)</option>
      <option>scaleZ(1.5)</option>
      <option>scale3d(1, 1.5, 1.5)</option>
      <option>skew(17deg, 13deg)</option>
      <option>skewX(17deg)</option>
      <option>skewY(17deg)</option>
      <option>translate(100px, 100px)</option>
      <option>translateX(100px)</option>
      <option>translateY(100px)</option>
      <option>translateZ(100px)</option>
      <option>translate3d(50px, 50px, 50px)</option>
      <option>perspective(200px)</option>
      <option>matrix(1, 2, -1, 1, 80, 80)</option>
      <option>matrix3d(1,0,0,0,0,1,3,0,0,0,1,0,50,100,0,1.1)</option>
    </select>
  </div>
</main>
```

CSS

```
main {
  width: 400px;
  height: 200px;
  padding: 50px;
  background-image: linear-gradient(135deg, white, cyan, white);
}

#example-element {
  width: 100px;
  height: 100px;
  transform-style: preserve-3d;
  transition: transform 1.5s;
  transform: rotate3d(1, 1, 1, 30deg);
}

.face {
  display: flex;
  align-items: center;
  justify-content: center;
  width: 100%;
  height: 100%;
  position: absolute;
  backface-visibility: inherit;
  font-size: 60px;
  color: white;
}

.front {
  background: rgb(90 90 90 / 70%);
  transform: translateZ(50px);
}

.back {
  background: rgb(0 210 0 / 70%);
  transform: rotateY(180deg) translateZ(50px);
}

.right {
  background: rgb(210 0 0 / 70%);
```

```
  transform: rotateY(90deg) translateZ(50px);
}

.left {
  background: rgb(0 0 210 / 70%);
  transform: rotateY(-90deg) translateZ(50px);
}

.top {
  background: rgb(210 210 0 / 70%);
  transform: rotateX(90deg) translateZ(50px);
}

.bottom {
  background: rgb(210 0 210 / 70%);
  transform: rotateX(-90deg) translateZ(50px);
}

.select-form {
  margin-top: 50px;
}
```

JavaScript

```
const selectElem = document.querySelector("select");
const example = document.querySelector("#example-element");

selectElem.addEventListener("change", () => {
  if (selectElem.value === "Choose a function") {
    return;
  }
  example.style.transform = `rotate3d(1, 1, 1, 30deg) ${selectElem.value}`;
  setTimeout(() => {
    example.style.transform = "rotate3d(1, 1, 1, 30deg)";
  }, 2000);
});
```

matrix() CSS function

The **`matrix()`** CSS function defines a homogeneous 2D transformation matrix. Its result is a `<transform-function>` data type.

> **Note:** The `matrix(a, b, c, d, tx, ty)` function is a shorthand for `matrix3d(a, b, 0, 0, c, d, 0, 0, 0, 0, 1, 0, tx, ty, 0, 1)`.

Try it

```
transform: matrix(1.2, 0.2, -1, 0.9, 0, 20);
```

```
transform: matrix(0.4, 0, 0.5, 1.2, 60, 10);
```

```
transform: matrix(0, 1, 1, 0, 0, 0);
```

```
transform: matrix(0.1, 1, -0.3, 1, 0, 0);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

Syntax

```
matrix(a, b, c, d, tx, ty)
```

Values

The `matrix()` function is specified with six values. The constant values are implied and not passed as parameters; the other parameters are described in the column-major order.

a b c d

Are `<number>`s describing the linear transformation.

tx ty

Are `<number>`s describing the translation to apply.

Cartesian coordinates on ℝ^2	Homogeneous coordinates on ℙ^2	Cartesian coordinates on ℝ^3	Homogeneous coordinates on ℙ^3
$\begin{pmatrix} a & c \\ b & d \end{pmatrix}$	$\begin{pmatrix} a & c & \text{tx} \\ b & d & \text{ty} \\ 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} a & c & \text{tx} \\ b & d & \text{ty} \\ 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} a & c & 0 & \text{tx} \\ b & d & 0 & \text{ty} \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$
	`[a b c d tx ty]`		

The values represent the following functions: `matrix(scaleX(), skewY(), skewX(), scaleY(), translateX(), translateY())`.

Formal syntax

```
<matrix()> =
  matrix( <number>#{6} )
```

This syntax reflects the latest standard as per CSS Transforms Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<div>Normal</div>
<div class="changed">Changed</div>
```

CSS

```
div {
  width: 80px;
  height: 80px;
  background-color: skyblue;
}

.changed {
  transform: matrix(1, 2, -1, 1, 80, 80);
  background-color: pink;
}
```

matrix3d() CSS function

The **`matrix3d()`** CSS function defines a 3D transformation as a 4x4 homogeneous matrix. Its result is a `<transform-function>` data type.

Try it

```
transform: matrix3d(
  -0.6,
  1.34788,
  0,
  0,
  -2.34788,
  -0.6,
  0,
  0,
  0,
  0,
  1,
  0,
  0,
  0,
  10,
  1
);
```

```
transform: matrix3d(
  0.5,
  0,
  -0.866025,
  0,
  0.595877,
  1.2,
  -1.03209,
  0,
  0.866025,
  0,
  0.5,
  0,
  25.9808,
  0,
  15,
  1
);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

Syntax

```
matrix3d(a1, b1, c1, d1, a2, b2, c2, d2, a3, b3, c3, d3, a4, b4, c4, d4)
```

Values

The `matrix3d()` function is specified with 16 values. They are described in the column-major order.

a1 b1 c1 d1 a2 b2 c2 d2 a3 b3 c3 d3

Are `<number>`s describing the linear transformation.

a4 b4 c4 d4

Are `<number>`s describing the translation to apply.

Cartesian coordinates on ℝ^2	**Homogeneous coordinates on ℝP^2**	**Cartesian coordinates on ℝ^3**	**Homogeneous coordinates on ℝP^3**
This transformation applies to the 3D space and can't be represented on the plane.		A generic 3D affine transformation can't be represented using a Cartesian-coordinate matrix, as translations are not linear transformations.	$\begin{pmatrix} a1 & a2 & a3 & a4 \\ b1 & b2 & b3 & b4 \\ c1 & c2 & c3 & c4 \\ d1 & d2 & d3 & d4 \end{pmatrix}$

Formal syntax

```
<matrix3d()> =
  matrix3d( <number>#{16} )
```

This syntax reflects the latest standard as per CSS Transforms Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Cube squashing example

The following example shows a 3D cube created from DOM elements and transforms, which can be hovered/focused to apply a `matrix3d()` transform to it.

HTML

```
<section id="example-element" tabindex="0">
  <div class="face front">1</div>
  <div class="face back">2</div>
  <div class="face right">3</div>
  <div class="face left">4</div>
  <div class="face top">5</div>
  <div class="face bottom">6</div>
</section>
```

CSS

```
#example-element {
  width: 100px;
  height: 100px;
  transform-style: preserve-3d;
  transition: transform 1.5s;
  transform: rotate3d(1, 1, 1, 30deg);
  margin: 50px auto;
}

#example-element:hover,
#example-element:focus {
  transform: rotate3d(1, 1, 1, 30deg)
    matrix3d(1, 0, 0, 0, 0, 1, 6, 0, 0, 0, 1, 0, 50, 100, 0, 1.1);
}

.face {
  display: flex;
  align-items: center;
  justify-content: center;
  width: 100%;
  height: 100%;
  position: absolute;
  backface-visibility: inherit;
  font-size: 60px;
  color: white;
}

.front {
  background: rgb(90 90 90 / 70%);
  transform: translateZ(50px);
}

.back {
  background: rgb(0 210 0 / 70%);
  transform: rotateY(180deg) translateZ(50px);
}

.right {
  background: rgb(210 0 0 / 70%);
  transform: rotateY(90deg) translateZ(50px);
}

.left {
  background: rgb(0 0 210 / 70%);
  transform: rotateY(-90deg) translateZ(50px);
}

.top {
  background: rgb(210 210 0 / 70%);
  transform: rotateX(90deg) translateZ(50px);
}

.bottom {
  background: rgb(210 0 210 / 70%);
  transform: rotateX(-90deg) translateZ(50px);
}
```

Result

Matrix translation and scale example

Another `transform3d()` example, which implements an animated combined translate and scale.

HTML

```
<div class="foo">
  Lorem ipsum dolor sit amet, consectetur adipisicing elit. Quos quaerat sit
  soluta, quisquam exercitationem delectus qui unde in facere necessitatibus aut
  quia porro dolorem nesciunt enim, at consequuntur aliquam esse?
</div>
```

CSS

```
html {
  width: 100%;
}
body {
  height: 100vh;
  /* Centering content */
  display: flex;
  flex-flow: row wrap;
  justify-content: center;
  align-content: center;
}
.foo {
  width: 50%;
  padding: 1em;
  color: white;
  background: #ff8c66;
  border: 2px dashed black;
  text-align: center;
  font-family: system-ui, sans-serif;
  font-size: 14px;
  /* Setting up animation for better demonstration */
  animation: MotionScale 2s alternate linear infinite;
}

@keyframes MotionScale {
  0% {
    /*
      Identity matrix is used as basis here.
      The matrix below describes the
      following transformations:
        Translates every X point by -50px
        Translates every Y point by -100px
        Translates every Z point by 0
        Scales down by 10%
    */
    /* prettier-ignore */
    transform: matrix3d(
      1, 0, 0, 0,
      0, 1, 0, 0,
      0, 0, 1, 0,
      -50, -100, 0, 1.1
    );
  }
  50% {
    /* prettier-ignore */
    transform: matrix3d(
      1, 0, 0, 0,
      0, 1, 0, 0,
      0, 0, 1, 0,
      0, 0, 0, 0.9
    );
  }
  100% {
    /* prettier-ignore */
    transform: matrix3d(
      1, 0, 0, 0,
      0, 1, 0, 0,
      0, 0, 1, 0,
      50, 100, 0, 1.1
    )
  }
}
```

perspective() CSS function

The **`perspective()`** CSS function defines a transformation that sets the distance between the user and the z=0 plane, the perspective from which the viewer would be if the 2-dimensional interface were 3-dimensional. Its result is a `<transform-function>` data type.

Try it

```
transform: perspective(0);
```

```
transform: perspective(none);
```

```
transform: perspective(800px);
```

```
transform: perspective(23rem);
```

```
transform: perspective(6.5cm);
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    <div class="face front">1</div>
    <div class="face back">2</div>
    <div class="face right">3</div>
    <div class="face left">4</div>
    <div class="face top">5</div>
    <div class="face bottom">6</div>
  </div>
</section>
```

```
#default-example {
  background: linear-gradient(skyblue, khaki);
  perspective: 800px;
  perspective-origin: 150% 150%;
}

#example-element {
  width: 100px;
  height: 100px;
  perspective: 550px;
  transform-style: preserve-3d;
}

.face {
  display: flex;
  align-items: center;
  justify-content: center;
  width: 100%;
  height: 100%;
  position: absolute;
  backface-visibility: inherit;
  font-size: 60px;
  color: white;
}

.front {
  background: rgb(90 90 90 / 0.7);
  transform: translateZ(50px);
}

.back {
  background: rgb(0 210 0 / 0.7);
  transform: rotateY(180deg) translateZ(50px);
}

.right {
  background: rgb(210 0 0 / 0.7);
  transform: rotateY(90deg) translateZ(50px);
}

.left {
  background: rgb(0 0 210 / 0.7);
  transform: rotateY(-90deg) translateZ(50px);
}

.top {
  background: rgb(210 210 0 / 0.7);
  transform: rotateX(90deg) translateZ(50px);
}

.bottom {
  background: rgb(210 0 210 / 0.7);
  transform: rotateX(-90deg) translateZ(50px);
}
```

The `perspective()` transform function is part of the `transform` value applied on the element being transformed. This differs from the `perspective` and `perspective-origin` properties which are attached to the parent of a child transformed in 3-dimensional space.

Syntax

```
perspective(d)
```

Values

d

Is a `<length>` representing the distance from the user to the z=0 plane. The z=0 plane is the plane where everything appears in a 2-dimensional view, or the screen. Values smaller than `1px` (including zero) are clamped to `1px`. Negative values are syntax errors.

Values other than `none` cause elements with positive z positions to appear larger, and elements with negative z positions to appear smaller. Elements with z positions equal to or larger than the perspective value disappear as though they are behind the user. Large values of perspective represent a small transformation; small values of `perspective()` represent a large transformation; `perspective(none)` represents perspective from infinite distance and no transformation.

Cartesian coordinates on $\mathbb{R}^2$	**Homogeneous coordinates on $\mathbb{RP}^2$**	**Cartesian coordinates on $\mathbb{R}^3$**	**Homogeneous coordinates on $\mathbb{RP}^3$**
This transformation applies to the 3D space and can't be represented on the plane.		This transformation is not a linear transformation in $\mathbb{R}^3$, and can't be represented using a Cartesian-coordinate matrix.	$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & -1/d & 1 \end{pmatrix}$

Formal syntax

```
<perspective()> =
  perspective( [ <length [0,∞]> | none ] )
```

This syntax reflects the latest standard as per CSS Transforms Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<p>Without perspective:</p>
<div class="no-perspective-box">
  <div class="face front">A</div>
  <div class="face top">B</div>
  <div class="face left">C</div>
</div>

<p>With perspective (9cm):</p>
<div class="perspective-box-far">
  <div class="face front">A</div>
  <div class="face top">B</div>
  <div class="face left">C</div>
</div>

<p>With perspective (4cm):</p>
<div class="perspective-box-closer">
  <div class="face front">A</div>
  <div class="face top">B</div>
  <div class="face left">C</div>
</div>
```

CSS

```
.face {
  position: absolute;
  width: 100px;
  height: 100px;
  line-height: 100px;
  font-size: 100px;
  text-align: center;
}

p + div {
  width: 100px;
  height: 100px;
  transform-style: preserve-3d;
  margin-left: 100px;
}
.no-perspective-box {
  transform: rotateX(-15deg) rotateY(30deg);
}

.perspective-box-far {
  transform: perspective(9cm) rotateX(-15deg) rotateY(30deg);
}

.perspective-box-closer {
  transform: perspective(4cm) rotateX(-15deg) rotateY(30deg);
}

.top {
  background-color: skyblue;
  transform: rotateX(90deg) translate3d(0, 0, 50px);
}

.left {
  background-color: pink;
  transform: rotateY(-90deg) translate3d(0, 0, 50px);
}

.front {
  background-color: limegreen;
  transform: translate3d(0, 0, 50px);
}
```

Result

- `<transform-function>`
- Individual transform properties:
  - `translate`
  - `scale`
  - `rotate`

rotate() CSS function

The **`rotate()`** CSS function defines a transformation that rotates an element around a fixed point on the 2D plane, without deforming it. Its result is a `<transform-function>` data type.

Try it

```
transform: rotate(0);
```

```
transform: rotate(90deg);
```

```
transform: rotate(-0.25turn);
```

```
transform: rotate(3.142rad);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

The fixed point that the element rotates around — mentioned above — is also known as the **transform origin**. This defaults to the center of the element, but you can set your own custom transform origin using the `transform-origin` property.

> **Note:** The SVG `transform` attribute has its own grammar, in which `rotate()` accepts two optional extra values giving the center of rotation, as in `rotate(45, 50, 50)`. That form is only valid in the attribute, not in CSS: the CSS `rotate()` function takes an angle alone, and the center is set with `transform-origin`.

Syntax

```
rotate(a)
```

Values

a

Is an `<angle>` representing the angle of the rotation. The direction of rotation depends on the writing direction. In a left-to-right context, a positive angle denotes a clockwise rotation, a negative angle a counter-clockwise one. In a right-to-left context, a positive angle denotes a counter-clockwise rotation, a negative angle a clockwise one. A rotation by 180° is called *point reflection*.

Cartesian coordinates on $\mathbb{R}^2$	Homogeneous coordinates on $\mathbb{RP}^2$	Cartesian coordinates on $\mathbb{R}^3$	Homogeneous coordinates on $\mathbb{RP}^3$
$\begin{pmatrix} \cos(a) & -\sin(a) \\ \sin(a) & \cos(a) \end{pmatrix}$	$\begin{pmatrix} \cos(a) & -\sin(a) & 0 \\ \sin(a) & \cos(a) & 0 \\ 0 & 0 & 1 \end{pmatrix}$ `[cos(a) sin(a) -sin(a) cos(a) 0 0]`	$\begin{pmatrix} \cos(a) & -\sin(a) & 0 \\ \sin(a) & \cos(a) & 0 \\ 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} \cos(a) & -\sin(a) & 0 & 0 \\ \sin(a) & \cos(a) & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$

Formal syntax

```
<rotate()> =
  rotate( [ <angle> | <zero> ] )
```

This syntax reflects the latest standard as per CSS Transforms Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

HTML

```
<div>Normal</div>
<div class="rotated">Rotated</div>
```

CSS

```
div {
  width: 80px;
  height: 80px;
  background-color: skyblue;
}

.rotated {
  transform: rotate(45deg); /* Equal to rotateZ(45deg) */
  background-color: pink;
}
```

Result

Combining rotation with another transformation

If you want to apply multiple transformations to an element, be careful about the order in which you specify your transformations. For example, if you rotate before translating, the translation will be along the new axis of rotation!

HTML

```
<div>Normal</div>
<div class="rotate">Rotated</div>
<div class="rotate-translate">Rotated + Translated</div>
<div class="translate-rotate">Translated + Rotated</div>
```

CSS

```
div {
  position: absolute;
  left: 40px;
  top: 40px;
  width: 100px;
  height: 100px;
  background-color: lightgray;
}

.rotate {
  background-color: transparent;
  outline: 2px dashed;
  transform: rotate(45deg);
}

.rotate-translate {
  background-color: pink;
```

```
  transform: rotate(45deg) translateX(180px);
}

.translate-rotate {
  background-color: gold;
  transform: translateX(180px) rotate(45deg);
}
```

Result

rotate3d() CSS function

The **`rotate3d()`** CSS function defines a transformation that rotates an element around a fixed axis in 3D space, without deforming it. Its result is a `<transform-function>` data type.

Try it

```
transform: rotate3d(0, 0, 0, 0);
```

```
transform: rotate3d(1, 1, 1, 45deg);
```

```
transform: rotate3d(2, -1, -1, -0.2turn);
```

```
transform: rotate3d(0, 1, 0.5, 3.142rad);
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    <div class="face front">1</div>
    <div class="face back">2</div>
    <div class="face right">3</div>
    <div class="face left">4</div>
    <div class="face top">5</div>
    <div class="face bottom">6</div>
  </div>
</section>
```

```
#default-example {
  background: linear-gradient(skyblue, khaki);
  perspective: 550px;
}

#example-element {
  width: 100px;
  height: 100px;
  transform-style: preserve-3d;
}

.face {
  display: flex;
  align-items: center;
  justify-content: center;
  width: 100%;
  height: 100%;
  position: absolute;
  backface-visibility: inherit;
  font-size: 60px;
  color: white;
}

.front {
  background: rgb(90 90 90 / 0.7);
  transform: translateZ(50px);
}

.back {
  background: rgb(0 210 0 / 0.7);
  transform: rotateY(180deg) translateZ(50px);
}

.right {
  background: rgb(210 0 0 / 0.7);
  transform: rotateY(90deg) translateZ(50px);
}

.left {
  background: rgb(0 0 210 / 0.7);
  transform: rotateY(-90deg) translateZ(50px);
}

.top {
  background: rgb(210 210 0 / 0.7);
  transform: rotateX(90deg) translateZ(50px);
}

.bottom {
  background: rgb(210 0 210 / 0.7);
  transform: rotateX(-90deg) translateZ(50px);
}
```

In 3D space, rotations have three degrees of freedom, which together describe a single axis of rotation. The axis of rotation is defined by an [x, y, z] vector and pass by the origin (as defined by the `transform-origin` property). If, as specified, the vector is not *normalized* (i.e., if the sum of the square of its three coordinates is not 1), the user agent will normalize it internally. A non-normalizable vector, such as the null vector, [0, 0, 0], will cause the rotation to be ignored, but without invalidating the whole CSS property.

> **Note:** Unlike rotations in the 2D plane, the composition of 3D rotations is usually not commutative. In other words, the order in which the rotations are applied impacts the result.

Syntax

```
rotate3d(x, y, z, a)
```

Values

`x`

Is a `<number>` describing the x-coordinate of the vector denoting the axis of rotation which can be a positive or negative number.

`y`

Is a `<number>` describing the y-coordinate of the vector denoting the axis of rotation which can be a positive or negative number.

`z`

Is a `<number>` describing the z-coordinate of the vector denoting the axis of rotation which can be a positive or negative number.

`a`

Is an `<angle>` representing the angle of the rotation. A positive angle denotes a clockwise rotation, a negative angle a counter-clockwise one.

Cartesian coordinates on $\mathbb{R}^2$	This transformation applies to the 3D space and can't be represented on the plane.
Homogeneous coordinates on $\mathbb{RP}^2$	
Cartesian coordinates on $\mathbb{R}^3$	$\begin{pmatrix} 1+(1-\cos(a))(x^2-1) & z\cdot\sin(a)+xy(1-\cos(a)) & -y\cdot\sin(a)+xz(1-\cos(a)) \\ -z\cdot\sin(a)+xy(1-\cos(a)) & 1+(1-\cos(a))(y^2-1) & x\cdot\sin(a)+yz(1-\cos(a)) \\ y\cdot\sin(a)+xz(1-\cos(a)) & -x\cdot\sin(a)+yz(1-\cos(a)) & 1+(1-\cos(a))(z^2-1) \end{pmatrix}$
Homogeneous coordinates on $\mathbb{RP}^3$	$\begin{pmatrix} 1+(1-\cos(a))(x^2-1) & z\cdot\sin(a)+xy(1-\cos(a)) & -y\cdot\sin(a)+xz(1-\cos(a)) & 0 \\ -z\cdot\sin(a)+xy(1-\cos(a)) & 1+(1-\cos(a))(y^2-1) & x\cdot\sin(a)+yz(1-\cos(a)) & 0 \\ y\cdot\sin(a)+xz(1-\cos(a)) & -x\cdot\sin(a)+yz(1-\cos(a)) & 1+(1-\cos(a))(z^2-1) & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$

Formal syntax

```
<rotate3d()> =
  rotate3d( <number> , <number> , <number> , [ <angle> | <zero> ] )
```

This syntax reflects the latest standard as per CSS Transforms Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Rotating on the y-axis

HTML

```
<div>Normal</div>
<div class="rotated">Rotated</div>
```

CSS

```
body {
  perspective: 800px;
}

div {
  width: 80px;
  height: 80px;
  background-color: skyblue;
}

.rotated {
  transform: rotate3d(0, 1, 0, 60deg);
  background-color: pink;
}
```

Result

Rotating on a custom axis

HTML

```
<div>Normal</div>
<div class="rotated">Rotated</div>
```

CSS

```
body {
  perspective: 800px;
}

div {
  width: 80px;
  height: 80px;
  background-color: skyblue;
}

.rotated {
  transform: rotate3d(1, 2, -1, 192deg);
  background-color: pink;
}
```

Result

See also

- `transform` property
- `rotate` property

rotateX() CSS function

The **`rotateX()`** CSS function defines a transformation that rotates an element around the x-axis (horizontal) without deforming it. Its result is a `<transform-function>` data type.

Try it

```
transform: rotateX(0);
```

```
transform: rotateX(45deg);
```

```
transform: rotateX(-0.2turn);
```

```
transform: rotateX(3.142rad);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

The axis of rotation passes through an origin, defined by the `transform-origin` CSS property.

> **Note:** `rotateX(a)` is equivalent to `rotate3d(1, 0, 0, a)`.

> **Note:** Unlike rotations in the 2D plane, the composition of 3D rotations is usually not commutative. In other words, the order in which the rotations are applied impacts the result.

Syntax

```
rotateX(a)
```

Values

`a`

Is an `<angle>` representing the angle of the rotation. A positive angle denotes a clockwise rotation, a negative angle a counter-clockwise one.

Cartesian coordinates on $\mathbb{R}^2$	Homogeneous coordinates on $\mathbb{RP}^2$	Cartesian coordinates on $\mathbb{R}^3$	Homogeneous coordinates on $\mathbb{RP}^3$
This transformation applies to the 3D space and can't be represented on the plane.		$\begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos(a) & -\sin(a) \\ 0 & \sin(a) & \cos(a) \end{pmatrix}$	$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos(a) & -\sin(a) & 0 \\ 0 & \sin(a) & \cos(a) & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$

Formal syntax

```
<rotateX()> =
  rotateX( [ <angle> | <zero> ] )
```

This syntax reflects the latest standard as per CSS Transforms Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<div>Normal</div>
<div class="rotated">Rotated</div>
```

CSS

```
div {
  width: 80px;
  height: 80px;
  background-color: skyblue;
}

.rotated {
  transform: rotateX(45deg);
  background-color: pink;
}
```

Result

rotateY() CSS function

The **`rotateY()`** CSS function defines a transformation that rotates an element around the y-axis (vertical) without deforming it. Its result is a `<transform-function>` data type.

Try it

```
transform: rotateY(0);
```

```
transform: rotateY(45deg);
```

```
transform: rotateY(-0.2turn);
```

```
transform: rotateY(3.142rad);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

The axis of rotation passes through an origin, defined by the `transform-origin` CSS property.

> **Note:** `rotateY(a)` is equivalent to `rotate3d(0, 1, 0, a)`.

> **Note:** Unlike rotations in the 2D plane, the composition of 3D rotations is usually not commutative. In other words, the order in which the rotations are applied impacts the result.

Syntax

```
rotateY(a)
```

Values

`a`

Is an `<angle>` representing the angle of the rotation. A positive angle denotes a clockwise rotation, a negative angle a counter-clockwise one.

Cartesian coordinates on $\mathbb{R}^2$	Homogeneous coordinates on $\mathbb{RP}^2$	Cartesian coordinates on $\mathbb{R}^3$	Homogeneous coordinates on $\mathbb{RP}^3$
This transformation applies to the 3D space and can't be represented on the plane.		$\begin{pmatrix} \cos(a) & 0 & \sin(a) \\ 0 & 1 & 0 \\ -\sin(a) & 0 & \cos(a) \end{pmatrix}$	$\begin{pmatrix} \cos(a) & 0 & \sin(a) & 0 \\ 0 & 1 & 0 & 0 \\ -\sin(a) & 0 & \cos(a) & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$

Formal syntax

```
<rotateY()> =
  rotateY( [ <angle> | <zero> ] )
```

This syntax reflects the latest standard as per CSS Transforms Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<div>Normal</div>
<div class="rotated">Rotated</div>
```

CSS

```
div {
  width: 80px;
  height: 80px;
  background-color: skyblue;
}

.rotated {
  transform: rotateY(60deg);
  background-color: pink;
}
```

Result

rotateZ() CSS function

The **`rotateZ()`** CSS function defines a transformation that rotates an element around the z-axis without deforming it. Its result is a `<transform-function>` data type.

Try it

```
transform: rotateZ(0);
```

```
transform: rotateZ(90deg);
```

```
transform: rotateZ(-0.25turn);
```

```
transform: rotateZ(3.142rad);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

The axis of rotation passes through an origin, defined by the `transform-origin` CSS property.

> **Note:** `rotateZ(a)` is equivalent to `rotate(a)` or `rotate3d(0, 0, 1, a)`.

> **Note:** Unlike rotations in the 2D plane, the composition of 3D rotations is usually not commutative. In other words, the order in which the rotations are applied impacts the result.

Syntax

```
rotateZ(a)
```

Values

`a`

Is an `<angle>` representing the angle of the rotation. A positive angle denotes a clockwise rotation, a negative angle a counter-clockwise one.

Cartesian coordinates on $\mathbb{R}^2$	Homogeneous coordinates on $\mathbb{RP}^2$	Cartesian coordinates on $\mathbb{R}^3$	Homogeneous coordinates on $\mathbb{RP}^3$
This transformation applies to the 3D space and can't be represented on the plane.		$\begin{pmatrix} \cos(a) & -\sin(a) & 0 \\ \sin(a) & \cos(a) & 0 \\ 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} \cos(a) & -\sin(a) & 0 & 0 \\ \sin(a) & \cos(a) & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$

Formal syntax

```
<rotateZ()> =
  rotateZ( [ <angle> | <zero> ] )
```

This syntax reflects the latest standard as per CSS Transforms Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<div>Normal</div>
<div class="rotated">Rotated</div>
```

CSS

```
div {
  width: 80px;
  height: 80px;
  background-color: skyblue;
}

.rotated {
  transform: rotateZ(45deg);
  background-color: pink;
}
```

Result

See also

scale() CSS function

The **`scale()`** CSS function defines a transformation that resizes an element on the 2D plane. Because the amount of scaling is defined by a vector [sx, sy], it can resize the horizontal and vertical dimensions at different scales. Its result is a `<transform-function>` data type.

Try it

```
transform: scale(1);
```

```
transform: scale(0.7);
```

```
transform: scale(1.3, 0.4);
```

```
transform: scale(-0.5, 1);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

This scaling transformation is characterized by a two-dimensional vector. Its coordinates define how much scaling is done in each direction. If both coordinates are equal, the scaling is uniform (*isotropic*) and the aspect ratio of the element is preserved (this is a homothetic transformation).

When a coordinate value is outside the [-1, 1] range, the element grows along that dimension; when inside, it shrinks. A negative value results in a point reflection in that dimension. The value `1` has no effect.

> **Note:** The `scale()` function only scales in 2D. To scale in 3D, use `scale3d()` instead.

Syntax

```
scale(sx)

scale(sx, sy)
```

Values

`sx`

A `<number>` or `<percentage>` representing the abscissa (horizontal, x-component) of the scaling vector.

`sy` Optional

A `<number>` or `<percentage>` representing the ordinate (vertical, y-component) of the scaling vector. If not defined, its default value is `sx`, resulting in a uniform scaling that preserves the element's aspect ratio.

Cartesian coordinates on $\mathbb{R}^2$	Homogeneous coordinates on $\mathbb{RP}^2$	Cartesian coordinates on $\mathbb{R}^3$	Homogeneous coordinates on $\mathbb{RP}^3$
$\begin{pmatrix} sx & 0 \\ 0 & sy \end{pmatrix}$	$\begin{pmatrix} sx & 0 & 0 \\ 0 & sy & 0 \\ 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} sx & 0 & 0 \\ 0 & sy & 0 \\ 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} sx & 0 & 0 & 0 \\ 0 & sy & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$
	`[sx 0 0 sy 0 0]`		

Formal syntax

```
<scale()> =
  scale( <number> , <number>? )
```

This syntax reflects the latest standard as per CSS Transforms Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Accessibility

Scaling/zooming animations are problematic for accessibility, as they are a common trigger for certain types of migraine. If you need to include such animations on your website, you should provide a control to allow users to turn off animations, preferably site-wide.

Also, consider making use of the `prefers-reduced-motion` media feature — use it to write a media query that will turn off animations if the user has reduced animation specified in their system preferences.

Examples

Scaling the X and Y dimensions together

HTML

```
<div>Normal</div>
<div class="scaled">Scaled</div>
```

CSS

```
div {
  width: 80px;
  height: 80px;
  background-color: skyblue;
}

.scaled {
  transform: scale(0.7); /* Equal to scaleX(0.7) scaleY(0.7) */
  background-color: pink;
}
```

Result

Scaling X and Y dimensions separately, and translating the origin

HTML

```
<div>Normal</div>
<div class="scaled">Scaled</div>
```

CSS

```
div {
  width: 80px;
  height: 80px;
  background-color: skyblue;
}

.scaled {
  transform: scale(2, 0.5); /* Equal to scaleX(2) scaleY(0.5) */
  transform-origin: left;
  background-color: pink;
}
```

Result

  width: 100px;
  height: 100px;
  perspective: 550px;
  transform-style: preserve-3d;
}

.face {
  display: flex;
  align-items: center;
  justify-content: center;
  width: 100%;
  height: 100%;
  position: absolute;
  backface-visibility: inherit;
  font-size: 60px;
  color: white;
}

.front {
  background: rgb(90 90 90 / 0.7);
  transform: translateZ(50px);
}

.back {
  background: rgb(0 210 0 / 0.7);
  transform: rotateY(180deg) translateZ(50px);
}

.right {
  background: rgb(210 0 0 / 0.7);
  transform: rotateY(90deg) translateZ(50px);
}

.left {
  background: rgb(0 0 210 / 0.7);
  transform: rotateY(-90deg) translateZ(50px);
}

.top {
  background: rgb(210 210 0 / 0.7);
  transform: rotateX(90deg) translateZ(50px);
}

.bottom {
  background: rgb(210 0 210 / 0.7);
  transform: rotateX(-90deg) translateZ(50px);
}
```

This scaling transformation is characterized by a three-dimensional vector. Its coordinates define how much scaling is done in each direction. If all three coordinates are equal, the scaling is uniform (*isotropic*) and the aspect ratio of the element is preserved (this is a homothetic transformation).

When a coordinate value is outside the [-1, 1] range, the element grows along that dimension; when inside, it shrinks. If it is negative, the result is a point reflection in that dimension. A value of 1 has no effect.

Syntax

```
scale3d(sx, sy, sz)
```

Values

`sx`

Is a `<number>` representing the abscissa (horizontal, x-component) of the scaling vector.

`sy`

Is a `<number>` representing the ordinate (vertical, y-component) of the scaling vector.

`sz`

Is a `<number>` representing the z-component of the scaling vector.

Cartesian coordinates on $\mathbb{R}^2$	Homogeneous coordinates on $\mathbb{RP}^2$	Cartesian coordinates on $\mathbb{R}^3$	Homogeneous coordinates on $\mathbb{RP}^3$
This transformation applies to the 3D space and can't be represented on the plane.		$\begin{pmatrix} sx & 0 & 0 \\ 0 & sy & 0 \\ 0 & 0 & sz \end{pmatrix}$	$\begin{pmatrix} sx & 0 & 0 & 0 \\ 0 & sy & 0 & 0 \\ 0 & 0 & sz & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$

Formal syntax

```
<scale3d()> =
  scale3d( [ <number> | <percentage> ]#{3} )
```

This syntax reflects the latest standard as per CSS Transforms Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Without changing the origin

HTML

```
<div>Normal</div>
<div class="scaled">Scaled</div>
```

CSS

```
div {
  width: 80px;
  height: 80px;
  background-color: skyblue;
}

.scaled {
  transform: perspective(500px) scale3d(2, 0.7, 0.2) translateZ(100px);
  background-color: pink;
}
```

Result

Translating the origin of the transformation

HTML

```
<div>Normal</div>
<div class="scaled">Scaled</div>
```

CSS

```
div {
  width: 80px;
  height: 80px;
  background-color: skyblue;
}

.scaled {
  transform: perspective(500px) scale3d(2, 0.7, 0.2) translateZ(100px);
  transform-origin: left;
  background-color: pink;
}
```

Result

scaleX() CSS function

The **`scaleX()`** CSS function defines a transformation that resizes an element along the x-axis (horizontally). Its result is a `<transform-function>` data type.

Try it

```
transform: scaleX(1);
```

```
transform: scaleX(0.7);
```

```
transform: scaleX(1.3);
```

```
transform: scaleX(-0.5);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

It modifies the abscissa (horizontal, x-coordinate) of each element point by a constant factor, except when the scale factor is 1, in which case the function is the identity transform. The scaling is not isotropic, and the angles of the element are generally not conserved, except for multiples of 90 degrees. `scaleX(-1)` defines an axial symmetry, with a vertical axis passing through the origin (as specified by the `transform-origin` property).

> **Note:** `scaleX(sx)` is equivalent to `scale(sx, 1)` or `scale3d(sx, 1, 1)`.

Syntax

```
scaleX(s)
```

Values

`s`

Is a `<number>` representing the scaling factor to apply on the abscissa (horizontal, x-coordinate) of each point of the element.

Cartesian coordinates on $\mathbb{R}^2$	Homogeneous coordinates on $\mathbb{RP}^2$	Cartesian coordinates on $\mathbb{R}^3$	Homogeneous coordinates on $\mathbb{RP}^3$
$\begin{pmatrix} s & 0 \\ 0 & 1 \end{pmatrix}$	$\begin{pmatrix} s & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$ `[s 0 0 1 0 0]`	$\begin{pmatrix} s & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} s & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$

Formal syntax

```
<scaleX()> =
  scaleX( <number> )
```

This syntax reflects the latest standard as per CSS Transforms Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<div>Normal</div>
<div class="scaled">Scaled</div>
```

CSS

```
div {
  width: 80px;
  height: 80px;
  background-color: skyblue;
}

.scaled {
  transform: scaleX(0.6);
  background-color: pink;
}
```

Result

See also

- `scaleY()`
- `scaleZ()`

  - `translate`
  - `rotate`
  - Note: there is no `skew` property

scaleY() CSS function

The **`scaleY()`** CSS function defines a transformation that resizes an element along the y-axis (vertically). Its result is a `<transform-function>` data type.

Try it

```
transform: scaleY(1);
```

```
transform: scaleY(0.7);
```

```
transform: scaleY(1.3);
```

```
transform: scaleY(-0.5);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

It modifies the ordinate (vertical, y-coordinate) of each element point by a constant factor, except when the scale factor is 1, in which case the function is the identity transform. The scaling is not isotropic, and the angles of the element are not conserved. `scaleY(-1)` defines an axial symmetry, with a horizontal axis passing through the origin (as specified by the `transform-origin` property).

> **Note:** `scaleY(sy)` is equivalent to `scale(1, sy)` or `scale3d(1, sy, 1)`.
>
> `transform: rotateX(180deg); === transform: scaleY(-1);`

Syntax

```
scaleY(s)
```

Values

`s`

Is a `<number>` representing the scaling factor to apply on the ordinate (vertical, y-coordinate) of each point of the element.

Cartesian coordinates on $\mathbb{R}^2$	Homogeneous coordinates on $\mathbb{RP}^2$	Cartesian coordinates on $\mathbb{R}^3$	Homogeneous coordinates on $\mathbb{RP}^3$
$\begin{pmatrix} 1 & 0 \\ 0 & s \end{pmatrix}$	$\begin{pmatrix} 1 & 0 & 0 \\ 0 & s & 0 \\ 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & 0 & 0 \\ 0 & s & 0 \\ 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & s & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$
	`[1 0 0 s 0 0]`		

Formal syntax

```
<scaleY()> =
  scaleY( <number> )
```

This syntax reflects the latest standard as per CSS Transforms Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<div>Normal</div>
<div class="scaled">Scaled</div>
```

CSS

```
div {
  width: 80px;
  height: 80px;
  background-color: skyblue;
}

.scaled {
  transform: scaleY(0.6);
  background-color: pink;
}
```

Result

See also

- `scaleZ()`
- `transform`
- `<transform-function>`
- `transform-origin`
- Individual transform properties:
  - `translate`
  - `scale`
  - `rotate`
  - Note: there is no `skew` property

scaleZ() CSS function

The **`scaleZ()`** CSS function defines a transformation that resizes an element along the z-axis. Its result is a `<transform-function>` data type.

Try it

```
transform: scaleZ(1);
```

```
transform: scaleZ(1.4);
```

```
transform: scaleZ(0.5);
```

```
transform: scaleZ(-1.4);
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    <div class="face front">1</div>
    <div class="face back">2</div>
    <div class="face right">3</div>
```

```
    <div class="face left">4</div>
    <div class="face top">5</div>
    <div class="face bottom">6</div>
  </div>
</section>
```

```
#default-example {
  background: linear-gradient(skyblue, khaki);
  perspective: 800px;
  perspective-origin: 150% 150%;
}

#example-element {
  width: 100px;
  height: 100px;
  perspective: 550px;
  transform-style: preserve-3d;
}

.face {
  display: flex;
  align-items: center;
  justify-content: center;
  width: 100%;
  height: 100%;
  position: absolute;
  backface-visibility: inherit;
  font-size: 60px;
  color: white;
}

.front {
  background: rgb(90 90 90 / 0.7);
  transform: translateZ(50px);
}

.back {
  background: rgb(0 210 0 / 0.7);
  transform: rotateY(180deg) translateZ(50px);
}

.right {
  background: rgb(210 0 0 / 0.7);
  transform: rotateY(90deg) translateZ(50px);
}

.left {
  background: rgb(0 0 210 / 0.7);
  transform: rotateY(-90deg) translateZ(50px);
}

.top {
  background: rgb(210 210 0 / 0.7);
  transform: rotateX(90deg) translateZ(50px);
}

.bottom {
  background: rgb(210 0 210 / 0.7);
  transform: rotateX(-90deg) translateZ(50px);
}
```

This scaling transformation modifies the z-coordinate of each element point by a constant factor, except when the scale factor is 1, in which case the function is the identity transform. The scaling is not isotropic, and the angles of the element are not conserved. `scaleZ(-1)` defines an axial symmetry, with the z-axis passing through the origin (as specified by the `transform-origin` property).

In the above interactive examples, `perspective: 550px;` (to create a 3D space) and `transform-style: preserve-3d;` (so the children, the 6 sides of the cube, are also positioned in the 3D space), have been set on the cube.

> **Note:** `scaleZ(sz)` is equivalent to `scale3d(1, 1, sz)`.

Syntax

```
scaleZ(s)
```

Values

`s`

Is a `<number>` representing the scaling factor to apply on the z-coordinate of each point of the element.

Cartesian coordinates on $\mathbb{R}^2$	Homogeneous coordinates on $\mathbb{RP}^2$	Cartesian coordinates on $\mathbb{R}^3$	Homogeneous coordinates on $\mathbb{RP}^3$
This transformation applies to the 3D space and can't be represented on the plane.		$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & s \end{pmatrix}$	$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & s & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$

Formal syntax

```
<scaleZ()> =
  scaleZ( [ <number> | <percentage> ] )
```

This syntax reflects the latest standard as per CSS Transforms Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<div>Normal</div>
<div class="perspective">Translated</div>
<div class="scaled-translated">Scaled</div>
```

CSS

```
div {
  width: 80px;
  height: 80px;
  background-color: skyblue;
}

.perspective {
  /* Includes a perspective to create a 3D space */
  transform: perspective(400px) translateZ(-100px);
  background-color: limegreen;
}

.scaled-translated {
  /* Includes a perspective to create a 3D space */
  transform: perspective(400px) scaleZ(2) translateZ(-100px);
  background-color: pink;
}
```

Result

skew() CSS function

The **`skew()`** CSS function defines a transformation that skews an element on the 2D plane. Its result is a `<transform-function>` data type.

Try it

```
transform: skew(0);
```

```
transform: skew(15deg, 15deg);
```

```
transform: skew(-0.06turn, 18deg);
```

```
transform: skew(0.312rad);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

This transformation is a shear mapping (transvection) that distorts each point within an element by a certain angle in the horizontal and vertical directions. The effect is as if you grabbed each corner of the element and pulled them along a certain angle.

The coordinates of each point are modified by a value proportionate to the specified angle and the distance to the origin. Thus, the farther from the origin a point is, the greater the value added to it.

Syntax

```
skew(ax)

skew(ax, ay)
```

Values

`ax`

Is an `<angle>` representing the angle to use to distort the element along the x-axis.

`ay` Optional

Is an `<angle>` representing the angle to use to distort the element along the y-axis. If not defined, its default value is `0`, resulting in a purely horizontal skewing.

Cartesian coordinates on $\mathbb{R}^2$	**Homogeneous coordinates** on $\mathbb{RP}^2$	**Cartesian coordinates** on $\mathbb{R}^3$	**Homogeneous coordinates** on $\mathbb{RP}^3$
$\begin{pmatrix} 1 & \tan(ax) \\ \tan(ay) & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & \tan(ax) & 0 \\ \tan(ay) & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & \tan(ax) & 0 \\ \tan(ay) & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & \tan(ax) & 0 & 0 \\ \tan(ay) & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$
	`[1 tan(ay) tan(ax) 1 0 0]`		

Formal syntax

```
<skew()> =
  skew( [ <angle> | <zero> ] , [ <angle> | <zero> ]? )
```

This syntax reflects the latest standard as per CSS Transforms Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Skewing on the x-axis only

HTML

```
<div>Normal</div>
<div class="skewed">Skewed</div>
```

CSS

```
body {
  margin: 20px;
}

div {
  width: 80px;
  height: 80px;
  background-color: skyblue;
}

.skewed {
  transform: skew(10deg); /* Equal to skewX(10deg) */
  background-color: pink;
}
```

Result

Skewing on both axes

HTML

```
<div>Normal</div>
<div class="skewed">Skewed</div>
```

CSS

```
body {
  margin: 20px;
}

div {
  width: 80px;
  height: 80px;
  background-color: skyblue;
}

.skewed {
  transform: skew(10deg, 10deg);
  background-color: pink;
}
```

Result

  - Note: there is no `skew` property

skewX() CSS function

The **`skewX()`** CSS function defines a transformation that skews an element in the horizontal direction on the 2D plane. Its result is a `<transform-function>` data type.

Try it

```
transform: skewX(0);
```

```
transform: skewX(35deg);
```

```
transform: skewX(-0.06turn);
```

```
transform: skewX(0.352rad);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

This transformation is a shear mapping (transvection) that distorts each point within an element by a certain angle in the horizontal direction. The abscissa (horizontal, x-coordinate) of each point is modified by a value proportionate to the specified angle and the distance to the origin; thus, the farther from the origin a point is, the greater will be the value added it.

> **Note:** `skewX(a)` is equivalent to `skew(a)`.

Syntax

```
skewX(a)
```

Values

`a`

Is an `<angle>` representing the angle to use to distort the element along the abscissa (horizontal, x-coordinate).

Cartesian coordinates on $\mathbb{R}^2$	Homogeneous coordinates on $\mathbb{RP}^2$	Cartesian coordinates on $\mathbb{R}^3$	Homogeneous coordinates on $\mathbb{RP}^3$
$\begin{pmatrix} 1 & \tan(a) \\ 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & \tan(a) & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & \tan(a) & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & \tan(a) & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$
	`[1 0 tan(a) 1 0 0]`		

Formal syntax

```
<skewX()> =
  skewX( [ <angle> | <zero> ] )
```

This syntax reflects the latest standard as per CSS Transforms Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<div>Normal</div>
<div class="skewed">Skewed</div>
```

CSS

```
div {
  width: 80px;
  height: 80px;
  background-color: skyblue;
}

.skewed {
  transform: skewX(10deg); /* Equal to skew(10deg) */
  background-color: pink;
}
```

Result

skewY() CSS function

The **`skewY()`** CSS function defines a transformation that skews an element in the vertical direction on the 2D plane. Its result is a `<transform-function>` data type.

Try it

```
transform: skewY(0);
```

```
transform: skewY(35deg);
```

```
transform: skewY(-0.06turn);
```

```
transform: skewY(0.352rad);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

This transformation is a shear mapping (transvection) that distorts each point within an element by a certain angle in the vertical direction. The ordinate (vertical, y-coordinate) of each point is modified by a value proportionate to the specified angle and the distance to the origin; thus, the farther from the origin a point is, the greater will be the value added it.

Syntax

```
skewY(a)
```

Values

`a`

Is an `<angle>` representing the angle to use to distort the element along the ordinate (vertical, y-coordinate).

Cartesian coordinates on $\mathbb{R}^2$	Homogeneous coordinates on $\mathbb{RP}^2$	Cartesian coordinates on $\mathbb{R}^3$	Homogeneous coordinates on $\mathbb{RP}^3$
$\begin{pmatrix} 1 & 0 \\ \tan(a) & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & 0 & 0 \\ \tan(a) & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$ `[1 tan(a) 0 1 0 0]`	$\begin{pmatrix} 1 & 0 & 0 \\ \tan(a) & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & 0 & 0 & 0 \\ \tan(a) & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$

Formal syntax

```
<skewY()> =
  skewY( [ <angle> | <zero> ] )
```

This syntax reflects the latest standard as per CSS Transforms Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<div>Normal</div>
<div class="skewed">Skewed</div>
```

CSS

```
div {
  width: 80px;
  height: 80px;
  background-color: skyblue;
}

.skewed {
  transform: skewY(40deg);
  background-color: pink;
}
```

Result

  - `scale`
  - `rotate`
  - Note: there is no `skew` property

translate() CSS function

The **`translate()`** CSS function repositions an element in the horizontal and/or vertical directions. Its result is a `<transform-function>` data type.

Try it

```
transform: translate(0);
```

```
transform: translate(42px, 18px);
```

```
transform: translate(-2.1rem, -2ex);
```

```
transform: translate(3ch, 3mm);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="static-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

```
#static-element {
  opacity: 0.4;
  position: absolute;
}

#example-element {
  position: absolute;
}
```

This transformation is characterized by a two-dimensional vector [tx, ty]. Its coordinates define how much the element moves in each direction.

Syntax

```
/* Single <length-percentage> values */
transform: translate(200px);
transform: translate(50%);

/* Double <length-percentage> values */
transform: translate(100px, 200px);
transform: translate(100px, 50%);
transform: translate(30%, 200px);
transform: translate(30%, 50%);
```

Values

Single `<length-percentage>` values

> This value is a `<length>` or `<percentage>` representing the abscissa (horizontal, x-component) of the translating vector [tx, 0]. The ordinate (vertical, y-component) of the translating vector will be set to `0`. For example, `translate(2px)` is equivalent to `translate(2px, 0)`. A percentage value refers to the width of the reference box defined by the `transform-box` property.

Double `<length-percentage>` values

> This value describes two `<length>` or `<percentage>` values representing both the abscissa (horizontal, x-component) and the ordinate (vertical, y-component) of the translating vector [tx, ty]. A percentage as first value refers to the width, as second part to the height of the reference box defined by the `transform-box` property.

Cartesian coordinates on ℝ^2	**Homogeneous coordinates on ℝP^2**	**Cartesian coordinates on ℝ^3**	**Homogeneous coordinates on ℝP^3**
A translation is not a linear transformation in ℝ^2 and can't be represented using a Cartesian-coordinate matrix.	$\begin{pmatrix} 1 & 0 & tx \\ 0 & 1 & ty \\ 0 & 0 & 1 \end{pmatrix}$ `[1 0 0 1 tx ty]`	$\begin{pmatrix} 1 & 0 & tx \\ 0 & 1 & ty \\ 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & 0 & 0 & tx \\ 0 & 1 & 0 & ty \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$

Formal syntax

```
<translate()> =
  translate( <length-percentage> , <length-percentage>? )

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Transforms Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using a single-axis translation

HTML

```
<div>Static</div>
<div class="moved">Moved</div>
<div>Static</div>
```

CSS

```
div {
  width: 60px;
  height: 60px;
  background-color: skyblue;
}

.moved {
  /* Equal to: translateX(10px) or translate(10px, 0) */
  transform: translate(10px);
  background-color: pink;
}
```

Result

Combining y-axis and x-axis translation

HTML

```
<div>Static</div>
<div class="moved">Moved</div>
<div>Static</div>
```

CSS

```
div {
  width: 60px;
  height: 60px;
  background-color: skyblue;
}

.moved {
  transform: translate(10px, 10px);
  background-color: pink;
}
```

Result

translate3d() CSS function

The **`translate3d()`** CSS function repositions an element in 3D space. Its result is a `<transform-function>` data type.

Try it

```
transform: translate3d(0, 0, 0);
```

```
transform: translate3d(42px, -62px, -135px);
```

```
transform: translate3d(-2.7rem, 0, 1rem);
```

```
transform: translate3d(5ch, 0.4in, 5em);
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    <div class="face front">1</div>
    <div class="face back">2</div>
    <div class="face right">3</div>
    <div class="face left">4</div>
    <div class="face top">5</div>
    <div class="face bottom">6</div>
  </div>
</section>
```

```
#default-example {
  background: linear-gradient(skyblue, khaki);
  perspective: 800px;
  perspective-origin: 150% 150%;
}

#example-element {
  width: 100px;
  height: 100px;
  perspective: 550px;
  transform-style: preserve-3d;
}

.face {
  display: flex;
  align-items: center;
  justify-content: center;
  width: 100%;
  height: 100%;
  position: absolute;
  backface-visibility: inherit;
  font-size: 60px;
  color: white;
}

.front {
  background: rgb(90 90 90 / 0.7);
  transform: translateZ(50px);
}

.back {
  background: rgb(0 210 0 / 0.7);
  transform: rotateY(180deg) translateZ(50px);
}

.right {
  background: rgb(210 0 0 / 0.7);
  transform: rotateY(90deg) translateZ(50px);
}

.left {
  background: rgb(0 0 210 / 0.7);
  transform: rotateY(-90deg) translateZ(50px);
}

.top {
  background: rgb(210 210 0 / 0.7);
  transform: rotateX(90deg) translateZ(50px);
}

.bottom {
  background: rgb(210 0 210 / 0.7);
  transform: rotateX(-90deg) translateZ(50px);
}
```

This transformation is characterized by a three-dimensional vector [tx, ty, tz]. Its coordinates define how much the element moves in each direction.

Syntax

```
translate3d(tx, ty, tz)
```

Values

`tx`

Is a `<length>` or `<percentage>` representing the abscissa (horizontal, x-component) of the translating vector [tx, ty, tz].

`ty`

Is a `<length>` or `<percentage>` representing the ordinate (vertical, y-component)of the translating vector [tx, ty, tz].

`tz`

Is a `<length>` representing the z-component of the translating vector. It can't be a `<percentage>` value; in that case the property containing the transform is considered invalid [tx, ty, tz].

Cartesian coordinates on $\mathbb{R}^2$	**Homogeneous coordinates on $\mathbb{RP}^2$**	**Cartesian coordinates on $\mathbb{R}^3$**	**Homogeneous coordinates on $\mathbb{RP}^3$**
This transformation applies to the 3D space and can't be represented on the plane.		A translation is not a linear transformation in $\mathbb{R}^3$ and can't be represented using a Cartesian-coordinate matrix.	$\begin{pmatrix} 1 & 0 & 0 & tx \\ 0 & 1 & 0 & ty \\ 0 & 0 & 1 & tz \\ 0 & 0 & 0 & 1 \end{pmatrix}$

Formal syntax

```
<translate3d()> =
  translate3d( <length-percentage> , <length-percentage> , <length> )

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Transforms Module Level 2, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using a single axis translation

HTML

```
<div>Static</div>
<div class="moved">Moved</div>
<div>Static</div>
```

CSS

```
div {
  width: 60px;
  height: 60px;
  background-color: skyblue;
}

.moved {
  /* Equivalent to perspective(500px) translateX(10px) */
  transform: perspective(500px) translate3d(10px, 0, 0px);
  background-color: pink;
}
```

Result

Combining z-axis and x-axis translation

HTML

```
<div>Static</div>
<div class="moved">Moved</div>
<div>Static</div>
```

CSS

```
div {
  width: 60px;
  height: 60px;
  background-color: skyblue;
}

.moved {
  transform: perspective(500px) translate3d(10px, 0, 100px);
  background-color: pink;
}
```

- translate

translateX() CSS function

The **translateX()** CSS function repositions an element horizontally on the 2D plane. Its result is a <transform-function> data type.

Try it

```
transform: translateX(0);
```

```
transform: translateX(42px);
```

```
transform: translateX(-2.1rem);
```

```
transform: translateX(3ch);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="static-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
</section>
```

```
#static-element {
  opacity: 0.4;
  position: absolute;
}
```

```
#example-element {
  position: absolute;
}
```

> **Note:** `translateX(tx)` is equivalent to `translate(tx, 0)` or `translate3d(tx, 0, 0)`.

Syntax

```
/* <length-percentage> values */
transform: translateX(200px);
transform: translateX(50%);
```

Values

`<length-percentage>`

Is a `<length>` or `<percentage>` representing the abscissa (horizontal, x-component) of the translating vector [tx, 0]. In Cartesian coordinate system it represents shift along x-axis. A percentage value refers to the width of the reference box defined by the `transform-box` property.

Cartesian coordinates on $\mathbb{R}^2$	**Homogeneous coordinates on $\mathbb{RP}^2$**	**Cartesian coordinates on $\mathbb{R}^3$**	**Homogeneous coordinates on $\mathbb{RP}^3$**
A translation is not a linear transformation in $\mathbb{R}^2$ and can't be represented using a Cartesian-coordinate matrix.	$\begin{pmatrix} 1 & 0 & t \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$ `[1 0 0 1 t 0]`	$\begin{pmatrix} 1 & 0 & t \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & 0 & 0 & t \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$

Formal syntax

```
<translateX()> =
  translateX( <length-percentage> )

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Transforms Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<div>Static</div>
<div class="moved">Moved</div>
<div>Static</div>
```

CSS

```
div {
  width: 60px;
  height: 60px;
  background-color: skyblue;
}

.moved {
  transform: translateX(10px); /* Equal to translate(10px) */
  background-color: pink;
}
```

Result

- `<transform-function>`
- `translate`

translateY() CSS function

The **`translateY()`** CSS function repositions an element vertically on the 2D plane. Its result is a `<transform-function>` data type.

Try it

```
transform: translateY(0);
```

```
transform: translateY(42px);
```

```
transform: translateY(-2.1rem);
```

```
transform: translateY(3ch);
```

```
<section id="default-example">
  <img
    class="transition-all"
    id="static-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
    width="200" />
  <img
    class="transition-all"
    id="example-element"
    src="/shared-assets/images/examples/firefox-logo.svg"
```

```
    width="200" />
</section>
```

```
#static-element {
  opacity: 0.4;
  position: absolute;
}

#example-element {
  position: absolute;
}
```

> **Note:** `translateY(ty)` is equivalent to `translate(0, ty)` or `translate3d(0, ty, 0)`.

Syntax

```
/* <length-percentage> values */
transform: translateY(200px);
transform: translateY(50%);
```

Values

`<length-percentage>`

The value is a `<length>` or `<percentage>` representing the ordinate (vertical, y-coordinate) of the translating vector [0, ty]. In Cartesian coordinate system it represents shift along y-axis. A percentage value refers to the height of the reference box defined by the `transform-box` property.

Cartesian coordinates on ℝ^2	**Homogeneous coordinates on ℙ^2**	**Cartesian coordinates on ℝ^3**	**Homogeneous coordinates on ℙ^3**
A translation is not a linear transformation in ℝ^2 and can't be represented using a Cartesian-coordinate matrix.	$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & t \\ 0 & 0 & 1 \end{pmatrix}$ `[1 0 0 1 0 t]`	$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & t \\ 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & t \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$

Formal syntax

```
<translateY()> =
  translateY( <length-percentage> )

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Transforms Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<div>Static</div>
<div class="moved">Moved</div>
<div>Static</div>
```

CSS

```
div {
  width: 60px;
  height: 60px;
  background-color: skyblue;
}

.moved {
  transform: translateY(10px);
  background-color: pink;
}
```

Result

- `<transform-function>`
- `translate`

translateZ() CSS function

The **`translateZ()`** CSS function repositions an element along the z-axis in 3D space, i.e., closer to or farther away from the viewer. Its result is a `<transform-function>` data type.

Try it

```
transform: translateZ(0);
```

```
transform: translateZ(42px);
```

```
transform: translateZ(-9.7rem);
```

```
transform: translateZ(-3ch);
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    <div class="face front">1</div>
    <div class="face back">2</div>
```

```
    <div class="face right">3</div>
    <div class="face left">4</div>
    <div class="face top">5</div>
    <div class="face bottom">6</div>
  </div>
</section>
```

```
#default-example {
  background: linear-gradient(skyblue, khaki);
  perspective: 800px;
  perspective-origin: 150% 150%;
}

#example-element {
  width: 100px;
  height: 100px;
  perspective: 550px;
  transform-style: preserve-3d;
}

.face {
  display: flex;
  align-items: center;
  justify-content: center;
  width: 100%;
  height: 100%;
  position: absolute;
  backface-visibility: inherit;
  font-size: 60px;
  color: white;
}

.front {
  background: rgb(90 90 90 / 0.7);
  transform: translateZ(50px);
}

.back {
  background: rgb(0 210 0 / 0.7);
  transform: rotateY(180deg) translateZ(50px);
}

.right {
  background: rgb(210 0 0 / 0.7);
  transform: rotateY(90deg) translateZ(50px);
}

.left {
  background: rgb(0 0 210 / 0.7);
  transform: rotateY(-90deg) translateZ(50px);
}

.top {
  background: rgb(210 210 0 / 0.7);
  transform: rotateX(90deg) translateZ(50px);
}

.bottom {
  background: rgb(210 0 210 / 0.7);
  transform: rotateX(-90deg) translateZ(50px);
}
```

This transformation is defined by a `<length>` which specifies how far inward or outward the element or elements move.

In the above interactive examples, `perspective: 550px;` (to create a 3D space) and `transform-style: preserve-3d;` (so the children, the 6 sides of the cube, are also positioned in the 3D space), have been set on the cube.

> **Note:** `translateZ(tz)` is equivalent to `translate3d(0, 0, tz)`.

Syntax

```
translateZ(tz)
```

Values

`tz`

A `<length>` representing the z-component of the translating vector [0, 0, tz]. In Cartesian coordinate system it represents shift along z-axis. A positive value moves the element towards the viewer, and a negative value farther away.

Cartesian coordinates on $\mathbb{R}^2$	**Homogeneous coordinates on $\mathbb{RP}^2$**	**Cartesian coordinates on $\mathbb{R}^3$**	**Homogeneous coordinates on $\mathbb{RP}^3$**
This transformation applies to the 3D space and can't be represented on the plane.		A translation is not a linear transformation in $\mathbb{R}^3$ and can't be represented using a Cartesian-coordinate matrix.	$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & t \\ 0 & 0 & 0 & 1 \end{pmatrix}$

Formal syntax

```
<translateZ()> =
  translateZ( <length> )
```

This syntax reflects the latest standard as per CSS Transforms Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

In this example, two boxes are created. One is positioned normally on the page, without being translated at all. The second is altered by applying perspective to create a 3D space, then moved towards the user.

HTML

```
<div>Static</div>
<div class="moved">Moved</div>
```

CSS

```
div {
  position: relative;
  width: 60px;
  height: 60px;
  left: 100px;
  background-color: skyblue;
}

.moved {
  transform: perspective(500px) translateZ(200px);
  background-color: pink;
}
```

What really matters here is the class "moved"; let's take a look at what it does. First, the `perspective()` function positions the viewer relative to the plane that lies where z=0 (in essence, the surface of the screen). A value of `500px` means the user is 500 pixels "in front of" the imagery located at z=0.

Then, the `translateZ()` function moves the element 200 pixels "outward" from the screen, toward the user. This has the effect of making the element appear larger when viewed on a 2D display, or closer when viewed using a VR headset or other 3D display device.

Note if the `perspective()` value is less than the `translateZ()` value, such as `transform: perspective(200px) translateZ(300px);` the transformed element will not be visible as it is further than the user's viewport. The smaller the difference between the perspective and translateZ values, the closer the user is to the element and the larger the translated element will seem.

> **Note:** As the composition of transforms isn't commutative, the order you write the different functions is significant. In particular, in general, you want `perspective()` to be placed before `translateZ()`.

type() CSS function

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`type()`** CSS function allows you to specify a particular data type, and is used by the following CSS features:

- The `attr()` function, to specify the data type that an attribute value should be parsed into.
- The `@function` at-rule, to specify the permitted data types for CSS custom function parameters and results.

> **Note:** The `@property` at-rule `syntax` descriptor value uses the same `<syntax>` to define the permitted data types for registered custom properties, however, this always takes the form of a string.

Syntax

```
/* Single value */
type(<color>)
type(auto)

/* "|" combinator for multiple types */
type(<length> | <percentage>)

/* Space-separated list of values */
type(<color>+)

/* Comma-separated list of values */
type(<length>#)

/* Multiple keywords */
type(red | blue | green)

/* Combination of data type and keyword */
type(<percentage> | auto)

/* Universal syntax value */
type(*)
```

Parameters

The `type()` function's syntax is as follows:

```
type(<syntax>)
```

The `<syntax>` parameter is an expression defining the data type. This can take the following forms:

`<ident>`

A CSS keyword value, written without angle brackets.

`<syntax-type>`

A type name, written in angle brackets, representing a CSS data type. The following data types are supported:

`<angle>`

Accepts any valid `<angle>` value.

`<color>`

Accepts any valid `<color>` value.

`<custom-ident>`

Accepts any valid `<custom-ident>` value.

`<image>`

Accepts any valid `<image>` value.

`<integer>`

Accepts any valid `<integer>` value.

`<length>`

Accepts any valid `<length>` value.

`<length-percentage>`

Accepts any valid `<length>` or `<percentage>` value and any valid `calc()` expression combining `<length>` and `<percentage>` values.

`<number>`

Accepts any valid `<number>` value.

`<percentage>`

Accepts any valid `<percentage>` value.

`<resolution>`

Accepts any valid `<resolution>` value.

`<string>`

Accepts any valid `<string>` value.

`<time>`

Accepts any valid `<time>` value.

`<transform-function>`

Accepts any valid `<transform-function>` value.

`<transform-list>`

Accepts a list of valid `<transform-function>` values. It is equivalent to "`<transform-function>+`", and may not be followed by a `+` or `#` token.

`<url>`

Accepts any valid `<url>` value.

`*`

The universal syntax.

You can combine `<syntax-type>` values using the following tokens:

`+`

A space-separated list of values is expected.

`#`

A comma-separated list of values is expected.

In addition, the `|` token can be used as a separator when specifying multiple values or combining `<ident>` and `<syntax-type>` values for the expected syntax.

Return value

A data type definition.

Description

The `type()` function is used when you need to define a data type. It can be considered as a subset of the overall value definition syntax used to define the set of valid values for every CSS property and function.

Most commonly, you'll see `type()` used to specify a single data type. The next example uses the `attr()` function to set the `background-color` property equal to the value of a user-defined `data-background` function. The required data type for the value has been specified as a `<color>`.

```
background-color: attr(data-background type(<color>), red);
```

You could also specify an exact keyword requirement (for example, `type(blue)`), but this would be overly limiting.

Specifying `type(*)` permits any valid CSS value. This is the universal syntax, which cannot be multiplied or combined with other syntax components.

Specifying multiple permitted types

You can use the `|` token as a separator when specifying a range of permitted data types, keywords, or a combination of both. For example:

- `type(<length> | <percentage>)`
- `type(red | green)`
- `type(<length> | auto)`

The following example shows how a `@function` at-rule can be used to define a custom function that takes two color parameters, and returns the first one unless the viewport width is less than `700px`, in which case it returns the second one. The first one is allowed to be `red` or `green`, while the second one has to be `blue`.

```
@function --color-choice(--color1 type(red | green), --color2 blue) {
  result: var(--color1);
  @media (width < 700px) {
    result: var(--color2);
  }
}
```

> **Note:** In the case of `@function` data types, you can omit the `type()` function and just include the value in cases where only one data type or keyword is specified. This is the case with the `blue` type definition in the previous custom function. This doesn't work with the `attr()` function.

Specifying lists of types

The `+` and `#` tokens can be appended to a `<syntax-type>` to specify that you are expecting a space-separated list or a comma-separated list, respectively. For example:

- A `<color>+` parameter expects a space-separated list of `<color>` values, for example `red blue #a60000 rgb(234 45 100)`.
- A `<length>#` parameter expects a comma-separated lists of `<length>` values, for example `30px, 1em, 15vw`.

You can combine multiple tokens using `|` as a separator. For example, `<color># | <integer>#` would expect a comma-separated list of `<color>` values or a comma-separated list of `<integer>` values.

Formal syntax

```
<type()> =
  type( <string> )
```

This syntax reflects the latest standard as per CSS Images Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

You can find several other examples in the `attr()` and `@function` documentation.

Basic <code>@function</code> data type definition

This example defines a CSS custom function that combines multiple strings.

HTML

The HTML contains a single `<section>` element with some text content.

```
<section>What you gonna say?</section>
```

CSS

In the CSS, we start by specifying a `@function` called `--combine-strings`. This has a parameter called `--strings`, the data type of which is specified as one or more space-separated `<string>` values. It returns the string values with a space and a heart emoji appended onto the end.

```
@function --combine-strings(--strings type(<string>+)) {
  result: var(--strings) " ❤️";
}
```

We then specify some basic styles for the `<section>` element and use the `--combine-strings()` function to specify the value of its `content` property, including two space-separated strings as the argument.

```
section {
  font-family: system-ui;
  background-color: lime;
  padding: 20px;
}

section::after {
  content: --combine-strings("hello" "goodbye");
}
```

Result

- `@function` at-rule
- `attr()` function
- Using CSS custom functions

unset CSS keyword

The **`unset`** CSS keyword resets a property to its inherited value if the property naturally inherits from its parent, and to its initial value if not. In other words, it behaves like the `inherit` keyword in the first case, when the property is an inherited property, and like the `initial` keyword in the second case, when the property is a non-inherited property.

`unset` can be applied to any CSS property, including the CSS shorthand property `all`.

Examples

Color

`color` is an inherited property.

HTML

```
<p>This text is red.</p>
<div class="foo">
  <p>This text is also red.</p>
</div>
<div class="bar">
  <p>This text is green (default inherited value).</p>
</div>
```

CSS

```
.foo {
  color: blue;
}
```

```
.bar {
  color: green;
}

p {
  color: red;
}

.bar p {
  color: unset;
}
```

Result

Border

`border` is a non-inherited property.

HTML

```
<p>This text has a red border.</p>
<div>
  <p>This text has a red border.</p>
</div>
<div class="bar">
  <p>This text has a black border (initial default, not inherited).</p>
</div>
```

CSS

```
div {
  border: 1px solid green;
}

p {
  border: 1px solid red;
}

.bar p {
  border-color: unset;
}
```

Result

See also

- Use the `initial` keyword to set a property to its initial value.
- Use the `inherit` keyword to make an element's property the same as its parent.
- Use the `revert` keyword to reset a property to the value established by the user-agent stylesheet (or by user styles, if any exist).
- Use the `revert-layer` keyword to reset a property to the value established in a previous cascade layer.
- Use the `revert-rule` keyword to reset a property to the value of an earlier matching style rule.
- The `all` property lets you reset all properties to their initial, inherited, reverted, or unset state at once.

url() CSS function

The **`url()`** CSS function is used to include a file. The parameter is an absolute URL, a relative URL, a blob URL, or a data URL. The **`url()`** function can be passed as a parameter of another CSS function, like the `attr()` function. Depending on the property for which it is a value, the resource sought can be an image, font, or a stylesheet. The `url()` functional notation is the value for the `<url>` data type.

> **Note:** There is a difference between a URI and a URL. A URI identifies a resource. A URL is a type of URI, and describes the *location* of a resource. A URI can be either a URL or a name (URN) of a resource.
>
> In CSS Level 1, the `url()` functional notation described only true URLs. In CSS Level 2, the definition of `url()` was extended to describe any URI, whether a URL or a URN. Confusingly, this meant that `url()` could be used to create a `<uri>` CSS data type. This change was not only awkward but, debatably, unnecessary, since URNs are rarely used in actual CSS. To alleviate the confusion, CSS Level 3 returned to the narrower, initial definition. Now, `url()` denotes only true `<url>`s.

Relative URLs are resolved relative to the stylesheet URL, not the web page URL. However, when a `url()` is used within a custom property (e.g., `--my-image: url(foo.jpg)`), the relative URL is not resolved immediately. It is resolved when the custom property is evaluated via `var()` substitution in a standard property. The base URL at that point is the stylesheet where the `var()` reference appears, not where the custom property was defined.

The **`url()`** function can be included as a value for `background`, `background-image`, `border-image`, `border-image-source`, `content`, `cursor`, `filter`, `list-style`, `list-style-image`, `mask`, `mask-image`, `offset-path`, `clip-path`, `src` as part of a `@font-face` block, and `@counter-style/symbol`

Syntax

```
/* Basic usage */
url("https://example.com/images/myImg.jpg");
url('https://example.com/images/myImg.jpg');
url(https://example.com/images/myImg.jpg);
url("…");
url(myImg.jpg);
url(#IDofSVGpath);

/* associated properties */
background-image: url("star.gif");
list-style-image: url('../images/bullet.jpg');
content: url("my-icon.jpg");
cursor: url(my-cursor.cur);
border-image-source: url(/media/diamonds.png);
src: url('fantastic-font.woff');
offset-path: url(#path);
mask-image: url("masks.svg#mask1");

/* Properties with fallbacks */
cursor: url(pointer.cur), pointer;

/* Associated short-hand properties */
background: url('star.gif') bottom right repeat-x blue;
```

```
border-image: url("/media/diamonds.png") 30 fill / 30px / 30px space;

/* As a parameter in another CSS function */
background-image: cross-fade(20% url(first.png), url(second.png));
mask-image: image(url(mask.png), skyblue, linear-gradient(black, transparent));

/* as part of a non-shorthand multiple value */
content: url(star.svg) url(star.svg) url(star.svg) url(star.svg) url(star.svg);

/* at-rules */
@document url("https://www.example.com/") { /* … */ }
@import url("https://www.example.com/style.css");
@namespace url(http://www.w3.org/1999/xhtml);
```

Values

`<string>`

A string specifying a URL, which is a relative or absolute address, or pointer, to the web resource to be included, or a data URL. You can also use a hash URL to reference the ID of an SVG shape or an SVG filter.

The quotes are generally optional—they are required if the URL includes parentheses, whitespace, or quotes (unless these characters are escaped), or if the address includes control characters above 0x7e. Normal string syntax rules apply: double quotes cannot occur inside double quotes and single quotes cannot occur inside single quotes unless escaped.

`<url-modifier>`

In the future, the `url()` function may support specifying a modifier, an identifier or a functional notation, which alters the meaning of the URL string. This is not supported and not fully defined in the specification.

Formal syntax

```
<url()> =
  url( <string> <url-modifier>* )  |
  <url-token>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

As the background property value

```
body {
  background: url("https://mdn.github.io/shared-assets/images/examples/leopard.jpg")
    #0000dd no-repeat fixed;
}
```

For setting an image as a list bullet

```
<ul>
  <li>One</li>
  <li>Two</li>
  <li>Three</li>
</ul>
```

```
ul {
  font-size: 3rem;
  margin: 0;
}
```

```
ul {
  list-style: outside
    url("https://mdn.github.io/shared-assets/images/examples/firefox-logo.svg");
}
```

Usage in the content property

HTML

```
<ul>
  <li>One</li>
  <li>Two</li>
  <li>Three</li>
</ul>
```

CSS

```
li::after {
  content: " - "
    url("https://mdn.github.io/shared-assets/images/examples/star-white_16x16.png");
}
```

Result

Using a data URL

CSS

```
body {
  background: url("data:image/svg+xml,%3Csvg xmlns='http://www.w3.org/2000/svg' width='90' height='45'%3E%3Cpath d='M10 10h60' stroke='%2300F' stroke-width='5'/%3E%3Cpath d='M10 20h60'
stroke='%230F0' stroke-width='5'/%3E%3Cpath d='M10 30h60' stroke='red' stroke-width='5'/%3E%3C/svg%3E");
}
```

Usage in filters

When a URL is used as a path for a filter, the URL must be one of the following:

1. The path to an SVG file with the ID of the filter appended.
2. the ID of the filter, if the SVG already exists on the page.

```
.blur {
  filter: url("my-file.svg#svg-blur"); /* the URL of an SVG file used as a filter */
}

.inline-blur {
  filter: url("#svg-blur"); /* the ID of an SVG that is embedded in the HTML page */
}
```

See also

- `image()`
- `image-set()`
- `cross-fade()`

`<url>` CSS type

The **`<url>`** CSS data type is a pointer to a resource.

Syntax

```
<url> = url()
```

Values

The value may be an absolute or relative URL.

`<url()>`

The `url()` function accepts a URL, which may be written as a quoted string or as an unquoted URL token.

> **Note:** The CSS values and units module also introduces the `src()` function as a `<url>` value. Currently, no browser supports this feature.

Description

The `<url>` data type, written with the `url()` function, represents a `URL`, which is a pointer to an internal or external resource. The resource can be an image, a video, a CSS file, a font file, an SVG feature, etc. The URL may be absolute or relative.

```
/* Relative URL */
url("styles.css")
url("assets/icon.svg")
url("../assets/image.png")

/* Absolute URL */
url("http://example.com/fonts/myFont.woff2")
url("https://example.com/images/background.jpg")

/* Data URL */
url("data:image/svg+xml,%3Csvg'%3E%3Cpath d='M10 10h60' stroke='%2300F' stroke-width='5'/%3E%3Cpath d='M10 20h60' stroke='%230F0' stroke-width='5'/%3E%3C/svg%3E")
url("...")
```

External resources and CORS

The ability to import external resources via the `<url>` value is implementation-defined and often restricted for security reasons.

Depending on the CSS property on which a `<url>` referencing external resources is applied, the resource may be subject to Cross-Origin Resource Sharing (CORS) restrictions.

Some CSS properties, including `mask-image`, `filter`, as well as `clip-path` and a few others when referring to `<svg>` image elements, may require successful CORS validation when they cause external, cross-origin resources to be fetched in CORS mode. If CORS validation fails, the resource may be blocked and therefore not used for rendering.

Note that the `<url>` value type does not enforce CORS validation itself, but individual CSS properties do.

When opening an HTML file directly with `file://`, resources may fail because CORS rules apply locally. Modern browsers treat `file://` as a unique origin, meaning cross-file resources can get blocked. In this case, an HTTP server may be hosted to avoid CORS errors. The security behavior of `file://` URLs also varies depending on the browser and the operating system's file permissions.

Examples

Relative URL

```
body {
  background-image: url("images/background.jpg");
}
```

Absolute URL

```
body {
  background-image: url("https://example.com/images/background.jpg");
}
```

- `url()`

var() CSS function

The **`var()`** CSS function can be used to insert the value of a custom property (sometimes called a "CSS variable") instead of any part of a value of another property.

The `var()` function cannot be used in property names, selectors or anything else besides property values. (Doing so usually produces invalid syntax, or else a value whose meaning has no connection to the variable.)

Try it

```
border-color: var(--color-a);
```

```
border-color: var(--color-b);
```

```
border-color: var(--color-c);
```

```
<section class="default-example" id="default-example">
  <div id="example-element">
    Three color options have been set on the :root use these to change the
    border color.
  </div>
</section>
```

```
:root {
  --color-a: pink;
  --color-b: green;
  --color-c: rebeccapurple;
}

#example-element {
  border: 10px solid black;
  padding: 10px;
}
```

Syntax

```
/* Basic usage */
var(--custom-prop);

/* With fallback */
var(--custom-prop,);  /* empty value as fallback */
var(--custom-prop, initial); /* initial value of the property as fallback */
var(--custom-prop, red);
var(--custom-prop, var(--default-value));
var(--custom-prop, var(--default-value, red));
```

The first argument to the function is the name of the custom property to be substituted. An optional second argument to the function serves as a fallback value. The fallback is used when the referenced custom property doesn't have a usable value — what the specification calls the guaranteed-invalid value. In practice, this means the fallback is used when:

- The custom property hasn't been declared on a rule that applies to the element, and it isn't registered (with `@property`) with an `initial-value` descriptor.
- The custom property is set to the `initial` keyword and isn't a registered custom property with an `initial-value`. Setting a non-registered custom property to `initial` resets it to the guaranteed-invalid value.
- The custom property's declared value is invalid at computed-value time — for example, because of a cyclic dependency between custom properties — and the property is non-registered or is registered with the universal `*` syntax.

If the custom property is registered with `@property` using a non-universal `syntax` and an `initial-value`, that initial value is substituted when no other declaration applies. The fallback is *not* used in that case.

The other CSS-wide keywords — `inherit`, `unset`, `revert`, `revert-layer`, and `revert-rule` — behave in the same way when set as a custom property value as they do on any other property. They can resolve the custom property to an inherited or previously-cascaded value rather than to the guaranteed-invalid value, so they don't necessarily trigger the fallback. For example, if `--foo` is set to `revert-layer` in one cascade layer and to a color in another layer, `var(--foo)` resolves to the color value instead of using the fallback.

The syntax of the fallback, like that of custom properties, allows commas. For example, `var(--foo, red, blue)` defines a fallback of `red, blue`; that is, anything between the first comma and the end of the function is considered a fallback value.

Values

`<custom-property-name>`

> A custom property's name represented by an identifier that starts with two dashes. Custom properties are solely for use by authors and users; CSS will never give them a meaning beyond what is presented here.

`<declaration-value>`

> A fallback value for the custom property, used when the referenced custom property has the guaranteed-invalid value (see the Syntax section above for the conditions under which this happens). This value may contain any character except some characters with special meaning like newlines, unmatched closing brackets, i.e., `)`, `]`, or `}`, top-level semicolons, or exclamation marks. The fallback value can itself be a custom property using the `var()` syntax. If the fallback value is omitted, and the custom property has the guaranteed-invalid value, the `var()` function resolves to an invalid value.

> **Note:** `var(--a,)` is valid, specifying that if the `--a` custom property has the guaranteed-invalid value, the `var()` should be replaced with nothing.

Formal syntax

```
<var()> =
  var( <custom-property-name> , <declaration-value>? )
```

This syntax reflects the latest standard as per CSS Custom Properties for Cascading Variables Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using a custom property set on :root

CSS

```
:root {
  --main-bg-color: pink;
}

body {
  background-color: var(--main-bg-color);
}
```

Result

Here, the value of the `background-color` property has been set via the custom property `--main-bg-color`. So the background color of the HTML body will be pink.

Using a custom property before it is set

CSS

```
body {
  background-color: var(--main-bg-color);
}

:root {
  --main-bg-color: pink;
}
```

Result

In this example, the background color of the HTML body will be pink even though the custom property is set later.

Using a custom property set in another file

HTML

```
<!doctype html>
<html lang="en-US">
  <head>
    <meta charset="utf-8" />
    <link rel="stylesheet" href="1.css" />
    <link rel="stylesheet" href="2.css" />
  </head>
  <body></body>
</html>
```

CSS

```
/* 1.css */
body {
  background-color: var(--main-bg-color);
}
```

```
/* 2.css */
:root {
  --main-bg-color: pink;
}
```

Result

The background color of the HTML body will be pink in this case even though the custom property is declared in another file.

Custom properties with fallbacks for use when the property has not been set

HTML

```
<div class="component">
  <h1 class="header">Header</h1>
  <p class="text">Text</p>
</div>
```

CSS

```
/* In the component's style: */
.component .header {
  /* header-color isn't set, and so remains blue, the fallback value */
  color: var(--header-color, blue);
}

.component .text {
  color: var(--text-color, black);
}

/* In the larger application's style: */
.component {
  --text-color: #008800;
}
```

Result

Since `--header-color` isn't set, the text "Header" will be blue, the fallback value.

Using a custom property as a fallback

CSS

```
:root {
  --backup-bg-color: teal;
}

body {
  background-color: var(--main-bg-color, var(--backup-bg-color, white));
}
```

Result

Since `--main-bg-color` isn't set, the body's `background-color` will fall back to `--backup-bg-color`, which is teal.

Invalid values

`var()` functions can resolve to invalid values if:

- The custom property is not defined and no fallback value is provided.
- The custom property is defined but its value is an invalid value for the property it is used in.

When this happens, the property is treated as if it has value `unset`. This is because variables can't "fail early" like other syntax errors can, so by the time the user agent realizes a property value is invalid, it has already thrown away the other cascaded values.

For example:

HTML

```
<p class="p1">Undefined variable</p>
<p class="p2">Invalid variable</p>
<p class="p3">Invalid literal color</p>
```

CSS

```
p {
  color: red;
}

.p1 {
  color: var(--invalid-color);
}

.p2 {
  --invalid-color: 20px;
  color: var(--invalid-color);
}

.p3 {
  color: 20px;
}
```

Result

Note how the paragraphs using `var()` are reset to the default black, but the paragraph with an invalid literal color is still red, because the `color: 20px` declaration is simply ignored.

WebKit (-webkit-) vendor-prefixed CSS extensions

A vendor prefix is used to indicate that a feature is specific to a certain browser. User agents based on WebKit or Blink (such as Safari and Chrome) support several extensions to CSS, which are prefixed with `-webkit-`.

-webkit-prefixed properties without standard equivalents

> **Note:** These properties work in WebKit- or Blink-based browsers except where support notes say otherwise. You should avoid using them on production websites.

A-C

- `-webkit-app-region` : No longer supported in Safari.
- `-webkit-border-horizontal-spacing`
- `-webkit-border-vertical-spacing`
- `-webkit-box-reflect`: Supported with `-webkit-` by every browser, for compatibility reasons.
- `-webkit-column-axis`: Not supported in Chrome.
- `-webkit-column-progression`: Not supported in Chrome.
- `-webkit-cursor-visibility`: Not supported in Chrome.

D-L

- `-webkit-font-smoothing`: See `font-smooth`.
- `-webkit-hyphenate-limit-after`: Not supported in Chrome.
- `-webkit-hyphenate-limit-before`: Not supported in Chrome.
- `-webkit-hyphenate-limit-lines`: Not supported in Chrome.
- `-webkit-line-align`: Not supported in Chrome.
- `-webkit-line-box-contain`: Not supported in Chrome.
- `-webkit-line-grid`: Not supported in Chrome.
- `-webkit-line-snap`: Not supported in Chrome.
- `-webkit-locale`
- `-webkit-logical-height`
- `-webkit-logical-width`

M

- `-webkit-mask-box-image`: See `mask-border` and `border-image`.
- `-webkit-mask-box-image-outset`: See `mask-border` and `border-image`.
- `-webkit-mask-box-image-repeat`: See `mask-border` and `border-image`.
- `-webkit-mask-box-image-slice`: See `mask-border` and `border-image`.
- `-webkit-mask-box-image-source`: See `mask-border` and `border-image`.
- `-webkit-mask-box-image-width`: See `mask-border` and `border-image`.
- `-webkit-mask-composite`: See `mask-border` and `border-image`.
- `-webkit-mask-position-x`: Supported with `-webkit-` by every browser for compatibility reasons.
- `-webkit-mask-position-y`: Supported with `-webkit-` by every browser for compatibility reasons.
- `-webkit-mask-repeat-x` : No longer supported; see `mask-repeat`.
- `-webkit-mask-repeat-y` : No longer supported; see `mask-repeat`.
- `-webkit-mask-source-type`: Not supported in Chrome.
- `-webkit-max-logical-height`
- `-webkit-max-logical-width`
- `-webkit-min-logical-height`
- `-webkit-min-logical-width`

N-Z

- `-webkit-nbsp-mode`: Not supported in Chrome.
- `-webkit-perspective-origin-x`
- `-webkit-perspective-origin-y`
- `-webkit-rtl-ordering`
- `-webkit-tap-highlight-color`: Only supported in Safari on iOS.
- `-webkit-text-decoration-skip`: Not supported in Chrome.
- `-webkit-text-decorations-in-effect`
- `-webkit-text-fill-color`
- `-webkit-text-security`
- `-webkit-text-stroke`
- `-webkit-text-stroke-color`
- `-webkit-text-stroke-width`
- `-webkit-text-zoom`: Not supported in Chrome.
- `-webkit-touch-callout` : Only supported in Safari on iOS.
- `-webkit-transform-origin-x`
- `-webkit-transform-origin-y`
- `-webkit-transform-origin-z`
- `-webkit-user-drag`
- `-webkit-user-modify`

-webkit-prefixed properties with standard equivalents

Several `-webkit-` prefixed properties have standard equivalents. Even if the name and syntax may be different, they shouldn't be used any more. For each of the properties below, use the standard equivalents.

A-B

- `-webkit-border-after`: Use `border-block-end`.
- `-webkit-border-after-color`: Use `border-block-end-color`.
- `-webkit-border-after-style`: Use `border-block-end-style`.
- `-webkit-border-after-width`: Use `border-block-end-width`.
- `-webkit-border-before`: Use `border-block-start`.
- `-webkit-border-before-color`: Use `border-block-start-color`.
- `-webkit-border-before-style`: Use `border-block-start-style`.
- `-webkit-border-before-width`: Use `border-block-start-width`.
- `-webkit-border-end`: Use `border-inline-end`.
- `-webkit-border-end-color`: Use `border-inline-end-color`.
- `-webkit-border-end-style`: Use `border-inline-end-style`.
- `-webkit-border-end-width`: Use `border-inline-end-width`.
- `-webkit-border-start`: Use `border-inline-start`.
- `-webkit-border-start-color`: Use `border-inline-start-color`
- `-webkit-border-start-style`: Use `border-inline-start-style`.
- `-webkit-border-start-width`: Use `border-inline-start-width`.
- `-webkit-box-align`: Use CSS flexbox with `align-items`.
- `-webkit-box-direction`: Use CSS flexbox with `flex-direction`.
- `-webkit-box-flex-group`: Use CSS flexbox with `flex-basis`, `flex-grow`, and `flex-shrink`.
- `-webkit-box-flex`: Use CSS flexbox with `flex-grow`.
- `-webkit-box-lines`: Use CSS flexbox with `flex-flow`.
- `-webkit-box-ordinal-group`: Use CSS flexbox with `order`.
- `-webkit-box-orient`: Use CSS flexbox with `flex-direction`.
- `-webkit-box-pack`: Use CSS flexbox with `justify-content`.
- `-webkit-box-reflect`: Use the CSS `element()` function.

C-I

- `-webkit-column-break-after`: Use CSS multicolumn layout with `break-after`.
- `-webkit-column-break-before`: Use CSS multicolumn layout with `break-before`.
- `-webkit-column-break-inside`: Use CSS multicolumn layout with `break-inside`.
- `-webkit-font-feature-settings`: Use `font-feature-settings` (the prefixed version not supported in Safari).
- `-webkit-hyphenate-character`: Use `hyphenate-character`.
- `-webkit-initial-letter`: Use `initial-letter`.

J-Z

- `-webkit-line-clamp`: Use `line-clamp`.
- `-webkit-margin-after`: Use `margin-block-end`.
- `-webkit-margin-before`: Use `margin-block-start`.
- `-webkit-margin-end`: Use `margin-inline-end`.
- `-webkit-margin-start`: Use `margin-inline-start`.
- `-webkit-padding-after`: Use `padding-block-end`.
- `-webkit-padding-before`: Use `padding-block-start`.
- `-webkit-padding-end`: Use `padding-inline-end`.
- `-webkit-padding-start`: Use `padding-inline-start`.

-webkit-prefixed property values

`-webkit-fill-available`

Used with sizing properties like `width` and `height`, to allow elements to take up all available space within their parent container. The `stretch` value provides a standard replacement, but `-webkit-fill-available` is supported as an alias by browsers for backwards-compatibility reasons.

Pseudo-classes

> **Note:** If there is an invalid pseudo-class within in a chain or group of selectors, the whole selector list is invalid.

- `:-webkit-any()`: Use `:is`
- `:-webkit-any-link`: Use `:any-link`
- `:-webkit-autofill`: Use `:autofill`

- `:-webkit-autofill-strong-password`: Use `:autofill`
- `:-webkit-drag`
- `:-webkit-full-page-media`: Use `:fullscreen`
- `:-webkit-full-screen`: Use `:fullscreen`
- `:-webkit-full-screen-ancestor`: Use `:fullscreen`
- `:-webkit-full-screen-document`: Use `:fullscreen`
- `:-webkit-full-screen-controls-hidden`: Use `:fullscreen`

Pseudo-elements

For web-compatibility reasons, Blink, WebKit, and Gecko browsers treat all pseudo-elements starting with `::-webkit-` as valid. If there is an invalid pseudo-element or pseudo-class within in a chain or group of selectors, the whole selector list is invalid. If a pseudo-element (but not pseudo-class) has a `-webkit-` prefix, Blink, WebKit and Gecko browsers assume it is valid, not invalidating the selector list.

- `::-webkit-file-upload-button`: Use `::file-selector-button`
- `::-webkit-inner-spin-button`
- `::-webkit-input-placeholder`: Use `::placeholder`
- `::-webkit-meter-bar`
- `::-webkit-meter-even-less-good-value`
- `::-webkit-meter-inner-element`
- `::-webkit-meter-optimum-value`
- `::-webkit-meter-suboptimum-value`
- `::-webkit-progress-bar`
- `::-webkit-progress-inner-element`
- `::-webkit-progress-value`
- `::-webkit-search-cancel-button`
- `::-webkit-search-results-button`
- `::-webkit-slider-runnable-track`
- `::-webkit-slider-thumb`

Media features

- `-webkit-animation`
- `-webkit-device-pixel-ratio`: Supported cross-browser
- `-webkit-transform-2d`
- `-webkit-transform-3d`: Supported cross-browser
- `-webkit-transition`

CSS Tutorials

Learning CSS may be a daunting task. In order to help you, we have written numerous **tutorials about CSS**. Some are aimed at complete beginners, while others present complex features to be used by more experienced users.

This page lists them all, with a short description. They are grouped by complexity so that you can choose the most appropriate for your level.

Beginner-level CSS tutorials

CSS basics

> This guide is aimed at complete beginners: You haven't written one single line of CSS? — this is for you. It explains the fundamental concepts of the language and guides you in writing basic stylesheets.

Using multiple backgrounds

> Backgrounds are fundamental for nice styling: CSS allows you to set several of them on each box. This tutorial explains how they interact and how to achieve nice effects.

Resizing background images

> CSS allows you to resize images used as an element's background. This tutorial describes how to achieve this.

Using media queries

> The size of the screens, or the kind of devices like touchscreens or printed sheets vary greatly nowadays. Media queries are the fundamental building blocks in building websites that render everywhere in their best quality.

Understanding CSS z-index

> Controlling superposition of boxes is a basic feature that is very quickly needed by Web developers. Though not that difficult, it requires a basic knowledge of CSS.

Intermediate-level CSS tutorials

After the release of CSS 2 (Level 1), new features have been added to CSS. Some of them are *fancy* and are pretty self-contained. They are easy to use for anybody with a fair knowledge of basic concepts.

CSS Counter Styles

> Counting items and pages is an easy task in CSS. Learn to use `counter-reset`, `counter-increment`, `counters()`, and `counter()`.

CSS Animations

> CSS Animations allow you to define configurations of style, as keyframes, and to transition between them defining an animation.

CSS Transitions

> CSS Transitions allow you to define an animation between several styles and to control the way this transition happens.

CSS Transforms

> Transforms allow you to change the position of elements by modifying their coordinate space: it allows for translating, rotating, and deforming them in the 2D or 3D spaces.

CSS Gradients

> Gradients are images that transition smoothly from one color to another. There are several types of gradients allowed in CSS: linear or radial, repeating or not. This tutorial describes how to use them.

Advanced-level CSS tutorials

CSS also got new features allowing you to create complex layouts. Though the simplest way to achieve such layout, they are more complex to use for people without too much experience.

CSS multi-column layouts

> CSS3 introduces a new layout allowing you to easily define multiple columns in an element. Though multi-column text is not that common on devices like screens, this is particularly useful on printed pages, or for indexes.

CSS flexible boxes layouts

> This new layout allow you to give boxes flexibility, allowing them to be resized smoothly. It is a powerful way to describe complex interfaces.
