CSS writing modes

The **CSS writing modes** module defines support for various international writing modes and their combinations, including left-to-right and right-to-left text ordering as well as horizontal and vertical orientations.

A *writing mode* in CSS is determined by the `writing-mode`, `direction`, and `text-orientation` properties defined in this module. It is defined primarily in terms of its inline base direction and block flow direction.

Some horizontal languages are left-to-right, including Latin and Indic scripts. Other horizontal languages are written right-to-left, including Hebrew and Arabic scripts. Sometimes text needs to be bidirectional, such as when mixing left-to-right and right-to-left scripts. Some languages can be written with a vertical orientation, for example, Chinese, Japanese, and Korean (CJK) scripts.

The CSS writing modes module addresses the orientations of all writing modes. Other modules, such as the CSS ruby layout module, provide rendering models and formatting controls related to the display text annotations.

Creating vertical form controls

The guide explains how to use the CSS `writing-mode` and `direction` properties to create and configure vertical form controls. This includes:

- `<input type="range">` sliders, `<progress>` bars, and `<meter>` elements.
- `<select>` elements.
- `<button>` elements and button input types such as `<input type="button">`, `<input type="reset">`, and `<input type="submit">`.
- `<textarea>` elements and text-based input types such as `<input type="text">`, `<input type="datetime-local">`, and `<input type="url">`.

General technique

In modern browsers, the `writing-mode` property can be set to a vertical value to vertically display form controls with text characters that are normally horizontal (for example in Latin languages), with text displayed at a 90-degree angle from the default. Normally vertical text characters, for example in Chinese or Japanese, are unaffected in this regard.

This is useful when creating vertical language forms.

Specifically:

- `writing-mode: vertical-lr` will create vertical form controls with a left-to-right block flow direction, meaning that in controls with wrapping or multiple lines of text, subsequent lines will appear to the right of previous lines.
- `writing-mode: vertical-rl` will create vertical form controls with a right-to-left block flow direction, meaning that in controls with wrapping or multiple lines of text, subsequent lines will appear to the left of previous lines.

You could use a transform to rotate the controls by 90 degrees, but that would place the controls in their own layer and cause unintended layout side effects such as other content being overlapped. Using `writing-mode` offers a more reliable solution.

> **Note:** While the `writing-mode` property is well supported, creating vertically-oriented form controls with `writing-mode` only gained full browser support in 2024.

> **Note:** The experimental `sideways-lr` and `sideways-rl` values have a similar effect as `vertical-lr` and `vertical-rl` respectively, except that normally vertical text characters (for example in Chinese or Japanese) are rotated 90 degrees to display on their sides, while horizontal text characters (for example in Latin languages) are unaffected by these values.

In addition, the `direction` property can be used to control the direction of the content inside the controls:

- `direction: ltr` will cause the content to start at the top and flow towards the bottom.
- `direction: rtl` will cause the content to start at the bottom and flow towards the top.

The `direction` property can be used to set the **inline base direction** — the primary direction in which content is ordered on a line, which defines on which sides the "start" and "end" of a line are. For text-based form controls the difference is obvious — the flow of text starts at the top or bottom. In non-text-based controls such as range sliders, `direction` sets the direction in which the control is drawn. For example, including `direction: ltr` on a vertical slider sets the lowest value at the top of the slider and the highest value at the bottom of the slider.

The sections below show how to create different types of vertical form control, along with examples of each. Consult the browser compatibility information on each of the linked reference pages to find out the exact support information for each type.

Range sliders, meters, and progress bars

Let's have a look at creating vertical range sliders, meters, and progress bars.

Basic example

A typical set of visual `<input type="range">` slider, `<progress>`, and `<meter>` controls is created like this:

```
<input type="range" min="0" max="11" value="9" step="1" />
<meter id="fuel" min="0" max="100" low="33" high="66" optimum="80" value="20">
  at 50/100
</meter>
<progress id="file" max="100" value="70">70%</progress>
```

> **Note:** Best practice is to include a `<label>` element for each form control, to associate a meaningful text description with each field for accessibility purposes (see Use meaningful text labels for more information). We haven't done that here, as this article focuses purely on aspects of the form controls' visual rendering, but you should make sure you do so in production code.

To display the controls vertically, we can use CSS like this:

```
input[type="range"],
meter,
progress {
  margin-block-end: 20px;
  writing-mode: vertical-lr;
}
```

`writing-mode: vertical-lr` (and `vertical-rl`) causes the controls to be displayed vertically in modern browsers.

The result of this looks like so:

Drawing the control from bottom to top

By default, the controls have a `direction` value of `ltr`. This causes your sliders, meters, and progress bars to be drawn from top to bottom, as seen above.

You can change this by setting `direction: rtl` — this causes them to be drawn from bottom to top instead:

```
<input type="range" min="0" max="11" value="9" step="1" />
<meter id="fuel" min="0" max="100" low="33" high="66" optimum="80" value="20">
  at 50/100
</meter>
<progress id="file" max="100" value="70">70%</progress>
```

```
input[type="range"],
meter,
progress {
  margin-block-end: 20px;
  writing-mode: vertical-lr;
  direction: rtl;
}
```

The result of this looks like so:

Creating vertical range sliders in older browsers

In older browsers that do not support the creation of vertical form controls with `writing-mode` and `direction`, there are limited alternatives available. The following only work on `<input type="range">`, causing the text to flow from bottom to top — they have no effect on `<meter>` and `<progress>` elements:

- The non-standard `appearance: slider-vertical` property can be used in older versions of Safari and Chrome.
- The non-standard `orient="vertical"` attribute can be added to the `<input type="range">` element itself in older versions of Firefox.

The HTML for this example includes an `<input type="range">` slider only, with `orient="vertical"` added to make it display vertically in older Firefox versions:

```
<input type="range" min="0" max="11" value="9" step="1" orient="vertical" />
```

To cause the controls to also display vertically in older versions of Chrome and Safari, we can use `appearance: slider-vertical`:

```
input[type="range"] {
  margin-block-end: 20px;
  appearance: slider-vertical;
}
```

The result looks like so:

Select elements

This section shows how to handle vertical `<select>` elements.

Select basic example

The below HTML creates two `<select>` elements, one where a single selection can be made and one with multiple selections:

```
<select multiple>
  <option>First</option>
  <option>Second</option>
  <option>Third</option>
  <option>Fourth</option>
  <option>Fifth</option>
</select>
<select>
  <option>First</option>
  <option>Second</option>
  <option>Third</option>
  <option>Fourth</option>
  <option>Fifth</option>
</select>
```

To display the controls vertically, we can use CSS like this:

```
select {
  inline-size: 100px;
  margin-block-end: 20px;
  writing-mode: vertical-rl;
}
```

The result of this looks like so:

Adjusting text direction and option order

Again, it is possible to use a `direction` property value of `rtl` to set the text direction to go from bottom to top, instead of the default direction of top to bottom.

It is also worth noting that in the above example, the inline direction for the select options goes from right to left because we used `writing-mode: vertical-rl`. If we use `writing-mode: vertical-lr` instead, the `<option>` text will appear from left to right.

We'll explore these two use cases using three listbox (`multiple`) `<select>` elements, to enable comparing the effects side-by-side.

```
<div class="controls">
  <div>
    <h2>writing-mode: vertical-lr</h2>
    <select multiple>
      <option>First</option>
      <option>Second</option>
      <option>Third</option>
      <option>Fourth</option>
      <option>Fifth</option>
    </select>
  </div>
  <div class="direction">
    <h2>direction: rtl & writing-mode: vertical-lr</h2>
    <select multiple>
      <option>First</option>
      <option>Second</option>
      <option>Third</option>
      <option>Fourth</option>
      <option>Fifth</option>
    </select>
  </div>
  <div class="reverse-option-order">
    <h2>writing-mode: vertical-rl</h2>
    <select multiple>
      <option>First</option>
      <option>Second</option>
      <option>Third</option>
      <option>Fourth</option>
      <option>Fifth</option>
    </select>
  </div>
</div>
```

In the CSS for this example, we set the following properties on the three listboxes:

1. `writing-mode: vertical-rl`, displaying just like in the previous example — text flowing top-to-bottom, and options displaying right-to-left.
2. `writing-mode: vertical-rl` and `direction: rtl`, with the options going from right-to-left but reversing the text flow from bottom-to-top.
3. `writing-mode: vertical-lr`, with the text going from top-to-bottom while reversing the option order from left-to-right.

```
.controls {
  box-sizing: border-box;
  display: flex;
  gap: 20px;
  font-family: sans-serif;
}

h2 {
  margin-top: 0;
  font-size: 1rem;
  text-align: center;
```

```
  flex: 1 0 100%;
}

.controls > div {
  margin-bottom: 20px;
  flex: 1;
  display: flex;
  align-items: flex-start;
  justify-content: space-around;
  flex-flow: row wrap;
}
```

```
select {
  inline-size: 100px;
  margin-block-end: 20px;
  writing-mode: vertical-rl;
}

.direction select {
  direction: rtl;
}

.reverse-option-order select {
  writing-mode: vertical-lr;
}
```

The result looks like so:

Buttons

This section shows how to handle vertical `<button>` elements. Note that while we have only used a `<button>` element in the examples below, the behavior is the same for other elements that create buttons, such as `<input>` types of `button`, `reset`, and `submit`.

Basic button example

The below HTML creates two `<button>` elements, one with a single line of text, and one with three:

```
<button>Press me</button> <button>Press me<br />Please?<br />Thanks</button>
```

To display the buttons vertically, we can use CSS like this:

```
button {
  inline-size: 100px;
  margin-block-end: 20px;
  writing-mode: vertical-rl;
}
```

The result looks like so:

Adjusting button text line order

When you swap the `writing-mode` value of `vertical-rl` to `vertical-lr`, subsequent lines of text will appear to the right of previous lines, rather than the left.

This example uses two copies of the three-text-line button we saw in the previous example, so you can easily see the effects of changing the writing mode:

```
<div>
  <h2>writing-mode: vertical-lr</h2>
  <button>Press me<br />Please?<br />Thanks</button>
</div>
<div class="reverse-line-order">
  <h2>writing-mode: vertical-rl</h2>
  <button>Press me<br />Please?<br />Thanks</button>
</div>
```

In the CSS, we set `writing-mode: vertical-rl` on the first button to lay out the line order from right to left. On the second button, we set `writing-mode: vertical-lr` to reverse the line order — left to right:

```
body {
  box-sizing: border-box;
  display: flex;
  gap: 20px;
  font-family: sans-serif;
}

h2 {
  margin-top: 0;
  font-size: 1rem;
  text-align: center;
  flex: 1 0 100%;
}

div {
  margin-bottom: 20px;
  flex: 1;
  display: flex;
  align-items: flex-start;
  justify-content: space-around;
  flex-flow: row wrap;
}
```

```
button {
  inline-size: 100px;
  margin-block-end: 20px;
  writing-mode: vertical-rl;
}

.reverse-line-order button {
  writing-mode: vertical-lr;
}
```

The result looks like so:

Text-based form controls

Last but not least, we'll look at handling vertical `<textarea>`s and textual `<input>` types. Note that, while the only `<input>` type we are including is an `<input type="text">` element in the examples below, the behavior is the same for other textual `<input>` types: `password`, `number`, `url`, etc.

Basic text input and textarea example

The below HTML creates a `<textarea>` and an `<input type="text">`:

```
<textarea>This is my textarea</textarea>
<input type="text" value="Input text" />
```

To display the input and textarea vertically, we can use CSS like this:

```
textarea,
input[type="text"] {
  inline-size: 100px;
  margin-block-end: 20px;
  writing-mode: vertical-rl;
}
```

The result looks like so:

Adjusting text direction and line layout order

You can use a `direction` property value of `rtl` to change the text direction from the default top-to-bottom to bottom-to-top. You can also set `writing-mode` to `vertical-lr` instead of `vertical-rl`, to cause multiple lines of text in `<textarea>`s to appear from left-to-right rather than the default right-to-left.

This example uses three copies of the same text controls we saw in the previous example, so you can easily see the effects of changing `direction` and `writing-mode` as discussed above:

```
<div class="controls">
  <div>
    <h2>writing-mode: vertical-lr</h2>
    <textarea>This is my textarea</textarea>
    <input type="text" value="Input text" />
  </div>
  <div class="direction">
    <h2>direction: rtl & writing-mode: vertical-lr</h2>
    <textarea>This is my textarea</textarea>
    <input type="text" value="Input text" />
  </div>
  <div class="reverse-line-order">
    <h2>writing-mode: vertical-rl</h2>
    <textarea>This is my textarea</textarea>
    <input type="text" value="Input text" />
  </div>
</div>
```

In the CSS, we set the following properties on the three sets of text controls:

1. `writing-mode: vertical-rl` to make it display just like in the previous example — text flowing top-to-bottom, and lines flowing right-to-left.
2. `writing-mode: vertical-rl` and `direction: rtl` to flow the lines from right-to-left but reverse the text flow from bottom-to-top.
3. `writing-mode: vertical-lr` to flow the text top-to-bottom but reverse the flow of lines — left-to-right. Note that this has no effect on `<input type="text">` elements, as they are always single lines.

```
.controls {
  box-sizing: border-box;
  display: flex;
  gap: 20px;
  font-family: sans-serif;
}

h2 {
  margin-top: 0;
  font-size: 1rem;
  text-align: center;
  flex: 1 0 100%;
}

.controls > div {
  margin-bottom: 20px;
  flex: 1;
  display: flex;
  align-items: flex-start;
  justify-content: space-around;
  flex-flow: row wrap;
}
```

```
textarea,
input[type="text"] {
  inline-size: 100px;
  margin-block-end: 20px;
  writing-mode: vertical-rl;
}

.direction textarea,
.direction input[type="text"] {
  writing-mode: vertical-rl;
  direction: rtl;
}

.reverse-line-order textarea,
.reverse-line-order input[type="text"] {
  writing-mode: vertical-lr;
}
```

The result looks like so:

Introduction to writing mode systems

CSS supports different content directionalities, or **writing modes**, including right-to-left, left-to-right, and top-to-bottom. The guide provides a brief overview of writing mode systems and their directionalities.

Block and inline

Before examining the directionality of various writing systems, it's important to understand the terms "block" and "inline". The term **inline** refers to how characters and words flow within a line. The term **block** refers to how lines, or blocks of content, stack up next to one another. The document's writing mode determines a document's block and inline directions. They are not based on physical directions such as left, right, top, and bottom.

Dimensions and directions

Everything on a web page is laid out in either the **inline** or **block** dimension. The *inline dimension* is the dimension along which a line of text runs in the current writing mode, whereas the *block dimension* is the dimension in which blocks — such as paragraphs — display one after the other. The inline dimension is perpendicular to the block dimension.

In an English document, with the text running horizontally left-to-right, or an Arabic document with the text running horizontally right-to-left, the inline dimension is horizontal, while the *inline direction* is left-to-right and right-to-left, respectively. In both cases, the block dimension is vertical, with the *block direction* being top-to-bottom. In a vertical writing mode such as Japanese, the inline dimension is vertical, as lines in that writing mode run vertically, while the block dimension is horizontal.

Inline and block boxes

The *outer display* type of boxes in a normal flowing layout determines how the box behaves alongside other elements on the page. *Inline boxes* wrap each line of text and are laid out along the inline dimension.

Block boxes represent containers on the page that can contain other block and inline elements. They are laid out along the block dimension and will extend in the inline dimension to fill all the space available in their container (provided a specific size is not set in the inline dimension using a property such as `inline-size`). Block boxes are only displayed from the top to the bottom of the page if you are using a writing mode that displays text horizontally, such as English.

The CSS logical properties and values module defines flow-relative mappings for many of the physical properties and values in CSS, which is helpful in understanding the basic concepts of logical properties and values.

Inline base and block flow directions

The *inline base direction* is the primary direction in which content is ordered on a line and defines the "start" and "end" of a line. The `direction` property specifies the inline base direction of a box and, together with the `unicode-bidi` property and the inherent directionality of any text content, determines the ordering of inline-level content within a line.

The *block flow direction* is the direction in which block-level and line boxes stack within a block container. The `writing-mode` property determines the block flow direction.

Writing system modes

Different writing systems have different writing modes. A horizontal writing mode is one with horizontal lines of text, i.e., a downward or upward block flow. A vertical writing mode is one with vertical lines of text, i.e., a leftward or rightward block flow.

Latin- and Slavic-based systems are typically written using a left-to-right inline direction with a top-to-bottom block flow direction. Latin-based languages include English, Spanish, Romanian, and Portuguese. Slavic-based languages include Ukrainian, Polish, and Czech.

```
<p lang="en-US" dir="auto">This is written in English</p>
<p lang="lt-LT" dir="auto">Tai parašyta lietuviu kalba</p>
<p lang="el-GR" dir="auto">Αυτό είναι γραμμένο στα ελληνικά</p>
```

Arabic-based systems are typically written using a right-to-left inline direction with a top-to-bottom block flow direction. There are several horizontal right-to-left languages, including Arabic, Aramaic, Azeri, Divehi, Fula, Hebrew, Kurdish, N'ko, Persian, Rohingya, Syriac, and Urdu.

```
<p lang="ur-PK" dir="auto">یہ اردو میں لکھا ہے۔</p>
<p lang="ku-CRB" dir="auto">ئەمە بە کوردی نووسراوە</p>
```

Han-based systems are commonly written using a left-to-right inline direction with a top-to-bottom block flow direction, or a top-to-bottom inline direction with a right-to-left block flow direction. Traditionally, Chinese, Vietnamese, Korean, and Japanese are written vertically in columns, going from top to bottom, with a right-to-left block direction, but will often be rendered horizontally online, going from left to right.

```
<p lang="ja-JP" dir="auto">これは日本語で書かれています</p>
```

Mongolian-based systems are typically written vertically, top to bottom, in columns that flow left to right; a top-to-bottom inline direction with a left-to-right block flow direction. This differs from Chinese, Japanese, and Korean, whose vertical text columns are read right to left. It derives from the fact that Mongolian script descended from Old Uyghur, which was written left-to-right.

```
<p lang="mn-Mong" dir="auto">ᠮᠣᠩᠭᠣᠯ ᠬᠡᠯᠡᠨ ᠤ ᠪᠢᠴᠢᠭ</p>
```

To render the writing modes correctly, we use the global HTML `dir` attribute. Because browsers can turn off CSS styling, it is recommended to use the `dir` attribute and `<bdo>` element to ensure correct bidirectional layout in the absence of a style sheet, rather than the CSS `direction` property.

For vertical languages, we use the `writing-mode` and `text-orientation` properties:

```
@import "https://fonts.googleapis.com/css2?family=Noto+Sans+Mongolian&display=swap";
```

```
:lang(ja) {
  writing-mode: vertical-rl;
  text-orientation: mixed;
}
:lang(mn-Mong) {
  writing-mode: vertical-lr;
  text-orientation: mixed;
}
```

```
:lang(ja),
:lang(mn-Mong) {
  float: left;
}

:lang(mn-Mong) {
```

```
  font-family: "Noto Sans Mongolian", sans-serif;
}
```

Mixing writing modes

While these different languages have different writing modes, sites that predominantly use one type of writing mode may contain content from a different language or writing mode. For example, articles in an Arabic, right-to-left language news site may include Latin-style numbers, which are written left to right. Many magazines and newspapers mix different writing modes on the same page. This guide, which demonstrates different writing modes, does too.

The typographic mode determines whether to use typographic conventions specific to vertical flow for vertical scripts (vertical typographic mode) or to use the typographic conventions of horizontal writing modes (horizontal typographic mode). This concept distinguishes vertical typesetting from rotated horizontal typesetting.

The `text-orientation` component of the writing mode controls the glyph orientation in vertical typographic modes, dictating whether a particular typographic character unit is typeset upright or typeset sideways.

How to

This page lists how-to guides for CSS.

CSS layout cookbook

> The CSS layout cookbook aims to bring together recipes for common layout patterns, things you might need to implement in your own sites. In addition to providing code you can use as a starting point in your projects, these recipes highlight the different ways layout specifications can be used, and the choices you can make as a developer.

CSS layout cookbook

The CSS layout cookbook aims to bring together recipes for common layout patterns, things you might need to implement in your own sites. In addition to providing code you can use as a starting point in your projects, these recipes highlight the different ways layout specifications can be used, and the choices you can make as a developer.

> **Note:** If you are new to CSS layout then you might first like to take a look at our CSS layout learning module, as this will give you the basic grounding you need to make use of the recipes here.

The Recipes

Recipe	Description	Layout Methods
Media objects	A two-column box with an image on one side and descriptive text on the other, e.g., a social media post.	CSS grid, `float` fallback, `fit-content` sizing
Columns	When to choose multi-column layout, flexbox or grid for your columns.	CSS grid, Multicol, Flexbox
Center an element	How to center an item horizontally and vertically.	Flexbox, Box Alignment
Sticky footers	Creating a footer which sits at the bottom of the container or viewport when the content is shorter.	CSS grid, Flexbox
Split navigation	A navigation pattern where some links are visually separated from the others.	Flexbox, `margin`
Breadcrumb navigation	Creating a list of links to allow the visitor to navigate back up through the page hierarchy.	Flexbox
List group with badges	A list of items with a badge to display a count.	Flexbox, Box Alignment
Pagination	Links to pages of content (such as search results).	Flexbox, Box Alignment
Card	A card component, which displays in a grid of cards.	Grid Layout
Grid wrapper	For aligning grid content within a central wrapper, while also allowing items to break out.	CSS grid

Contribute a Recipe

As with all of MDN we would love you to contribute a recipe in the same format as the ones shown above. See the guide for adding Layout Cookbook recipes for a template and guidelines for writing your own example.

Breadcrumb navigation

Breadcrumb navigation helps the user to understand their location in the website by providing a breadcrumb trail back to the start page. The items typically display inline, with a separator between each item, indicating the hierarchy between individual pages.

Requirements

Display the hierarchy of the site by displaying inline links, with a separator between the items, indicating the hierarchy between individual pages, with the current page appearing last.

Recipe

Click "Play" in the code blocks below to edit the example in the MDN Playground:

```
<nav aria-label="Breadcrumb" class="breadcrumb">
  <ol>
    <li><a href="#">Home</a></li>
    <li><a href="#">Category</a></li>
    <li><a href="#">Sub Category</a></li>
    <li><a href="#">Type</a></li>
    <li><span aria-current="page">Product</span></li>
  </ol>
</nav>
```

```
body {
  font: 1.2em sans-serif;
}
```

```
.breadcrumb {
  padding: 0 0.5rem;
}

.breadcrumb ol {
  display: flex;
  flex-wrap: wrap;
  list-style: none;
  margin: 0;
  padding: 0;
  align-items: end;
}

.breadcrumb li:not(:last-child)::after {
  display: inline-block;
  margin: 0 0.25rem;
  content: "→";
}
```

> **Note:** The example above uses a complex selector to insert content before every `li` except the last one. This could also be achieved using a complex selector targeting all `li` elements except the first:
>
> ```
> .breadcrumb li:not(:first-child)::before {
>   content: "→";
> }
> ```
>
> Feel free to choose the solution that you prefer.

Choices made

To display list items inline, we use flexbox layout, thus demonstrating how a line of CSS can give us our navigation. The separators are added using CSS generated content. You could change these to any separator that you like.

Accessibility concerns

We used the `aria-label` and `aria-current` attributes to help assistive technology users understand what this navigation is and where the current page is in the structure. See the related links for more information.

Be aware that the separator arrows → added via the `content` CSS property in the example above are exposed to assistive technologies (AT), including screen readers and braille displays. For a quieter solution, use a decorative `<img>` in your HTML with an empty `alt` attribute. An ARIA `role` set to `none` or `presentation` will also prevent the image from being exposed to AT.

Alternatively, silence the CSS generated content by including an empty string as alternative text, preceded by a slash (/); for example, `content: url("arrow.png") / "";`.

If including generated separators that will be exposed to AT, opt for creating the generated content using the `::after` pseudo-element selector instead of `::before`, so the separator content is announced after the HTML content instead of before it.

- Using the `aria-current` attribute

Card

This pattern is a list of "card" components with optional footers. A card contains a title, an image, a description or other content, and an attribution or footer. Cards are generally displayed within a group or collection.

Requirements

Create a group of cards, with each card component containing a heading, image, content, and, optionally, a footer.

Each card in the group of cards should be the same height. The optional card footer should stick to the bottom of the card.

The cards in the group should line up in two dimensions — both vertically and horizontally.

Recipe

Click "Play" in the code blocks below to edit the example in the MDN Playground:

```
<div class="cards">
  <article class="card">
    <header>
      <h2>A short heading</h2>
    </header>

    <img
      src="https://mdn.github.io/shared-assets/images/examples/balloons.jpg"
      alt="Hot air balloons" />
    <div class="content">
      <p>
        The idea of reaching the North Pole by means of balloons appears to have
        been entertained many years ago.
      </p>
    </div>
  </article>

  <article class="card">
    <header>
      <h2>A short heading</h2>
    </header>

    <img
      src="https://mdn.github.io/shared-assets/images/examples/balloons2.jpg"
      alt="Hot air balloons" />
    <div class="content">
      <p>Short content.</p>
    </div>
    <footer>I have a footer!</footer>
  </article>

  <article class="card">
    <header>
      <h2>A longer heading in this card</h2>
    </header>

    <img
      src="https://mdn.github.io/shared-assets/images/examples/balloons.jpg"
      alt="Hot air balloons" />
    <div class="content">
      <p>
        In a curious work, published in Paris in 1863 by Delaville Dedreux,
        there is a suggestion for reaching the North Pole by an aerostat.
      </p>
    </div>
    <footer>I have a footer!</footer>
  </article>
  <article class="card">
    <header>
      <h2>A short heading</h2>
    </header>

    <img
      src="https://mdn.github.io/shared-assets/images/examples/balloons2.jpg"
      alt="Hot air balloons" />
    <div class="content">
      <p>
        The idea of reaching the North Pole by means of balloons appears to have
        been entertained many years ago.
      </p>
    </div>
  </article>
</div>
```

```
body {
  font: 1.2em sans-serif;
}

img {
  max-width: 100%;
}

.cards {
  max-width: 700px;
  margin: 1em auto;

  display: grid;
  grid-template-columns: repeat(auto-fill, minmax(230px, 1fr));
  grid-gap: 20px;
}

.card {
  border: 1px solid #999999;
  border-radius: 3px;

  display: grid;
  grid-template-rows: max-content 200px 1fr;
}

.card img {
  object-fit: cover;
  width: 100%;
  height: 100%;
}

.card h2 {
  margin: 0;
  padding: 0.5rem;
```

```
}

.card .content {
  padding: 0.5rem;
}

.card footer {
  background-color: #333333;
  color: white;
  padding: 0.5rem;
}
```

Choices made

Each card is laid out using CSS grid layout despite the layout being one-dimensional. This enables the use of content sizing for the grid tracks. To set up a single-column grid we can use the following:

```
.card {
  display: grid;
  grid-template-rows: max-content 200px 1fr;
}
```

`display: grid` converts the element into a grid container. The three values of the `grid-template-rows` property divide the grid into a minimum of three rows, defining the height of the first three children of the card, in order.

Each `card` contains a `<header>`, `<img>`, and `<div>`, in that order, with some also containing a `<footer>`.

The heading row, or track, is set to `max-content`, which prevents it from stretching. The image track is set to 200 pixels tall. The third track, where the content lives, is set to `1fr`. This means it will fill any additional space.

Any children beyond the three with explicitly defined sizes create rows in the implicit grid, which fits the content added to it. These are auto-sized by default. If a card contains a footer, it is auto-sized. The footer, when present, sticks to the bottom of the grid. The footer is auto-sized to fit its content; the content `<div>` then stretches take up any additional space.

The following ruleset creates the grid of cards:

```
.cards {
  display: grid;
  grid-template-columns: repeat(auto-fill, minmax(230px, 1fr));
  gap: 20px;
}
```

The `grid-template-columns` property defines the widths of the grid columns. In this case, we set the grid to auto-fill, with repeated columns that are minimally `230px` but allowed to grow to fill the available space. The `gap` property sets a gap of `20px` between adjacent rows and adjacent columns.

> **Note:** The various elements in separate cards do not align with each other, as each card is an independent grid. Lining up the components in each card with the same components in adjacent cards can be done with subgrid.

Alternative methods

Flexbox can also be used to lay out each card. With flexbox, the dimensions of each card's rows are set with the `flex` property on each row, rather than on the card container.

With flexbox, the dimensions of the flex items are defined on the children rather than the parent. Whether you choose to use grid or flexbox depends on your preference, whether you prefer controlling the tracks from the container or prefer adding rules to the items.

We chose grid for the cards as, generally, you want cards to be lined up both vertically and horizontally. Additionally, lining up the components within each card to the components of adjacent cards can be done with subgrid. Flex has no hack-free equivalent to subgrid.

Accessibility concerns

Depending on the content of your card, there may be things you could or should do to enhance accessibility. See Inclusive components: Card by Heydon Pickering, for a very detailed explanation of these issues.

Center an element

In this recipe, you will see how to center one box inside another by using flexbox and grid, centering content both horizontally and vertically.

Requirements

To place an item into the center of another box horizontally and vertically.

Recipe

Click "Play" in the code blocks below to edit the example in the MDN Playground:

```
<div class="container">
  <div class="item">I am centered!</div>
</div>
```

```
.item {
  border: 2px solid rgb(95 97 110);
  border-radius: 0.5em;
  padding: 20px;
  width: 10em;
}

.container {
  border: 2px solid rgb(75 70 74);
  border-radius: 0.5em;
  font: 1.2em sans-serif;

  height: 200px;
  display: flex;
  align-items: center;
  justify-content: center;
}
```

Using flexbox

To center a box within another box, first turn the containing box into a flex container by setting its `display` property to `flex`. Then set `align-items` to `center` for vertical centering (on the block axis) and `justify-content` to `center` for horizontal centering (on the inline axis). And that's all it takes to center one box inside another!

HTML

```
<div class="container">
  <div class="item">I am centered!</div>
</div>
```

CSS

```
div {
  border: solid 3px;
  padding: 1em;
  max-width: 75%;
}

.item {
  border: 2px solid rgb(95 97 110);
  border-radius: 0.5em;
  padding: 20px;
  width: 10em;
}

.container {
  height: 8em;
  border: 2px solid rgb(75 70 74);
  border-radius: 0.5em;
  font: 1.2em sans-serif;

  display: flex;
  align-items: center;
  justify-content: center;
}
```

We set a height for the container to demonstrate that the inner item is indeed vertically centered within the container.

Result

Instead of applying `align-items: center;` on the container, you can also vertically center the inner item by setting `align-self` to `center` on the inner item itself.

Using grid

Another method you can use for centering one box inside another is to first make the containing box a grid container and then set its `place-items` property to `center` to center align its items on both the block and inline axes.

HTML

```
<div class="container">
  <div class="item">I am centered!</div>
</div>
```

CSS

```
div {
  border: solid 3px;
  padding: 1em;
  max-width: 75%;
}

.item {
  border: 2px solid rgb(95 97 110);
  border-radius: 0.5em;
  padding: 20px;
  width: 10em;
}

.container {
  height: 8em;
  border: 2px solid rgb(75 70 74);
  border-radius: 0.5em;
  font: 1.2em sans-serif;

  display: grid;
  place-items: center;
}
```

Result

Instead of applying `place-items: center;` on the container, you can achieve the same centering by setting `place-content: center;` on the container or by applying either `place-self: center` or `margin: auto;` on the inner item itself.

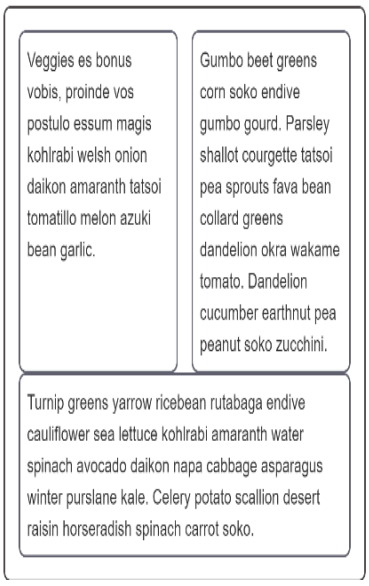
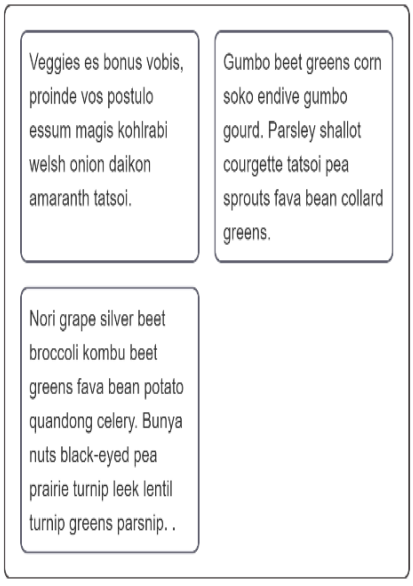
- CSS box alignment guide

Column layouts

You will often need to create a layout which has a number of columns, and CSS provides several ways to do this. Whether you use Multi-column, Flexbox, or Grid layout will depend on what you are trying to achieve, and in this recipe we explore these options.





Requirements

There are a number of design patterns you might want to achieve with your columns:

- A continuous thread of content broken up into newspaper-style columns.
- A single row of items arranged as columns, with all heights being equal.
- Multiple rows of columns lined up by row and column.

The recipes

You need to choose different layout methods in order to achieve your requirements.

A continuous thread of content — multi-column layout

If you create columns using multi-column layout your text will remain as a continuous stream filling each column in turn. The columns must all be the same size, and you are unable to target an individual column or the content of an individual column.

You can control the gaps between columns with the `column-gap` or `gap` properties, and add a rule between columns using `column-rule`.

Click "Play" in the code blocks below to edit the example in the MDN Playground:

```
<div class="container">
  <p>
    Veggies es bonus vobis, proinde vos postulo essum magis kohlrabi welsh onion
    daikon amaranth tatsoi tomatillo melon azuki bean garlic.
  </p>
  <p>
    Gumbo beet greens corn soko endive gumbo gourd. Parsley shallot courgette
    tatsoi pea sprouts fava bean collard greens dandelion okra wakame tomato.
    Dandelion cucumber earthnut pea peanut soko zucchini.
  </p>
  <p>
    Turnip greens yarrow ricebean rutabaga endive cauliflower sea lettuce
    kohlrabi amaranth water spinach avocado daikon napa cabbage asparagus winter
    purslane kale. Celery potato scallion desert raisin horseradish spinach
  </p>
</div>
```

```
.container {
  border: 2px solid rgb(75 70 74);
  border-radius: 0.5em;
  padding: 20px;
  font: 1.2em sans-serif;

  column-width: 10em;
  column-rule: 1px solid rgb(75 70 74);
}
```

In this example, we used the `column-width` property to set a minimum width that the columns need to be before the browser adds an additional column. The `columns` shorthand property can be used to set the `column-width` and `column-count` properties, either of which can define the maximum number of columns allowed.

Use multicol when:

- You want your text to display in newspaper-like columns.
- You have a set of small items you want to break into columns.
- You do not need to target individual column boxes for styling.

A single row of items with equal heights — flexbox

Flexbox can be used to break content into columns by setting `display: flex;` to make a parent element a flex-container. Just adding this one property turns all the children (child elements, pseudo-elements, and text nodes) into flex items along a single line. Setting the same `flex` shorthand property with a single numeric value distributes all the available space equally, generally making all the flex items the same size as long as none have non-wrapping content forcing the item to be larger.

Margins or the `gap` property can be used to create gaps between items, but there is currently no CSS property that adds rules between flex items.

```
<div class="container">
  <p>
    Veggies es bonus vobis, proinde vos postulo essum magis kohlrabi welsh onion
    daikon amaranth tatsoi tomatillo melon azuki bean garlic.
  </p>

  <p>
    Gumbo beet greens corn soko endive gumbo gourd. Parsley shallot courgette
    tatsoi pea sprouts fava bean collard greens dandelion okra wakame tomato.
    Dandelion cucumber earthnut pea peanut soko zucchini.
  </p>

  <p>
    Turnip greens yarrow ricebean rutabaga endive cauliflower sea lettuce
    kohlrabi amaranth water spinach avocado daikon napa cabbage asparagus winter
    purslane kale. Celery potato scallion desert raisin horseradish spinach
    carrot soko.
  </p>
</div>
```

```
.container {
  border: 2px solid rgb(75 70 74);
  border-radius: 0.5em;
  padding: 20px 10px;
  font: 1.2em sans-serif;

  display: flex;
}

.container > * {
  padding: 10px;
  border: 2px solid rgb(95 97 110);
  border-radius: 0.5em;

  margin: 0 10px;
  flex: 1;
}
```

To create a layout with flex items that wrap onto new rows, set the `flex-wrap` property on the container to `wrap`. Note that each flex line distributes space for that line only. Items in one line will not necessarily line up with items on other lines, as you'll see in the example below. This is why flexbox is described as one-dimensional. It is designed for controlling layout as a row or a column, but not both at the same time.

```
<div class="container">
  <p>
    Veggies es bonus vobis, proinde vos postulo essum magis kohlrabi welsh onion
    daikon amaranth tatsoi tomatillo melon azuki bean garlic.
  </p>
```

```
  <p>
    Gumbo beet greens corn soko endive gumbo gourd. Parsley shallot courgette
    tatsoi pea sprouts fava bean collard greens dandelion okra wakame tomato.
    Dandelion cucumber earthnut pea peanut soko zucchini.
  </p>

  <p>
    Turnip greens yarrow ricebean rutabaga endive cauliflower sea lettuce
    kohlrabi amaranth water spinach avocado daikon napa cabbage asparagus winter
    purslane kale. Celery potato scallion desert raisin horseradish spinach
    carrot soko.
  </p>
</div>
```

```
.container {
  border: 2px solid rgb(75 70 74);
  border-radius: 0.5em;
  padding: 20px 10px;
  width: 500px;
  font: 1.2em sans-serif;

  display: flex;
  flex-wrap: wrap;
}

.container > * {
  padding: 10px;
  border: 2px solid rgb(95 97 110);
  border-radius: 0.5em;

  margin: 0 10px;
  flex: 1 1 200px;
}
```

Use flexbox:

- For single rows or columns of items.
- When you want to do alignment on the cross axis after laying out your items.
- When you are happy for wrapped items to share out space along their line only and not line up with items in other lines.

Lining items up in rows and columns — grid layout

If you want a two-dimensional grid where items line up in rows *and* columns, then you should choose CSS grid layout. Similar to how flexbox works on the direct children of the flex container, grid layout works on the direct children of the grid container. Just set `display: grid;` on the container. Properties set on this container — like `grid-template-columns` and `grid-template-rows` — define how the items are distributed along rows and columns.

Click "Play" in the code blocks below to edit the example in the MDN Playground:

```
<div class="container">
  <p>
    Veggies es bonus vobis, proinde vos postulo essum magis kohlrabi welsh onion
    daikon amaranth tatsoi.
  </p>

  <p>
    Gumbo beet greens corn soko endive gumbo gourd. Parsley shallot courgette
    tatsoi pea sprouts fava bean collard greens.
  </p>

  <p>
    Nori grape silver beet broccoli kombu beet greens fava bean potato quandong
    celery. Bunya nuts black-eyed pea prairie turnip leek lentil turnip greens
    parsnip. .
  </p>
</div>
```

```
.container {
  border: 2px solid rgb(75 70 74);
  border-radius: 0.5em;
  padding: 20px;
  width: 500px;
  font: 1.2em sans-serif;

  display: grid;
  grid-template-columns: 1fr 1fr;
  grid-gap: 20px;
}

.container > * {
  padding: 10px;
  border: 2px solid rgb(95 97 110);
  border-radius: 0.5em;
  margin: 0;
}
```

Use grid:

- For multiple rows or columns of items.
- When you want to be able to align the items on the block and inline axes.
- When you want items to line up in rows and columns.

- Guide to flexbox
- Guide to CSS grid layout

Contribute a recipe

If you would like to contribute an example for the Layout Cookbook, then this page explains the steps to take to have your example published.

What makes a good recipe?

The simplest possible version of any useful web design pattern. Each line of CSS that you include should be there to help demonstrate the pattern, so leave out anything there purely to make the example look pretty. The idea is that someone can take the pattern and use it in a site with their own styles.

A recipe consists of:

- A live example, stored in the CSS Examples GitHub repo.
- A downloadable version of that example, also stored in the CSS Examples repo.
- A page in the CSS layout cookbook section of the site, which should include the following components:
    1. Introduction
    2. Requirements
    3. Recipe
    4. Decisions
    5. Useful fallbacks or alternative methods (when relevant)
    6. Accessibility concerns
    7. Browser compatibility (only for CSS properties not fully supported)
    8. Additional resources

Steps to publish a recipe

To create a recipe and add it to the CSS layout cookbook, follow these steps:

- What makes a good recipe?
- Steps to publish a recipe
    - 1. Build a pattern
    - 2. Create a live example
    - 3. Create a downloadable version
    - 4. Open a pull request with your example
    - 5. Create your page

1. Build a pattern

Before turning your example into a recipe, start by creating your pattern as a basic HTML page. Think about what you are trying to demonstrate and keep it as simple as possible. Use descriptive words like "container" or "item" if adding class names.

Ensure that you've tested the HTML and CSS across multiple browsers, viewport sizes, and devices. Also ensure that any CSS styling follows accessibility guidelines. While it's okay to use CSS properties with limited support, be sure to include browser support information when creating the page, particularly in the browser compatibility section. In some cases, creating a second version of your example with fallback support can be helpful.

2. Create a live example

The live examples on cookbook pages, such as for centering an element, and elsewhere on MDN allow readers to play with the code and change relevant parts without being overwhelmed with all of the code. Your recipe will be demonstrated by way of one or more examples.

Fork the CSS Examples repo and then take a look in the `css-cookbook` folder. There is a cookbook-template.html file. Copy this file and use it as a starting point. Save this in the `css-cookbook` directory with a name that makes sense for your pattern. The template contains comments to guide you in adding various parts at the appropriate places.

The important parts of this template are as follows:

- There is a stylesheet for the editor panels with some basic body styling and a JavaScript file for the editor functionality. Leave these files as they are.
- The `<head>` contains two style blocks. The first style block is for elements that readers do not need to change to play with the example. The second style block contains items that readers might want to play with. We typically add all our CSS to the first block, then choose the rules to move to the second block. The rules in the second block should be those that are fundamental to the pattern, perhaps those where a reader can change a CSS value and see the pattern update.
- You need to add the HTML for your component twice: first inside the section with the class `preview`, and then inside the `<textarea>` with the class `playable-html`.
- The editable CSS from the second `<head>` block must also be copied into the `playable-css` section.

A working example is center.html, which is embedded on the page Center an element. You can use this to see how to add the various bits correctly.

If you've forked the repo and have our CSS and JavaScript files with your example, opening your live example in a browser should display everything working exactly as it would appear on an MDN page.

Useful tips

- Do not indent the CSS and HTML inside the text areas; instead, align the code with the start of the lines. This will look better when it is rendered.
- If any images are required, put them in the directory with the examples. You are welcome to use any images already present.
- You can adjust the height of the text areas by changing the height in the inline styles.

3. Create a downloadable version

As the examples include all of our live example code, we want to provide readers with just the code they need for their example, omitting any unnecessary items. Create a copy of your live example, and add `--download` to its name. For example, the download version of `center.html` is `center--download.html`. This file will be similar to your initial example. It should be a basic version of your pattern as a single HTML page.

It can be handy to include the body CSS rules from our included stylesheet. Take a look at `cookbook-template--download.html` as a guide; these rules are provided as a starting point.

4. Open a pull request with your example

Open a pull request (PR) on the CSS Examples repo. This allows us to help you with any changes to the example that may be needed before you create your page. Plus, the example will need to be live to be included. This is why it makes sense to first create the code examples and then the explanatory guide. In your PR, explain the pattern and what you are demonstrating. See our guidelines for opening a pull request.

5. Create your page

After your example PR is merged, open a pull request to create a new page in the Layout Cookbook directory. Use our template for Cookbook pages. The template explains the requirements of each section, and you can refer to other cookbook examples for more help.

Remember to add a link to your new recipe on the main Layout cookbook page.

If you have any questions or want someone to take a look at your page, get in touch via any of our communication channels.

Cookbook template

> **Note:** This is a template page for a CSS Cookbook page. Please use this as a raw template when you create a new cookbook page. *Comment in italics are information about how to use part of the template.*

Description of the problem this recipe solves or the pattern you are demonstrating.

Requirements

What does this pattern need to include, or what problems does it need to solve? List that here.

Recipe

Change the example code. The last parameter is the live example height, which you can change as needed. Mention that you can click "Play" in code blocks to edit the example in the MDN Playground.

```
<div class="container">
  <div class="item">I am centered!</div>
</div>
```

```
.container {
  border: 2px solid rgb(75 70 74);
  border-radius: 0.5em;

  height: 200px;
  display: flex;
  align-items: center;
  justify-content: center;
}

.item {
  border: 2px solid rgb(95 97 110);
  border-radius: 0.5em;
  padding: 20px;

  width: 10em;
}
```

Choices made

Explain your decisions when creating the pattern. Why did you choose a certain method? If you want to add an additional example here — for example a version with fallbacks, please do. This section is deliberately loose as patterns range from the very simple to more complex.

Useful fallbacks or alternative methods

If there are useful alternative methods for building the recipe, or fallback recipes to use if you have to support non-supporting browsers, include them in separate sections down here.

Accessibility concerns

Include this is there are any specific things to watch out for in regard to accessibility. If not relevant for your pattern this can be omitted.

See also

- *Links of link of related properties:* `example-property`
- *Links to article showing how to use the property in context: "Using ... article"*
- *Very good external links. Don't be afraid of external links, but they should be outstanding, and not only mention minor details.*

Grid wrapper

The grid wrapper pattern is useful for aligning grid content within a central wrapper while also allowing items to break out and align to the edge of the containing element or page.

Requirements

Items placed on the grid should be able to align to a horizontally-centered max-width wrapper or the outer edges of the grid, or both.

Recipe

Click "Play" in the code blocks below to edit the example in the MDN Playground:

```
<div class="grid">
  <div class="wrapper">
    <p>
      This item aligns to a central "wrapper" – columns that have a maximum
      width.
    </p>
  </div>
  <div class="full-width">
    <p>This item aligns to the edge of the grid container.</p>
  </div>
  <div class="left-edge">
    <p>
      This item aligns to the left edge of the grid container and the right edge
      of the wrapper.
    </p>
  </div>
  <div class="right-wrapper">
    <p>This item aligns to the right edge of the "wrapper" columns.</p>
  </div>
</div>
```

```
body {
  font: 1.2em sans-serif;
}
.grid {
  display: grid;
  grid-template-columns: minmax(20px, 1fr) repeat(6, minmax(0, 60px)) minmax(
      20px,
      1fr
```

```
    );
  grid-auto-rows: minmax(100px, auto);
  grid-gap: 10px;
}

.grid > * {
  border: 2px solid rgb(95 97 110);
  border-radius: 0.5em;
  padding: 20px;
}

.full-width {
  grid-column: 1 / -1;
}

.wrapper {
  grid-column: 2 / -2;
}

.left-edge {
  grid-column: 1 / -2;
}

.right-wrapper {
  grid-column: 4 / -2;
}
```

Choices made

This recipe uses the CSS grid `minmax()` function to define the grid track sizes in the `grid-template-columns` property. For the central columns with a maximum width, we can set a minimum value of `0` or greater and a maximum value that specifies the maximum size the column tracks will grow to. Using relative or absolute `<length>` units (pixels, ems, rems) will create a fixed maximum size for the central wrapper, whereas using `<percentage>` values or viewport units will cause the wrapper to grow or shrink in response to its context.

The outer two columns have a maximum size of `1fr`, meaning that they will each expand to fill the remaining available space in the grid container.

Useful fallbacks or alternative methods

To center the grid horizontally on the page you can set a `max-width` along with left and right `auto` `margin`s:

```
.grid {
  max-width: 96vw; /* Limits the width to 96% of the width of the viewport */
  margin: 0 auto; /* horizontally centers the container */
}
```

Accessibility concerns

Although CSS grid enables positioning items anywhere (within reason), ensuring that your underlying markup follows a logical order is important (see CSS grid layout and accessibility for more details).

List group with badges

In this recipe we will create a list group pattern with badges that indicate a count.

Requirements

The list items should be displayed with the badges. The badge should be aligned right and vertically centered. The badge must be centered vertically whether there is a single line of content or multiple lines of text.

Recipe

Click "Play" in the code blocks below to edit the example in the MDN Playground:

```
<ul class="list-group">
  <li>
    Item One
    <span class="badge">2</span>
  </li>
  <li>
    Item Two
    <span class="badge">10</span>
  </li>
  <li>
    Item Three
    <span class="badge">9</span>
  </li>
  <li>
    Item Four
    <span class="badge">0</span>
  </li>
</ul>
```

```
body {
  font: 1.2em / 1.5 sans-serif;
  padding: 0;
  margin: 1em;
}
.list-group {
  list-style: none;
  margin: 0;
  padding: 0;
  border: 1px solid #cccccc;
  border-radius: 0.5em;
  width: 20em;
}

.list-group li {
  border-top: 1px solid #cccccc;
  padding: 0.5em;
  display: flex;
  justify-content: space-between;
  align-items: center;
}

.list-group li:first-child {
  border-top: 0;
}

.list-group .badge {
  background-color: rebeccapurple;
  color: white;
  font-weight: bold;
  font-size: 80%;
  border-radius: 10em;
  min-width: 1.5em;
  padding: 0.25em;
  text-align: center;
}
```

Choices made

Flexbox makes this particular pattern straightforward and also facilitates making changes to the layout.

To ensure the text and badge line up correctly, I use the `justify-content` property with a value of `space-between`. This places any extra space between the items. In the live example, if you remove this property, you will see the badge move to the end of the text on items with text shorter than the one line.

To align the content horizontally, I use the `align-items` property to align the text and badge on the cross axis. If you want the badge to align to the top of the content instead, change this to `align-items: flex-start`.

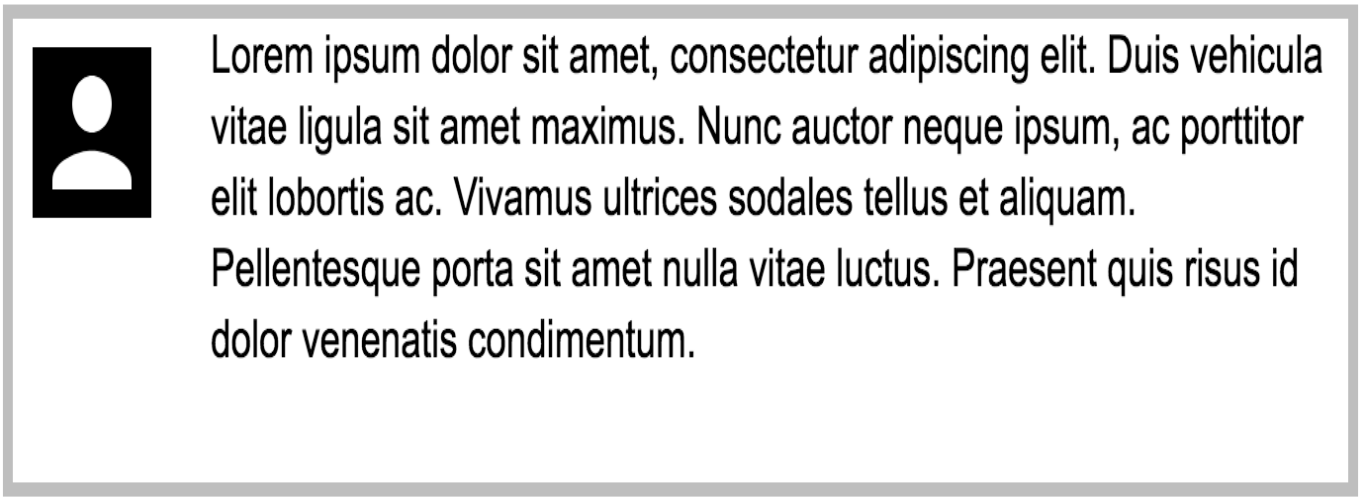
Media objects

The *Media Object* is a pattern we see all over the web. It refers to a two-column box with an image on one side and descriptive text on the other, e.g., a social media post.



Requirements

Media Object pattern needs some or all of the following characteristics:

- Stacked on Mobile, two columns on Desktop.
- The image can be on the left or right.
- The image might be small or large.
- Media Objects can be nested.
- The Media Object should clear the contents no matter which side is tallest.

The recipe

Click "Play" in the code blocks below to edit the example in the MDN Playground:

```
<div class="media">
  <div class="img">
    <img
      src="https://mdn.github.io/shared-assets/images/examples/balloons_square.jpg"
      alt="Balloons" />
  </div>

  <div class="content">
    <p>
      Lorem ipsum dolor sit amet, consectetur adipiscing elit. Duis vehicula
      vitae ligula sit amet maximus. Nunc auctor neque ipsum, ac porttitor elit
      lobortis ac. Vivamus ultrices sodales tellus et aliquam. Pellentesque
      porta sit amet nulla vitae luctus. Praesent quis risus id dolor venenatis
      condimentum.
    </p>
  </div>
  <div class="footer">An optional footer goes here.</div>
</div>

<div class="media">
  <div class="img">
    <img
      src="https://mdn.github.io/shared-assets/images/examples/sharp-account_box-24px.svg"
      width="80px"
      alt="Account" />
  </div>
  <div class="content">
    <p>
      Lorem ipsum dolor sit amet, consectetur adipiscing elit. Duis vehicula
      vitae ligula sit amet maximus. Nunc auctor neque ipsum, ac porttitor elit
      lobortis ac. Vivamus ultrices sodales tellus et aliquam. Pellentesque
      porta sit amet nulla vitae luctus. Praesent quis risus id dolor venenatis
      condimentum.
    </p>
  </div>
  <div class="footer"></div>
</div>
```

```
<div class="media media-flip">
  <div class="img">
    <img
      src="https://mdn.github.io/shared-assets/images/examples/balloons_square.jpg"
      alt="Balloons" />
  </div>

  <div class="content">
    <p>
      Lorem ipsum dolor sit amet, consectetur adipiscing elit. Duis vehicula
      vitae ligula sit amet maximus. Nunc auctor neque ipsum, ac porttitor elit
      lobortis ac. Vivamus ultrices sodales tellus et aliquam. Pellentesque
      porta sit amet nulla vitae luctus. Praesent quis risus id dolor venenatis
      condimentum.
    </p>
  </div>
  <div class="footer">An optional footer goes here.</div>
</div>

<div class="media">
  <a class="img">
    <img
      src="https://mdn.github.io/shared-assets/images/examples/balloons_square.jpg"
```

```
      alt="Balloons" />
  </a>

  <div class="content">
    <p>
      Lorem ipsum dolor sit amet, consectetur adipiscing elit. Duis vehicula
      vitae ligula sit amet maximus. Nunc auctor neque ipsum, ac porttitor elit
      lobortis ac. Vivamus ultrices sodales tellus et aliquam. Pellentesque
      porta sit amet nulla vitae luctus. Praesent quis risus id dolor venenatis
      condimentum.
    </p>
  </div>

  <div class="footer"></div>

  <div class="media">
    <a class="img">
      <img
        src="https://mdn.github.io/shared-assets/images/examples/balloons_square.jpg"
        alt="Balloons" />
    </a>

    <div class="content">
      <p>
        Lorem ipsum dolor sit amet, consectetur adipiscing elit. Duis vehicula
        vitae ligula sit amet maximus.
      </p>
    </div>

    <div class="footer"></div>
  </div>
</div>
```

```
body {
  font: 1.2em sans-serif;
}

img {
  max-width: 100%;
}

p {
  margin: 0 0 1em 0;
}

@media (width >= 500px) {
  .media {
    display: grid;
    grid-template-columns: fit-content(200px) 1fr;
    grid-template-rows: 1fr auto;
    grid-template-areas:
      "image content"
      "image footer";
    grid-gap: 20px;
    margin-bottom: 4em;
  }

  .media-flip {
    grid-template-columns: 1fr fit-content(250px);
    grid-template-areas:
      "content image"
      "footer image";
  }

  .img {
    grid-area: image;
  }

  .content {
    grid-area: content;
  }

  .footer {
    grid-area: footer;
  }
}
```

Choices made

I have chosen to use grid layout for the media object as it allows me to control the layout in two dimensions when I need to. This means that when we have a footer, with short content above, the footer can be pushed down to the bottom of the media object.

Another reason to use grid layout is in order that I can use `fit-content` for the track sizing of the image. By using `fit-content` with a maximum size of 200 pixels, when we have a small image such as the icon, the track only gets as large as the size of that image — the `max-content` size. If the image is larger, the track stops growing at 200 pixels and as the image has a `max-width` of 100% applied, it scales down so that it continues to fit inside the column.

By using `grid-template-areas` to achieve the layout, I can see the pattern in the CSS. I define my grid once the viewport is 500 pixels wide, so on smaller devices the media object stacks.

An option for the pattern is to flip it to switch the image to the other side — this is done by adding the `media-flip` class, which defines a flipped grid template causing the layout to be mirrored.

When we nest one media object inside another we need to place it into the second track in the regular layout, and the first track when flipped.

Pagination

This cookbook pattern demonstrates the navigation pattern used to display pagination, where the user can move between pages of content such as search results.

Requirements

The pagination pattern typically displays items in a row. To ensure that the pagination is understandable by people using a screen reader, we mark the items up as a list inside a `<nav>` element, and then use CSS to display the layout visually as a row.

Typically, the pagination component will be centered horizontally underneath the content.

Recipe

Click "Play" in the code blocks below to edit the example in the MDN Playground:

```
<nav aria-label="pagination">
  <ul class="pagination">
    <li>
      <a href="">
        <span aria-hidden="true">&amp;laquo;</span>
        <span class="visuallyhidden">previous set of pages</span>
      </a>
    </li>
    <li>
      <a href=""><span class="visuallyhidden">page </span>1</a>
    </li>
    <li>
      <a href="" aria-current="page">
        <span class="visuallyhidden">page </span>2
      </a>
    </li>
    <li>
      <a href=""> <span class="visuallyhidden">page </span>3 </a>
    </li>
    <li>
      <a href=""> <span class="visuallyhidden">page </span>4 </a>
    </li>
    <li>
      <a href="">
        <span class="visuallyhidden">next set of pages</span
        ><span aria-hidden="true">&amp;raquo;</span>
      </a>
    </li>
  </ul>
</nav>
```

```
.visuallyhidden {
  border: 0;
  clip: rect(0 0 0 0);
  height: auto;
  margin: 0;
  overflow: hidden;
  padding: 0;
  position: absolute;
  width: 1px;
  white-space: nowrap;
}

nav {
  border-top: 1px solid #eeeeee;
  margin-top: 1em;
  padding-top: 0.5em;
  font: 1.2em sans-serif;

  display: flex;
  justify-content: center;
}

.pagination {
  list-style: none;
  margin: 0;
  padding: 0;
  display: flex;
}

.pagination li {
  margin: 0 1px;
}

.pagination a {
  display: block;
  padding: 0.5em 1em;
  border: 1px solid #999999;
  border-radius: 0.2em;
  text-decoration: none;
}

.pagination a[aria-current="page"] {
  background-color: #333333;
  color: white;
}
```

Choices made

This pattern is laid out using flexbox — one flex container nested inside another. The `<nav>` element is designated a flex container in order that we can center the list inside using the `justify-content` property.

The list itself also becomes a flex container to lay the items out as a row. To space the items out we can either use a `margin` on the flex items or add a `gap` on the flex container.

```
.pagination {
  list-style: none;
  margin: 0;
  padding: 0;
  display: flex;
  gap: 2px;
}
```

Accessibility concerns

We want to ensure that a person using a screen reader understands what this navigation does, and where they will go when clicking a link. To help with this we have added `aria-label="pagination"` on the `<nav>` element.

We have also added some additional content that would be read by a screen reader but is hidden visually, and set the `aria-hidden` attribute on the paging arrows.

The "See Also" section at the end of this document has links to related accessibility topics.

Split navigation

The **split navigation** is a navigation pattern where one or more elements are separated from the rest of the navigation items.

Requirements

A common navigation pattern is to have one element pushed away from the others. We can use flexbox to achieve this, without needing to make the two sets of items into two separate flex containers.

Recipe

Click "Play" in the code blocks below to edit the example in the MDN Playground:

```
<nav>
  <ul class="main-nav">
    <li><a href="">About</a></li>
    <li><a href="">Products</a></li>
    <li><a href="">Our Team</a></li>
    <li class="push"><a href="">Contact</a></li>
  </ul>
</nav>
```

```
.main-nav {
  margin: 0;
  padding: 0;
  list-style: none;
  font: 1.2em sans-serif;

  display: flex;
}

.main-nav a {
  padding: 0.5em 1em;
  display: block;
}

.push {
  margin-left: auto;
}
```

Choices made

This pattern combines auto margins with flexbox to split the items.

An auto margin absorbs all available space in the direction it is applied. This is how centering a block with auto margins works — you have a margin on each side of the block trying to take up all of the space, thus pushing the block into the middle.

In this case the left auto margin takes up any available space and pushes the item over to the right. You could apply the class `push` to any item in the list.

Sticky footers

A sticky footer pattern is one where the footer of your page "sticks" to the bottom of the viewport in cases where the content is shorter than the viewport height. We'll look at a couple of techniques for creating one in this recipe.

Requirements

The sticky footer pattern needs to meet the following requirements:

- Footer sticks to the bottom of the viewport when content is short.
- If the content of the page extends past the viewport bottom, the footer gets pushed down, always sitting below the content as normal.

The recipe

Click "Play" in the code blocks below to edit the example in the MDN Playground:

```
<div class="wrapper">
  <header class="page-header">This is the header</header>
  <main class="page-body">
    <p contenteditable>
      The footer sticks to the bottom even though this paragraph is short. Add
      content to this editable area to see the footer push down when needed to
      fit the content.
    </p>
  </main>
  <footer class="page-footer">Sticky footer</footer>
</div>
```

```
* {
  box-sizing: inherit;
}

html {
  height: 100%;
  box-sizing: border-box;
}

body {
  height: 100%;
  font: 1.2em sans-serif;
}

.wrapper {
  min-height: 100%;
  display: grid;
  grid-template-rows: auto 1fr auto;
}

.page-header,
.page-footer {
  background-color: rgb(75 70 74);
  color: white;
  padding: 20px;
}

.page-body {
  padding: 20px;
}

.page-body p {
  border: 1px solid grey;
}
```

> **Note:** In this example and the following one we are using a wrapper set to `min-height: 100%`. You can also achieve this for a full page by setting a `min-height` of `100vh` on the `<body>` and then using it as your grid container.

Choices made

In the above example we achieve the sticky footer using CSS grid layout. The `.wrapper` has a minimum height of `100%` which means it is as tall as the container it is in. We then create a single column grid layout with three rows, one row for each part of our layout.

Grid auto-placement will place our items in source order and so the header goes into the first auto sized track, the main content into the `1fr` track and the footer into the final auto sized track. The `1fr` track will take up all available space and so grows to fill the gap.

Alternate method

You can also use flexbox to create a sticky footer.

```
<div class="wrapper">
  <header class="page-header">This is the header</header>
  <main class="page-body">
    <p contenteditable>
      The footer sticks to the bottom even though this paragraph is short. Add
      content to this editable area to see the footer push down when needed to
      fit the content.
    </p>
  </main>
  <footer class="page-footer">Sticky footer</footer>
</div>
```

```
* {
  box-sizing: border-box;
}

html,
body {
  box-sizing: border-box;
  height: 100%;
  padding: 0;
```

```
  margin: 0;
  font: 1.2em sans-serif;
}

.wrapper {
  box-sizing: border-box;
  min-height: 100%;

  display: flex;
  flex-direction: column;
}

.page-header,
.page-footer {
  background-color: rgb(75 70 74);
  color: white;
  padding: 20px;

  flex-grow: 0;
  flex-shrink: 0;
}

.page-body {
  padding: 20px;

  flex-grow: 1;
}

.page-body p {
  border: 1px solid grey;
}
```

The flexbox example starts out in the same way, but we use `display:flex` rather than `display:grid` on the `.wrapper`; we also set `flex-direction` to `column`. Then we set our main content to `flex-grow: 1` and the other two elements to `flex-shrink: 0` — this prevents them from shrinking smaller when content fills the main area.

CSS reference

Use this **CSS reference** to browse an alphabetical index of all of the standard CSS properties, pseudo-classes, pseudo-elements, data types, functional notations and at-rules. You can also browse key CSS concepts and a list of selectors organized by type. Also included is a brief DOM-CSS / CSSOM reference.

Basic rule syntax

Style rule syntax

```
style-rule ::=
    selectors-list {
      properties-list
    }
```

Where:

```
selectors-list ::=
    selector[:pseudo-class] [::pseudo-element]
    [, selectors-list]

properties-list ::=
    [property : value] [; properties-list]
```

See the index of *selectors*, *pseudo-classes*, and *pseudo-elements* below. The syntax for each specified *value* depends on the data type defined for each specified *property*.

Style rule examples

```
strong {
  color: red;
}

div.menu-bar li:hover > ul {
  display: block;
}
```

For a beginner-level introduction to the syntax of selectors, see our guide on CSS Selectors. Be aware that any syntax error in a rule definition invalidates the entire rule. Invalid rules are ignored by the browser. Note that CSS rule definitions are entirely (Unicode) text-based, whereas DOM-CSS / CSSOM (the rule management system) is object-based.

At-rule syntax

As the structure of at-rules varies widely, please see At-rule to find the syntax of the specific one you want.

Index

> **Note:** This index does not include SVG-exclusive presentation attributes, which can be used as CSS properties on SVG elements.

> **Note:** The property names in this index do **not** include the JavaScript names which do differ from the CSS standard names.

Selectors

The following are the various selectors, which allow styles to be conditional based on various features of elements within the DOM.

Basic selectors

Basic selectors are fundamental selectors; these are the most basic selectors that are frequently combined to create other, more complex selectors.

- Universal selector `*`
- Type selector `elementname`
- Class selector `.classname`
- ID selector `#idname`
- Attribute selector `[attr=value]`

Grouping selectors

Selector list `A, B`

> Specifies that both `A` and `B` elements are selected. This is a grouping method to select several matching elements.

Combinators

Combinators are selectors that establish a relationship between two or more simple selectors, such as "`A` is a child of `B`" or "`A` is adjacent to `B`", creating a complex selector.

Next-sibling combinator `A + B`

> Specifies that the elements selected by both `A` and `B` have the same parent and that the element selected by `B` immediately follows the element selected by `A` horizontally.

Subsequent-sibling combinator `A ~ B`

Specifies that the elements selected by both `A` and `B` share the same parent and that the element selected by `A` comes before—but not necessarily immediately before—the element selected by `B`.

Child combinator `A > B`

Specifies that the element selected by `B` is the direct child of the element selected by `A`.

Descendant combinator `A B`

Specifies that the element selected by `B` is a descendant of the element selected by `A`, but is not necessarily a direct child.

Column combinator `A || B`

Specifies that the element selected by `B` is located within the table column specified by `A`. Elements which span multiple columns are considered to be a member of all of those columns.

Pseudo

Pseudo classes `:`

Specifies a special state of the selected element(s).

Pseudo elements `::`

Represents entities that are not included in HTML.

See also selectors in the Selectors specification and the pseudo-element specification.

CSS at-rules

At-rules are CSS statements that instruct CSS how to behave. They are used to group and structure style rules and other at-rules, declare style information not directly associated with selected content, and manage syntactic constructs such as imports and namespaces keyword mappings. They begin with an at-sign, `@` (U+0040 COMMERCIAL AT), followed by an identifier.

@charset CSS at-rule

The **`@charset`** CSS rule specifies the character encoding used in the style sheet. This syntax is useful when using non-ASCII characters in some CSS properties, like `content`. Although the first character in `@charset` is the `@` symbol, it is not an at-rule. It is a specific byte sequence that can only be placed at the very beginning of a stylesheet. No other characters, except the Unicode byte-order mark, are allowed before it. It also does not follow normal CSS syntax rules such as use of quotes or whitespace.

If a `@charset` is not recognized as the charset declaration, it is parsed as a normal at-rule. The CSS syntax module deprecates this fallback behavior, defining it as an unrecognized legacy rule to be dropped when a stylesheet is grammar-checked.

As there are several ways to define the character encoding of a style sheet, the browser will try the following methods in the following order (and stop as soon as one yields a result):

1. The value of the Unicode byte-order character placed at the beginning of the file.
2. The value given by the `charset` attribute of the `Content-Type:` HTTP header or the equivalent in the protocol used to serve the style sheet.
3. The `@charset` CSS declaration.
4. Use the character encoding defined by the referring document: the `charset` attribute of the `<link>` element. This method is obsolete and should not be used.
5. Assume that the document is UTF-8.

Syntax

```
@charset "UTF-8";
@charset "iso-8859-15";
```

Parameters

charset

A `<string>` denoting the character encoding to be used. It must be the name of a web-safe character encoding defined in the IANA-registry, and must be double-quoted, following exactly one space character (U+0020), and immediately terminated with a semicolon. If several names are associated with an encoding, only the one marked with *preferred* must be used.

Formal syntax

Note that the `@charset` rule is not parsed via syntax, but via a specific byte sequence of the following form:

```
@charset "<charset>";
```

Examples

Valid and invalid charset declarations

```
@charset "UTF-8"; /* Set the encoding of the style sheet to Unicode UTF-8 */
```

```
@charset 'iso-8859-15'; /* Invalid, wrong quotes used */
@charset  "UTF-8"; /* Invalid, more than one space */
 @charset "UTF-8"; /* Invalid, there is a character (a space) before the declarations */
@charset UTF-8; /* Invalid, the charset is a CSS <string> and requires double-quotes */
```

- Character set glossary entry
- Unicode glossary entry

@color-profile CSS at-rule

The **`@color-profile`** CSS at-rule defines and names a color profile which can later be used in the `color()` function to specify a color.

Syntax

```
@color-profile --swop5c {
  src: url("https://example.org/SWOP2006_Coated5v2.icc");
}
```

Parameters

profile name

Either a `<dashed-ident>` or the identifier `device-cmyk`.

Descriptors

`src`

Specifies the URL to retrieve the color-profile information from.

`rendering-intent`

If the color profile contains more than one rendering intent, this descriptor allows one to be selected as the one to use to define how to map the color to smaller gamuts than this profile is defined over.

If used, it must be one of the following keywords:

`relative-colorimetric`

Media-relative colorimetric is required to leave source colors that fall inside the destination medium gamut unchanged relative to the respective media white points. Source colors that are out of the destination medium gamut are mapped to colors on the gamut boundary using a variety of different methods.

`absolute-colorimetric`

ICC-absolute colorimetric is required to leave source colors that fall inside the destination medium gamut unchanged relative to the adopted white (a perfect reflecting diffuser). Source colors that are out of the destination medium gamut are mapped to colors on the gamut boundary using a variety of different methods.

`perceptual`

This method is often the preferred choice for images, especially when there are substantial differences between the source and destination (such as a screen display image reproduced on a reflection print). It takes the colors of the source image and re-optimizes the appearance for the destination medium using proprietary methods.

`saturation`

This option was created to preserve the relative saturation (chroma) of the original, and to keep solid colors pure. However, it experienced interoperability problems like the perceptual intent.

Formal syntax

```
@color-profile =
  @color-profile [ <dashed-ident> | device-cmyk ] { <declaration-list> }
```

This syntax reflects the latest standard as per CSS Color Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

This example demonstrates using offset printing to ISO 12647-2:2004 using the CGATS/SWOP TR005 2007 characterization data on grade 5 paper with an ink limit of 300% Total Area Coverage, and medium gray component replacement (GCR). This example is from the specification.

The `src` descriptor specifies the URL to retrieve the color-profile information from.

```
@color-profile --swop5c {
  src: url("https://example.org/SWOP2006_Coated5v2.icc");
}
.header {
  background-color: color(--swop5c 0% 70% 20% 0%);
}
```

Browser compatibility

Currently, no browsers support this feature.

- CSS colors module

@container CSS at-rule

The **`@container`** CSS at-rule is a conditional group rule that applies styles to a containment context. Style declarations are filtered by a condition and applied to the elements within the container if the condition is true. The condition is evaluated when the queried container size, `<style-feature>`, or scroll-state changes.

The condition must specify a `container-name`, a `<container-query>`, or both.

The `container-name` property specifies a list of query container names, which are used to filter which containers are targeted by the `@container` rules. If only a `container-name` value is included (a name-only container query), the contained rules are applied to any containers with one or more of those `container-name` values set on them.

The container features in the `<container-query>` are evaluated against the selected containers. If no `<container-name>` is specified, the `<container-query>` features are evaluated against the nearest ancestor query container that has the matching `container-type`.

Syntax

```
/* With a <size-query> */
@container (width > 400px) {
  h2 {
    font-size: 1.5em;
  }
}

/* With an optional <container-name> */
@container tall (height > 30rem) {
  p {
    line-height: 1.6;
  }
}

/* With a <container-name> only (query is optional) */
@container sidebar {
  h2 {
    background: blue;
  }
}

/* With a <scroll-state> */
@container scroll-state(scrollable: top) {
  .back-to-top-link {
    visibility: visible;
  }
}

/* With an anchored query */
@container anchored(fallback: bottom) {
  .infobox::before {
    content: "▲";
    bottom: 100%;
    top: auto;
```

```
  }
}

/* With a <container-name> and a <scroll-state> */
@container sticky-heading scroll-state(stuck: top) {
  h2 {
    background: purple;
    color: white;
  }
}

/* Multiple queries in a single condition */
@container (width > 400px) and style(--responsive: true) {
  h2 {
    font-size: 1.5em;
  }
}

/* Condition list */
@container card (width > 400px), style(--responsive: true), scroll-state(stuck: top) {
  h2 {
    font-size: 1.5em;
  }
}

/* Boolean style() queries */
@container style(--theme: one) or style(--theme: two) {
  /* matched container styles */
}
@container style((--theme: one) or (--theme: two)) {
  /* matched container styles */
}
@container style(--theme: one) and style(--theme: two) {
  /* matched container styles */
}
@container style((--theme: one) and (--theme: two)) {
  /* matched container styles */
}
@container not style(--theme: one) {
  /* matched container styles */
}

/* range style() queries */
@container style(--number > 4) {
  /* matched container styles */
}
```

Parameters

`<container-condition>`

One or both of `<container-name>` and `<container-query>`. Styles defined in the `<stylesheet>` are applied if the condition is `true`.

`<container-name>` Optional

The name of the container to query; it is specified as an `<ident>`. If the query evaluates to `true`, the declared styles are applied to the container's descendant elements.

`<container-query>` Optional

A set of features that are evaluated against the query container when the size, `<style-feature>`, scroll-state, or applied position-try fallback of the container changes.

Logical keywords in container queries

Logical keywords can be used to define the container condition:

- `and` combines two or more conditions.
- `or` combines two or more conditions.
- `not` negates the condition. Only one `not` condition is allowed per container query and it cannot be used with the `and` or `or` keywords.

```
@container (width > 400px) and (height > 400px) {
  /* <stylesheet> */
}

@container (width > 400px) or (height > 400px) {
  /* <stylesheet> */
}

@container not (width < 400px) {
  /* <stylesheet> */
}
```

Named containment contexts

A containment context can be named using the `container-name` property.

```
.post {
  container-name: sidebar;
  container-type: inline-size;
}
```

The shorthand syntax for this is to use `container` in the form `container: <name> / <type>`, for example:

```
.post {
  container: sidebar / inline-size;
}
```

In container queries, the `container-name` property is used to filter the set of containers to those with a matching query container name:

```
@container sidebar (width > 400px) {
  /* <stylesheet> */
```

```
}
```

Details about usage and naming restrictions are described in the `container-name` page.

Descriptors

The `<container-condition>` queries include size, scroll-state, and anchored container descriptors.

Size container descriptors

The `<container-condition>` can include one or more boolean size queries, each within a set of parentheses. A size query includes a size descriptor, a value, and — depending on the descriptor — a comparison operator. The queries always measure the content box as the comparison. The syntax for including multiple conditions is the same as for `@media` size feature queries.

```
@container (min-width: 400px) {
  /* … */
}
@container (orientation: landscape) and (width > 400px) {
  /* … */
}
@container (15em <= block-size <= 30em) {
  /* … */
}
```

`aspect-ratio`

: The `aspect-ratio` of the container calculated as the width to the height of the container expressed as a `<ratio>` value.

`block-size`

: The `block-size` of the container expressed as a `<length>` value.

`height`

: The height of the container expressed as a `<length>` value.

`inline-size`

: The `inline-size` of the container expressed as a `<length>` value.

`orientation`

: The orientation of the container, either `landscape` or `portrait`.

`width`

: The width of the container expressed as a `<length>` value.

Scroll-state container descriptors

Scroll-state container descriptors are specified inside the `<container-condition>` as an argument for the `scroll-state()` function, for example:

```
@container scroll-state(scrollable: top) {
  /* … */
}
@container scroll-state(scrolled: block-end) {
  /* … */
}
@container scroll-state(stuck: inline-end) {
  /* … */
}
@container scroll-state(snapped: both) {
  /* … */
}
```

Supported keywords for scroll-state container descriptors include physical and flow relative values.

`scrollable`

: Queries whether the container can be scrolled in the given direction via user-initiated scrolling, such as by dragging the scrollbar or using a trackpad gesture. In other words, is there overflowing content in the given direction that can be scrolled to? Valid `scrollable` values include the following keywords:

  `none`

  : The container is not a scroll container or otherwise cannot be scrolled in any direction.

  `top`

  : The container can be scrolled towards its top edge.

  `right`

  : The container can be scrolled towards its right-hand edge.

  `bottom`

  : The container can be scrolled towards its bottom edge.

  `left`

  : The container can be scrolled towards its left-hand edge.

  `x`

  : The container can be scrolled horizontally towards either or both of its left-hand or right-hand edges.

  `y`

  : The container can be scrolled vertically towards either or both of its top or bottom edges.

  `block-start`

  : The container can be scrolled towards its block-start edge.

`block-end`

The container can be scrolled towards its block-end edge.

`inline-start`

The container can be scrolled towards its inline-start edge.

`inline-end`

The container can be scrolled towards its inline-end edge.

`block`

The container can be scrolled in its block direction towards either or both of its block-start or block-end edges.

`inline`

The container can be scrolled in its inline direction towards either or both of its inline-start and inline-end edges.

If the test passes, the rules inside the `@container` block are applied to descendants of the scroll container.

To evaluate whether a container is scrollable, without being concerned about the direction, use the `none` value with the `not` operator:

```
@container not scroll-state(scrollable: none) {
  /* … */
}
```

`scrolled`

Queries whether the container was most recently scrolled in a specified direction. Valid `scrolled` values include the following keywords:

`none`

The container is not a scroll container or otherwise has not previously been scrolled in any direction.

`top`

The container was most recently scrolled towards its top edge.

`right`

The container was most recently scrolled towards its right-hand edge.

`bottom`

The container was most recently scrolled towards its bottom edge.

`left`

The container was most recently scrolled towards its left-hand edge.

`x`

The container was most recently scrolled towards either its left-hand or right-hand edges.

`y`

The container was most recently scrolled towards either its top or bottom edges.

`block-start`

The container was most recently scrolled towards its block-start edge.

`block-end`

The container was most recently scrolled towards its block-end edge.

`inline-start`

The container was most recently scrolled towards its inline-start edge.

`inline-end`

The container was most recently scrolled towards its inline-end edge.

`block`

The container was most recently scrolled towards either its block-start or block-end edges.

`inline`

The container was most recently scrolled towards either its inline-start or inline-end edges.

If the test returns true, the rules nested in the `@container` block are applied to the descendants of the scroll container.

To evaluate whether a container has recently been scrolled, without being concerned about the direction, use the `none` value with the `not` operator:

```
@container not scroll-state(scrolled: none) {
  /* … */
}
```

`snapped`

Queries whether the container is going to be snapped to a scroll snap container ancestor along the given axis. Valid `snapped` values include the following keywords:

`none`

The container is not a scroll snap target for its ancestor scroll container. When implementing a `snapped: none` query, containers that *are* snap targets for the scroll container will *not* have the `@container` styles applied, whereas non-snap targets *will* have the styles applied.

`x`

The container is a horizontal scroll snap target for its ancestor scroll container, that is, it is snapping horizontally to its ancestor.

`y`

The container is a vertical scroll snap target for its ancestor scroll container, that is, it is snapping vertically to its ancestor.

`block`

The container is a block-axis scroll snap target for its ancestor scroll container, that is, it is snapping to its ancestor in the block direction.

`inline`

The container is an inline-axis scroll snap target for its ancestor scroll container, that is, it is snapping to its ancestor in the inline direction.

`both`

The container is both a horizontal and vertical scroll snap target for its ancestor scroll container and is snapping to its ancestor in both directions. The container won't match if it is only snapping to its ancestor along the horizontal *or* vertical axis. It needs to be both.

To evaluate a container with a non-`none` `snapped` scroll-state query, it must be a container with a scroll container ancestor having a `scroll-snap-type` value other than `none`. A `snapped: none` query will match even when there is no scroll container ancestor.

Evaluations occur when `scrollsnapchanging` events fire on the scroll snap container. If the test passes, the rules inside the `@container` block are applied to descendants of the container.

To evaluate whether a container is a snap target, without being concerned about the direction, use the `none` value with the `not` operator:

```
@container not scroll-state(snapped: none) {
  /* … */
}
```

`stuck`

Queries whether a container with a `position` value of `sticky` is stuck to an edge of its scrolling container ancestor. Valid `stuck` values include the following keywords:

`none`

The container is not stuck to any edges of its container. Note that `none` queries will match even if the container does not have `position: sticky` set on it.

`top`

The container is stuck to the top edge of its container.

`right`

The container is stuck to the right-hand edge of its container.

`bottom`

The container is stuck to the bottom edge of its container.

`left`

The container is stuck to the left-hand edge of its container.

`block-start`

The container is stuck to the block-start edge of its container.

`block-end`

The container is stuck to the block-end edge of its container.

`inline-start`

The container is stuck to the inline-start edge of its container.

`inline-end`

The container is stuck to the inline-end edge of its container.

To evaluate a container with a non-`none` `stuck` scroll-state query, it must have `position: sticky` set on it, and be inside a scroll container. If the test passes, the rules inside the `@container` block are applied to descendants of the `position: sticky` container.

It is possible for two values from adjacent axes to match at the same time:

```
@container scroll-state((stuck: top) and (stuck: left)) {
  /* … */
}
```

However, two values from opposite edges will never match at the same time:

```
@container scroll-state((stuck: left) and (stuck: right)) {
  /* … */
}
```

To evaluate whether a container is stuck, without being concerned about the direction, use the `none` value with the `not` operator:

```
@container not scroll-state(stuck: none) {
  /* … */
}
```

Anchored container descriptors

Anchored container descriptors are specified inside the `<container-condition>` as an argument for the `anchored()` function, for example:

```
@container anchored(fallback: top) {
  /* … */
}
@container anchored(fallback: flip-block flip-inline) {
  /* … */
}
@container anchored(fallback: --custom-fallback) {
```

```
  /* … */
}
```

`fallback`

Queries whether a specific position-try fallback is currently active on an anchor-positioned container, as specified via the `position-try-fallbacks` property. Valid `fallback` values include any component value that is valid for inclusion in a `position-try-fallbacks` property value.

If the `fallback` value named in the test is currently active on the anchor-positioned container, the test passes, and the rules inside the `@container` block are applied to descendants of the anchor-positioned container.

Formal syntax

```
@container =
  @container <container-condition># { <rule-list> }

<container-condition> =
  [ <container-name>? <container-query>? ]!

<container-name> =
  <custom-ident>

<container-query> =
  not <query-in-parens>                              |
  <query-in-parens> [ [ and <query-in-parens> ]* | [ or <query-in-parens> ]* ]

<query-in-parens> =
  ( <container-query> )                 |
  ( <size-feature> )                    |
  style( <style-query> )                |
  scroll-state( <scroll-state-query> )  |
  <general-enclosed>

<style-query> =
  not <style-in-parens>                              |
  <style-in-parens> [ [ and <style-in-parens> ]* | [ or <style-in-parens> ]* ]  |
  <style-feature>

<scroll-state-query> =
  not <scroll-state-in-parens>                       |
  <scroll-state-in-parens> [ [ and <scroll-state-in-parens> ]* | [ or <scroll-state-in-parens> ]* ]  |
  <scroll-state-feature>

<general-enclosed> =
  [ <function-token> <any-value>? ) ]  |
  [ ( <any-value>? ) ]

<style-in-parens> =
  ( <style-query> )    |
  ( <style-feature> )  |
  <general-enclosed>

<style-feature> =
  <style-feature-plain>    |
  <style-feature-boolean>  |
  <style-range>

<scroll-state-in-parens> =
  ( <scroll-state-query> )    |
  ( <scroll-state-feature> )  |
  <general-enclosed>

<style-feature-plain> =
  <style-feature-name> : <style-feature-value>

<style-feature-boolean> =
  <style-feature-name>

<style-range> =
  <style-range-value> <mf-comparison> <style-range-value>  |
  <style-range-value> <mf-lt> <style-range-value> <mf-lt> <style-range-value>  |
  <style-range-value> <mf-gt> <style-range-value> <mf-gt> <style-range-value>

<style-range-value> =
  <custom-property-name>  |
  <style-feature-value>

<mf-comparison> =
  <mf-lt>  |
  <mf-gt>  |
  <mf-eq>

<mf-lt> =
  '<' '='?

<mf-gt> =
  '>' '='?

<mf-eq> =
  '='
```

This syntax reflects the latest standard as per CSS Conditional Rules Module Level 5, Media Queries Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting styles based on a container's size

Consider the following example of a card component with a title and some text:

```
<div class="post">
  <div class="card">
    <h2>Card title</h2>
    <p>Card content</p>
  </div>
</div>
```

A container context can be created using the `container-type` property, in this case using the `inline-size` value on the `.post` class. You can then use the `@container` at-rule to apply styles to the element with the `.card` class in a container that's narrower than `650px`.

```
const post = document.querySelector(".post");
const span = document.createElement("span");
span.textContent = `.post width: ${post.clientWidth}px`;
post.parentNode.insertBefore(span, post.nextSibling);
// update on resize
window.addEventListener("resize", () => {
  span.textContent = `.post width: ${post.clientWidth}px`;
});
```

```
span {
  display: block;
  text-align: center;
}
.card {
  margin: 10px;
  border: 2px dotted;
  font-size: 1.5em;
}
.post {
  border: 2px solid;
}
```

```
/* A container context based on inline size */
.post {
  container-type: inline-size;
}

/* Apply styles if the container is narrower than 650px */
@container (width < 650px) {
  .card {
    width: 50%;
    background-color: lightgray;
    font-size: 1em;
  }
}
```

Creating named container contexts

Given the following HTML example which is a card component with a title and some text:

```
<div class="post">
  <div class="card">
    <h2>Card title</h2>
    <p>Card content</p>
  </div>
</div>
```

First, create a container context using the `container-type` and `container-name` properties. The shorthand syntax for this declaration is described in the `container` page.

```
.post {
  container-type: inline-size;
  container-name: summary;
}
```

Next, target that container by adding the name to the container query:

```
@container summary (width >= 400px) {
  .card {
    font-size: 1.5em;
  }
}
```

Nested container queries

It's not possible to target multiple containers in a single container query. It is possible to nest container queries which has the same effect.

The following query evaluates to true and applies the declared style if the container named `summary` is wider than `400px` and has an ancestor container wider than `800px`:

```
@container summary (width > 400px) {
  @container (width > 800px) {
    /* <stylesheet> */
  }
}
```

Container style queries

Container queries can also evaluate the computed style of the container element. A *container style query* is a `@container` query that uses one or more `style()` functional notations. The boolean syntax and logic combining style features into a style query is the same as for CSS feature queries.

```
@container style(<style-feature>),
    not style(<style-feature>),
    style(<style-feature>) and style(<style-feature>),
    style(<style-feature>) or style(<style-feature>) {
  /* <stylesheet> */
}
```

The parameter of each `style()` is a single `<style-feature>`. A **`<style-feature>`** can be a valid CSS declaration (the **plain** form), a CSS property or `<custom-property-name>` on its own (the **boolean** form), or a range comparison (the **range** form).

```
@container style(--themeBackground),
    not style(background-color: red),
    style(color: green) and style(background-color: transparent),
    style(--themeColor: blue) or style(--themeColor: purple) {
```

```
  /* <stylesheet> */
}
```

A style feature without a value evaluates to true if the computed value is different from the initial value for the given property.

If the `<style-feature>` passed as the `style()` function's argument is a declaration, the style query evaluates to true if the declaration's value is the same as the computed value of that property for the container being queried. Otherwise, it resolves to false.

The following container query checks if the computed value of the container element's `--accent-color` is `blue`:

```
@container style(--accent-color: blue) {
  /* <stylesheet> */
}
```

> **Note:** If a custom property has a value of `blue`, the equivalent hexadecimal code `#0000ff` will not match unless the property has been defined as a color with `@property` so the browser can properly compare computed values.

Style features that query a shorthand property are true if the computed values match for each of its longhand properties, and false otherwise. For example, `@container style(border: 2px solid red)` will resolve to true if all 12 longhand properties (`border-bottom-style`, etc.) that make up that shorthand are true.

Note that `!important` is allowed in style queries but is ignored.

```
/* !important is valid but has no effect */
@container style(--themeColor: purple !important) {
  /* <stylesheet> */
}
```

The global `revert` and `revert-layer` are invalid as values in a `<style-feature>` and cause the container style query to be false.

Range syntax

In addition to the plain `<style-feature-name>: <value>` form described above, a `<style-feature>` can be written as a **range** comparison using `=`, `<`, `<=`, `>`, or `>=`. Range syntax enables **numeric** comparisons that the plain form can't, such as `style(--columns >= 3)` or `style(--gap = 1rem)`. It compares the resolved values of both sides numerically.

To evaluate a range, the browser:

1. Resolves each side (custom property names are looked up as if used with `var()`).
2. Parses each side as a `<number>`, `<percentage>`, `<length>`, `<angle>`, `<time>`, `<frequency>`, or `<resolution>`. If either side can't be parsed as one of those types, or the two sides don't have the same type, the query is false.
3. Computes each side (evaluating any `calc()` expressions) and performs the numeric comparison.

This means range syntax can't be used to compare keyword-like values: `style(--theme = dark)` is always false because `dark` isn't a numeric type. Use the plain syntax for those, for example `style(--theme: dark)`.

Either side of a range can be a custom property name, a `var()` reference, a literal value, or a `calc()` expression, in either order:

```
@container style(3 = --n) {
  /* … */
}
@container style(var(--n) = 3) {
  /* … */
}
@container style(calc(6/2) = var(--n)) {
  /* … */
}
```

A range can also take a three-value form, with both comparators pointing the same way, to test whether a value falls within an interval:

```
@container style(0 < --n < 10) {
  /* true when --n is greater than 0 and less than 10 */
}
@container style(100px > --width > 50px) {
  /* true when --width is less than 100px and greater than 50px */
}
```

In other words, `style(0 < --n < 10)` is equivalent to `style(0 < --n) and style(--n < 10)`. The middle value is tested against both bounds, rather than being chained left-to-right.

> **Note:** Plain and range syntax behave differently even when they look similar. Given `--n: calc(6/2)`, the query `style(--n: 3)` is **false** because the plain form compares the property's computed value (`calc(6/2)`) directly against `3`. The equivalent range query `style(--n = 3)` is **true** because the range form computes both sides numerically before comparing. See Plain versus range syntax in style queries in the container style queries guide for more details.

Scroll-state queries

@counter-style CSS at-rule

The **`@counter-style`** CSS at-rule lets you extend predefined list styles and define your own counter styles that are not part of the predefined set of styles. The `@counter-style` rule contains descriptors defining how the counter value is converted into a string representation.

While CSS provides many useful predefined counter styles, the `@counter-style` at-rule offers an open-ended method for creating counters. This at-rule caters to the needs of worldwide typography by allowing authors to define their own counter styles when the predefined styles don't fit their requirements.

Syntax

```
@counter-style thumbs {
  system: cyclic;
  symbols: "\1F44D";
  suffix: " ";
}
```

The `@counter-style` at-rule is identified by a counter style name, and the style of the named counter can be fine-tuned using a `<declaration-list>` consisting of one or more descriptors and their values.

Counter style name

`<counter-style-name>`

Provides a name for your counter style. It is specified as a case-sensitive `<custom-ident>` without quotes. The value should not be equal to `none`. Like all custom identifiers, the value of your counter style can't be a CSS-wide keyword. Avoid other enumerated CSS property values, including values of list and counter style properties. The name of your counter can't be the case-insensitive `list-style-type` property values of `decimal`, `disc`, `square`, `circle`, `disclosure-open`, and `disclosure-closed`.

> **Note:** The non-overridable counter style names `decimal`, `disc`, `square`, `circle`, `disclosure-open`, and `disclosure-closed` cannot be used as the name of a custom counter. However, they are valid in other contexts where the `<counter-style-name>` data type is expected, such as in `system: extends <counter-style-name>`.

Descriptors

`system`

Specifies the algorithm to be used for converting the integer value of a counter to a string representation. If the value is `cyclic`, `numeric`, `alphabetic`, `symbolic`, or `fixed`, the `symbols` descriptor must also be specified. If the value is `additive`, the `additive-symbols` descriptor must also be specified.

`symbols`

Specifies the symbols that are to be used for the marker representations. Symbols can contain strings, images, or custom identifiers. This descriptor is required if the `system` descriptor is set to `cyclic`, `numeric`, `alphabetic`, `symbolic`, or `fixed`.

`additive-symbols`

Defines the *additive tuples* for additive systems. While the symbols specified in the `symbols` descriptor are used for constructing marker representation by most algorithms, additive counter systems, such as Roman numerals, consist of a series of weighted symbols. The descriptors is a list of counter symbol along with their non-negative integer weights, listed by weight in descending order. This descriptor is required if the `system` descriptor is set to `additive`.

`negative`

Specifies to symbols to be appended or prepended to the counter representation if the value is negative.

`prefix`

Specifies a symbol that should be prepended to the marker representation. Prefixes are added to the representation in the final stage, before any characters added to negative counter values by the `negative` descriptor.

`suffix`

Specifies, similar to the prefix descriptor, a symbol that is appended to the marker representation. Suffixes come after the marker representation, including after any characters added to negative counter values by the `negative` descriptor.

`range`

Defines the range of values over which the counter style is applicable. If a counter style is used to represent a counter value outside of the ranges defined by this descriptor, the counter style will drop back to its `fallback` style.

`pad`

Is used when you need the marker representations to be of a minimum length. For example if you want the counters to start at 01 and go through 02, 03, 04, etc., then the `pad` descriptor is to be used. For representations larger than the specified `pad` value, the marker is constructed as normal.

`speak-as`

Describes how speech synthesizers, such as screen readers, should announce the counter style. For example, the value of the list item marker can be read out as numbers or alphabets for ordered lists or as audio cues for unordered lists, based on the value of this descriptor.

`fallback`

Specifies the counter name of the system to fall back to if either the specified system is unable to construct the representation of a counter value or if the counter value is outside the specified `range`. If the fallback counter also fails to represent the value, then that counter's fallback is used, if one is specified. If there are either no fallback counters described or if the chain of fallback systems are unable to represent a counter value, then it will ultimately fall back to the `decimal` style.

Formal syntax

```
@counter-style =
  @counter-style <counter-style-name> { <declaration-list> }

<counter-style-name> =
  <custom-ident>
```

This syntax reflects the latest standard as per CSS Counter Styles Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Specifying symbols with counter-style

```
@counter-style circled-alpha {
  system: fixed;
```

```
  symbols: Ⓐ Ⓑ Ⓒ Ⓓ Ⓔ Ⓕ Ⓖ Ⓗ Ⓘ Ⓙ Ⓚ Ⓛ Ⓜ Ⓝ Ⓞ Ⓟ Ⓠ Ⓡ Ⓢ Ⓣ Ⓤ Ⓥ Ⓦ Ⓧ Ⓨ Ⓩ;
  suffix: " ";
}
```

The above counter style rule can be applied to lists like this:

```
.items {
  list-style: circled-alpha;
}
```

The above code produces the following result:

```
<ol class="items">
  <li>one</li>
  <li>two</li>
  <li>three</li>
  <li>four</li>
  <li>five</li>
</ol>
<p>...</p>
<ol class="items" start="25">
  <li>twenty-five</li>
  <li>twenty-six</li>
  <li>twenty-seven</li>
  <li>twenty-eight</li>
</ol>
```

See more examples on the demo page (code).

Ready-made counter styles

Find a collection of over 100 `counter-style` code snippets in the Ready-made Counter Styles document. This document provides counters that meet the needs of languages and cultures around the world.

The Counter styles converter pulls from this list to test and create copy and paste code for counter styles.

additive-symbols CSS at-rule descriptor

The **`additive-symbols`** descriptor of the `@counter-style` at-rule is used to specify counter symbols when the `@counter-style` `system` descriptor value is set as `additive`. The additive system is used to construct sign-value numbering systems such as Roman numerals.

Syntax

```
/* Single tuple */
additive-symbols: 3 "*";

/* Comma-separated list of tuples */
additive-symbols:
  3 "0",
  2 "\2E\20",
  1 url("symbol.png");

/* Binary counter */
additive-symbols:
  2 "1",
  1 "0";

/* Etruscan (a civilization in ancient Italy) counter  */
additive-symbols:
  100 "*",
  50 "↑",
  10 "X",
  5 "Λ",
  1 "|";
```

Values

The descriptor accepts a comma-separated list of *additive tuples* with each tuple consisting of the following two values separated by a space:

`<integer>`

A non-negative integer values specifying the integer weight of the associated symbol value of the tuple.

`<symbol>`

Specifies the counter symbol to be used for the weight value defined by the associated `<integer>` weight value of the tuple.

> **Note:** The additive tuples must be specified in order of descending weight; otherwise, the descriptor declaration isn't valid and is ignored.

Description

The `additive-symbols` descriptor defines a comma-separated list of *additive tuples*. Each *additive tuple* contains a space-separated non-negative integer and counter symbol. To be valid, the list must be in the descending order of integer. The integer and symbol are concatenated together to form the counter symbol.

When the `system` descriptor value is `cyclic`, `numeric`, `alphabetic`, `symbolic`, or `fixed`, use the `symbols()` descriptor instead of `additive-symbols`.

Formal definition

Related at-rule	`@counter-style`

Initial value	`n/a (required)`
Computed value	as specified

Formal syntax

```
additive-symbols =
  [ <integer [0,∞]> && <symbol> ]#

<integer> =
  <number-token>

<symbol> =
  <string>        |
  <image>         |
  <custom-ident>

<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
  <gradient>

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-set()> =
  image-set( <image-set-option># )

<cross-fade()> =
  cross-fade( <cf-image># )

<element()> =
  element( <id-selector> )

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Counter Styles Level 3, CSS Images Module Level 4, CSS Images Module Level 5, CSS Values and Units Module Level 4, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Specifying additive symbols

HTML

In this example, `system: additive` along with the `additive-symbols` descriptor values specify how numbers should be represented as Roman numerals. The value of each `<li>` element in the list is converted to a Roman numeral according to the rules defined in `@counter-style`.

```
<ul>
  <li>One</li>
  <li>Two</li>
  <li>Three</li>
  <li>Four</li>
  <li>Five</li>
  <li value="109">109</li>
  <li>110</li>
</ul>
```

CSS

```
@counter-style uppercase-roman {
  system: additive;
  additive-symbols:
    1000 M,
    900 CM,
    500 D,
    400 CD,
    100 C,
    90 XC,
    50 L,
    40 XL,
    10 X,
    9 IX,
    5 V,
    4 IV,
    1 I;
}

ul {
  list-style: uppercase-roman;
  padding-left: 5em;
}
```

Result

For the list item with the value of `109`, the numeral `C` represents `100`, and `IX` represents `9`. This generates `CIX` counter for the list item `109`. The next list item automatically gets a value of `110`. The roman numeral `CX` is derived from `C` for `100` and `X` for `10`.

fallback CSS at-rule descriptor

The **`fallback`** descriptor of the `@counter-style` at-rule can be used to specify a counter style to fall back to if the counter style being defined cannot create a marker representation for a particular counter value.

Syntax

```
/* Keyword values */
fallback: lower-alpha;
fallback: custom-gangnam-style;
```

Value

The descriptor takes a single `<counter-style-name>` as its value:

`<counter-style-name>`

> Provides the name of the counter style to be used as the fallback, which is either the case-sensitive `<custom-ident>` of a custom CSS counter style (without quotes) or a case-insensitive `list-style-type` property value such as `decimal`, `disc`, and so on.

If omitted, the counter fallback defaults to `decimal`.

Description

The counter style provided as the value of the `fallback` descriptor is used when a `range` descriptor is specified for a counter style; the `fallback` style is used to represent all the values that fall outside the range. The `fallback` style is also used when the `fixed` `system` is used and there are not enough symbols to cover all the list items; the `fallback` style is used to represent all the values beyond the scope of the fixed system. In both these cases, and any other time the defined counter cannot create a specific counter value, the `fallback` style is used.

If the specified fallback style is also unable to construct a representation, then the `fallback` value of that fallback counter is used. If that fallback style's fallback is also unable to construct a representation, then that fallback's fallback is used. This falling back continues until a fallback is found that can construct the counter-representation. If no fallback `fallback` value is able to construct a representation—if a fallback style doesn't have a `fallback` value set, or if a `fallback` value is not specified or invalid—the `fallback` defaults to `decimal`.

Formal definition

Related at-rule	`@counter-style`
Initial value	`decimal`
Computed value	as specified

Formal syntax

```
fallback =
  <counter-style-name>

<counter-style-name> =
  <custom-ident>
```

This syntax reflects the latest standard as per CSS Counter Styles Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Specifying a fallback counter style

HTML

```
<ul class="list">
  <li>One</li>
  <li>Two</li>
  <li>Three</li>
  <li>Four</li>
  <li>Five</li>
</ul>
```

CSS

```
@counter-style fallback-example {
  system: fixed;
  symbols: "\24B6" "\24B7" "\24B8";
  fallback: upper-alpha;
}

.list {
  list-style: fallback-example;
}
```

Result

See also

- Other `@counter-style` descriptors: `system`, `symbols`, `additive-symbols`, `negative`, `prefix`, `suffix`, `range`, `pad`, and `speak-as`
- `list-style`, `list-style-image`, `list-style-position`
- `symbols()`: the functional notation for creating anonymous counter styles

negative CSS at-rule descriptor

The **`negative`** descriptor of the `@counter-style` at-rule lets you define how negative counter values are represented when defining custom counter styles. The value of the `negative` descriptor defines the symbols to be added before and after the counter representation when the counter's value is negative.

Syntax

```
/* One <symbol> value */
negative: "--"; /* Adds '--' before if counter value is negative */

/* Two <symbol> values */
negative: "(" ")"; /* Adds '(- before and ')' after if counter value is negative */
```

Values

The `negative` descriptor accepts up to two `<symbol>` values.

`<symbol>`

> If only one value is specified, it is added before the counter representation when the counter is negative. If two values are specified, the first one is added before and the second one is added after the counter representation when the counter is negative.

Description

If the counter value is negative, the specified `<symbol>` for the `negative` descriptor is added before the counter representation, replacing the default `-` for negative values. The second `<symbol>`, if specified, is added after the counter representation.

The `negative` descriptor is relevant in two cases: if counter styles have the `system` value of `symbolic`, `alphabetic`, `numeric`, and `additive` and the count is negative; and if `system` value is `extends` and the extended counter style itself uses a negative sign. For systems that don't support negative counter values, specifying the `negative` descriptor has no effect and is ignored.

Formal definition

Related at-rule	`@counter-style`
Initial value	`"-" hyphen-minus`
Computed value	as specified

Formal syntax

```
negative =
  <symbol> <symbol>?

<symbol> =
  <string>        |
  <image>         |
  <custom-ident>

Examples

Rendering negative counters

This example extends the `decimal` list style. The `negative` descriptor is used to add `(-` and `)` before and after negative counter values.

HTML

```
<ol start="-3">
  <li>Negative three</li>
  <li>Negative two</li>
  <li>Negative one</li>
  <li>Zero</li>
  <li>One</li>
</ol>
```

CSS

```
@counter-style neg {
  system: extends decimal;
```

```
  negative: "(-" ")";
  suffix: ": ";
}

ol {
  list-style: neg;
}
```

Result

The prefix and suffix listed as the value of the `negative` descriptor are only added to the marker when the counter value is less than zero.

pad CSS at-rule descriptor

The **`pad`** descriptor of the `@counter-style` at-rule is used to set a minimum length for marker representations.

Syntax

```
pad: 3 "0";
pad: "+" 5;
```

Values

The descriptor accepts the following two values, which are separated by a space and can be specified in any order:

`<integer>`

Specifies the minimum length that all marker representations must reach. The value must be non-negative. In the case of the `pad` descriptor, this value is also known as the *pad length*.

`<symbol>`

Specifies the symbol to be used for padding if the minimum length defined by the `<integer>` is not reached. In the case of the `pad` descriptor, this value is also known as the *padding symbol*.

Description

Use the `pad` descriptor when you need the marker representations to be of a minimum length. If a marker representation is shorter than the specified pad length, then the marker representation will be padded with the specified padding symbol. Marker representations longer than the pad length are displayed without any additional padding.

The `pad` descriptor takes an `<integer>` for the minimum marker length and a `<symbol>` for the padding. A common use case of the `pad` descriptor is when you need a list to start numbering from `01` and go through `02`, `03`, `04`, and so on, instead of just `1`, `2`, `3`, and `4`. By specifying the `pad` descriptor as `pad: 2 "0"` in this case, the browser ensures to make the counter at least two characters long and adds a padding with `0` to reach the minimum two-character length where needed. Counters that are already two or more characters long in this example will be displayed normally, without padding.

Formal definition

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Counter Styles Level 3, CSS Images Module Level 4, CSS Images Module Level 5, CSS Values and Units Module Level 4, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Padding a counter

This example extends the `decimal` `system` to create a counter that is at least three characters long, padding shorter counters with `0` to reach that minimum length. A `suffix` descriptor has been added to make the output more legible.

HTML

```
<ul>
  <li>One</li>
  <li>Two</li>
  <li>Three</li>
  <li value="40">Forty</li>
  <li>Forty-one</li>
  <li value="200">Two hundred</li>
  <li value="3000">Three thousand</li>
  <li>and so on</li>
</ul>
```

CSS

```
@counter-style pad-example {
  system: extends decimal;
  suffix: ": ";
  pad: 3 "0";
}

ul {
  list-style: pad-example;
}
```

prefix CSS at-rule descriptor

The `@counter-style` rule's **`prefix`** descriptor specifies content that will be added to the beginning of the counter's marker representation.

When the counter value is negative, the `prefix` comes before the negative sign and any other `<symbol>`s added by the `negative` descriptor.

Syntax

```
/* <symbol> value: string, image, or identifier */
prefix: "»";
prefix: "Page ";
prefix: url("bullet.png");
```

Values

The **`prefix`** descriptor takes as its value a single `<symbol>`:

`<symbol>`

> Specifies a `<symbol>` — a `<string>`, `<image>`, or `<custom-ident>` — that is prepended to the marker representation.

Formal definition

Related at-rule	`@counter-style`
Initial value	"" (the empty string)
Computed value	as specified

Formal syntax

```
prefix =
  <symbol>

<symbol> =
  <string>        |
  <image>         |
  <custom-ident>

<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
  <gradient>

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )
```

```
<image-set()> =
  image-set( <image-set-option># )

<cross-fade()> =
  cross-fade( <cf-image># )

<element()> =
  element( <id-selector> )

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Counter Styles Level 3, CSS Images Module Level 4, CSS Images Module Level 5, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Adding a prefix to a counter

In this example, each counter number is prefixed by "Book " (with a space) and followed by a colon (`:`). The colon is added with the `suffix` descriptor.

HTML

```
<ol class="books">
  <li>Flamer, by Mike Curato</li>
  <li>Gender Queer: A Memoir, by Maia Kobabe</li>
  <li>Tricks, by Ellen Hopkins</li>
  <li>The Handmaid's Tale: The Graphic Novel, by Margaret Atwood</li>
  <li>Crank, by Ellen Hopkins</li>
</ol>
```

CSS

```
@counter-style books {
  system: numeric;
  symbols: "0" "1" "2" "3" "4" "5" "6" "7" "8" "9";
  prefix: "Book ";
  suffix: ": ";
}

.books {
  list-style: books;
  padding-left: 15ch;
}
```

range CSS at-rule descriptor

The **`range`** descriptor lets the author specify one or more ranges of counter values for which the style is applied when defining custom counter styles with the `@counter-style` at-rule. When the `range` descriptor is included, the defined counter will only be used for values in the set ranges. If the counter value is outside the specified range, the fallback style will be used to construct the representation of that marker.

Syntax

```
/* Keyword value */
range: auto;

/* Range values */
range: 2 5;
range: infinite 10;
range: 6 infinite;
range: infinite infinite;

/* Multiple range values */
range:
  2 5,
  8 10;
range:
  infinite 6,
  10 infinite;
```

Values

The value is a comma-separated list of ranges each including a lower and upper limit or the keyword `auto`.

`auto`

The entire set of numbers representable by the counter `system`. Those range values depends on the counter system:

- For `cyclic`, `numeric`, and `fixed` systems, the range is negative `infinity` to positive `infinity`.
- For `alphabetic` and `symbolic` systems, the range is `1` to positive `infinity`.
- For `additive` systems, the range is `0` to `positive` infinity.
- When using `extend` to extend a system, the range is whatever `auto` would produce for the system being extended, including extensions of complex predefined styles, such as some Japanese, Korean, Chinese, and Ethiopian counter styles.

```
[ [ <integer> | infinite ]{2} ]#
```

Each range within the comma separated list of ranges includes two values, each being either an `<integer>` or the keyword `infinite`. If `infinite` is used as the first value in a range, it represents negative infinity; if it is used as the second value, it represents positive infinity. The first value of each range is the lower bound for the range and the second value is the upper bound, inclusive. If the lower bound of any range in the list is higher than the upper bound, the entire `range` descriptor is invalid and will be ignored.

Description

The value of the `range` descriptor can be either `auto` or a comma separated list of lower and upper bound ranges specified using negative or positive integers or the keyword `infinite`.

Understanding <code>auto</code>

When the value is set to `auto`, the range is the default range for the counter system. If the `system` is `cyclic`, `numeric`, or `fixed`, the range will be from negative infinity to positive infinity. If the `system` is `alphabetic` or `symbolic`, the range will be from `1` to positive `infinity`. For `system: additive`, `auto` results in the range `0` to positive `infinity`.

When extending a counter, if `range` is set to `auto`, the range value will be the range of the `system` of the counter that is being extended, not the `range` value, if any, of that counter. For example, if counter "B" has the `system: extends A` set, with counter being an `alphabetic` counter, setting `range: auto` on "B" sets the range of "B" from `1` to `infinity`. This is the range of the `alphabetic` system, not necessarily the range set in the "A" counter style definition. With `range: auto` set on "B", the `range` is set to the default range of the `alphabetic` system, not the `range` value set in counter A's descriptor list.

<code>infinite</code> explained

When range is specified as integers (versus `auto`), the value `infinite` can be used to denote infinity. If *infinite* is specified as the first value in a range, then it is interpreted as negative infinity. If used as the upper bound, the second value in the range pair, it is taken as positive infinity.

List of ranges

The value of `range` is either `auto`, discussed above, or a comma separated list of one or more ranges. The range of the counter style is the union of all the ranges defined in the list.

Each range in the list of ranges takes two values. Those values are either an `<integer>` or the keyword `infinite`. The first value is the *lower bound*, inclusive. The second value is the *upper bound*, inclusive. For two integer values, the lower value must come first. If the lower bound of any range in the list is higher than the upper bound, the entire `range` descriptor is invalid and will be ignored. The `infinite` keyword will not invalidate the range, because the position of `infinite` determines its value; either negative or positive infinity based on whether it's the lower bound or upper bound, respectively.

Formal definition

Related at-rule	`@counter-style`
Initial value	`auto`
Computed value	as specified

Formal syntax

```
range =
  [ [ <integer> | infinite ]{2} ]#  |
  auto

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Counter Styles Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting counter style over a range

HTML

```
<ul class="list">
  <li>One</li>
  <li>Two</li>
  <li>Three</li>
  <li>Four</li>
  <li>Five</li>
  <li>Six</li>
  <li>Seven</li>
  <li>Eight</li>
  <li>Nine</li>
  <li>Ten</li>
</ul>
```

CSS

```
@counter-style range-multi-example {
  system: cyclic;
  symbols: "\25A0" "\25A1";
  range:
    2 4,
    7 9;
}

.list {
  list-style: range-multi-example;
}
```

Result

The first range is the list of ranges includes 2, 3, and 4. The second includes 7, 8, and 9. The range is the union of these two ranges, or 2, 3, 4, 7, 8, and 9.

speak-as CSS at-rule descriptor

The **speak-as** descriptor specifies how a counter symbol constructed with a given `@counter-style` will be represented in the spoken form. For example, an author can specify a counter symbol to be either spoken as its numerical value or just represented with an audio cue.

Syntax

```
/* Keyword values */
speak-as: auto;
speak-as: bullets;
speak-as: numbers;
speak-as: words;
speak-as: spell-out;

/* @counter-style name value */
speak-as: <counter-style-name>;
```

Values

`auto`

If the value of `speak-as` is specified as `auto`, then the effective value of `speak-as` will be determined based on the value of the `system` descriptor:

- If the value of `system` is `alphabetic`, the effective value of `speak-as` will be `spell-out`.
- If `system` is `cyclic`, the effective value of `speak-as` will be `bullets`.
- If `system` is `extends`, the value of `speak-as` will be the same as if `speak-as: auto` is specified on the extended style.
- For all other cases, specifying `auto` has the same effect as specifying `speak-as: numbers`.

`bullets`

A phrase or an audio cue defined by the user agent for representing an unordered list item will be read out.

`numbers`

The numerical value of the counter will be read out in the document language.

`words`

The user agent will generate a counter value as normal and read it out as a word in the document language.

`spell-out`

The user agent will generate a counter representation as normal and would read it out letter by letter. If the user agent doesn't know how to read out a particular counter symbol, the user agent might read it out as if the value of `speak-as` was `numbers`.

`<counter-style-name>`

The name of another counter style, specified as a `<custom-ident>`. If included, the counter will be spoken out in the form specified in that counter style, kind of like specifying the `fallback` descriptor. If the specified style does not exist, `speak-as` defaults to `auto`.

Accessibility

Assistive technology support is very limited for the `speak-as` property. Do not rely on it to convey information critical to understanding the page's purpose.

Let's Talk About Speech CSS | CSS Tricks (2017)

Formal definition

Related at-rule	`@counter-style`
Initial value	`auto`
Computed value	as specified

Formal syntax

```
speak-as =
  auto                |
  bullets             |
  numbers             |
  words               |
  spell-out           |
  <counter-style-name>

<counter-style-name> =
  <custom-ident>
```

This syntax reflects the latest standard as per CSS Counter Styles Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting the spoken form for a counter

In this example, the counter system is fixed with unintelligible symbols used for the visual markers. However, the `speak-as` descriptor is used to set the list item markers as numbers in the accessibility tree. When supported, numbers rather than visual markers will be read out by screen readers.

To experience the result of the `speak-as` descriptor, use assistive technology such as VoiceOver or another screen reader or view the accessibility panel in the developer tools of a browser that supports `speak-as`.

HTML

```
<ul class="list">
  <li>I had one apple</li>
  <li>I ate two bananas</li>
  <li>I devoured three oranges</li>
  <li>I am not hungry for dinner</li>
  <li>But I'll have five scoops of ice cream for dessert</li>
</ul>
```

CSS

```
@counter-style speak-as-example {
  system: fixed;
  symbols: 🅐 🅑 🅒 🅓 🅔;
  suffix: " ";
  speak-as: numbers;
}

.list {
  list-style: speak-as-example;
}
```

Result

- CSS lists and counters module

suffix CSS at-rule descriptor

The **`suffix`** descriptor of the `@counter-style` rule specifies content that will be added to the end of the marker representation.

Syntax

```
/* <symbol> value: string, image, or identifier  */
suffix: "";
suffix: ") ";
suffix: url("bullet.png");
```

Values

The **`suffix`** descriptor takes as its value a single `<symbol>`:

`<symbol>`

Specifies a `<symbol>` that is appended to the marker representation. It may be a `<string>`, `<image>`, or `<custom-ident>`.

Formal definition

Related at-rule	`@counter-style`
Initial value	". " (full stop followed by a space)
Computed value	as specified

Formal syntax

```
suffix =
  <symbol>

<symbol> =
  <string>        |
  <image>         |
  <custom-ident>

<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
  <gradient>

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-set()> =
  image-set( <image-set-option># )

<cross-fade()> =
  cross-fade( <cf-image># )

<element()> =
  element( <id-selector> )

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Counter Styles Level 3, CSS Images Module Level 4, CSS Images Module Level 5, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting a suffix for a counter

HTML

```
<ul class="choices">
  <li>One</li>
  <li>Two</li>
  <li>Three</li>
  <li>None of the above</li>
</ul>
```

CSS

```
@counter-style options {
  system: fixed;
  symbols: A B C D;
  suffix: ") ";
}

.choices {
  list-style: options;
}
```

Result

- `symbols()`: the functional notation for creating anonymous counter styles
- CSS counter styles module
- CSS lists and counters module

symbols CSS at-rule descriptor

The **`symbols`** CSS descriptor of the `@counter-style` at-rule is used to specify the symbols for creating counter representations in the specified counter system. Specifying this descriptor is mandatory when the value of the `system` descriptor is `cyclic`, `numeric`, `alphabetic`, `symbolic`, or `fixed`.

Syntax

```
symbols: A B C D E;
symbols: "\24B6" "\24B7" "\24B8" D E;
symbols: "0" "1" "2" "4" "5" "6" "7" "8" "9";
symbols: url("one.svg") url("two.svg") url("three.svg");
symbols: indic-numbers;
```

Values

The `symbols` descriptor is specified as a list of one or more space-separated `<symbol>` values.

`<symbol>`

Specifies the symbol to use within the counter system. Each symbol in the list can be either a `<string>`, an `<image>`, or a `<custom-ident>`. The `<image>` value can, in turn, be specified as a `<url>` or `<gradient>`.

> **Note:** When using an identifier for a symbol, note that ASCII non-letters such as `*`, `"`, and `\` are not considered identifiers. They must be either quoted as a string or escaped.

Description

A symbol can be a string, image, or identifier. It is used within the `@counter-style` at-rule.

When the value of the `system` descriptor is `cyclic`, `numeric`, `alphabetic`, `symbolic`, or `fixed`, the `symbols` descriptor must be specified. For the `additive` system, use the `additive-symbols` descriptor instead to specify the symbols.

While a space between quoted symbols is not required, it makes CSS more readable. To use a quote as a symbol, either escape the quote character or enclose the character within different quotes, such as `"'"`.

When defining symbols with identifiers instead of strings, be sure to use identifier syntax rules. For example, as noted above, ASCII non-letters such as `*` are not identifiers and must be either quoted or escaped. Hex escape characters are followed by a space. This space may look like the space separating two identifiers, but it enables digits to follow hex-escaped characters. This means that two spaces must be included after a hex-escaped identifier to separate it from the next identifier. For example, it is better to use the string `"\2A 1"` instead of `\2A 1` with two spaces, as your code tools might remove double spaces. It is generally safer to quote identifiers that need to be escaped or use strings.

Formal definition

Related at-rule	`@counter-style`
Initial value	`n/a (required)`
Computed value	as specified

Formal syntax

```
symbols =
  <symbol>+

<symbol> =
  <string>        |
  <image>         |
  <custom-ident>

<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
  <gradient>

<image()> =
```

```
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-set()> =
  image-set( <image-set-option># )

<cross-fade()> =
  cross-fade( <cf-image># )

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Counter Styles Level 3, CSS Images Module Level 4, CSS Images Module Level 5, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting counter symbols

In this example, the list of values for the `symbols` descriptor include letters (`A`, `D`, `E`), a number within quotes (`"1"`), and a hex-escape identifier within quotes (`"\24B7"`) for the character Ⓑ.

HTML

```
<ul class="list">
  <li>One</li>
  <li>Two</li>
  <li>Three</li>
  <li>Four</li>
  <li>Five</li>
</ul>
```

CSS

```
@counter-style symbols-example {
  system: fixed;
  symbols: A "1" "\24B7" D E;
}

.list {
  list-style: symbols-example;
}
```

system CSS at-rule descriptor

The **`system`** descriptor specifies the algorithm to be used for converting the integer value of a counter to a string representation. It is used in a `@counter-style` to define the behavior of the defined style.

If the algorithm specified in the `system` descriptor is unable to construct the representation for a particular counter value, then that value's representation will be constructed using the fallback system provided.

Syntax

```
/* Keyword values */
system: cyclic;
system: numeric;
system: alphabetic;
system: symbolic;
system: additive;
system: fixed;

/* Other values */
system: fixed 3;
system: extends decimal;
system: extends circled-letters;
```

Values

This may take one of three forms:

- One of the keyword values `cyclic`, `numeric`, `alphabetic`, `symbolic`, `additive`, or `fixed`.
- The keyword value `fixed` along with an integer.
- The keyword value `extends` along with a `<counter-style-name>` value.

The values include:

`cyclic`

Cycles through the list of symbols provided in the `symbols` descriptor. Once the end of the list is reached, the cycle will loop back to the beginning and start over. This value is useful both for basic bullet styles with just one symbol and for styles with multiple symbols. At least one symbol must be specified in the `symbols` descriptor, otherwise the counter style is not valid.

`numeric`

Interprets the counter symbols as digits in a place-value numbering system. The numeric system is similar to the `alphabetic` system, described above. The main difference is that in the `alphabetic` system, the first counter symbol given in the `symbols` descriptor is interpreted as `1`, the next as `2`, and so on. However, in the numeric system, the first counter symbol is interpreted as 0, the next as `1`, then `2`, and so on.

At least two counter symbols must be specified in the `symbols` descriptor or the counter style is not valid.

`alphabetic`

Interprets the specified symbols as digits, to an alphabetic numbering system. If the characters `"a"` to `"z"` are specified as symbols in a counter style, with the `alphabetic` system, then the first 26 counter representations will be `"a"`, `"b"` up to `"z"`. Until this point, the behavior is the same as that of the `symbolic` system, described above. However, after `"z"`, it will continue as `"aa"`, `"ab"`, `"ac"`...

The `symbols` descriptor must contain at least two symbols or the counter style is not valid. The first counter symbol provided in the `symbols` descriptor is interpreted as `1`, the next as `2`, and so on. This system is also defined strictly over positive counter values.

`symbolic`

Cycles through the symbols provided in the `symbols` descriptor list repeatedly, doubling, tripling, and so on, the symbols on each successive pass through the list. For example, if two symbols " ▪ " and " ■ " are specified in the `symbols` descriptor, on each successive pass, they will become " ▪ ▪ " and " ■ ■ ", then " ▪ ▪ ▪ " and " ■ ■ ■ ", and so on in subsequent passes. At least one symbol must be specified in the `symbols` descriptor, otherwise the counter style is not valid. This counter system works for positive counter values only.

`additive`

Used to represent "sign-value" numbering systems, such as Roman numerals, which rather than reuse digits in different positions to obtain different values, define additional digits for larger values. The value of a number in such a system can be found out by adding the digits in the number.

An additional descriptor called `additive-symbols` must be specified with at least one *additive tuple*, or else the counter style rule will not be valid. An additive tuple is similar to a composite counter symbol, which is made up of two parts: a normal counter symbol and a non-negative integer weight. The additive tuples must be specified in the descending order of their weights or the system is invalid.

`fixed` Or `fixed <integer>`

Defines a finite set of symbols, iterating once through the list of symbols provided in the `symbols` descriptor. Once the specified symbols have been iterated through, the fallback counter style is used. This keyword value is useful in cases where the counter style values are finite. At least one symbol must be specified in the `symbols` descriptor, otherwise the counter style is not valid. The `fixed` keyword can be followed by an optional `<integer>` value. If specified, the `<integer>` value indicates the item in the list that will get the first symbol from the list of symbols. If omitted, the default value of `integer` is `1`, which gives the first item in the list the first symbol.

`extends`

Extends the algorithm of another browser- or author-defined counter style by allowing the alteration of some aspects of the extended counter style. Any unspecified descriptors and their values are inherited from the extended counter style specified. If the counter style name specified with `extends` is not yet defined, the `decimal` counter style will be extended by default.

It must not contain a `symbols` or `additive-symbols` descriptor, otherwise the counter style rule will be invalid. If one or more counter styles definitions form a cycle with their `extends` values, the browser will treat all the participating counter styles as extending from the `decimal` style.

> **Note:** The `symbols` descriptor is required when the value is `cyclic`, `numeric`, `alphabetic`, `symbolic`, or `fixed`. The `additive-symbols` descriptor is required if the `additive` value is set.

Formal definition

Related at-rule	`@counter-style`
Initial value	`symbolic`
Computed value	as specified

Formal syntax

```
system =
  cyclic                          |
  numeric                         |
  alphabetic                      |
  symbolic                        |
  additive                        |
  [ fixed <integer>? ]            |
  [ extends <counter-style-name> ]

<integer> =
  <number-token>

<counter-style-name> =
  <custom-ident>
```

This syntax reflects the latest standard as per CSS Counter Styles Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Cyclic counter

The `cyclic` value iterates through the list of symbols, repeating the list as necessary:

CSS

```
<ul>
  <li>One</li>
  <li>Two</li>
  <li>Three</li>
  <li>Four</li>
  <li>Five</li>
  <li>Six</li>
</ul>
```

```
@counter-style fisheye {
  system: cyclic;
  symbols: ◉ ⓘ;
  suffix: ": ";
}
```

```
ul {
  list-style: fisheye;
}
```

Result

Fixed counter

The `fixed` value iterates through the list of symbols only once, starting the single cycle at the list item number indicated by the `integer` value:

CSS

```
<ul>
  <li>One</li>
  <li>Two</li>
  <li>Three</li>
  <li>Four</li>
  <li>Five</li>
  <li>Six</li>
</ul>
```

```
@counter-style circled-digits {
  system: fixed 3;
  symbols: ① ② ③;
  suffix: ": ";
}

ul {
  list-style: circled-digits;
}
```

Result

Symbolic counter

The `symbolic` value loops through the list defined in the `symbols` descriptor, doubling and tripling the number of symbols for the second and third cycles through the list, respectively:

CSS

```
<ul>
  <li>One</li>
  <li>Two</li>
  <li>Three</li>
  <li>Four</li>
  <li>Five</li>
  <li>Six</li>
  <li>Seven</li>
  <li>Eight</li>
</ul>
```

```
@counter-style abc {
  system: symbolic;
  symbols: a b c;
  suffix: ". ";
}

ul {
  list-style: abc;
}
```

Result

Alphabetic counter

CSS

```
<ul>
  <li>One</li>
  <li>Two</li>
  <li>Three</li>
  <li>Four</li>
  <li>Five</li>
  <li>Six</li>
  <li>Seven</li>
  <li>Eight</li>
</ul>
```

```
@counter-style abc {
  system: alphabetic;
  symbols: a b c;
  suffix: ". ";
}

ul {
  list-style: abc;
}
```

Result

Numeric counter

The first symbol provided in the `symbols` descriptor is interpreted as `0` here.

CSS

```
<ul>
  <li>One</li>
  <li>Two</li>
  <li>Three</li>
  <li>Four</li>
```

```
  <li>Five</li>
  <li>Six</li>
  <li>Seven</li>
  <li>Eight</li>
</ul>
```

```
@counter-style abc {
  system: numeric;
  symbols: a b c;
  suffix: ". ";
}

ul {
  list-style: abc;
}
```

Result

Numeric counter with numeric symbols

As shown in the following example, if digits from `0` to `9` are specified as symbols, this counter style will render symbols same as the decimal counter style.

CSS

```
<ul class="list">
  <li>One</li>
  <li>Two</li>
  <li>Three</li>
  <li>Four</li>
  <li>Five</li>
  <li>Six</li>
  <li>Seven</li>
  <li>Eight</li>
  <li>Nine</li>
  <li>Ten</li>
</ul>
```

```
@counter-style numbers {
  system: numeric;
  symbols: "0" "1" "2" "3" "4" "5" "6" "7" "8" "9";
  suffix: ".";
}

ul {
  list-style: numbers;
}
```

Result

Additive counter

This example renders a list using Roman numerals. Notice that a `range` is specified. This is because the representation will produce correct Roman numerals only until the counter value of `3999`. Once outside of the range, the rest of the counter representations will be based on the `decimal` style, which is the fallback. If you need to represent counter values as Roman numerals, you could use either one of the predefined counter styles, `upper-roman` or `lower-roman`, rather than recreating the rule yourself.

HTML

We use the `start` attribute on the `<ol>` element to demonstrate that counting doesn't need to start at `1`. Additionally, we use the `value` attribute on the fifth `<li>` element to demonstrate that the counters you define using `@counter-style` behave just like native counters.

```
<ol start="48">
  <li>48</li>
  <li>49</li>
  <li>50</li>
  <li>51</li>
  <li value="109">109</li>
  <li>110</li>
</ol>
```

CSS

```
@counter-style uppercase-roman {
  system: additive;
  range: 1 3999;
  additive-symbols:
    1000 M,
    900 CM,
    500 D,
    400 CD,
    100 C,
    90 XC,
    50 L,
    40 XL,
    10 X,
    9 IX,
    5 V,
    4 IV,
    1 I;
}

ol {
  list-style: uppercase-roman;
  padding-left: 5em;
}
```

Result

Extending a counter

This example uses the algorithm, symbols, and other properties of `lower-alpha`, one of the several native `list-style-type` counter values, but extends it by removing the period (`'.'`) after the counter representation and enclosing the characters in parentheses, as in `(a)` and `(b)`.

HTML

```
<ul class="list">
  <li>One</li>
  <li>Two</li>
  <li>Three</li>
  <li>Four</li>
  <li>Five</li>
</ul>
```

CSS

```
@counter-style alpha-modified {
  system: extends lower-alpha;
  prefix: "(";
  suffix: ") ";
}

ul {
  list-style: alpha-modified;
}
```

Result

@custom-media CSS at-rule

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`@custom-media`** CSS at-rule defines aliases for long or complex media queries. Instead of repeating the same hardcoded `<media-query-list>` in multiple `@media` at-rules, it can be defined once in a `@custom-media` at-rule and referenced throughout the stylesheet whenever needed.

Syntax

```
@custom-media <extension-name> [<media-query-list> | true | false ];

@custom-media --media-query-name (width < 1200px);
@custom-media --media-query-name (width < 1200px), (orientation: portrait);
```

Values

`<extension-name>`

A `<dashed-ident>`; the name identifying the custom media query.

Represented value

The value aliased by the custom media query. Possible values are:

`<media-query-list>`

A comma-separated list of `<media-query>` values.

`true`

The `@custom-media` value always evaluates to `true`.

`false`

The `@custom-media` value always evaluates to `false`.

Description

When building responsive interfaces, the same media condition often needs to be repeated across multiple `@media` at-rules, sometimes across different files and teams. Duplicating media queries increases the risk of mistakes, makes refactoring harder, and creates unnecessary maintenance overhead. Any time a media query changes, every instance must be found and updated manually — a process that can be both error-prone and difficult to track in large codebases.

The `@custom-media` at-rule solves this problem by letting you define **named aliases** for media queries. Instead of repeating the full media query everywhere, you declare the media condition once as a custom media query and reference its alias throughout your stylesheets. With this in place, updating the underlying media query requires a single change in one location.

Custom media queries can be composed from others by referencing their alias names inside the media query features. This enables building more expressive, layered conditions. However, a custom media query cannot refer to itself, nor can it form part of a circular chain of references. Any circular dependency — direct or indirect — invalidates all custom media queries involved in that loop.

If multiple `@custom-media` rules define the same `<dashed-ident>` name, the rule that is in scope at the time a `@media` rule is evaluated is used. Earlier references are not retroactively updated when a later `@custom-media` rule is declared.

Evaluating media queries with logical operators

Custom media queries accept the full range of CSS logical operators — `not`, `and`, and `or` (comma-separated or using the `or` keyword).

Because a `@custom-media` value is just a normal `<media-query-list>`, you can combine, invert, or group conditions exactly as you would in a regular `@media` rule.

Using the `not` operator

The `not` operator negates an entire media condition. This is useful when you want a rule to apply only when a specific condition is `false`.

```
@custom-media --no-script not (scripting);

@media (--no-script) {
}
```

Using the `and` operator

The `and` operator lets you combine multiple conditions that must all be `true`.

```
@custom-media --medium-screen (min-width: 40em) and (max-width: 60em);

@media (--medium-screen) {
}
```

This alias only matches when the viewport is within the specified width range.

Using the `or` operator

The logical `or` operator (or its comma alias, when combining media types) creates a media query that matches if any of the listed conditions are `true`.

```
@custom-media --screen-or-print screen, print;
@custom-media --narrow-or-tall (width < 600px) or (height > 800px);

@media (--screen-or-print) {
}

@media (--narrow-or-tall) {
}
```

The `--screen-or-print` alias uses a comma to match either the `screen` or `print` media type. The `--narrow-or-tall` alias uses the `or` keyword to combine two media features, matching when the viewport is narrower than 600px, taller than 800px, or both.

Formal syntax

```
@custom-media =
  @custom-media <extension-name> [ <media-query-list> | true | false ] ;
```

This syntax reflects the latest standard as per Media Queries Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Updating multiple media queries

In this example, the `@custom-media` at-rule is used on a responsive website that uses a particular breakpoint in several places:

```
@custom-media --narrow-window (width < 32em);

@media (--narrow-window) {
}

@media (--narrow-window) and (hover) {
}

@media (--narrow-window) and (orientation: portrait) {
}
```

If the breakpoint needs to be changed, it can be updated in one place to adjust all dependent media queries across the whole site.

Grouping multiple responsive breakpoints

Here, the `@custom-media` at-rule is used to set multiple breakpoints in a single place, improving maintainability and simplifying responsive design management across multiple stylesheets:

```
/* general.css */

@custom-media --mobile-screen (width < 480px);
@custom-media --tablet-screen (width < 768px);
@custom-media --laptop-screen (width < 1024px);
@custom-media --desktop-screen (width < 1440px);
@custom-media --widescreen (width > 1441px);
```

```
/* layout.css */

.container {
  padding: 1rem;
}

@media (--mobile-screen) {
  .container {
    padding: 0.5rem;
  }
}

@media (--laptop-screen) {
  .container {
    max-width: 1200px;
  }
}

@media (--widescreen) {
  .container {
    max-width: 1400px;
    padding: 2rem;
  }
}
```

```
/* typography.css */

@media (--tablet-screen) {
  .container {
```

```
    font-size: 0.9rem;
  }
}

@media (--laptop-screen) {
  .container {
    font-size: 1rem;
  }
}

@media (--widescreen) {
  .container {
    font-size: 1.1rem;
  }
}
```

Grouping all the breakpoints in a single location makes it easier to maintain the responsive design. When a breakpoint needs adjustment, it only requires a single update to the associated `@custom-media` definition, ensuring consistency across all stylesheets.

Using <code>true</code> and <code>false</code> keywords

The following example shows how the `true` and `false` keywords can be used with `@custom-media` to create media queries that always or never match, respectively.

```
@custom-media --enabled true;
@custom-media --disabled false;

@media (--enabled) {
  /* These styles always apply */
  body {
    background-color: blue;
  }
}

@media (--disabled) {
  /* These styles never apply */
  body {
    background-color: red;
  }
}
```

This can be useful for feature flags or conditional logic within stylesheets.

Overriding existing <code>@custom-media</code> rules

In this example, one `@custom-media` rule is overridden by another `@custom-media` rule using the same `<dashed-ident>` name.

```
@custom-media --mobile-breakpoint (width < 320px);

@media (--mobile-breakpoint) {
  .container {
    grid-template-columns: 2fr 1fr;
  }
}

@custom-media --mobile-breakpoint (width < 480px);
```

When multiple `@custom-media` rules use the same name, the rule that is in scope at the time a `@media` rule is evaluated is used. Earlier references are not retroactively updated when a later `@custom-media` rule is declared.

For example, in the code above, the `--mobile-breakpoint` reference inside the `@media` rule is evaluated as `(width < 320px)`, so the `.container` rule is only applied when the viewport is less than 320px wide, even though `--mobile-breakpoint` is redefined as `(width < 480px)` later in the stylesheet.

> **Note:** The overriding behavior of `@custom-media` is still under discussion in the CSS specification and may change in the future. See the Browser compatibility section for current support status.

@document CSS at-rule

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`@document`** CSS at-rule restricts the style rules contained within it based on the URL of the document. It is designed primarily for user-defined style sheets (see userchrome.org for more information), though it can be used on author-defined style sheets, too.

Syntax

```
@document url("https://www.example.com/")
{
  h1 {
    color: green;
  }
}
```

An `@document` rule can specify one or more matching functions. If any of the functions apply to a given URL, the rule will take effect on that URL. The functions available are:

`url()`

Matches an exact URL.

`url-prefix()`

Matches if the document URL starts with the value provided.

`domain()`

Matches if the document URL is on the domain provided (or a subdomain of it).

`media-document()`

Matches the media according to the string in parameter, one of `video`, `image`, `plugin` or `all`.

`regexp()`

Matches if the document URL is matched by the regular expression provided. The expression must match the entire URL.

The values provided to the `url()`, `url-prefix()`, `domain()`, and `media-document()` functions can be optionally enclosed by single or double quotes. The values provided to the `regexp()` function *must* be enclosed in quotes.

Escaped values provided to the `regexp()` function must additionally be escaped from the CSS. For example, a `.` (period) matches any character in regular expressions. To match a literal period, you would first need to escape it using regular expression rules (to `\.`), then escape that string using CSS rules (to `\\.`).

`@document` is currently only supported in Firefox; if you wanted to replicate using such functionality in your own non-Firefox browser, you could try using this polyfill by @An-Error94, which uses a combination of a user script, data-* attributes, and attribute selectors.

> **Note:** There is a -moz-prefixed version of this property — `@-moz-document`. This has been limited to use only in user and UA sheets in Firefox 59 in Nightly and Beta — an experiment designed to mitigate potential CSS injection attacks (See Firefox bug 1035091).

Formal syntax

```
@document [ <url>                   |
            url-prefix(<string>)    |
            domain(<string>)        |
            media-document(<string>) |
            regexp(<string>)
          ]# {
  <group-rule-body>
}
```

Examples

Specifying document for CSS rule

```
@document url("http://www.w3.org/"),
          url-prefix("http://www.w3.org/Style/"),
          domain("mozilla.org"),
          media-document("video"),
          regexp("https:.*") {
  /* CSS rules here apply to:
     - The page "http://www.w3.org/"
     - Any page whose URL begins with "http://www.w3.org/Style/"
     - Any page whose URL's host is "mozilla.org"
       or ends with ".mozilla.org"
     - Any standalone video
     - Any page whose URL starts with "https:" */

  /* Make the above-mentioned pages really ugly */
  body {
    color: purple;
    background: yellow;
  }
}
```

Specifications

Initially in Level 3, `@document` was postponed to Level 4, but then subsequently removed.

- Per-site user style sheet rules on the www-style mailing list.

@font-face CSS at-rule

The **`@font-face`** CSS at-rule specifies a custom font with which to display text; the font can be loaded from either a remote server or a locally-installed font on the user's own computer.

Syntax

```
@font-face {
  font-family: "Trickster";
  src:
    local("Trickster"),
    url("trickster-COLRv1.woff2") format("woff2") tech(color-COLRv1),
    url("trickster-outline.woff2") format("woff2");
}
```

Descriptors

`ascent-override`

Defines the ascent metric for the font.

`descent-override`

Defines the descent metric for the font.

`font-display`

Determines how a font face is displayed based on whether and when it is downloaded and ready to use.

`font-family`

Specifies a name that will be used as the font face value for font properties. A `font-family` name is required for the `@font-face` rule to be valid.

`font-stretch`

A `font-stretch` value. Accepts two values to specify a range that is supported by a font face, for example `font-stretch: 50% 200%;`

`font-style`

A `font-style` value. Accepts two values to specify a range that is supported by a font face, for example `font-style: oblique 20deg 50deg;`

`font-weight`

A `font-weight` value. Accepts two values to specify a range that is supported by a font face, for example `font-weight: 100 400;`

`font-feature-settings`

Allows control over advanced typographic features in OpenType fonts.

`font-variation-settings`

Allows low-level control over OpenType or TrueType font variations, by specifying the four-letter axis names of the features to vary, along with their variation values.

`font-width`

Allows authors to specify a normal, condensed, or expanded face for the specified fonts.

`line-gap-override`

Defines the line gap metric for the font.

`size-adjust`

Defines a multiplier for glyph outlines and metrics associated with this font. This makes it easier to harmonize the designs of various fonts when rendered at the same font size.

`src`

Specifies references to font resources including hints about the font format and technology. A `src` is required for the `@font-face` rule to be valid.

`unicode-range`

The range of Unicode code points to be used from the font.

Description

It's common to use both `url()` and `local()` together, so that the user's installed copy of the font is used if available, falling back to downloading a copy of the font if it's not found on the user's device.

If the `local()` function is provided, specifying a font name to look for on the user's device, and if the user agent finds a match, that local font is used. Otherwise, the font resource specified using the `url()` function is downloaded and used.

Browsers attempt to load resources in their list declaration order, so usually `local()` should be written before `url()`. Both functions are optional, so a rule block containing only one or more `local()` without `url()` is possible. If more specific fonts with `format()` or `tech()` values are desired, these should be listed *before* versions that don't have these values, as the less specific variant would otherwise be tried and used first.

For web delivery, it's generally best to serve fonts in WOFF2 format, because it compresses fonts more efficiently than older formats like WOFF or OpenType, reducing file size and improving load times. WOFF2 is also well supported in modern browsers, making it a safe default choice for most websites.

By allowing authors to provide their own fonts, `@font-face` makes it possible to design content without being limited to the so-called "web-safe" fonts (that is, the fonts that are so common that they're considered to be universally available). The ability to specify the name of a locally-installed font to look for and use makes it possible to customize the font beyond the basics while making it possible to do so without relying on an internet connection.

> **Note:** Fallback strategies for loading fonts on older browsers are described in the `src` descriptor page.

The `@font-face` at-rule may be used not only at the top level of a CSS, but also inside any CSS conditional-group at-rule.

Font MIME Types

Format	MIME type
TrueType	`font/ttf`
OpenType	`font/otf`
Web Open Font Format	`font/woff`
Web Open Font Format 2	`font/woff2`

Notes

- Web fonts are subject to the same domain restriction (font files must be on the same domain as the page using them), unless HTTP access controls are used to relax this restriction.
- `@font-face` cannot be declared within a CSS selector. For example, the following will not work:

```
.className {
  @font-face {
    font-family: "MyHelvetica";
    src:
      local("Helvetica Neue Bold"), local("HelveticaNeue-Bold"),
      url("MgOpenModernaBold.woff2");
    font-weight: bold;
  }
}
```

Formal syntax

```
@font-face =
  @font-face { <declaration-list> }
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Specifying a downloadable font

This example specifies a downloadable font to use, applying it to the entire body of the document:

```
<body>
  This is Bitstream Vera Serif Bold.
</body>
```

```
@font-face {
  font-family: "Bitstream Vera Serif Bold";
  src: url("https://mdn.github.io/shared-assets/fonts/FiraSans-Regular.woff2");
}

body {
  font-family: "Bitstream Vera Serif Bold", serif;
}
```

Specifying local font alternatives

In this example, the user's local copy of "Helvetica Neue Bold" is used; if the user does not have that font installed (both the full font name and the Postscript name are tried), then the downloadable font named "MgOpenModernaBold.woff2" is used instead:

```
@font-face {
  font-family: "MyHelvetica";
  src:
    local("Helvetica Neue Bold"), local("HelveticaNeue-Bold"),
    url("MgOpenModernaBold.woff2");
  font-weight: bold;
}
```

ascent-override CSS at-rule descriptor

The **`ascent-override`** CSS descriptor for the `@font-face` at-rule defines the ascent metric for the font. The ascent metric is the height above the baseline that CSS uses to lay out line boxes in an inline formatting context.

Syntax

```
ascent-override: normal;
ascent-override: 90%;
```

Values

`normal`

The default value. When used the metric value is obtained from the font file.

`<percentage>`

A `<percentage>` value.

Formal definition

Related at-rule	`@font-face`
Initial value	`normal`
Percentages	as specified
Computed value	as specified

Formal syntax

```
ascent-override =
  [ normal | <percentage [0,∞]> ]{1,2}
```

This syntax reflects the latest standard as per CSS Fonts Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Overriding metrics of a fallback font

The `ascent-override` property can help when overriding the metrics of a fallback font to better match those of a primary web font.

```
@font-face {
  font-family: "web-font";
  src: url("https://example.com/font.woff");
}

@font-face {
  font-family: "local-font";
  src: local("Local Font");
  ascent-override: 125%;
}
```

descent-override CSS at-rule descriptor

The **descent-override** CSS descriptor for the @font-face at-rule defines the descent metric for the font. The descent metric is the height below the baseline that CSS uses to lay out line boxes in an inline formatting context.

Syntax

```
descent-override: normal;
descent-override: 90%;
```

Values

normal

The default value. When used the metric value is obtained from the font file.

<percentage>

A <percentage> value.

Formal definition

Related at-rule	@font-face
Initial value	normal
Percentages	as specified
Computed value	as specified

Formal syntax

```
descent-override =
  [ normal | <percentage [0,∞]> ]{1,2}
```

This syntax reflects the latest standard as per CSS Fonts Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Overriding metrics of a fallback font

The descent-override property can help when overriding the metrics of a fallback font to better match those of a primary web font.

```
@font-face {
  font-family: "web-font";
  src: url("https://example.com/font.woff");
}

@font-face {
  font-family: "local-font";
  src: local("Local Font");
  descent-override: 125%;
}
```

font-display CSS at-rule descriptor

The **font-display** descriptor for the @font-face at-rule determines how a font face is displayed based on whether and when it is downloaded and ready to use.

Syntax

```
/* Keyword values */
font-display: auto;
font-display: block;
font-display: swap;
font-display: fallback;
font-display: optional;
```

Values

auto

The font display strategy is defined by the user agent.

`block`

Gives the font face a short block period and an infinite swap period.

`swap`

Gives the font face an extremely small block period and an infinite swap period.

`fallback`

Gives the font face an extremely small block period and a short swap period.

`optional`

Gives the font face an extremely small block period and no swap period.

> **Note:** In Firefox, the preferences `gfx.downloadable_fonts.fallback_delay` and `gfx.downloadable_fonts.fallback_delay_short` provide the duration of the "short" and "extremely small" periods, respectively.

Description

The font display timeline is based on a timer that begins the moment the user agent attempts to use a given downloaded font face. The timeline is divided into the three periods below which dictate the rendering behavior of any elements using the font face:

- Font block period: If the font face is not loaded, any element attempting to use it must render an *invisible* fallback font face. If the font face successfully loads during this period, it is used normally.
- Font swap period: If the font face is not loaded, any element attempting to use it must render a fallback font face. If the font face successfully loads during this period, it is used normally.
- Font failure period: If the font face is not loaded, the user agent treats it as a failed load causing normal font fallback.

Formal definition

Related at-rule	`@font-face`
Initial value	`auto`
Computed value	as specified

Formal syntax

```
font-display =
  auto      |
  block     |
  swap      |
  fallback  |
  optional
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Specifying fallback font-display

```
@font-face {
  font-family: "ExampleFont";
  src: url("/path/to/fonts/example-font.woff2") format("woff2");
  font-weight: normal;
  font-style: normal;
  font-display: fallback;
}
```

font-family CSS at-rule descriptor

The **`font-family`** CSS descriptor sets the font family for a font specified in an `@font-face` at-rule.

The value is used for name matching against a particular `@font-face` when styling elements using the `font-family` property. Any name may be used, and this overrides any name specified in the underlying font data.

Syntax

```
/* <string> values */
font-family: "font family";
font-family: "another font family";

/* <custom-ident> value */
font-family: example-font;
```

Values

`<family-name>`

Specifies the name of the font family.

Formal definition

Related at-rule	`@font-face`
Initial value	`n/a (required)`

Computed value	as specified

Formal syntax

```
font-family =
  <font-family-name>

<font-family-name> =
  <string>         |
  <custom-ident>+
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting the font family name

```
@font-face {
  font-family: "Some font family";
  src: url("some_font_name.ttf");
}
```

font-feature-settings CSS at-rule descriptor

The **font-feature-settings** CSS descriptor allows you to define the initial settings to use for the font defined by the @font-face at-rule. You can further use this descriptor to control typographic font features such as ligatures, small caps, and swashes, for the font defined by @font-face. The values for this descriptor are the same as the font-feature-settings property, except for the global keyword values.

Since this descriptor sets feature values on the font object in the @font-face at-rule and not on an entire element, only some glyphs in an element may be rendered using this descriptor.

Syntax

```
/* Use the default settings */
font-feature-settings: normal;

/* Set values for OpenType feature tags */
font-feature-settings: "smcp";
font-feature-settings: "smcp" on;
font-feature-settings: "swsh" 2;
```

Values

This descriptor is specified as either the keyword normal or as a comma-separated list of <feature-tag-value> values. When rendering text, the list of OpenType <feature-tag-value> values are passed to the text layout engine to enable or disable font features.

normal

Indicates that text is laid out using default font settings. This is the default value.

<feature-tag-value>

Represents a space-separated tuple consisting of a tag name and an optional value.

The tag name is always a <string> of four ASCII characters. If the tag name has more or fewer characters or if it contains characters outside the U+20 – U+7E code point range, the descriptor is invalid.

The optional value can be a positive integer or the keyword on or off. The keywords on and off are synonyms for the values 1 and 0, respectively. If no value is set, the default is 1. For non-boolean OpenType features (e.g., stylistic alternates), the value implies a particular glyph to be selected; for boolean features, the value turns the feature on or off.

Formal definition

Related at-rule	@font-face
Initial value	normal
Computed value	as specified

Formal syntax

```
font-feature-settings =
  normal               |
  <feature-tag-value>#

<feature-tag-value> =
  <opentype-tag> [ <integer [0,∞]> | on | off ]?

<opentype-tag> =
  <string>

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Enabling swash glyphs using the @font-face at-rule

In this example, the tag name swsh and a boolean value 1 are used as the value for the font-feature-settings descriptor in the @font-face at-rule.

HTML

```
<p class="swash-off">Swash is off here</p>
<p class="swash-on">Swash is on here</p>
```

CSS

```
@font-face {
  font-family: "MonteCarlo";
  src: url("/shared-assets/fonts/monte-carlo/monte-carlo-regular.woff2");
}
@font-face {
  font-family: "MonteCarlo2";
  src: url("/shared-assets/fonts/monte-carlo/monte-carlo-regular.woff2");
  font-feature-settings: "swsh" 1;
}
p {
  font-size: 3rem;
  margin: 0.7rem 3rem;
}
.swash-off {
  font-family: "MonteCarlo", cursive;
}
.swash-on {
  font-family: "MonteCarlo2", cursive;
}
```

Result

Line 1 shows the default ornate design of the MonteCarlo font, and line 2 shows the default glyphs being replaced with swash glyphs.

See also

- Other `@font-face` descriptors: `font-family`, `font-style`, `font-variation-settings`, `font-weight`, `src`

font-stretch CSS at-rule descriptor

> **Note:** The `font-stretch` descriptor was renamed to `font-width` in the CSS Fonts specification. To preserve compatibility, the specification retains `font-stretch` as a legacy alias for the `font-width` descriptor.

The **`font-stretch`** CSS descriptor allows authors to specify a normal, condensed, or expanded face for the fonts specified in the `@font-face` at-rule.

For a particular font family, authors can download various font faces corresponding to the different styles of the same font family, and then use the `font-stretch` descriptor to specify the font face's stretch explicitly.

Syntax

```
/* Single values */
font-stretch: ultra-condensed;
font-stretch: extra-condensed;
font-stretch: condensed;
font-stretch: semi-condensed;
font-stretch: normal;
font-stretch: semi-expanded;
font-stretch: expanded;
font-stretch: extra-expanded;
font-stretch: ultra-expanded;
font-stretch: 50%;
font-stretch: 100%;
font-stretch: 200%;

/* Multiple values */
font-stretch: 75% 125%;
font-stretch: condensed ultra-condensed;
```

The `font-stretch` descriptor can take a single value from the list below.

Values

`normal`

Specifies a normally condensed font face.

`semi-condensed, condensed, extra-condensed, ultra-condensed`

Specifies a more condensed font face than normal, with ultra-condensed being the most condensed.

`semi-expanded, expanded, extra-expanded, ultra-expanded`

Specifies a more expanded font face than normal, with ultra-expanded being the most expanded.

`<percentage>`

A `<percentage>` value between 50% and 200% (inclusive). Negative values are not allowed for this descriptor.

In earlier versions of the `font-stretch` specification, the descriptor accepts only the nine keyword values. CSS Fonts Level 4 extends the syntax to accept a `<percentage>` value as well. This enables variable fonts to offer a continuous variation of character widths. For TrueType or OpenType variable fonts, the `wdth` variation is used to implement varying widths.

If the font does not provide a face that exactly matches the given value, then values less than `100%` map to a condensed face, and values greater than or equal to `100%` map to an expanded face.

Keyword to numeric mapping

The table below shows the mapping between keyword values and numeric percentages:

Keyword	Percentage
`ultra-condensed`	50%
`extra-condensed`	62.5%

Keyword	Percentage
`condensed`	75%
`semi-condensed`	87.5%
`normal`	100%
`semi-expanded`	112.5%
`expanded`	125%
`extra-expanded`	150%
`ultra-expanded`	200%

Variable fonts

Most fonts have a particular width that corresponds to one of the keyterm values. However, variable fonts can support a range of widths with fine granularity, giving the designer a greater degree of control over the chosen weight. For this, percentage ranges are useful.

For TrueType or OpenType variable fonts, the `wdth` variation is used to implement varying glyph widths.

Accessibility

People with dyslexia and other cognitive conditions may have difficulty reading fonts that are too condensed, especially if the font has a low color contrast ratio.

- Understanding Success Criterion 1.4.8 | W3C Understanding WCAG 2.0

Formal definition

Related at-rule	`@font-face`
Initial value	`normal`
Computed value	as specified

Formal syntax

```
font-width =
  auto                |
  <'font-width'>{1,2}

<font-width> =
  normal              |
  <percentage [0,∞]>  |
  ultra-condensed     |
  extra-condensed     |
  condensed           |
  semi-condensed      |
  semi-expanded       |
  expanded            |
  extra-expanded      |
  ultra-expanded
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting a percentage range for font-stretch

The following example uses the League Mono font. It synthesizes different font families from the same font file using the `font-stretch` descriptor with different keywords and percentages.

```
<p>League Mono</p>
<p>League Mono</p>
<p>League Mono</p>
```

```
@font-face {
  font-family: "League Mono Ultra Condensed";
  src: url("/shared-assets/fonts/LeagueMono-VF.ttf") format("truetype");
  font-stretch: ultra-condensed; /* same as 50% */
}

@font-face {
  font-family: "League Mono Normal";
  src: url("/shared-assets/fonts/LeagueMono-VF.ttf") format("truetype");
  font-stretch: 100%; /* same as normal */
}

@font-face {
  font-family: "League Mono Ultra Expanded";
  src: url("/shared-assets/fonts/LeagueMono-VF.ttf") format("truetype");
  font-stretch: ultra-expanded; /* same as 200% */
}

p:nth-child(1) {
  font-family: "League Mono Ultra Condensed", sans-serif;
}

p:nth-child(2) {
  font-family: "League Mono Normal", sans-serif;
}

p:nth-child(3) {
  font-family: "League Mono Ultra Expanded", sans-serif;
}
```

- `font-feature-settings` descriptor
- `font-variation-settings` descriptor
- `src` descriptor
- `unicode-range` descriptor

font-style CSS at-rule descriptor

The **`font-style`** CSS descriptor allows authors to specify font styles for the fonts specified in the `@font-face` at-rule.

For a particular font family, authors can download various font faces that correspond to the different styles of the same font family and then use the `font-style` descriptor to explicitly specify the font face's style. The values for this CSS descriptor are the same as that of the corresponding `font-style` property.

Syntax

```
font-style: normal;
font-style: italic;
font-style: oblique;
font-style: oblique 30deg;
font-style: oblique 30deg 50deg;
```

Values

`normal`

Selects the normal version of the font-family.

`italic`

Specifies that font-face is an italicized version of the normal font.

`oblique`

Specifies that the font-face is an artificially sloped version of the normal font.

`oblique` with angle

Selects a font classified as `oblique`, and additionally specifies an angle for the slant of the text.

`oblique` with angle range

Selects a font classified as `oblique`, and additionally specifies a range of allowable angle for the slant of the text. Note that a range is only supported when the `font-style` is `oblique`; for `font-style: normal` or `italic`, no second value is allowed.

Formal definition

Related at-rule	`@font-face`
Initial value	`normal`
Computed value	as specified

Formal syntax

```
font-style =
  auto                                  |
  normal                                |
  italic                                |
  left                                  |
  right                                 |
  oblique [ <angle [-90deg,90deg]>{1,2} ]?
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

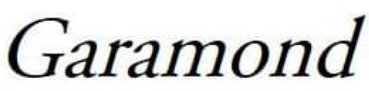
Examples

Specifying an italic font style

As an example, consider the garamond font family, in its normal form, we get the following result:

```
@font-face {
  font-family: "garamond";
  src: url("garamond.woff2");
}
```

The italicized version of this text uses the same glyphs present in the unstyled version, but they are artificially sloped by a few degrees.



On the other hand, if a true italicized version of the font family exists, we can include it in the `src` descriptor and specify the font style as italic, so that it is clear that the font is italicized. True italics use different glyphs and are a bit different from their upright counterparts, having some unique features and generally have a rounded and calligraphic quality. These fonts are specially created by font designers and are **not** artificially sloped.

```
@font-face {
  font-family: "garamond";
  src: url("garamond-italic.woff2");
  font-style: italic;
}
```

- font-feature-settings
- font-variation-settings
- src
- unicode-range

font-variation-settings CSS at-rule descriptor

The **font-variation-settings** CSS descriptor allows authors to specify low-level OpenType or TrueType font variations in the @font-face at-rule. The values for this descriptor are the same as the font-variation-settings property, except for the global keyword values.

Since this descriptor sets variation values on the font object in the @font-face at-rule and not on an entire element, only some glyphs in an element may be rendered using this descriptor.

Syntax

```
/* Use the default settings */
font-variation-settings: normal;

/* Set values for OpenType axis names */
font-variation-settings: "xhgt" 0.7;
```

Values

normal

Text is laid out using default settings.

<string> <number>

When rendering text, the list of OpenType axis names is passed to the text layout engine to enable or disable font features. Each setting is always a <string> of 4 ASCII characters, followed by a <number> indicating the axis value. If the <string> has more or fewer characters or contains characters outside the U+20 - U+7E code point range, the whole property is invalid. The <number> can be fractional or negative.

Formal definition

Related at-rule	@font-face
Initial value	normal
Computed value	as specified

Formal syntax

```
font-variation-settings =
  normal                |
  [ <string> <number> ]#
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting font weight and stretch in a @font-face rule

```
@font-face {
  font-family: "OpenTypeFont";
  src: url("open_type_font.woff2") format("woff2");
  font-weight: normal;
  font-style: normal;
  font-variation-settings:
    "wght" 400,
    "wdth" 300;
}
```

- Other @font-face descriptors: font-display, font-family, font-feature-settings, font-stretch, font-style, font-weight, src, unicode-range
- Related font properties: font-feature-settings, font-variation-settings

font-weight CSS at-rule descriptor

The **font-weight** CSS @font-face descriptor enables authors to specify a single font weight, or a range of font weights, for the font specified in a @font-face at-rule. This is then used by the browser to select the appropriate font when a CSS rule sets a desired font weight.

Typically, a developer will want to use fonts from a single font family in a range of different weights. With traditional, or *static* fonts, a single font file contains characters from a font family in a specific weight and style: for example, "Helvetica bold italic". To enable displaying light, regular, bold, or extra-bold fonts when the font-weight property calls a specific weight, you can define multiple @font-face at-rules for the same family (all with the same font-family descriptor value), one for each weight or range of weights.

To declare the font to be used for a range of font weights, declare a space-separated pair of font-weight values as the value for the `font-weight` descriptor. When CSS rules set a font weight by setting the `font-weight` property or the `font` shorthand property, the appropriate font will then be used.

For example, if the descriptor is `font-weight: 400 600;`, when the property is `font-weight: 450` or `font-weight: 550`, that font will be used for that font-family. Whether the font is a static or a variable font, the font matching the range will be used. In this case, if the font is a static font, `450` and `550` will appear the same. If the font is a variable font, the latter will be bolder.

The descriptor is the same for all fonts, but the range you'll set for a variable font will generally be greater, possibly even `1 1000` to use the same font for all font weight property values.

Syntax

```
/* Single values */
font-weight: normal;
font-weight: bold;
font-weight: 400;

/* Defining a range */
font-weight: normal bold;
font-weight: 300 500;
```

Values

The `font-weight` descriptor takes one of the following forms:

- The keyword `auto`.
- A single `<font-weight-absolute>` value.
- A pair of `<font-weight-absolute>` values, separated by a space.

Each `<font-weight-absolute>` may be any one of the following:

`normal`

Normal font weight. Same as `400`.

`bold`

Bold font weight. Same as `700`.

`<number>`

A `<number>` value between 1 and 1000, inclusive. Higher numbers represent weights that are bolder than (or as bold as) lower numbers. Certain commonly used values correspond to common weight names, as described in the Common weight name mapping section below.

Common weight name mapping

The numerical values `100` to `900` roughly correspond to the following common weight names:

Value	Common weight name
100	Thin (Hairline)
200	Extra Light (Ultra Light)
300	Light
400	Normal
500	Medium
600	Semi Bold (Demi Bold)
700	Bold
800	Extra Bold (Ultra Bold)
900	Black (Heavy)

Variable fonts

Most fonts have a particular weight which corresponds to one of the numbers in Common weight name mapping. However some fonts, called variable fonts, can support a range of weights with more or less fine granularity, and this can give the designer a much closer degree of control over the chosen weight.

For TrueType or OpenType variable fonts, the "wght" variation is used to implement varying weights.

Accessibility

People experiencing low vision conditions may have difficulty reading text set with a `font-weight` value of `100` (Thin/Hairline) or `200` (Extra Light), especially if the font has a low contrast color ratio.

- MDN Understanding WCAG, Guideline 1.4 explanations
- Understanding Success Criterion 1.4.8 | W3C Understanding WCAG 2.0

Formal definition

Related at-rule	`@font-face`
Initial value	`normal`
Computed value	as specified

Formal syntax

```
font-weight =
  auto                          |
  <font-weight-absolute>{1,2}

<font-weight-absolute> =
  normal                        |
  bold                          |
  <number [1,1000]>
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Selecting normal and bold fonts

In this example we include two fonts, one normal weight, one bold weight, from the "Fira Sans" font family using two `@font-face` at rules. We set `font-weight` descriptors to match the weight of the fonts.

After this, CSS rules can select the normal or the bold font for the "Fira Sans" family just by setting the `font-weight` property. Note that the `<strong>` HTML element also selects the bold font, because by default `<strong>` elements have a CSS `font-weight` property value of `bold`.

HTML

```
<p class="one">Fira Sans, `normal` weight paragraph</p>
<p class="two">Fira Sans, `bold` weight paragraph</p>
<p><strong>Fira Sans, &lt;strong&gt; element (`bold`)</strong></p>
```

CSS

```
@font-face {
  font-family: "Fira Sans";
  font-weight: normal;
  src: url("https://mdn.github.io/shared-assets/fonts/FiraSans-Regular.woff2");
}

@font-face {
  font-family: "Fira Sans";
  font-weight: bold;
  src: url("https://mdn.github.io/shared-assets/fonts/FiraSans-Bold.woff2");
}

body {
  font-family: "Fira Sans", serif;
  font-size: 2rem;
}

p.one {
  font-weight: normal;
}

p.two {
  font-weight: bold;
}
```

Result

Setting font-weight ranges

This example demonstrates how authors can include multiple fonts for multiple font-weights (and font-styles), by including multiple `@font-face` declarations with the same `font-family` value. By setting the `font-weight` descriptors using ranges from 1 to 1000, in the rest of your stylesheets, you can declare a `font-weight` (or `font-style`), and know the appropriate font will be used.

HTML

```
<p class="one">This has a font weight of 100</p>
<p class="three">This has a font weight of 300</p>
<p class="four">This has a font weight of 400</p>
<p class="five">This has a font weight of 500</p>
<p class="seven">This has a font weight of 700</p>
<p class="nine">This has a font weight of 900</p>
```

CSS

We include four `@font-face` declarations for four different fonts from the `FireSans` font family, as seen in the previous example. Each declaration is set to a different range of font-weight values, but all use the same font name.

The first declaration uses `FiraSans-Regular` and its associated `font-weight` range includes the entire possible range of font weight values.

The other three declarations use the light, bold, and extra-bold versions of the font, and their associated `font-weight` ranges define subsets of the range as follows:

- the light font is associated with the range 1-300
- the bold font is associated with the range 500-700
- the extra-bold font is associated with the range 700-1000

The CSS cascade ensures that the three latter declarations override parts of the range that was set in the `FiraSans-Regular` declaration.

```
@font-face {
  font-family: "Fira Sans";
  font-weight: 1 1000;
  src: url("https://mdn.github.io/shared-assets/fonts/FiraSans-Regular.woff2");
}

@font-face {
  font-family: "Fira Sans";
  font-weight: 1 300;
  src: url("https://mdn.github.io/shared-assets/fonts/FiraSans-Light.woff2");
}

@font-face {
  font-family: "Fira Sans";
  font-weight: 500 700;
  src: url("https://mdn.github.io/shared-assets/fonts/FiraSans-Bold.woff2");
}

@font-face {
  font-family: "Fira Sans";
  font-weight: 700 1000;
  src: url("https://mdn.github.io/shared-assets/fonts/FiraSans-ExtraBold.woff2");
}

body {
  font-family: "Fira Sans", serif;
  font-size: 2rem;
}
```

```
p.one {
  font-weight: 100;
}

p.three {
  font-weight: 300;
}

p.four {
  font-weight: 400;
}

p.five {
  font-weight: 500;
}

p.seven {
  font-weight: 700;
}

p.nine {
  font-weight: 900;
}
```

Result

The `seven` paragraph uses the extra bold font. While `font-weight: 700` matches both the `FiraSans-Bold` and `FiraSans-ExtraBold` declarations, as the FiraSans-ExtraBold is declared later, it overrides the `FiraSans-Bold` for that value.

Similarly, the `100` and `300` both use the light font; although `FiraSans-Regular` and `FiraSans-Light` both include `300` in their ranges, `FiraSans-Light` is declared later. Alternatively, we could have declared `FiraSans-Regular` after `FiraSans-Light`, but we would need to change the `font-weight` descriptor range if we do so.

Setting a range for a variable font

In this example we're using the `font-weight` descriptor to restrict the range of weights that can be set when using a variable font.

We include a variable font, "League Mono", using a single `@font-face` at-rule. We use a `font-weight: 300 700` value to effectively limit the range of weights that are available. If a CSS rule uses our "League Mono" font, then if it specifies a weight outside this range the weight it gets is clamped to the range.

HTML

We include a paragraph with `<output>` initially set to `400`, as that is the default font-weight for unstyled paragraph text. This paragraph is nestled between two other paragraphs, so you can compare rendered versus declared font weight values.

We include an `<input/range>` of type `range`, nested in a `<label>`, setting the `step` to `50`.

```
<p>LeagueMono, font-weight: 300 (comparison)</p>
<p id="example">LeagueMono, font-weight: <output>400</output> (example)</p>
<p>LeagueMono, font-weight: 700 (comparison)</p>
<label
  >Change the font weight:
  <input type="range" min="50" max="1000" step="50" value="400" />
</label>
```

CSS

We set the `font-weight` descriptor range to `300 700`, clamping the variable font to that range.

```
@font-face {
  font-family: "LeagueMono";
  src: url("https://mdn.github.io/shared-assets/fonts/LeagueMono-VF.ttf");
  font-weight: 300 700;
}

p {
  font-family: "LeagueMono", serif;
  font-size: 1.5rem;
}

p:first-of-type {
  font-weight: 300;
}

p:last-of-type {
  font-weight: 700;
}
```

JavaScript

We include an event handler that updates the paragraph's `font-weight` property value, and updates the text to reflect the change:

```
const text = document.querySelector("#example");
const log = document.querySelector("output");
const range = document.querySelector("input");

range.addEventListener("change", () => {
  text.style.fontWeight = range.value;
  log.innerText = range.value;
});
```

Result

Change the font weight of the paragraph via the range. Note that the example paragraph does not get lighter than the `300` paragraph above it or bolder than the `700` paragraph below it; the font weight is clamped to the range defined by the `font-weight` descriptor.

font-width CSS at-rule descriptor

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

> **Note:** The `font-width` descriptor is the modern replacement for the `font-stretch` descriptor, which is a legacy alias. While `font-width` is the specification's preferred name, `font-stretch` currently has broader browser support. Check the fallback example and browser compatibility table for details.

The **`font-width`** CSS descriptor allows authors to specify a normal, condensed, or expanded face for the fonts specified in the `@font-face` at-rule.

For a particular font family, authors can download various font faces corresponding to the different styles of the same font family, and then use the `font-width` descriptor to specify the font face's width explicitly. The available `font-width` descriptor values are the same as those of the corresponding `font-width` property.

Syntax

```
/* Single values */
font-width: ultra-condensed;
font-width: extra-condensed;
font-width: condensed;
font-width: semi-condensed;
font-width: normal;
font-width: semi-expanded;
font-width: expanded;
font-width: extra-expanded;
font-width: ultra-expanded;
font-width: 50%;
font-width: 100%;
font-width: 200%;

/* Multiple values */
font-width: 75% 125%;
font-width: condensed ultra-condensed;
```

The `font-width` descriptor can take a single value from the list below.

Values

`normal`

Specifies a normally condensed font face.

`semi-condensed`, `condensed`, `extra-condensed`, `ultra-condensed`

Specifies a more condensed font face than normal, with ultra-condensed being the most condensed.

`semi-expanded`, `expanded`, `extra-expanded`, `ultra-expanded`

Specifies a more expanded font face than normal, with ultra-expanded being the most expanded.

`<percentage>`

A `<percentage>` value between 50% and 200% (inclusive). Negative values are not allowed for this descriptor.

In earlier versions of the `font-width` specification, the descriptor accepts only the nine keyword values. CSS Fonts Level 4 extends the syntax to accept a `<percentage>` value as well. This enables variable fonts to offer a continuous variation of character widths. For TrueType or OpenType variable fonts, the `wdth` variation is used to implement varying widths.

If the font does not provide a face that exactly matches the given value, then values less than `100%` map to a condensed face, and values greater than or equal to `100%` map to an expanded face.

Keyword to numeric mapping

The table below shows the mapping between keyword values and numeric percentages:

Keyword	Percentage
`ultra-condensed`	50%
`extra-condensed`	62.5%
`condensed`	75%
`semi-condensed`	87.5%
`normal`	100%
`semi-expanded`	112.5%
`expanded`	125%
`extra-expanded`	150%
`ultra-expanded`	200%

Variable fonts

Most fonts have a particular width that corresponds to one of the keyterm values. However, variable fonts can support a range of widths with fine granularity, giving the designer a greater degree of control over the chosen weight. For this, percentage ranges are useful.

For TrueType or OpenType variable fonts, the `wdth` variation is used to implement varying glyph widths.

Accessibility

People with dyslexia and other cognitive conditions may have difficulty reading fonts that are too condensed, especially if the font has a low color contrast ratio.

- Understanding Success Criterion 1.4.8 | W3C Understanding WCAG 2.0

Formal definition

Value not found in DB!

Formal syntax

```
font-width =
  auto                |
  <'font-width'>{1,2}

<font-width> =
  normal              |
  <percentage [0,∞]>  |
  ultra-condensed     |
  extra-condensed     |
  condensed           |
  semi-condensed      |
  semi-expanded       |
  expanded            |
  extra-expanded      |
  ultra-expanded
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting a percentage range for font-width

The following example uses the League Mono font. It synthesizes different font families from the same font file using the `font-width` descriptor with different keywords and percentages.

```
<p>League Mono</p>
<p>League Mono</p>
<p>League Mono</p>
```

```
@font-face {
  font-family: "League Mono Ultra Condensed";
  src: url("/shared-assets/fonts/LeagueMono-VF.ttf") format("truetype");
  font-width: ultra-condensed; /* same as 50% */
}

@font-face {
  font-family: "League Mono Normal";
  src: url("/shared-assets/fonts/LeagueMono-VF.ttf") format("truetype");
  font-width: 100%; /* same as normal */
}

@font-face {
  font-family: "League Mono Ultra Expanded";
  src: url("/shared-assets/fonts/LeagueMono-VF.ttf") format("truetype");
  font-width: ultra-expanded; /* same as 200% */
}

p:nth-child(1) {
  font-family: "League Mono Ultra Condensed", sans-serif;
}

p:nth-child(2) {
  font-family: "League Mono Normal", sans-serif;
}

p:nth-child(3) {
  font-family: "League Mono Ultra Expanded", sans-serif;
}
```

Providing a font-stretch fallback

Because `font-width` does not yet have broad browser support, you may want to include the legacy `font-stretch` descriptor as a fallback. Place `font-stretch` before `font-width` so that supporting browsers use the modern descriptor:

```
@font-face {
  font-family: "MyFont";
  src: url("my-font.woff2") format("woff2");
  font-stretch: condensed; /* for browsers that don't support font-width */
  font-width: condensed;
}
```

> **Note:** You can automate this fallback pattern using the postcss-preset-env plugin for PostCSS, which includes the postcss-font-width-property transform to convert `font-width` declarations to `font-stretch` automatically.

- `font-feature-settings` property
- `font-variation-settings` descriptor
- `src` descriptor
- `unicode-range` descriptor

line-gap-override CSS at-rule descriptor

The **`line-gap-override`** CSS descriptor for the `@font-face` at-rule defines the line-gap metric for the font. The line-gap metric is the font recommended line-gap or external leading.

Syntax

```
line-gap-override: normal;
line-gap-override: 90%;
```

Values

`normal`

The default value. When used the metric value is obtained from the font file.

`<percentage>`

A `<percentage>` value.

Formal definition

Related at-rule	`@font-face`
Initial value	`normal`
Percentages	as specified
Computed value	as specified

Formal syntax

```
line-gap-override =
  [ normal | <percentage [0,∞]> ]{1,2}
```

This syntax reflects the latest standard as per CSS Fonts Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Overriding metrics of a fallback font

The `line-gap-override` property can help when overriding the metrics of a fallback font to better match those of a primary web font.

```
@font-face {
  font-family: "web-font";
  src: url("https://example.com/font.woff");
}

@font-face {
  font-family: "local-font";
  src: local("Local Font");
  line-gap-override: 125%;
}
```

- `font-style`
- `font-stretch`
- `font-feature-settings`
- `font-variation-settings`
- `src`
- `size-adjust`
- `unicode-range` descriptor

size-adjust CSS at-rule descriptor

The **`size-adjust`** CSS descriptor for the `@font-face` at-rule defines a multiplier for glyph outlines and metrics associated with this font. This makes it easier to harmonize the designs of various fonts when rendered at the same font size.

The `size-adjust` descriptor behaves in a similar fashion to the `font-size-adjust` property. It calculates an adjustment per font by matching ex heights.

Syntax

```
size-adjust: 90%;
```

Values

`<percentage>`

A `<percentage>` value with an initial value of 100%.

All metrics associated with this font are scaled by the given percentage. This includes glyph advances, baseline tables, and overrides provided by `@font-face` descriptors.

Formal definition

Related at-rule	`@font-face`
Initial value	`100%`
Percentages	as specified
Computed value	as specified

Formal syntax

```
size-adjust =
  <percentage [0,∞]>
```

This syntax reflects the latest standard as per CSS Fonts Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Overriding metrics of a fallback font

The `size-adjust` property can help when overriding the metrics of a fallback font to better match those of a primary web font.

```
@font-face {
  font-family: "web-font";
  src: url("https://example.com/font.woff");
}

@font-face {
  font-family: "local-font";
  src: local("Local Font");
  size-adjust: 90%;
}
```

- `unicode-range` descriptor
- `font-size-adjust` property

src CSS at-rule descriptor

The **`src`** CSS descriptor for the `@font-face` at-rule specifies the resource containing font data. It is required for the `@font-face` rule to be valid.

Syntax

```
/* <url> values */
src: url("https://example.com/path/to/font.woff"); /* Absolute URL */
src: url("path/to/font.woff"); /* Relative URL */
src: url("path/to/svgFont.svg#example"); /* Fragment identifying font */

/* <font-face-name> values */
src: local(font); /* Unquoted name */
src: local(some font); /* Name containing space */
src: local("font"); /* Quoted name */
src: local("some font"); /* Quoted name containing a space */

/* <tech(<font-tech>)> values */
src: url("path/to/fontCOLRv1.otf") tech(color-COLRv1);
src: url("path/to/fontCOLR-svg.otf") tech(color-SVG);

/* <format(<font-format>)> values */
src: url("path/to/font.woff") format("woff");
src: url("path/to/font.woff2") format("woff2");

/* Multiple resources */
src:
  url("path/to/font.woff") format("woff"),
  url("path/to/font.woff2") format("woff2");

/* Multiple resources with font format and technologies */
src:
  url("trickster-COLRv1.woff2") format("woff2") tech(color-COLRv1),
  url("trickster-outline.woff2") format("woff2");
```

Values

`url()`

Specifies an external reference consisting of a `<url>`, followed by optional hints using the `format()` and `tech()` component values that specify the format and font technology of the resource referenced by the URL. The `format()` and `tech()` components are a comma-separated list of strings of known font formats and technologies. If a user agent doesn't support the font technology or formats, it skips downloading the font resource. If no format or technology hints are supplied, the font resource is always downloaded.

`format()`

An optional declaration that follows the `url()` value that provides a hint for the user agent on the font format. If the value is not supported or invalid, the browser may not download the resource, potentially saving bandwidth. If omitted, the browser will download the resource and then detect the format. If including a font source for backward-compatibility that is not in the list of defined keywords, enclose the format string in quotes. Possible values are described in the Font formats section below.

`tech()`

An optional declaration that follows the `url()` value that provides a hint for the user agent on the font technology. The value for `tech()` may be one of the keywords described in Font technologies.

`local(<font-face-name>)`

Specifies the font name should the font be available on the user's device. Enclosing the font name in quotes is optional.

> **Note:** For OpenType and TrueType fonts, `<font-face-name>` is used to match either the Postscript name or the full font name in the name table of locally available fonts. Which type of name is used varies by platform and font, so you should include both of these names to assure proper matching across platforms. Platform substitutions for a given font name must not be used.

> **Note:** Locally available fonts may have been preinstalled on the user's device, or may have been actively installed by the user.
>
> While the set of preinstalled fonts is likely to be the same for all users of a particular device, the set of user-installed fonts is not. By discovering the set of user-installed fonts, a site can therefore build a fingerprint for the device, helping the site to track users across the web.

> To prevent this, user agents may ignore user-installed fonts when using `local()`.

`<font-face-name>`

Specifies the full name or postscript name of a locally-installed font face using the `local()` component value, which uniquely identifies a single font face within a larger family. The name can optionally be enclosed in quotes. The font face name is not case-sensitive.

> **Note:** The Local Font Access API can be used to access the user's locally installed font data — this includes higher-level details such as names, styles, and families, as well as the raw bytes of the underlying font files.

Description

The value of this descriptor is a prioritized, comma-separated list of external references or locally-installed font face names, where each resource is specified using `url()` or `local()`. When a font is needed, the user agent iterates over the set of references listed using the first one it can successfully activate. Fonts containing invalid data or local font faces that are not found are ignored and the user agent loads the next font in the list.

If multiple `src` descriptors are set, only the last declared rule that is able to load a resource is applied. If the last `src` descriptor can load a resource and doesn't include a `local()` font, the browser may download external font files and ignore the local version even if there is one available on the device.

> **Note:** Values within descriptors that the browser considers invalid are ignored. Some browsers will ignore the whole descriptor if any item is invalid, even if only one item is invalid. This may affect design of fallbacks. See Browser compatibility for more information.

As with other URLs in CSS, the URL may be relative, in which case it is resolved relative to the location of the style sheet containing the `@font-face` rule. In the case of SVG fonts, the URL points to an element within a document containing SVG font definitions. If the element reference is omitted, a reference to the first defined font is implied. Similarly, font container formats that can contain more than one font load only one of the fonts for a given `@font-face` rule. Fragment identifiers are used to indicate which font to load. If a container format lacks a defined fragment identifier scheme, a 1-based indexing scheme (e.g., "font-collection#1" for the first font, "font-collection#2" for the second font, etc.) is used.

If the font file is a container for multiple fonts, a fragment identifier is included to indicate the sub-font that should be used, as shown below:

```
@font-face {
  font-family: "WhichFont";
  /* WhichFont is the PostScript name of a font in the font file */
  src: url("collection.otc#WhichFont");
}
@font-face {
  font-family: "WhichFont-svg";
  /* WhichFont is the element id of a font in the SVG Font file */
  src: url("fonts.svg#WhichFont");
}
```

Font formats

The following table shows the valid font keywords and their corresponding font formats. To check if a font format is supported by a browser within CSS, use the `@supports` rule.

Keyword	Font Format	Common extensions
`collection`	OpenType Collection	.otc, .ttc
`embedded-opentype`	Embedded OpenType	.eot
`opentype`	OpenType	.otf, .ttf
`svg`	SVG Font (deprecated)	.svg, .svgz
`truetype`	TrueType	.ttf
`woff`	WOFF 1.0	.woff
`woff2`	WOFF 2.0	.woff2

> **Note:**
>
> - `format(svg)` stands for SVG fonts, and `tech(color-SVG)` stands for OpenType fonts with SVG table (also called OpenType-SVG color fonts), which are completely different.
> - The `opentype` and `truetype` values are equivalent whether the font file uses cubic bezier curves (within CFF/CFF2 table) or quadratic bezier curves (within glyph table).

Older non-normalized `format()` values have the following equivalent syntax; provided as a string enclosed in quotes for backward-compatibility reasons:

Old syntax	Equivalent syntax
`format("woff2-variations")`	`format(woff2) tech(variations)`
`format("woff-variations")`	`format(woff) tech(variations)`
`format("opentype-variations")`	`format(opentype) tech(variations)`
`format("truetype-variations")`	`format(truetype) tech(variations)`

Font technologies

The following table shows valid values for the `tech()` descriptor and their corresponding font technologies. To check if a font technology is supported by a browser within CSS, use the `@supports` at-rule.

Keyword	Description
`color-cbdt`	Color bitmap data tables
`color-colrv0`	Multi-colored glyphs via COLR version 0 table
`color-colrv1`	Multi-colored glyphs via COLR version 1 table
`color-sbix`	Standard bitmap graphics tables
`color-svg`	SVG multi-colored tables
`features-aat`	TrueType `morx` and `kerx` tables
`features-graphite`	Graphite features, namely `Silf`, `Glat`, `Gloc`, `Feat`, and `Sill` tables
`features-opentype`	OpenType `GSUB` and `GPOS` tables

Keyword	Description
`incremental`	Incremental font loading
`palettes`	Font palettes by means of `font-palette` to select one of many color palettes in the font
`variations`	Font variations in TrueType and OpenType fonts to control the font axis, weight, glyphs, etc.

Formal definition

Related at-rule	`@font-face`
Initial value	`n/a (required)`
Computed value	as specified

Formal syntax

```
src =
  <font-src-list>
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

```
<font-src> =
  <url> [ format( <font-format> ) ]? [ tech( <font-tech># ) ]?  |
  local( <font-family-name> )

<font-format> =
  <string>           |
  collection         |
  embedded-opentype  |
  opentype           |
  svg                |
  truetype           |
  woff               |
  woff2

<font-tech> =
  <font-features-tech>  |
  <color-font-tech>     |
  variations            |
  palettes              |
  incremental

<font-family-name> =
  <string>         |
  <custom-ident>+

<font-features-tech> =
  features-opentype  |
  features-aat       |
  features-graphite

<color-font-tech> =
  color-COLRv0  |
  color-COLRv1  |
  color-SVG     |
  color-sbix    |
  color-CBDT
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4, CSS Fonts Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Specifying font resources using url() and local()

The example below shows how to define two font faces with the same font family. The `font-family` is named `MainText`. The first font face has a regular font, and the second one is a bold version of the same font family.

```
/* Defining a regular font face */
@font-face {
  font-family: "MainText";
  src:
    local("Futura-Medium"),
    url("FuturaMedium.woff") format("woff"),
    url("FuturaMedium.woff2") format("woff2");
}

/* Defining a different bold font face for the same family */
@font-face {
  font-family: "MainText";
  src:
    local("Gill Sans Bold") /* full font name */,
    local("GillSans-Bold") /* postscript name */,
    url("GillSansBold.woff") format("woff"),
    url("GillSansBold.woff2") format("woff2"),
    url("GillSansBold.svg#MyFontBold"); /* Referencing an SVG font fragment by id */
  font-weight: bold;
}

/* Using the regular font face */
p {
  font-family: "MainText", sans-serif;
}

/* Font-family is inherited, but bold fonts are used */
p.bold {
  font-weight: bold;
}
```

Specifying font resources using tech() and format() values

The following example shows how to use the `tech()` and `format()` values to specify font resources. A font using `color-colrv1` technology and `opentype` format is specified using the `tech()` and `format()` values. A color font will be activated if the user agent supports it, and an `opentype` non-color is provided as a fallback.

```
@font-face {
  font-family: "Trickster";
  src:
    url("trickster-COLRv1.woff2") format("woff2") tech(color-COLRv1),
    url("trickster-outline.woff2") format("woff2");
}

/* Using the font face */
p {
  font-family: "Trickster", fantasy;
}
```

Specifying fallbacks for older browsers

Browsers should use a `@font-face` with a single `src` descriptor listing possible sources for the font. Since the browser will use the first resource that it is able to load, items should be specified in the order of your preference for their usage.

Generally this means that local files should appear before remote files and that resources with `format()` or `tech()` constraints should appear before resources that don't have them (otherwise the less-constrained version would always be selected). For example:

```
@font-face {
  font-family: "MgOpenModernaBold";
  src:
    url("MgOpenModernaBoldIncr.woff2") format("woff2") tech(incremental),
    url("MgOpenModernaBold.woff2") format("woff2");
}
```

A browser that does not support `tech()` above should ignore the first item and attempt to load the second resource.

Some browsers do not yet ignore invalid items, and instead fail the whole `src` descriptor if any value is invalid. If working with these browsers you can specify multiple `src` descriptors as fallbacks. Note that multiple `src` descriptors are attempted in reverse-order, so at the end we have our normal descriptor with all the items.

```
@font-face {
  font-family: "MgOpenModernaBold";
  src: url("MgOpenModernaBold.woff2") format("woff2");
  src: url("MgOpenModernaBoldIncr.woff2") format("woff2") tech(incremental);
  src:
    url("MgOpenModernaBoldIncr.woff2") format("woff2") tech(incremental),
    url("MgOpenModernaBold.woff2") format("woff2");
}
```

Checking if the user agent supports a font

The following example shows how to check if the user agent supports a font technology using the `@supports` rule. The block of CSS inside `@supports` will be applied if the user agent supports `color-COLRv1` technology.

```
@supports font-tech(color-COLRv1) {
  @font-face {
    font-family: "Trickster";
    src: url("trickster-COLRv1.woff2") format("woff2") tech(color-COLRv1);
  }

  .colored_text {
    font-family: "Trickster", fantasy;
  }
}
```

- `font-weight`
- `font-feature-settings`
- `font-variation-settings`
- `unicode-range`

unicode-range CSS at-rule descriptor

The **`unicode-range`** CSS descriptor sets the specific range of characters to be used from a font defined using the `@font-face` at-rule and made available for use on the current page. If the page doesn't use any character in this range, the font is not downloaded; if it uses at least one, the whole font is downloaded.

Syntax

```
/* <unicode-range> values */
unicode-range: U+26; /* single code point */
unicode-range: U+0-7F;
unicode-range: U+0025-00FF; /* code point range */
unicode-range: U+4??; /* wildcard range */
unicode-range: U+0025-00FF, U+4??; /* multiple values */
```

Values

single code point

A single Unicode character code point, for example `U+26`.

code point range

A range of Unicode code points. So for example, `U+0025-00FF` means *include all characters in the range `U+0025` to `U+00FF`*.

wildcard range

A range of Unicode code points containing wildcard characters, that is using the `'?'` character, so for example `U+4??` means *include all characters in the range `U+400` to `U+4FF`*.

Description

The purpose of this descriptor is to allow the font resources to be segmented so that a browser only needs to download the font resource needed for the text content of a particular page. For example, a site with many localizations could provide separate font resources for English, Greek and Japanese. For users viewing the English version of a page, the font resources for Greek and Japanese fonts wouldn't need to be downloaded, saving bandwidth.

Formal definition

Related at-rule	`@font-face`
Initial value	`U+0-10FFFF`
Computed value	as specified

Formal syntax

```
unicode-range =
  <unicode-range-token>#
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using a different font for a single character

In this example, we create a single `<div>` element, with a text string that includes an ampersand that we want to style with a different font. To make it obvious, we will use a sans-serif font, *Helvetica*, for the text, and a serif font, *Times New Roman*, for the ampersand.

In the CSS we are in effect defining a completely separate `@font-face` that only includes a single character in it, meaning that only this character will be styled with this font. We could also have done this by wrapping the ampersand in a `<span>` and applying a different font just to that, but that is an extra element and rule set.

HTML

```
<div>Me & You = Us</div>
```

CSS

```
@font-face {
  font-family: "Ampersand";
  src: local("Times New Roman");
  unicode-range: U+26;
}

div {
  font-size: 4em;
  font-family: "Ampersand", "Helvetica", sans-serif;
}
```

@font-feature-values CSS at-rule

The **`@font-feature-values`** CSS at-rule lets you use a common name in the `font-variant-alternates` property for features activated differently in OpenType. This can help simplify your CSS when using multiple fonts.

The `@font-feature-values` at-rule may be used either at the top level of your CSS or inside any CSS conditional-group at-rule.

Syntax

```
@font-feature-values Font Name {
  font-display: swap;
  @styleset {
    nice-style: 12;
  }
  @swash {
    fancy: 2;
  }
}
```

Each `@font-feature-values` block can contain a list of feature value blocks (listed below), as well as the `font-display` descriptor.

Feature value blocks

`@swash`

Specifies a feature name that will work with the `swash()` functional notation of `font-variant-alternates`. A swash feature value definition allows only one value: `ident1: 2` is valid, but `ident2: 2 4` isn't.

`@annotation`

Specifies a feature name that will work with the `annotation()` functional notation of `font-variant-alternates`. An annotation feature value definition allows only one value: `ident1: 2` is valid, but `ident2: 2 4` isn't.

`@ornaments`

Specifies a feature name that will work with the `ornaments()` functional notation of `font-variant-alternates`. An ornaments feature value definition allows only one value: `ident1: 2` is valid, but `ident2: 2 4` isn't.

`@stylistic`

Specifies a feature name that will work with the `stylistic()` functional notation of `font-variant-alternates`. A stylistic feature value definition allows only one value: `ident1: 2` is valid, but `ident2: 2 4` isn't.

`@styleset`

Specifies a feature name that will work with the `styleset()` functional notation of `font-variant-alternates`. A styleset feature value definition allows an unlimited number of values: `ident1: 2 4 12 1` maps to the OpenType values `ss02`, `ss04`, `ss12`, and `ss01`. Note that values higher than `99` are valid, but don't map to any OpenType values and are ignored.

`@character-variant`

Specifies a feature name that will work with the `character-variant()` functional notation of `font-variant-alternates`. A character-variant feature value definition allows either one or two values: `ident1: 3` maps to `cv03=1`, and `ident2: 2 4` maps to `cv02=4`, but `ident2: 2 4 5` is invalid.

Formal syntax

```
@font-feature-values =
  @font-feature-values <font-family-name># { <declaration-rule-list> }

<font-family-name> =
  <string>         |
  <custom-ident>+
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using @styleset in a @font-feature-values rule

```
/* At-rule for "nice-style" in Font One */
@font-feature-values Font One {
  @styleset {
    nice-style: 12;
  }
}

/* At-rule for "nice-style" in Font Two */
@font-feature-values Font Two {
  @styleset {
    nice-style: 4;
  }
}

/* Apply the at-rules with a single declaration */
.nice-look {
  font-variant-alternates: styleset(nice-style);
}
```

See also

- The `font-variant-alternates` property that uses values that this at-rule defines.

font-display CSS at-rule descriptor

The **`font-display`** descriptor for the `@font-feature-values` at-rule sets the default value of how a font face is displayed based on whether and when it is downloaded. Setting a value for the `font-display` descriptor within a `@font-feature-values` block sets the default value of the `font-display` descriptor for the `@font-face` at-rule for all the fonts with the same `font-family` value.

Syntax

```
/* Keyword values */
font-display: auto;
font-display: block;
font-display: swap;
font-display: fallback;
font-display: optional;
```

Values

`auto`

The font display strategy is defined by the user agent.

`block`

Gives the font face a short block period, generally around 3 seconds, and an infinite swap period.

`swap`

Gives the font face an extremely small block period and an infinite swap period.

`fallback`

Gives the font face an extremely small block period and a short swap period.

`optional`

Gives the font face an extremely small block period and no swap period.

Description

The `font-display` descriptor for `@font-feature-values` determines the font display timeline; it does so by setting a default `font-display` value for `@font-face` for the same `font-family` name. When `font-display` is omitted in `@font-face`, the user agent first looks for the `font-display` value that has been set via `@font-feature-values` for the relevant font-family. If no value is found, the user agent uses the `auto` value for `font-display`, in which case, the user agent determines the font display strategy.

The font display timeline is based on a timer that starts when the user agent attempts to use a specific downloaded font face. The timeline is divided into three periods, as listed below. These periods dictate the rendering behavior of any element that uses the font face.

- Font **block** period: If the font face is not loaded, elements attempting to use the font are rendered with an *invisible* fallback font face. The browser blocks visible text rendering, saving a space for the to-be-displayed text based on metrics of the fallback font. During the block period, text is not visible. At the end of the block period, if the font has not loaded, the text is rendered in the fallback font.

- Font **swap** period: The swap period occurs after the block period (if there is one) and if the font face has not yet been loaded successfully. Elements attempting to use the not-yet-loaded font are rendered using the next available fallback font face. The formerly invisible fallback font face is painted onto the screen. If the font loads successfully during the swap period, the text that was rendered in the fallback font is updated — or swapped — with the newly loaded font. This step triggers a repaint.
- Font **failure** period: If the font face has not loaded by the time the swap period expires or by the time the block period expires (if there is no swap period, as is the case with `optional`), the user agent treats the font as a failed load. As a result, the content becomes visible in the fallback font.

The `font-display` descriptor allows you to set a default display policy for all `@font-face` rules, including those not under author control, such as third-party `@font-face` rules. When the `font-display` value is set via `@font-feature-values`, it becomes the default `font-display` value, and is applied to the entire font-family. However, any `font-display` value defined within individual `@font-face` blocks will override this default, but only for those blocks where the descriptor is defined.

Examples

```
@font-feature-values "Leitura" {
  font-display: swap;
  @swash {
    fancy: 1;
  }
}
```

The `font-display` descriptor in this example sets the default `font-display` value for the "Leitura" font to `swap` for all the `@font-face` blocks. Now there might be several `@font-face` blocks importing multiple font files for a single font-family. If one of those `@font-face` blocks includes a `font-display` descriptor, the specified value will be used for that specific font file only. All other blocks not including a `font-display` descriptor will default to `swap` instead of the user-agent's standard default `auto`.

Browser compatibility

Currently, no browsers support this feature.

See also

- `font-display` descriptor for `@font-face` at-rule
- CSS fonts module

@font-palette-values CSS at-rule

The **`@font-palette-values`** CSS at-rule allows you to customize the default values of font-palette created by the font-maker.

Syntax

```
@font-palette-values --identifier {
  font-family: "Bixa";
}
.my-class {
  font-palette: --identifier;
}
```

The <dashed-ident> is a user-defined identifier, that while it looks like a CSS custom property behaves in a different way and is not wrapped in a CSS var() function.

Descriptors

`base-palette`

Specifies the name or index of the base-palette, created by the font-maker, to use.

`font-family`

Specifies the name of the font family that this palette can be applied to. A `font-family` name is required for the `@font-palette-values` rule to be valid.

`override-colors`

Specifies the colors in the base palette to override.

Formal syntax

```
@font-palette-values =
  @font-palette-values <dashed-ident> { <declaration-list> }
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Overriding colors in an existing palette

This example shows how you can change some or all of the colors in a color font.

HTML

```
<p>default colors</p>
<p class="alternate">alternate colors</p>
```

CSS

```
@import "https://fonts.googleapis.com/css2?family=Bungee+Spice";
p {
  font-family: "Bungee Spice", fantasy;
  font-size: 2rem;
}
@font-palette-values --Alternate {
  font-family: "Bungee Spice";
  override-colors:
    0 #00ffbb,
    1 #007744;
}
.alternate {
  font-palette: --Alternate;
}
```

Result

When overriding colors of the normal or base-palette at index 0 you do not need to declare which base-palette to use. This should only be done when overriding a different base-palette. If you are overriding all the colors then there is also no need to specify the base-palette to use.

See also

- `font-palette` property
- `font-family` descriptor
- `base-palette` descriptor
- `override-colors` descriptor
- `CSSFontPaletteValuesRule`

base-palette CSS at-rule descriptor

The **`base-palette`** CSS descriptor is used to specify the name or index of a pre-defined palette to be used for creating a new palette. If the specified `base-palette` does not exist, then the palette defined at index 0 will be used.

Syntax

```
@font-palette-values --one {
  base-palette: 1;
}
```

The `base-palette` descriptor is specified using a zero-based index of the font-maker created palettes.

Values

`<index>`

Specifies the index of the pre-defined palette to use.

Formal definition

Related at-rule	`@font-palette-values`
Initial value	`n/a (required)`
Computed value	as specified

Formal syntax

```
base-palette =
  light           |
  dark            |
  <integer [0,∞]>

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Changing the default palette in a font

Using the Rocher Color Font, this example shows two instances of switching the default palette in the font to an alternate palette created by the font-maker.

HTML

```
<h2>default base-palette</h2>
<h2 class="two">base-palette at index 2</h2>
<h2 class="five">base-palette at index 5</h2>
```

CSS

```
@font-face {
  font-family: "Rocher";
  src: url("[path-to-font]/RocherColorGX.woff2") format("woff2");
}

h2 {
  font-family: "Rocher", fantasy;
}

@font-palette-values --two {
  font-family: "Rocher";
  base-palette: 2;
}

@font-palette-values --five {
  font-family: "Rocher";
  base-palette: 5;
}

.two {
  font-palette: --two;
}

.five {
  font-palette: --five;
}
```

Result

See also

- `override-colors` descriptor
- `font-palette` property
- `CSSFontPaletteValuesRule.basePalette`

font-family CSS at-rule descriptor

The @font-palette-values descriptor **`font-family`** is used to specify which font-family palette values are to be applied to. This need to match exactly the values used when setting the CSS font-family.

Syntax

```
@font-palette-values --Dark-mode {
  font-family: "Bungee Spice";
  /* other palette settings follow */
}
```

Other palette values that follow apply only to the specified font family. You can create @font-palette-values for other font families by using the same <dashed-ident>s. This means that if you have multiple Color Fonts and can use the same identifier for each.

Values

`<family-name>`

Specifies the name of the font-family.

Formal definition

Related at-rule	`@font-palette-values`
Initial value	`n/a (required)`
Computed value	as specified

Formal syntax

```
font-family =
  <font-family-name>#

<font-family-name> =
  <string>         |
  <custom-ident>+
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using matching family names

In this example, when the `font-family` descriptor is used in the @font-palette-values at-rule, the same value is used for the `font-family`, as when it is declared.

HTML

```
<h2>This is spicy</h2>
<h2 class="extra-spicy">This is extra hot & spicy</h2>
```

CSS

```
@import "https://fonts.googleapis.com/css2?family=Bungee+Spice";
@font-palette-values --bungee-extra-spicy {
  font-family: "Bungee Spice";
  override-colors:
    0 darkred,
    1 red;
}

h2 {
  font-family: "Bungee Spice", fantasy;
}

h2.extra-spicy {
  font-palette: --bungee-extra-spicy;
}
```

Result

Using the same palette identifier for multiple font-families

In this example, two @font-palette-values at-rules are set for two font families, but both the at-rules use the same dashed-ident identifier, `--Dark-Mode`. This helps to set the font-palette property for multiple elements, `h1` and `h2` in this case, at the same time. This can be useful when you want to update font colors to match your site's branding.

```
@font-palette-values --Dark-Mode {
  font-family: "Bungee Spice";
```

```
  /* palette settings for Bungee Spice */
}

@font-palette-values --Dark-Mode {
  font-family: "Bixa";
  /* palette settings for Bixa */
}

h1,
h2 {
  font-palette: --Dark-Mode;
}

h1 {
  font-family: "Bungee Spice", fantasy;
}

h2 {
  font-family: "Bixa", fantasy;
}
```

See also

- font-family
- @font-palette-values
- override-colors descriptor
- font-palette property
- CSSFontPaletteValuesRule.fontFamily

override-colors CSS at-rule descriptor

The **override-colors** CSS descriptor is used to override colors in the chosen base-palette for a color font.

Syntax

```
/* basic syntax */
override-colors: <index of color> <color>;

/* using color names */
override-colors: 0 red;

/* using hex-color */
override-colors: 0 #ff0000;

/* using rgb */
override-colors: 0 rgb(255 0 0);

/* overriding multiple colors */
override-colors:
  0 red,
  1 green,
  2 blue;
```

The override-colors descriptor takes a comma-separated list of the color index and new color value.

The color index is zero-based and any color value can be used.

For each key-value pair of index and color, the color with the index in the specified base-palette will be overwritten. If the color font does not have a color at the specified index, it will be ignored.

Values

[<integer [0,∞]> <absolute-color-base>]

Specifies the index of a color in a base-palette and the color to overwrite it with.

Formal definition

Related at-rule	@font-palette-values
Initial value	n/a (required)
Computed value	as specified

Formal syntax

```
override-colors =
  [ <integer [0,∞]> <color> ]#

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Changing colors of emojis

This example shows how to override colors in the Noto Color Emoji color font to match your site's brand.

HTML

```
<section class="hats">
  <div class="hat">
    <h2>Original Hat</h2>
    <div class="emoji">🧢</div>
  </div>
  <div class="hat">
    <h2>Red Hat</h2>
    <div class="emoji red-hat">🧢</div>
```

```
  </div>
</section>
```

CSS

```
.hats {
  display: flex;
  flex-direction: row;
  justify-content: space-around;
}
```

```
@font-face {
  font-family: "Noto Color Emoji";
  font-style: normal;
  font-weight: normal;
  src: url("https://fonts.gstatic.com/l/font?kit=Yq6P-KqIXTD0t4D9z1ESnKM3-HpFabts6diywYkdG3gjD0U&skey=a373f7129eaba270&v=v24")
    format("woff2");
}

.emoji {
  font-family: "Noto Color Emoji", emoji;
  font-size: 3rem;
}
@font-palette-values --red {
  font-family: "Noto Color Emoji";
  override-colors:
    0 rgb(74 11 0),
    1 rgb(149 22 1),
    2 rgb(183 27 1),
    3 rgb(193 28 1),
    4 rgb(230 34 1);
}
.red-hat {
  font-palette: --red;
}
```

Result

Changing a color in an alternate base-palette

Using Rocher Color Font, this example shows how to override one color in the font.

HTML

```
<h2 class="normal-palette">Normal Palette</h2>
<h2 class="override-palette">Override Palette</h2>
```

CSS

```
@font-face {
  font-family: "Rocher";
  src: url("[path-to-font]/RocherColorGX.woff2") format("woff2");
}
h2 {
  font-family: "Rocher", fantasy;
}
@font-palette-values --override-palette {
  font-family: "Rocher";
  base-palette: 3;
}
@font-palette-values --override-palette {
  font-family: "Rocher";
  base-palette: 3;
  override-colors: 0 rebeccapurple;
}
.normal-palette {
  font-palette: --normal-palette;
}
.override-palette {
  font-palette: --override-palette;
}
```

Result

This example shows that in `base-palette 3`, the color at index 0 is overridden with `rebeccapurple`.

@function CSS at-rule

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`@function`** CSS at-rule enables defining CSS custom functions. Once defined, a custom function can be called using the `<dashed-function>` syntax (for example, `--my-function(30px, 3)`) within any property value.

Syntax

```
@function --function-name(<function-parameter>#?) [returns <css-type>]? {
  <declaration-rule-list>
}

<function-parameter> = --param-name <css-type>? [ : <default-value> ]?
```

The different parts of the `@function` syntax are as follows:

`--function-name`

The identifying name of the function, a `<dashed-ident>` that starts with `--` and is followed by a valid, user-defined identifier. It is case-sensitive.

`<function-parameter>#?` Optional

Zero or more function parameter definitions. Multiple parameter definitions are separated by commas. Each parameter consists of:

`--param-name`

A CSS custom property name to identify the parameter, a `<dashed-ident>` that starts with `--` and is followed by a valid, user-defined identifier. It is case-sensitive. Function parameters can be considered custom properties that are locally scoped to the function body.

`<css-type>` Optional

A CSS data type or a `type()` function that defines the accepted data type(s) for the parameter. If this is not specified, any data type will be valid for the parameter (the same as specifying `type(*)`).

`<default-value>` Optional

A CSS value specifying the default value to assign to the parameter if it is not specified when the function is called. This value must be valid according to the `<css-type>` if specified. The default value is separated from the other parts of the parameter definition with a colon (`:`).

`[returns <css-type>]?` Optional

A CSS data type or a `type()` function, preceded by the keyword `returns`, which defines the accepted return type(s) for the parameter. If this is not specified, any data type will be valid for the parameter (the same as specifying `returns type(*)`), although bear in mind that the function will be invalid if the return type does not match the type produced by the `result` descriptor.

`<declaration-rule-list>`

One or more CSS declarations or at-rules that define the body of the function, which contains its logic. Included declarations can include:

- CSS custom properties, which are locally scoped to the function body.
- The `result` descriptor, either directly inside the `@function` at-rule, or inside a nested at-rule.

Descriptors

`result`

A valid property value that defines the result returned by the CSS custom function. The expression contained in the value is evaluated, and the result is returned.

Description

CSS custom functions allow you to define reusable sections of logic that will return different values depending on the parameters they accept as inputs and the logic defined inside the function body.

A typical CSS function looks like this:

```
@function --transparent(--color, --alpha) {
  result: oklch(from var(--color) l c h / var(--alpha));
}
```

The function has a name of `--transparent` and takes two custom properties as parameters, `--color` and `--alpha`, which can be used locally inside the function body. The body contains a single line, which is a `result` descriptor that defines the value returned by the function. The value of the `result` descriptor uses CSS relative color syntax to convert the input `--color` value into an `oklch()` color with the alpha channel value specified in the input `--alpha` value.

You can then call this function anywhere you want to produce a semi-transparent version of an existing color, for example:

```
section {
  --base-color: #faa6ff;
  background-color: --transparent(var(--base-color), 0.8);
}
```

The function is called by using `<dashed-function>` syntax, which is the function name with parentheses on the end. The desired argument values are specified inside the parentheses.

> **Note:** If multiple CSS functions are given the same name, the function in the stronger cascade `@layer` wins. If all of them are in the same layer, the function defined last in the source order wins.

Specifying data types

It is possible to specify data types for the function parameters and return types. For example:

```
@function --transparent(--color <color>, --alpha <number>) returns <color> {
  result: oklch(from var(--color) l c h / var(--alpha));
}
```

Now the function will only produce a valid value if the input arguments are a `<color>` and a `<number>`, respectively, and the `result` is a `<color>`. If not, for example:

```
section {
  --base-color: #faa6ff;
  background-color: --transparent(var(--base-color), 50%);
}
```

then the value will become invalid at computed-value time (because the specified `--alpha` argument is a `<percentage>` and not a `<number>` as expected) and the `background-color` will end up being set to `transparent`.

You can specify multiple accepted data types using a `type()` function with the `|` symbol as a separator, for example:

```
@function --transparent(--color <color>, --alpha type(<number> | <percentage>))
  returns <color> {
  result: oklch(from var(--color) l c h / var(--alpha));
}
```

With this adjustment, the `--transparent(var(--base-color), 50%)` function call is now valid.

Specifying default values

You can also specify default values for parameters, after a colon at the end of their definition. For example:

```
@function --transparent(--color <color>, --alpha <number>: 0.8) returns <color> {
  result: oklch(from var(--color) l c h / var(--alpha));
}
```

The `--alpha` parameter's default value is now `0.8`. If you want to use this value, you can omit the second argument when calling the function:

```
section {
  --base-color: #faa6ff;
  background-color: --transparent(var(--base-color));
}
```

> **Note:** If an invalid value is passed in as a function argument and a default value is specified in that parameter definition, the invalid value will be ignored, and the default value will be used instead.

Passing comma-containing values as arguments

In the next example, the `--max-plus-x()` function expects to be passed a comma-separated list of lengths and a single length as arguments. It uses the CSS `max()` function to determine which of the list of lengths is the largest, adds it to the single length, then returns the result.

```
@function --max-plus-x(--list <length>#, --x <length>) {
  result: calc(max(var(--list)) + var(--x));
}
```

The first argument needs to be a comma-separated list, which could be misinterpreted as three separate arguments. To get around this problem, you can wrap the value in curly braces when passing it into the function call:

```
div {
  width: --max-plus-x({1px, 7px, 2px}, 3px); /* 10px */
}
```

Including custom properties inside functions

As we've already seen, function parameters are defined as custom properties, which are then available inside the function body.

You can also specify custom properties inside the function body that will act as locally-scoped constants. In the following example, we define a function called `--anim-1s()`, which returns an `animation` shorthand value where the duration and easing values are always the same, and only the animation name and count are varied.

```
@function --anim-1s(--animation, --count) {
  --duration: 1s;
  --easing: linear;
  result: var(--animation) var(--duration) var(--count) var(--easing);
}
```

This kind of usage allows you to write easier, more expressive syntax for animations, provided you know that you always want the duration and easing function to be the same:

```
animation: --anim-1s(bounce, 2);
```

It is also worth noting that you can call one custom function from inside another. In such cases, a custom function can access local variables and function parameters from functions higher up in the call stack. Here, the outer function's parameter and local custom property will be available inside the scope of the inner function:

```
@function --outer(--outer-arg) {
  --outer-local: 2;
  result: --inner();
}

@function --inner() returns <number> {
  result: calc(var(--outer-arg) + var(--outer-local));
}

div {
  z-index: --outer(1); /* 3 */
}
```

In addition, custom properties defined on the same element where the custom function is being called will be available to it:

```
@function --double-z() returns <number> {
  result: calc(var(--z) * 2);
}

div {
  --z: 3;
  z-index: --double-z(); /* 6 */
}
```

When a custom property of the same name is defined in multiple places, function parameters override custom properties defined on the same element, and local custom properties defined inside the function body override both. In the following example, the `--add-a-b-c()` function uses the `--a` property from the `div` rule's custom property, the `--b` property from the function parameter, and the `--c` local custom property.

```
@function --add-a-b-c(--b, --c) {
  --c: 300;
  result: calc(var(--a) + var(--b) + var(--c));
}

div {
```

```
  --a: 1;
  --b: 2;
  --c: 3;
  z-index: --add-a-b-c(20, 30); /* 321 */
}
```

Including complex logic

You can include more complex logic in functions using constructs such as `@media` at-rules and `if()` functions. For example, the next function takes two arguments, one for a narrow-screen layout and one for a wide-screen layout. It returns the latter by default, but returns the former when the viewport width is less than `700px` wide, as detected using a media query.

```
@function --narrow-wide(--narrow, --wide) {
  result: var(--wide);
  @media (width < 700px) {
    result: var(--narrow);
  }
}
```

You can include multiple `result` descriptors to express different results for different logic outcomes.

> **Note:** CSS functions behave in the same way as the rest of CSS regarding conflict resolution — last in source order wins. Therefore, in the above function, the `result` is `var(--wide)` unless the media query test returns true, in which case it is overridden by `var(--narrow)`.
>
> There are no early returns in CSS functions like there are in JavaScript functions. In the above function, if the media query was written first, before the single `result` line, the `result` would always be `var(--wide)` because it would override `var(--narrow)` in cases where the media query test returns true.

We could rewrite the CSS custom function to use an `if()` function instead:

```
@function --narrow-wide(--narrow, --wide) {
  result: if(media(width < 700px): var(--narrow) ; else: var(--wide));
}
```

Formal syntax

```
@function =
  @function <function-token> <function-parameter>#? ) [ returns <css-type> ]? { <declaration-rule-list> }

<function-parameter> =
  <custom-property-name> <css-type>? [ : <default-value> ]?

<css-type> =
  <syntax-component>  |
  <type()>

<default-value> =
  <declaration-value>

<syntax-component> =
  <syntax-single-component> <syntax-multiplier>?  |
  '<' transform-list '>'

<type()> =
  type( <string> )

<syntax-single-component> =
  '<' <syntax-type-name> '>'  |
  <ident>

<syntax-multiplier> =
  '#'  |
  '+'

<syntax-type-name> =
  angle               |
  color               |
  custom-ident        |
  image               |
  integer             |
  length              |
  length-percentage   |
  number              |
  percentage          |
  resolution          |
  string              |
  time                |
  url                 |
  transform-function
```

This syntax reflects the latest standard as per CSS Functions and Mixins Module, CSS Images Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

For more examples, see our Using CSS custom functions guide.

Basic <code>@function</code> usage

This example shows a basic function that doubles the value passed into it.

HTML

The markup features a `<p>` element containing some text content:

```
<p>Some content</p>
```

CSS

In our styles, we first define the CSS custom function. The function is called `--double`, and accepts a single parameter of any type, which we've called `--value`. Inside the function body, we include a `result` descriptor that uses the `calc()` function to double the passed argument:

```
@function --double(--value) {
  result: calc(var(--value) * 2);
}
```

Next, we define a `--base-spacing` custom property with a value of `10px`. We assign that property to the `border-radius` value, but then double it for the `padding` value using the `--double()` custom function.

```
html,
body {
  height: 100%;
}

body {
  margin: 0;
  display: grid;
  place-items: center;
  font-family: system-ui;
}
```

```
p {
  --base-spacing: 10px;
  border-radius: var(--base-spacing);
  padding: --double(var(--base-spacing));
  width: 50%;
  background-color: wheat;
}
```

@import CSS at-rule

The **`@import`** CSS at-rule is used to import style rules from other valid stylesheets. An `@import` rule *must* be defined at the top of the stylesheet, before any other at-rule (except @charset and @layer) and style declarations, or it will be ignored.

Syntax

```
@import url;
@import url layer;
@import url layer(layer-name);
@import url layer(layer-name) supports(supports-condition);
@import url layer(layer-name) supports(supports-condition) list-of-media-queries;
@import url layer(layer-name) list-of-media-queries;
@import url supports(supports-condition);
@import url supports(supports-condition) list-of-media-queries;
@import url list-of-media-queries;
```

where:

url

> Is a `<string>` or a `<url>` type representing the location of the resource to import. The URL may be absolute or relative.

list-of-media-queries

> Is a comma-separated list of media queries, which specify the media-dependent conditions for applying the CSS rules defined in the linked URL. If the browser does not support any of these queries, it does not load the linked resource.

layer-name

> Is the name of a cascade layer into which the contents of the linked resource are imported. See `layer()` for more information.

supports-condition

> Indicates the feature(s) that the browser must support in order for the stylesheet to be imported. If the browser does not conform to the conditions specified in the *supports-condition*, it may not fetch the linked stylesheet, and even if downloaded through some other path, will not load it. The syntax of `supports()` is almost identical to that described in `@supports`, and that topic can be used as a more complete reference.

Use `@import` together with the `layer` keyword or `layer()` function to import external style sheets (from frameworks, widget stylesheets, libraries, etc.) into layers.

Description

Imported rules must come before all other types of rules, except `@charset` rules and layer creating `@layer` statements.

```
* {
  margin: 0;
  padding: 0;
}
/* more styles */
@import "my-imported-styles.css";
```

As the `@import` at-rule is declared after the styles it is invalid and hence ignored.

```
@import "my-imported-styles.css";
* {
  margin: 0;
  padding: 0;
}
/* more styles */
```

The `@import` rule is not a nested statement. Therefore, it cannot be used inside conditional group at-rules.

So that user agents can avoid retrieving resources for unsupported media types, authors may specify media-dependent import conditions. These conditional imports specify comma-separated media queries after the URL. In the absence of any media query, the import is not conditional on the media used. Specifying `all` for the `list-of-media-queries` has the same effect.

Similarly, user agents can use the `supports()` function in an `@import` at-rule to only fetch resources if a particular feature set is (or is not) supported. This allows authors to take advantage of recently introduced CSS features, while providing graceful fallbacks for older browser versions. Note that the conditions in the `supports()` function of an `@import` at-rule can be obtained in JavaScript using `CSSImportRule.supportsText`.

The `@import` rule can also be used to create a cascade layer by importing rules from a linked resource. Rules can also be imported into an existing cascade layer. The `layer` keyword or the `layer()` function is used with `@import` for this purpose. Declarations in style rules from imported stylesheets interact with the cascade as if they were written literally into the stylesheet at the point of the import.

Formal syntax

```
@import =
  @import [ <url> | <string> ] [ [ layer | layer( <layer-name> ) ] || [ scope | scope( <scope-start> | <scope-boundaries> ) ] || <supports-import-condition> ]? <media-import-condition> ;

```

This syntax reflects the latest standard as per CSS Cascading and Inheritance Level 5, CSS Cascading and Inheritance Level 6, CSS Conditional Rules Module Level 3, CSS Conditional Rules Module Level 4, CSS Conditional Rules Module Level 5, CSS Fonts Module Level 5, Media Queries Level 5, Selectors Level 4, Selectors Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Importing CSS rules

```
@import "custom.css";
@import url("chrome://communicator/skin/communicator.css");
```

The two examples above show how to specify the *url* as a `<string>` and as a `url()` function.

Importing CSS rules conditional on media queries

```
@import "fine-print.css" print;
@import "bluish.css" print, screen;
@import "common.css" screen;
@import "landscape.css" screen and (orientation: landscape);
```

The `@import` rules in the above examples show media-dependent conditions that will need to be true before the linked CSS rules are applied. So for instance, the last `@import` rule will load the `landscape.css` stylesheet only on a screen device in landscape orientation.

Importing CSS rules conditional on feature support

```
@import "grid.css" supports(display: grid) screen and (width <= 400px);
@import "flex.css" supports((not (display: grid)) and (display: flex)) screen
  and (width <= 400px);
```

The `@import` rules above illustrate how you might import a layout that uses a grid if `display: grid` is supported, and otherwise imports CSS that uses `display: flex`. While you can only have one `supports()` statement, you can combine any number of feature checks with `not`, `and`, and `or`. However, you must use parenthesis to define precedence when you mix them, e.g., `supports((..) or (..) and not (..))` is invalid, but `supports((..) or ((..) and (not (..))))` is valid. Note that if you just have a single declaration then you don't need to wrap it in additional parentheses: this is shown in the first example above.

The examples above show support conditions using basic declaration syntax. You can also specify CSS functions in `supports()`, and it will evaluate to `true` if they are supported and can be evaluated on the user-agent. For example, the code below shows an `@import` that is conditional on both child combinators (`selector()`) and the `font-tech()` function:

```
@import "whatever.css"
  supports((selector(h2 > p)) and (font-tech(color-COLRv1)));
```

Importing CSS rules into a cascade layer

```
@import "theme.css" layer(utilities);
```

In the above example, a cascade layer named `utilities` is created and it will include rules from the imported stylesheet `theme`.

```
@import "headings.css" layer(default);
@import "links.css" layer(default);

@layer default {
  audio[controls] {
    display: block;
  }
}
```

In the above example, the rules in `headings.css` and `links.css` stylesheets cascade within the same layer as the `audio[controls]` rule.

```
@import "theme.css" layer();
@import "style.css" layer;
```

This is an example of creating two separate unnamed cascade layers and importing the linked rules into each one separately. A cascade layer declared without a name is an unnamed cascade layer. Unnamed cascade layers are finalized when created: they do not provide any means for re-arranging or adding styles and they cannot be referenced from outside.

layer() CSS function

The **`layer()`** CSS function is used along with the `@import` at-rule to put the imported resource in a separate named cascade layer.

Syntax

```
@import url layer(layer-name);
@import "dark.css" layer(framework.themes.dark);
```

The `framework.themes.dark` is the layer into which the CSS file would be imported.

Formal syntax

```
layer() =
  layer( <layer-name> )

<layer-name> =
  <ident> [ '.' <ident> ]*
```

This syntax reflects the latest standard as per CSS Cascading and Inheritance Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

- CSS at-rule functions
- CSS cascading and inheritance module

@keyframes CSS at-rule

The **`@keyframes`** CSS at-rule controls the intermediate steps in a CSS animation sequence by defining styles for keyframes (or waypoints) along the animation sequence. This gives more control over the intermediate steps of the animation sequence than transitions.

Syntax

```
@keyframes slide-in {
  from {
    transform: translateX(0%);
  }

  to {
    transform: translateX(100%);
  }
}
```

Values

`<keyframes-name>`

A case-sensitive `<custom-ident>` or string naming the keyframe list.

`from`

Equivalent to the value `0%`.

`to`

Equivalent to the value `100%`.

`<percentage>`

A percentage through the animation sequence at which the specified keyframe should occur.

`<timeline-range-name> <percentage>`

A percentage through the specified `animation-range` at which the specified keyframe should occur.

Description

To use keyframes, create a `@keyframes` rule with a name that is then used by the `animation-name` property to match an animation to its keyframe declaration. Each `@keyframes` rule contains a style list of keyframe selectors, which specify percentages along the animation when the keyframe occurs, and a block containing the styles for that keyframe.

You can list the keyframe percentages in any order; they will be handled in the order they should occur.

JavaScript can access the `@keyframes` at-rule with the CSS object model interface `CSSKeyframesRule`.

Valid keyframe lists

If a keyframe rule doesn't specify the start or end states of the animation (that is, `0%`/`from` and `100%`/`to`), browsers will use the element's existing styles for the start/end states. This can be used to animate an element from its initial state and back.

Properties that can't be animated in keyframe rules are ignored, but supported properties will still be animated.

Resolving duplicates

If multiple keyframe sets exist for a given name, the last one encountered by the parser is used. `@keyframes` rules don't cascade, so animations never derive keyframes from more than one rule set.

If a given animation time offset is duplicated, all keyframes in the `@keyframes` rule for that percentage are used for that frame. There is cascading within a `@keyframes` rule if multiple keyframes specify the same percentage values.

When properties are left out of some keyframes

Properties that aren't specified in every keyframe are interpolated if possible — properties that can't be interpolated are dropped from the animation. For example:

```
@keyframes identifier {
  0% {
    top: 0;
    left: 0;
  }
  30% {
    top: 50px;
  }
  68%,
  72% {
    left: 50px;
  }
  100% {
    top: 100px;
    left: 100%;
  }
}
```

Here, the `top` property animates using the `0%`, `30%`, and `100%` keyframes, and `left` animates using the `0%`, `68%`, `72%` and `100%` keyframes.

When a keyframe is defined multiple times

If a keyframe is defined multiple times but not all affected properties are in each keyframe, all values specified in these keyframes are considered. For example:

```
@keyframes identifier {
  0% {
    top: 0;
  }
  50% {
    top: 30px;
    left: 20px;
  }
  50% {
    top: 10px;
  }
  100% {
    top: 0;
  }
}
```

In this example, at the `50%` keyframe, the values used are `top: 10px` and `left: 20px`.

<code>!important</code> in a keyframe

Declarations in a keyframe qualified with the `important` flag set are ignored.

```
@keyframes important1 {
  0% {
    margin-top: 50px;
  }
  50% {
    margin-top: 150px !important; /* ignored */
  }
  100% {
    margin-top: 100px;
  }
}

@keyframes important2 {
  from {
    margin-top: 50px;
    margin-bottom: 100px;
  }
  to {
    margin-top: 150px !important; /* ignored */
    margin-bottom: 50px;
  }
}
```

Formal syntax

```
@keyframes =
  @keyframes <keyframes-name> { <qualified-rule-list> }
```

```
<keyframes-name> =
  <custom-ident>  |
  <string>
```

This syntax reflects the latest standard as per CSS Animations Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

@layer CSS at-rule

The **`@layer`** CSS at-rule is used to declare a cascade layer and can also be used to define the order of precedence in case of multiple cascade layers.

Try it

```
@layer module, state;

@layer state {
  .alert {
    background-color: brown;
  }
  p {
    border: medium solid limegreen;
  }
}

@layer module {
  .alert {
    border: medium solid violet;
    background-color: yellow;
    color: white;
  }
}
```

```
<p class="alert">Beware of the zombies</p>
```

Syntax

```
/* statement at-rules */
@layer layer-name;
@layer layer-name, layer-name, layer-name;

/* block at-rules */
@layer {rules}
@layer layer-name {rules}
```

where:

layer-name

Is the name of the cascade layer.

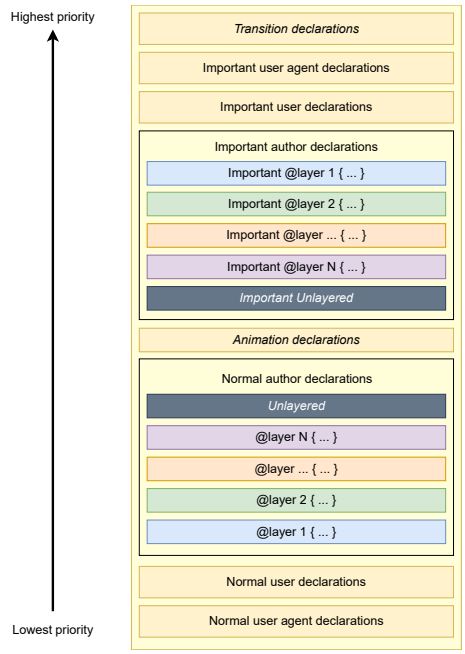
rules

Is the set of CSS rules in the cascade layer.

Description

Rules within a cascade layer cascade together, giving more control over the cascade to web developers. Styles that are not defined in a layer always override styles declared in named and anonymous layers.

The following diagram shows layer priorities where layers are declared in 1, 2, ..., N order.



As noted in the above diagram, *important declarations*, declarations with the `!important` flag, have priority over *normal declarations*, or regular declarations without the `!important` flag. The order of precedence among important rules is the inverse of normal rules. Transitions have the greatest precedence. Next in order of highest to lowest priority are the important user agent declarations, important user declarations, and important author declarations; in that order. Users can specify styles using browser preferences, operating system preferences, or browser extensions. Their important declarations take precedence over *author*, or *web developer* written, important declarations.

Within author styles, all important declarations within CSS layers take precedence over any important declarations declared outside of a layer, while all normal declarations within CSS layers have a lower priority than declarations declared outside of a layer. The declaration order matters. The first declared layer gets the lowest priority and the last declared layer gets the highest priority. However, the priority is reversed when the `!important` flag is used.

The `@layer` at-rule is used to create a cascade layer in one of three ways.

The first way is to use a `@layer` block at-rule to create a named cascade layer with the CSS rules for that layer inside, like so:

```
@layer utilities {
  .padding-sm {
    padding: 0.5rem;
  }

  .padding-lg {
    padding: 0.8rem;
  }
}
```

The second way is to use a `@layer` statement at-rule to create one or more comma-separated named cascade layers without assigning any styles. This can be a single layer, as shown below:

```
@layer utilities;
```

Multiple layers can be defined at once, as shown below:

```
@layer theme, layout, utilities;
```

This is useful because the initial order in which layers are declared indicates which layer has precedence. As with declarations, the last layer to be listed will win if declarations are found in multiple layers. Therefore, with the preceding example, if a competing rule was found in `theme` and `utilities`, the one in `utilities` would win and be applied.

A rule in `utilities` would be applied *even if it has lower specificity* than the rule in `theme`. This is because once the layer order has been established, specificity and order of appearance are ignored. This enables using simpler CSS selectors because you do not have to ensure that a selector will have high enough specificity to override competing rules; all you need to ensure is that it appears in a later layer.

> **Note:** Having declared your layer names, thus setting their order, you can add CSS rules to the layer by re-declaring the name. The styles are then appended to the layer and the layer order will not be changed.

The third way is to create an unnamed layer using a `@layer` block at-rule without including a layer name. For example:

```
@layer {
  p {
    margin-block: 1rem;
  }
}
```

This creates an *anonymous cascade layer*. This layer functions in the same way as named layers; however, rules cannot be assigned to it later. The order of precedence for anonymous layers is the order in which layers are declared, named or not, and lower than the styles declared outside of a layer.

Another way to create a cascade layer is by using `@import`. In this case, the rules would be in the imported stylesheet. Remember that the `@import` at-rule must precede all other types of rules, except `@charset` and `@layer` statements (not `@layer` blocks).

```
@import "theme.css" layer(utilities);
```

Nesting layers

Layers may be nested. For example:

```
@layer framework {
  @layer layout {
```

```
  }
}
```

To append rules to the `layout` layer inside `framework`, join the two names with a `.`.

```
@layer framework.layout {
  p {
    margin-block: 1rem;
  }
}
```

Formal syntax

```
@layer =
  @layer <layer-name>? { <rule-list> }  |
  @layer <layer-name># ;

<layer-name> =
  <ident> [ '.' <ident> ]*
```

This syntax reflects the latest standard as per CSS Cascading and Inheritance Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

In the following example, two CSS rules are created. One for the `<p>` element outside of any layer and one inside a layer named `type` for `.box p`.

Without layers, the selector `.box p` would have the highest specificity, and therefore, the text `Hello, world!` will display in green. As the `type` layer comes before the anonymous layer created to hold non-layer content, the text will be purple.

Also notice the order. Even though we declare the non-layered style first, it's still applied *after* the layer styles.

HTML

```
<div class="box">
  <p>Hello, world!</p>
</div>
```

CSS

```
p {
  color: rebeccapurple;
}

@layer type {
  .box p {
    font-weight: bold;
    font-size: 1.3em;
    color: green;
  }
}
```

Result

Assigning rules to existing layers

In the following example, two layers are created with no rules applied, then CSS rules are applied to the two layers. The `base` layer defines a `color`, `border`, `font-size`, and `padding`. The `special` layer defines a different color. As `special` comes last when the layers were defined, the color it provides is used and the text is displayed using `rebeccapurple`. All of the other rules from `base` still apply.

HTML

```
<div class="item">
  I am displayed in <code>color: rebeccapurple</code> because the
  <code>special</code> layer comes after the <code>base</code> layer. My green
  border, font-size, and padding come from the <code>base</code> layer.
</div>
```

CSS

```
@layer base, special;

@layer special {
  .item {
    color: rebeccapurple;
  }
}

@layer base {
  .item {
    color: green;
    border: 5px solid green;
    font-size: 1.3em;
    padding: 0.5em;
  }
}
```

@media CSS at-rule

The **`@media`** CSS at-rule can be used to apply part of a style sheet based on the result of one or more media queries. With it, you specify a media query and a block of CSS to apply to the document if and only if the media query matches the device on which the content is being used.

> **Note:** In JavaScript, the rules created using `@media` can be accessed with the `CSSMediaRule` CSS object model interface.

Try it

```
abbr {
  color: #860304;
  font-weight: bold;
  transition: color 0.5s ease;
}

@media (hover: hover) {
  abbr:hover {
    color: #001ca8;
    transition-duration: 0.5s;
  }
}

@media not all and (hover: hover) {
  abbr::after {
    content: " (" attr(title) ")";
  }
}
```

```
<p>
  <abbr title="National Aeronautics and Space Administration">NASA</abbr> is a
  U.S. government agency that is responsible for science and technology related
  to air and space.
</p>
```

Syntax

```
/* At the top level of your code */
@media screen and (width >= 900px) {
  article {
    padding: 1rem 3rem;
  }
}

/* Nested within another conditional at-rule */
@supports (display: flex) {
  @media screen and (width >= 900px) {
    article {
      display: flex;
    }
  }
}
```

The `@media` at-rule may be placed at the top level of your code or nested inside any other conditional group at-rule.

For a discussion of media query syntax, please see Using media queries.

Description

A media query's `<media-query-list>` includes `<media-type>`s, `<media-feature>`s, and logical operators.

Media types

A *`<media-type>`* describes the general category of a device. Except when using the `only` logical operator, the media type is optional and the `all` type is implied.

`all`

Suitable for all devices.

`print`

Intended for paged material and documents viewed on a screen in print preview mode. (Please see paged media for information about formatting issues that are specific to these formats.)

`screen`

Intended primarily for screens.

> **Note:** CSS2.1 and Media Queries 3 defined several additional media types (`tty`, `tv`, `projection`, `handheld`, `braille`, `embossed`, and `aural`, but they were deprecated in Media Queries 4 and shouldn't be used.

Media features

A *`<media feature>`* describes specific characteristics of the user agent, output device, or environment. Media feature expressions test for their presence, value, or range of values, and are entirely optional. Each media feature expression must be surrounded by parentheses.

`any-hover`

Does any available input mechanism allow the user to hover over elements?

`any-pointer`

Is any available input mechanism a pointing device, and if so, how accurate is it?

`aspect-ratio`

Width-to-height aspect ratio of the viewport.

`color`

Number of bits per color component of the output device, or zero if the device isn't color.

`color-gamut`

Approximate range of colors that are supported by the user agent and output device.

`color-index`

Number of entries in the output device's color lookup table, or zero if the device does not use such a table.

`device-aspect-ratio`

Width-to-height aspect ratio of the output device. Deprecated in Media Queries Level 4.

`device-height`

Height of the rendering surface of the output device. Deprecated in Media Queries Level 4.

`device-posture`

Detects the device's current posture, that is, whether the viewport is in a flat or folded state. Defined in the Device Posture API.

`device-width`

Width of the rendering surface of the output device. Deprecated in Media Queries Level 4.

`display-mode`

The mode in which an application is being displayed: for example, fullscreen or picture-in-picture mode. Added in Media Queries Level 5.

`dynamic-range`

Combination of brightness, contrast ratio, and color depth that are supported by the user agent and the output device. Added in Media Queries Level 5.

`forced-colors`

Detect whether user agent restricts color palette. Added in Media Queries Level 5.

`grid`

Does the device use a grid or bitmap screen?

`height`

Height of the viewport.

`horizontal-viewport-segments`

Detects whether the device has a specified number of viewport segments laid out horizontally.

`hover`

Does the primary input mechanism allow the user to hover over elements?

`inverted-colors`

Is the user agent or underlying OS inverting colors? Added in Media Queries Level 5.

`monochrome`

Bits per pixel in the output device's monochrome frame buffer, or zero if the device isn't monochrome.

`orientation`

Orientation of the viewport.

`overflow-block`

How does the output device handle content that overflows the viewport along the block axis?

`overflow-inline`

Can content that overflows the viewport along the inline axis be scrolled?

`pointer`

Is the primary input mechanism a pointing device, and if so, how accurate is it?

`prefers-color-scheme`

Detect if the user prefers a light or dark color scheme. Added in Media Queries Level 5.

`prefers-contrast`

Detects if the user has requested the system increase or decrease the amount of contrast between adjacent colors. Added in Media Queries Level 5.

`prefers-reduced-data`

Detects if the user has requested the web content that consumes less internet traffic.

`prefers-reduced-motion`

The user prefers less motion on the page. Added in Media Queries Level 5.

`prefers-reduced-transparency`

Detects if a user has enabled a setting on their device to reduce the transparent or translucent layer effects used on the device.

`resolution`

Pixel density of the output device.

`scan`

Whether display output is progressive or interlaced.

`scripting`

Detects whether scripting (i.e., JavaScript) is available. Added in Media Queries Level 5.

`shape`

Detects the shape of the device to distinguish rectangular and round displays.

`update`

How frequently the output device can modify the appearance of content.

`vertical-viewport-segments`

Detects whether the device has a specified number of viewport segments laid out vertically. Added in Media Queries Level 5.

`video-dynamic-range`

Combination of brightness, contrast ratio, and color depth that are supported by the video plane of user agent and the output device. Added in Media Queries Level 5.

`width`

Width of the viewport including width of scrollbar.

`-moz-device-pixel-ratio`

The number of device pixels per CSS pixel. Use the `resolution` feature with the `dppx` unit instead.

`-webkit-animation`

The browser supports `-webkit` prefixed CSS `animation`. Use the `@supports (animation)` feature query instead.

`-webkit-device-pixel-ratio`

The number of device pixels per CSS pixel. Use the `resolution` feature with the `dppx` unit instead.

`-webkit-transform-2d`

The browser supports `-webkit` prefixed 2D CSS `transform`. Use the `@supports (transform)` feature query instead.

`-webkit-transform-3d`

The browser supports `-webkit` prefixed 3D CSS `transform`. Use the `@supports (transform)` feature query instead.

`-webkit-transition`

The browser supports `-webkit` prefixed CSS `transition`. Use the `@supports (transition)` feature query instead.

Logical operators

The *logical operators* `not`, `and`, `only`, and `or` can be used to compose a complex media query. You can also combine multiple media queries into a single rule by separating them with commas.

`and`

Used for combining multiple media features together into a single media query, requiring each chained feature to return `true` for the query to be `true`. It is also used for joining media features with media types.

`not`

Used to negate a media query, returning `true` if the query would otherwise return `false`. If present in a comma-separated list of queries, it will only negate the specific query to which it is applied.

> **Note:** In Level 3, the `not` keyword can't be used to negate an individual media feature expression, only an entire media query.

`only`

Applies a style only if an entire query matches. It is useful for preventing older browsers from applying selected styles. When not using `only`, older browsers would interpret the query `screen and (width <= 500px)` as `screen`, ignoring the remainder of the query, and applying its styles on all screens. If you use the `only` operator, you *must also* specify a media type.

`,` (comma)

Commas are used to combine multiple media queries into a single rule. Each query in a comma-separated list is treated separately from the others. Thus, if any of the queries in a list is `true`, the entire media statement returns `true`. In other words, lists behave like a logical `or` operator.

`or`

Equivalent to the `,` operator. Added in Media Queries Level 4.

User agent client hints

Some media queries have corresponding user agent client hints. These are HTTP headers that request content that is pre-optimized for the particular media requirement. They include `Sec-CH-Prefers-Color-Scheme` and `Sec-CH-Prefers-Reduced-Motion`.

Formal syntax

```
@media =
  @media <media-query-list> { <rule-list> }
```

This syntax reflects the latest standard as per CSS Conditional Rules Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Accessibility

To best accommodate people who adjust a site's text size, use `em`s when you need a `<length>` for your media queries.

Both `em` and `px` are valid units, but `em` works better if the user changes the browser text size.

Also consider media queries or HTTP user agent client hints to improve the user's experience. For example, the media query `prefers-reduced-motion` or the equivalent HTTP header `Sec-CH-Prefers-Reduced-Motion` can be used to minimize the amount of animation or motion used based on user preferences.

Security

Because media queries provide insights into the capabilities—and by extension, the features and design—of the device the user is working with, there is the potential that they could be abused to construct a "fingerprint" which identifies the device, or at least categorizes it to some degree of detail that may be undesirable to users.

Because of this potential, a browser may opt to fudge the returned values in some manner in order to prevent them from being used to precisely identify a computer. A browser might also offer additional measures in this area; for example, if Firefox's "Resist Fingerprinting" setting is enabled, many media queries report default values rather than values representing the actual device state.

Examples

Testing for print and screen media types

```
@media print {
  body {
    font-size: 10pt;
  }
}

@media screen {
  body {
    font-size: 13px;
  }
}

@media screen, print {
  body {
    line-height: 1.2;
  }
}
```

The range syntax allows for less verbose media queries when testing for any feature accepting a range, as shown in the below examples:

```
@media (height > 600px) {
  body {
    line-height: 1.4;
  }
}

@media (400px <= width <= 700px) {
  body {
    line-height: 1.4;
  }
}
```

For more examples, please see Using media queries.

-moz-device-pixel-ratio CSS media feature

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`-moz-device-pixel-ratio`** Gecko-only CSS media feature can be used to apply styles based on the number of device pixels per CSS pixel.

> **Warning:** Do not use this feature. Use the `resolution` feature with the `dppx` unit instead.

> **Note:** This media feature is also implemented by WebKit as `-webkit-device-pixel-ratio`. The min and max prefixes as implemented by Gecko are named `min--moz-device-pixel-ratio` and `max--moz-device-pixel-ratio`; but the same prefixes as implemented by WebKit are named `-webkit-min-device-pixel-ratio` and `-webkit-max-device-pixel-ratio`.

Syntax

`<number>`

The number of device pixels per CSS pixel.

Media: `@media` **Accepts min/max prefixes:** yes

Examples

Basic compatibility example

`-moz-device-pixel-ratio` may be used for compatibility with Firefox older than 16, and alongside `-webkit-device-pixel-ratio` for compatibility with WebKit-based browsers that do not support `dppx`.

Example:

```
/* First, set for WebKit-based browsers */
@media (-webkit-min-device-pixel-ratio: 2),
  (min--moz-device-pixel-ratio: 2) /* Older Firefox browsers (prior to firefox 16) */,
  (min-resolution: 2dppx) /* The standard way */,
  (min-resolution: 192dpi); /* dppx fallback */
```

> **Note:** See this CSSWG article for compatibility good practices regarding `resolution` and `dppx`.

Specifications

Not part of any standard.

-webkit-animation CSS media feature

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

> **Note:** All browsers support the `animation` property without vendor prefixes. Only WebKit (Safari), and not Chromium, based browsers supports the `-webkit-animation` media feature. No browsers support `animation`, without the prefix, as a media query. Use the `@supports (animation)` feature query instead.

The **`-webkit-animation`** Boolean CSS media feature is a WebKit extension whose value is `true` if vendor-prefixed CSS `animation`s are supported.

Apple has a description in Safari CSS Reference.

> **Note:** This media feature is only supported by WebKit. If possible, use an `@supports` feature query instead.

Syntax

The `-webkit-animation` media feature is a Boolean whose value is `true` if the vendor-prefixed CSS animation properties are supported *and* the browser supports prefixed property media queries.

Values

`true`

The browser supports `-webkit` prefixed CSS `animation`.

`false`

The browser doesn't support these prefixed CSS animations.

Examples

Example of -webkit-animation

```
@media (-webkit-animation) {
  /* CSS to use if -webkit- prefixed animations are supported AND the browser supports prefixed properties as media queries */
}
```

Specifications

Not part of any standard.

See also

- `@supports` and using feature queries

-webkit-device-pixel-ratio CSS media feature

The **`-webkit-device-pixel-ratio`** is a non-standard Boolean CSS media feature which is an alternative to the standard `resolution` media feature.

> **Note:** If possible, use the `resolution` media feature query instead, which is a standard media feature. While this prefixed media feature is a WebKit feature, other browser engines may support it. See browser compatibility below.

Syntax

The `-webkit-device-pixel-ratio` feature is specified as a `<number>` value. It is a range feature, meaning that you can also use the prefixed **`-webkit-min-device-pixel-ratio`** and **`-webkit-max-device-pixel-ratio`** variants to query minimum and maximum values, respectively.

Values

`<number>`

The number of device pixels used to represent each CSS `px`. Although the value is a `<number>`, and thus doesn't syntactically allow units, its implicit unit is `dppx`.

Implementation

```
/* A unit of "dppx" is implied: */
@media (-webkit-min-device-pixel-ratio: 2) {
  /* … */
}
/* It is equivalent to: */
@media (min-resolution: 2dppx) {
  /* … */
}

/* Similarly: */
@media (-webkit-max-device-pixel-ratio: 2) {
  /* … */
}
/* It is equivalent to: */
```

```
@media (max-resolution: 2dppx) {
  /* … */
}
```

Examples

HTML

```
<p>This is a test of your device's pixel density.</p>
```

CSS

```
/* Exact resolution */
@media (-webkit-device-pixel-ratio: 1) {
  p {
    color: red;
  }
}

/* Minimum resolution */
@media (-webkit-min-device-pixel-ratio: 1.1) {
  p {
    font-size: 1.5em;
  }
}

/* Maximum resolution */
@media (-webkit-max-device-pixel-ratio: 3) {
  p {
    background: yellow;
  }
}
```

Result

- W3C Suggested Method to UnPrefix

-webkit-transform-2d CSS media feature

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

> **Note:** All browsers support the `transform` property without vendor prefixes. Only WebKit (Safari), and not Chromium, based browsers supports the `-webkit-transform-2d` media feature. No browsers support `transform`, without the prefix or `2d` extension, as a media query. Use the `@supports (transform)` feature query instead.

The **`-webkit-transform-2d`** Boolean CSS media feature is a WebKit extension whose value is `true` if vendor-prefixed CSS 2D `transform`s and non-standard vendor-prefixed media queries are supported.

Apple has a description in Safari CSS Reference.

Syntax

`-webkit-transform-2d` is a Boolean CSS media feature whose value is `true` if the browser supports `-webkit` prefixed CSS 2D `transform`s.

Values

`true`

The browser supports the 2D CSS transforms with the `-webkit` prefix.

`false`

The 2D CSS transforms prefixed with `-webkit` are not supported by the browser.

Examples

Basic example

```
@media (-webkit-transform-2d) {
  div {
    -webkit-transform: translate(100px, 100px);
  }
}
```

This media feature is only supported by WebKit. The unprefixed `transform` property is supported in all modern browsers. If possible, use an `@supports` feature query instead:

```
@supports (-webkit-transform: translate(100px, 100px)) {
  div {
    -webkit-transform: translate(100px, 100px);
  }
}
```

Specifications

Not part of any standard.

See also

- `-webkit-transform-3d`
- `-webkit-transition`
- `-webkit-animation`
- `transform` and using CSS transforms
- `@media` and Using media queries
- `@supports` and using feature queries

-webkit-transform-3d CSS media feature

The **`-webkit-transform-3d`** Boolean CSS media feature is a WebKit extension whose value is `true` if vendor-prefixed CSS 3D `transform`s are supported.

> **Note:** While this media feature is currently supported by most browsers. If possible, use an `@supports` feature query instead.

Syntax

`-webkit-transform-3d` is a Boolean CSS media feature whose value is `true` if the browser supports `-webkit` prefixed CSS 3D `transform`s.

Values

`true`

The browser supports the 3D CSS transforms with the `-webkit` prefix and supports non-standard, prefixed media queries.

`false`

The 3D CSS transforms prefixed with `-webkit` are not supported by the browser.

Examples

Examples of media queries with -webkit-transform-3d

```
@media (-webkit-transform-3d) {
  .foo {
    transform-style: preserve-3d;
  }
}
```

A better method for checking for browser support is using a feature query:

```
@supports (transform-style) {
  .foo {
    transform-style: preserve-3d;
  }
}
```

See also

- `-webkit-transform-2d`
- `-webkit-transition`
- `-webkit-animation`
- `transform` and using CSS transforms
- `@media` and Using media queries
- `@supports` and using feature queries

-webkit-transition CSS media feature

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

> **Note:** All browsers support the `transition` property without vendor prefixes. Only WebKit (Safari), and not Chromium, based browsers support the `-webkit-transition` media feature. No browsers support `transition` without the prefix as a media query (though some browsers do support - `-webkit-transform-3d`). Use the `@supports (transition)` feature query instead.

The **`-webkit-transition`** Boolean non-standard CSS media feature is a WebKit extension whose value is `true` if the browsing context supports CSS transitions.

Apple has a description in Safari CSS Reference; this is now called `transition` there.

> **Note:** You should not use this media feature; it was never specified, has never been widely implemented, and has been removed from most browsers. Use a `@supports` feature query instead.

Syntax

```
@media (-webkit-transition) {
  /* CSS to use if this media feature and prefixed transitions are supported */
}
```

Examples

Use @supports instead

Do not use the `-webkit-transition` media feature. Instead, test for transition support using the CSS `@supports` at-rule, like this:

```
@supports (transition: initial) {
  /* CSS to use if transitions are supported */
}
```

Obsolete example

Before this became obsolete, you could use `-webkit-transition` in your CSS like this:

```
@media (-webkit-transition) {
  /* CSS to use if transitions are supported */
}
```

Specifications

Not part of any standard.

See also

- `-webkit-transform-3d`
- `-webkit-transform-2d`
- `-webkit-animation`
- `transition` and using CSS transitions
- `@media` and Using media queries
- `@supports` and using feature queries

any-hover CSS media feature

The **`any-hover`** CSS media feature can be used to test whether *any* available input mechanism can hover over elements.

Syntax

The `any-hover` feature is specified as a keyword value chosen from the list below.

`none`

None of the available input mechanism(s) can hover conveniently, or there is no pointing input mechanism.

`hover`

One or more available input mechanisms can conveniently hover over elements.

Examples

Testing whether input methods can hover

HTML

```
<a href="#">Try hovering over me!</a>
```

CSS

```
@media (any-hover: hover) {
  a:hover {
    background: yellow;
  }
}
```

Result

See also

- the `hover` media feature

any-pointer CSS media feature

The **`any-pointer`** CSS media feature tests whether the user has *any* pointing device (such as a mouse), and if so, how accurate it is.

> **Note:** If you want to test the accuracy of the *primary* pointing device, use `pointer` instead.

Syntax

The `any-pointer` feature is specified as a keyword value chosen from the list below.

`none`

No pointing device is available.

`coarse`

At least one input mechanism includes a pointing device of limited accuracy.

`fine`

At least one input mechanism includes an accurate pointing device.

> **Note:** More than one value can match if the available devices have different characteristics, although `none` only matches when none of them are pointing devices.

Examples

This example creates a small checkbox for users with at least one fine pointer and a large checkbox for users with at least one coarse pointer. The big checkbox takes precedence because it is declared after the small one.

HTML

```
<input id="test" type="checkbox" /> <label for="test">Look at me!</label>
```

CSS

```
input[type="checkbox"]:checked {
  background: gray;
}

@media (any-pointer: fine) {
```

```
  input[type="checkbox"] {
    appearance: none;
    width: 15px;
    height: 15px;
    border: 1px solid blue;
  }
}

@media (any-pointer: coarse) {
  input[type="checkbox"] {
    appearance: none;
    width: 30px;
    height: 30px;
    border: 2px solid red;
  }
}
```

Result

See also

- The `pointer` media feature

aspect-ratio CSS media feature

The **`aspect-ratio`** CSS media feature can be used to test the aspect ratio of the viewport.

Syntax

The `aspect-ratio` feature is specified as a `<ratio>` value representing the width-to-height aspect ratio of the viewport. It is a range feature, meaning you can also use the prefixed **`min-aspect-ratio`** and **`max-aspect-ratio`** variants to query minimum and maximum values, respectively.

Examples

In the example below, a `<div>` element is contained in an `<iframe>`. The iframe creates its own viewport. Resize the `<iframe>` to see `aspect-ratio` in action.

Note that, when none of the media query conditions are true, the background will turn white because none of the below rules will be applied to the `<div>` inside the `<iframe>`. See if you can find which width and height values trigger this!

HTML

```
<iframe
  id="outer"
  srcdoc="<div id='inner'>Watch this element as you resize iframe viewport's width and height.</div>">
</iframe>
```

CSS

```
/* Minimum allowed aspect ratio */
/* Select aspect ratios 8/5 = 1.6 and above */
@media (min-aspect-ratio: 8/5) {
  div {
    background: #9999ff; /* blue */
  }
}

/* Maximum allowed aspect ratio */
/* Select aspect ratios 3/2 = 1.5 and below */
@media (max-aspect-ratio: 3/2) {
  div {
    background: #99ff99; /* green */
  }
}

/* Exact aspect ratio, put it at the bottom to avoid override */
@media (aspect-ratio: 1/1) {
  div {
    background: #ff9999; /* red */
  }
}
```

Result

```
<label id="wf" for="w">width:165</label>
<input id="w" name="w" type="range" min="100" max="250" step="5" value="165" />
<label id="hf" for="w">height:165</label>
<input id="h" name="h" type="range" min="100" max="250" step="5" value="165" />
<label id="ratio">aspect-ratio: 165/165 = 1</label>

<iframe
  id="outer"
  srcdoc="<style> @media (min-aspect-ratio: 8/5) { div { background: #9999ff; } } @media (max-aspect-ratio: 3/2) { div { background: #99ff99; } } @media (aspect-ratio: 1/1) { div { background:
#ff9999; } }</style><div id='inner'> Watch this element as you resize iframe viewport's width and height.</div>">
</iframe>
```

```
iframe {
  display: block;
  border: 1px dashed black;
}
```

```
outer.style.width = outer.style.height = "165px";

const updateRatio = () => {
  ratio.textContent = `aspect-ratio: ${w.value}/${h.value} = ${(w.value / h.value).toFixed(2)}`;
};

w.onchange = w.oninput = () => {
  outer.style.width = `${w.value}px`;
  wf.textContent = `width: ${w.value}`;
  updateRatio();
```

```
};

h.onchange = h.oninput = () => {
  outer.style.height = `${h.value}px`;
  hf.textContent = `height: ${h.value}`;
  updateRatio();
};
```

Note the `min-aspect-ratio: 8/5` sets the *lower* bound to 1.6, so this media query selects elements with aspect ratios 1.6 and above. The `max-aspect-ratio: 3/2` sets the *upper* bound, so this media query selects elements with aspect ratios 1.5 and below. The `aspect-ratio: 1/1` overrides the max aspect ratio rule because it has been declared after and selects elements with aspect ratios exactly `1`.

From the initial state, as you reduce height, the aspect ratio starts increasing from one. So the div's background color goes from red(1) < green(1.5) < white < blue(1.6).

color CSS media feature

The **`color`** CSS media feature can be used to test the number of bits per color component (red, green, blue) of the output device.

Syntax

The `color` feature is specified as an `<integer>` value that represents the number of bits per color component (red, green, blue) of the output device. If the device is not a color device, the value is zero. It is a range feature, meaning that you can also use the prefixed **`min-color`** and **`max-color`** variants to query minimum and maximum values, respectively.

> **Note:** If the various color components are represented by different numbers of bits, the smallest number is used. For example, if a display uses 5 bits for blue and red and 6 bits for green, then the device is considered to use 5 bits per color component. If the device uses indexed colors, the minimum number of bits per color component in the color table is used.

See Applying color to HTML elements using CSS to learn more about using CSS to apply color to HTML.

Examples

HTML

```
<p>
  This text should be black on non-color devices, red on devices with a low
  number of colors, and greenish on devices with a high number of colors.
</p>
```

CSS

```
p {
  color: black;
}

/* Any color device */
@media (color) {
  p {
    color: red;
  }
}

/* Any color device with at least 8 bits per color component */
@media (min-color: 8) {
  p {
    color: #24ba13;
  }
}
```

color-gamut CSS media feature

The **`color-gamut`** CSS media feature is used to apply CSS styles based on the approximate range of color gamut supported by the user agent and the output device.

Syntax

The `color-gamut` feature is specified as one of the following color spaces as keyword values:

`srgb`

> The user agent and the output device can support approximately the sRGB gamut or more. This includes the vast majority of color displays.

`p3`

> The user agent and the output device can support approximately the gamut specified by the Display P3 color space or more. The P3 gamut is larger than and includes the sRGB gamut.

`rec2020`

> The user agent and the output device can support approximately the gamut specified by the ITU-R Recommendation BT.2020 color space or more. The REC. 2020 gamut is larger than and includes the P3 gamut.

Examples

HTML

```
<p>This is a test.</p>
```

CSS

```
p {
  padding: 10px;
  border: solid;
}

@media (color-gamut: srgb) {
  p {
    background: #f4ae8a;
  }
}
```

color-index CSS media feature

The **`color-index`** CSS media feature can be used to test the number of entries in the output device's color lookup table.

Syntax

The `color-index` feature is specified as an `<integer>` value representing the number of entries in the output device's color lookup table. (This value is zero if the device does not use such a table.) It is a range feature, meaning that you can also use the prefixed **`min-color-index`** and **`max-color-index`** variants to query minimum and maximum values, respectively.

Examples

Basic example

HTML

```
<p>This is a test.</p>
```

CSS

```
p {
  color: black;
}

@media (color-index) {
  p {
    color: red;
  }
}

@media (min-color-index: 15000) {
  p {
    color: #1475ef;
  }
}
```

Result

Custom stylesheet

This HTML will apply a special stylesheet for devices that have at least 256 colors.

```
<link rel="stylesheet" href="https://cdn.example.com/base.css" />
<link
  rel="stylesheet"
  media="(color-index >= 256)"
  href="https://cdn.example.com/color-stylesheet.css" />
```

device-aspect-ratio CSS media feature

> **Note:** To query for the aspect ratio of the viewport, developers should use the `aspect-ratio` media feature instead.

The **`device-aspect-ratio`** CSS media feature can be used to test the width-to-height aspect ratio of an output device.

Syntax

The `device-aspect-ratio` feature is specified as a `<ratio>`. It is a range feature, meaning that you can also use the prefixed **`min-device-aspect-ratio`** and **`max-device-aspect-ratio`** variants to query minimum and maximum values, respectively.

Examples

Using min-device-aspect-ratio

```
article {
  padding: 1rem;
}

@media screen and (min-device-aspect-ratio: 16/9) {
  article {
```

```
    padding: 1rem 5vw;
  }
}
```

device-height CSS media feature

> **Note:** To query for the height of the viewport, developers should use the `height` media feature instead.

The **`device-height`** CSS media feature can be used to test the height of an output device's rendering surface.

Syntax

The `device-height` feature is specified as a `<length>` value. It is a range feature, meaning that you can also use the prefixed **`min-device-height`** and **`max-device-height`** variants to query minimum and maximum values, respectively.

Examples

Applying a special stylesheet for devices that are shorter than 800 pixels

```
<link
  rel="stylesheet"
  media="screen and (max-device-height: 799px)"
  href="https://cdn.example.com/short-styles.css" />
```

device-posture CSS media feature

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`device-posture`** CSS media feature can be used to detect the device's current posture, that is, whether the viewport is in a flat (`continuous`) or folded state (`folded`).

Syntax

The `device-posture` feature is specified as a keyword value chosen from the list below:

`continuous`

> Indicates a flat screen state. Foldable devices are `continuous` while they are flat; either fully opened or fully closed. Non-foldable devices are considered flat and therefore always `continuous` — this includes seamless curved displays and standard desktop, laptop, tablet, and mobile screens.

`folded`

> Indicates a folded screen state. Foldable devices are `folded` while used in a book or laptop posture.

Examples

In this example, the `device-posture` media feature detects when a device is in a folded posture, adding a margin based on its `orientation` to create a larger gutter between the application's two panels for easier reading.

```
@media (device-posture: folded) and (orientation: landscape) {
  .list-view {
    margin-inline-end: 60px;
  }
}

@media (device-posture: folded) and (orientation: portrait) {
  .list-view {
    margin-block-end: 60px;
  }
}
```

To see the above code in action, view the Device Posture API demo on a foldable device if possible. Current browser developer tools enable emulating foldable devices, but don't include emulation of partially folded devices — only fully open or closed devices — so they will always return `continuous`.

device-width CSS media feature

> **Note:** To query for the width of the viewport, developers should use the `width` media feature instead.

The **`device-width`** CSS media feature can be used to test the width of an output device's rendering surface.

Syntax

The `device-width` feature is specified as a `<length>` value. It is a range feature, meaning that you can also use the prefixed **`min-device-width`** and **`max-device-width`** variants to query minimum and maximum values, respectively.

Examples

Applying a special stylesheet for devices that are narrower than 800 pixels

```
<link
  rel="stylesheet"
```

```
  media="screen and (max-device-width: 799px)"
  href="https://cdn.example.com/narrow-styles.css" />
```

display-mode CSS media feature

The **`display-mode`** CSS media feature can be used to test whether a web app is being displayed in a normal browser tab or in some alternative way, such as a standalone app or fullscreen mode.

For example:

- A progressive web app can set its display mode by setting the `display` member in its manifest. In this case, the value of `display-mode` identifies the value that was set (but note that this may not be the same as the value requested in the manifest, since a browser may not support the requested mode).
- Any web app can use the Fullscreen API or the Document Picture-in-Picture API to set the display mode, and in this case the value of `display-mode` identifies the mode that was set.

The `display-mode` value applies to the top-level browsing context and any child browsing contexts.

Syntax

The `display-mode` feature is specified as a keyword value chosen from the list below.

`browser`

The application opens in a conventional browser tab or new window, depending on the browser and platform.

`fullscreen`

All of the available display area is used and no user agent chrome is shown. This can be used to apply CSS only when the app has been put in fullscreen mode by the Fullscreen API or by using the `fullscreen` value of the `display` member of the Wep App Manifest.

`minimal-ui`

The application will look and feel like a standalone application, but will have a minimal set of UI elements for controlling navigation. The elements will vary by browser.

`picture-in-picture`

This mode allows users to continue consuming specific content while they interact with other sites or applications on their device. The app is displayed in a floating and always-on-top window. This can be used to apply CSS only when the app has been put in Picture-in-Picture mode by the Document Picture-in-Picture API.

`standalone`

The application will look and feel like a standalone application. This can include the application having a different window, its own icon in the application launcher, etc. In this mode, the user agent will exclude UI elements for controlling navigation, but can include other UI elements such as a status bar.

`window-controls-overlay`

In this mode, the application looks and feels like a standalone desktop application, and the Window Controls Overlay feature is enabled.

Examples

Apply CSS if the application is in fullscreen mode

```
@media (display-mode: fullscreen) {
  body {
    margin: 0;
    border: 5px solid black;
  }
}
```

Provide a light and dark color scheme to Picture-in-Picture content

In this example, we combine the `display-mode: picture-in-picture` value with the `prefers-color-scheme` media feature to create light and dark color schemes that are applied based on the user's color scheme preference, only when the app is being shown in Picture-in-Picture mode.

```
@media (display-mode: picture-in-picture) and (prefers-color-scheme: light) {
  body {
    background: antiquewhite;
  }
}

@media (display-mode: picture-in-picture) and (prefers-color-scheme: dark) {
  body {
    background: #333333;
  }

  a {
    color: antiquewhite;
  }
}
```

See Using the Document Picture-in-Picture API for more information and a full example.

dynamic-range CSS media feature

The **`dynamic-range`** CSS media feature can be used to test the combination of brightness, contrast ratio, and color depth that are supported by the user agent and the output device.

> **Note:** Some devices have high dynamic range capabilities that are not always 'on' and need to be activated (sometimes programmatically, sometimes by the user, sometimes based on the content). This media feature does not test whether the dynamic range capability is active; it only tests whether the device is capable of high dynamic range visuals.

Syntax

The `dynamic-range` feature is specified as a keyword value chosen from the list below.

`standard`

> This value matches any visual device and excludes devices lacking visual capabilities. A user agent or an output device that matches `high` will also match the `standard` value.

`high`

> This value matches user agents and output devices that support high peak brightness, high contrast ratio, and color depth greater than 24 bit or 8 bit per color component of RGB. **Peak brightness** refers to how bright the brightest point a light-emitting device, such as an LCD screen, can produce. In the case of a light-reflective device, such as paper or e-ink, peak brightness refers to the point that at least absorbs light. **Contrast ratio** refers to the ratio of the luminance of the brightest color to that of the darkest color that the system is capable of producing. Currently, there is no precise way to measure peak brightness and contrast ratio, and the determination of what counts as high peak brightness and high contrast ratio depends on the user agent.

Examples

```
@media (dynamic-range: standard) {
  p {
    color: red;
  }
}

@media (dynamic-range: high) {
  p {
    color: green;
  }
}
```

forced-colors CSS media feature

The **`forced-colors`** CSS media feature is used to detect if the user agent has enabled a forced colors mode where it enforces a user-chosen limited color palette on the page. An example of a forced colors mode is Windows High Contrast mode.

Syntax

The `forced-colors` media feature indicates whether or not the browser is currently in forced-colors mode.

Values

`none`

> Forced colors mode is not active; the page's colors are not being forced into a limited palette.

`active`

> Indicates that forced colors mode is active. The browser provides the color palette to authors through the CSS system color keywords and, if appropriate, triggers the appropriate value of `prefers-color-scheme` so that authors can adapt the page. The browser selects the value for `prefers-color-scheme` based on the lightness of the `Canvas` system color (see the color adjust spec for more details).

Usage notes

Properties affected by forced-color mode

In forced colors mode, the values of the following properties are treated as if they have no author-level values specified. That is, browser-specified values are used instead. The browser-specified values do not affect the style cascade; the values are instead forced by the browser at paint time.

These browser-specified values are selected from the set of system colors — this ensures a consistent contrast for common UI elements for users that have forced colors enabled.

- `color`
- `background-color`
- `text-decoration-color`
- `text-emphasis-color`
- `border-color`
- `outline-color`
- `column-rule-color`
- `-webkit-tap-highlight-color`
- SVG fill attribute
- SVG stroke attribute

Additionally the following properties have special behavior in forced colors mode:

- `box-shadow` is forced to 'none'
- `text-shadow` is forced to 'none'
- `background-image` is forced to 'none' for values that are not url-based
- `color-scheme` is forced to 'light dark'
- `scrollbar-color` is forced to 'auto'

The system colors that are forced for the above properties depend on the context of the element. For example the `color` property on button element will be forced to `ButtonText`. On normal text it will be forced to `CanvasText`. See the list of system colors for additional details of when each might be appropriate in various UI contexts.

> **Note:** User agents choose system colors based on native element semantics, *not* on added ARIA roles. As an example, adding `role="button"` to a `div` will **not** cause an element's color to be forced to `ButtonText`

In addition to these adjustments, browsers will help ensure text legibility by drawing "backplates" behind text. This is particularly important for preserving contrast when text is placed on top of images.

There are some cases where the user agent does not force the values for the above properties:

When `forced-color-adjust` is set to `none` on an element, none of the forced color values will apply, and author styles will be applied as normal. Additionally, the backplate for text will be disabled.

When `forced-color-adjust` is set to `preserve-parent-color` on an element, and the `color` value on the element does not inherit from its parent, then the element will behave the same as setting `preserve-parent-color` to `none`.

When a system color is specified, it will be used instead of the value that would otherwise have been forced.

You can also use system colors with any property *other* than those listed above, to ensure that the rest of the page integrates with the restricted color palette available in forced colors mode.

Accessibility concerns

In general, web authors should **not** be using the `forced-colors` media feature to create a separate design for users with this feature enabled. Instead, its intended usage is to make small tweaks to improve usability or legibility when the default application of forced colors does not work well for a given portion of a page.

The high contrast provided by forced colors mode's reduced palette and text backplates is often essential for some users to be able to read or use a given website, so adjustments that affect content should be chosen carefully and targeted to content that is otherwise not legible.

User preferences

This media feature is active only if the user has enabled color scheme preferences in their operating system. One example of such a feature is High Contrast mode on Windows.

Examples

> **Note:** The below example will only work when using a browser that supports this media feature, and with a preference such as High Contrast mode enabled in your OS.

This example is a button that normally gets its contrast via `box-shadow`. Under forced colors mode, box-shadow is forced to none, so the example uses the forced-colors media feature to ensure there is a border of the appropriate color (ButtonText in this case)

HTML

```
<button class="button">Press me!</button>
```

CSS

```
.button {
  border: 0;
  padding: 10px;
  box-shadow:
    -2px -2px 5px gray,
    2px 2px 5px gray;
}

@media (forced-colors: active) {
  .button {
    /* Use a border instead, since box-shadow is forced to 'none' in forced-colors mode */
    border: 2px ButtonText solid;
  }
}
```

Result

grid CSS media feature

The **`grid`** CSS media feature can be used to test whether the output device uses a grid-based screen.

Most modern computers and smartphones have bitmap-based screens. Examples of grid-based devices include text-only terminals and basic phones with only one fixed font.

Syntax

The `grid` feature is specified as a value representing whether the output device is grid-based — `1` if it is, and `0` if not.

Examples

HTML

```
<p class="unknown">I don't know if you're using a grid device. :-(</p>
<p class="bitmap">You are using a bitmap device.</p>
<p class="grid">You are using a grid device! Neato!</p>
```

CSS

```
:not(.unknown) {
  color: lightgray;
}

@media (grid: 0) {
  .unknown {
    color: lightgray;
  }

  .bitmap {
    color: red;
    text-transform: uppercase;
  }
}

@media (grid: 1) {
  .unknown {
    color: lightgray;
  }

  .grid {
    color: black;
    text-transform: uppercase;
  }
}
```

Result

- @media

height CSS media feature

The **`height`** CSS media feature can be used to apply styles based on the height of the viewport (or the page box, for paged media).

Syntax

The `height` feature is specified as a `<length>` value representing the viewport height. It is a range feature, meaning that you can also use the prefixed **`min-height`** and **`max-height`** variants to query minimum and maximum values, respectively.

Examples

HTML

```
<div>Watch this element as you resize your viewport's height.</div>
```

CSS

```
/* Exact height */
@media (height: 360px) {
  div {
    color: red;
  }
}

/* Minimum height */
@media (min-height: 25rem) {
  div {
    background: yellow;
  }
}

/* Maximum height */
@media (max-height: 40rem) {
  div {
    border: 2px solid blue;
  }
}
```

horizontal-viewport-segments CSS media feature

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`horizontal-viewport-segments`** CSS media feature detects whether the device has a specified number of viewport segments laid out horizontally (side by side).

Related to the Viewport Segments API, the `vertical-viewport-segments` feature can be used to create responsive designs that work well on multi-viewport devices — devices with a display that is divided into logically separate viewport segments, such as foldable or hinged devices.

Syntax

The `horizontal-viewport-segments` feature is specified as an `<integer>` value of `1` or greater, representing the number of horizontal viewport segments the device has.

- The value will be `1` for:
  - A non-foldable device (for example, a standard single-screen smartphone or tablet)
  - A foldable device that is either unfolded or closed (in the `continuous` device posture).
  - A two-screen hinged device or a foldable device that is currently folded and is oriented vertically so the segments are on top of each other.
- The value will be `2` for a two-screen hinged device or a foldable device that is currently folded (in the `folded` device posture) and is oriented horizontally so the segments are side by side.
- The value may be greater than `2` for foldable devices with more than one fold.

Examples

Basic <code>horizontal-viewport-segments</code> usage

In this snippet we use a `horizontal-viewport-segments` media query to handle the case of foldable devices where the segments are side-by-side.

We set the left container to have a width equal to the left segment width (`env(viewport-segment-width 0 0)`), and the right container to have a width equal to the right segment width (`env(viewport-segment-width 1 0)`).

To calculate how much width the fold takes up in between the two, we subtract the left edge offset of the right container from the right edge offset of the left container (`calc(env(viewport-segment-left 1 0) - env(viewport-segment-right 0 0));`).

```
.wrapper {
  height: 100%;
  display: flex;
}

@media (horizontal-viewport-segments: 2) {
  .wrapper {
    flex-direction: row;
  }

  .list-view {
    width: env(viewport-segment-width 0 0);
```

```
  }

  .fold {
    width: calc(
      env(viewport-segment-left 1 0) - env(viewport-segment-right 0 0)
    );
    background-color: black;
    height: 100%;
  }

  .detail-view {
    width: env(viewport-segment-width 1 0);
  }
}
```

See our Viewport segment API demo for a full working demo (source code). Also check out Using the Viewport Segments API for a full demo explanation.

- Viewport Segments API
- Origin trial for Foldable APIs via developer.chrome.com (2024)

hover CSS media feature

The **`hover`** CSS media feature can be used to test whether the user's *primary* input mechanism can hover over elements.

Syntax

The `hover` feature is specified as a keyword value chosen from the list below.

`none`

> The primary input mechanism cannot hover at all or cannot conveniently hover (e.g., many mobile devices emulate hovering when the user performs an inconvenient long tap), or there is no primary pointing input mechanism.

`hover`

> The primary input mechanism can conveniently hover over elements.

Examples

HTML

```
<a href="#">Try hovering over me!</a>
```

CSS

```
/* default hover effect */
a:hover {
  color: black;
  background: yellow;
}

@media (hover: hover) {
  /* when hover is supported */
  a:hover {
    color: white;
    background: black;
  }
}
```

inverted-colors CSS media feature

The **`inverted-colors`** CSS media feature is used to test if the user agent or the underlying operating system has inverted all colors.

Inversion of colors can have unpleasant side effects, such as shadows turning into highlights, which can reduce the readability of the content. Using this media feature, you can detect if inversion is happening and style the content accordingly while respecting user preference.

Syntax

```
/* Keyword value */
@media (inverted-colors: inverted) {
  /* styles to apply if inversion of colors is detected */
}
```

The `inverted-colors` feature is specified as one of the following keyword values:

`none`

> Indicates that the colors are displayed normally and no inversion of colors has happened. This keyword value evaluates as false.

`inverted`

> Indicates that all pixels within the displayed area have been inverted. This keyword value evaluates as true.

Examples

Applying styles if color inversion is detected

This example demonstrates the effects of both `inverted-colors` media feature keyword values and when the `inverted-colors` media feature is not supported.

HTML

```
<p>
  If color inversion is detected, this text will appear blue on white (the
  inverse of yellow on black) along with a line over the text. If no color
  inversion is happening, the text will appear red on light gray without the
  line over the text.
</p>
<p>
  If the text is gray and no overline is present, it means your browser doesn't
  support the
  <code>inverted-colors</code> media feature.
</p>
```

CSS

```
p {
  color: gray;
}

@media (inverted-colors: inverted) {
  p {
    background: black;
    color: yellow;
    text-decoration: overline;
  }
}

@media (inverted-colors: none) {
  p {
    background: #eeeeee;
    color: red;
  }
}
```

monochrome CSS media feature

The **`monochrome`** CSS media feature can be used to test the number of bits per pixel in the monochrome frame buffer of the output device.

Syntax

The `monochrome` feature is specified as an `<integer>` representing the number of bits per pixel in the monochrome frame buffer. If the device is not a monochrome device, the value is zero. It is a range feature, meaning that you can also use the prefixed **`min-monochrome`** and **`max-monochrome`** variants to query minimum and maximum values, respectively.

Examples

HTML

```
<p class="mono">Your device supports monochrome pixels!</p>
<p class="no-mono">Your device doesn't support monochrome pixels.</p>
```

CSS

```
p {
  display: none;
}

/* Any monochrome device */
@media (monochrome) {
  p.mono {
    display: block;
    color: #333333;
  }
}

/* Any non-monochrome device */
@media (monochrome: 0) {
  p.no-mono {
    display: block;
    color: #ee3636;
  }
}
```

Result

orientation CSS media feature

The **`orientation`** CSS media feature can be used to test the orientation of the viewport (or the page box, for paged media).

> **Note:** This feature does not correspond to *device* orientation. Opening the soft keyboard on many devices in portrait orientation will cause the viewport to become wider than it is tall, thereby causing the browser to use landscape styles instead of portrait.

Syntax

The `orientation` feature is specified as a keyword value chosen from the list below.

Keyword values

`portrait`

The viewport is in a portrait orientation, i.e., the height is greater than or equal to the width.

`landscape`

The viewport is in a landscape orientation, i.e., the width is greater than the height.

Examples

Portrait orientation

In this example we have three boxes in the HTML, and use the `orientation` media feature to switch between a row layout (in landscape) and a column layout (in portrait).

The example output is embedded in an `<iframe>` whose height is greater than its width, so the boxes get a column layout.

HTML

```
<div>Box 1</div>
<div>Box 2</div>
<div>Box 3</div>
```

CSS

```
body {
  display: flex;
}

div {
  background: yellow;
  width: 200px;
  height: 200px;
  margin: 0.5rem;
  padding: 0.5rem;
}

@media (orientation: landscape) {
  body {
    flex-direction: row;
  }
}

@media (orientation: portrait) {
  body {
    flex-direction: column;
  }
}
```

Result

Landscape orientation

This example has exactly the same code as the previous example: it has three boxes in the HTML, and uses the `orientation` media feature to switch between a row layout (in landscape) and a column layout (in portrait).

However, in this example, the example output is embedded in an `<iframe>` whose height is less than its width, so the boxes get a row layout.

HTML

```
<div>Box 1</div>
<div>Box 2</div>
<div>Box 3</div>
```

CSS

```
body {
  display: flex;
}

div {
  background: yellow;
  width: 200px;
  height: 200px;
  margin: 0.5rem;
  padding: 0.5rem;
}

@media (orientation: landscape) {
  body {
    flex-direction: row;
  }
}

@media (orientation: portrait) {
  body {
    flex-direction: column;
  }
}
```

overflow-block CSS media feature

The **`overflow-block`** CSS media feature can be used to test how the output device handles content that overflows the initial containing block along the block axis.

> **Note:** The `overflow-block` property does not determine whether overflow occurs; rather, it reveals the device's handling of such overflow. Typically, on screens in most browsers, the behavior will be "scroll": when content exceeds the available vertical space, the device allows you to scroll to access the overflowed content.

Syntax

The `overflow-block` feature is specified as a keyword value chosen from the list below.

`none`

Content that overflows the block axis is not displayed.

`scroll`

Content that overflows the block axis can be seen by scrolling to it.

`optional-paged`

Content that overflows the block axis can be seen by scrolling to it, but page breaks can be manually triggered (such as via `break-inside`, etc.) to cause the following content to display on the following page.

`paged`

Content is broken up into discrete pages; content that overflows one page in the block axis is displayed on the following page.

Examples

HTML

```
<p>
  Lorem ipsum dolor sit amet, consectetur adipiscing elit. Nullam ac turpis
  eleifend, fringilla velit ac, aliquam tellus. Vestibulum ante ipsum primis in
  faucibus orci luctus et ultrices posuere cubilia Curae; Nunc velit erat,
  tempus id rutrum sed, dapibus ut urna. Integer vehicula nibh a justo imperdiet
  rutrum. Nam faucibus pretium orci imperdiet sollicitudin. Nunc id facilisis
  dui. Proin elementum et massa et feugiat. Integer rutrum ullamcorper eleifend.
  Proin sit amet tincidunt risus. Sed nec augue congue eros accumsan tincidunt
  sed eget ex.
</p>
```

CSS

```
@media (overflow-block: scroll) {
  p {
    color: red;
  }
}
```

overflow-inline CSS media feature

The **`overflow-inline`** CSS media feature can be used to test how the output device handles content that overflows the initial containing block along the inline axis.

> **Note:** The `overflow-inline` property does not determine whether overflow occurs; rather, it reveals the device's handling of such overflow. Typically, on screens in most browsers, the behavior will be "scroll": when content exceeds the available horizontal space, the device allows you to scroll to access the overflowed content.

Syntax

The `overflow-inline` feature is specified as a keyword value chosen from the list below.

`none`

Content that overflows the inline axis is not displayed.

`scroll`

Content that overflows the inline axis can be seen by scrolling to it.

Examples

HTML

```
<p>
  Lorem ipsum dolor sit amet, consectetur adipiscing elit. Nullam ac turpis
  eleifend, fringilla velit ac, aliquam tellus. Vestibulum ante ipsum primis in
  faucibus orci luctus et ultrices posuere cubilia Curae; Nunc velit erat,
  tempus id rutrum sed, dapibus ut urna. Integer vehicula nibh a justo imperdiet
  rutrum. Nam faucibus pretium orci imperdiet sollicitudin. Nunc id facilisis
  dui. Proin elementum et massa et feugiat. Integer rutrum ullamcorper eleifend.
  Proin sit amet tincidunt risus. Sed nec augue congue eros accumsan tincidunt
  sed eget ex.
</p>
```

CSS

```
p {
  white-space: nowrap;
}

@media (overflow-inline: scroll) {
  p {
    color: red;
  }
}
```

Result

pointer CSS media feature

The **`pointer`** CSS media feature tests whether the user has a pointing device (such as a mouse), and if so, how accurate the *primary* pointing device is.

> **Note:** If you want to test the accuracy of *any* pointing device, use `any-pointer` instead.

Syntax

The `pointer` feature is specified as a keyword value chosen from the list below.

`none`

The primary input mechanism does not include a pointing device.

`coarse`

The primary input mechanism includes a pointing device of limited accuracy, such as a finger on a touchscreen.

`fine`

The primary input mechanism includes an accurate pointing device, such as a mouse.

Examples

This example creates a small checkbox for users with fine primary pointers and a large checkbox for users with coarse primary pointers.

HTML

```
<input id="test" type="checkbox" /> <label for="test">Look at me!</label>
```

CSS

```
input[type="checkbox"] {
  appearance: none;
  border: solid;
  margin: 0;
}

input[type="checkbox"]:checked {
  background: gray;
}

@media (pointer: fine) {
  input[type="checkbox"] {
    width: 15px;
    height: 15px;
    border-width: 1px;
    border-color: blue;
  }
}

@media (pointer: coarse) {
  input[type="checkbox"] {
    width: 30px;
    height: 30px;
    border-width: 2px;
    border-color: red;
  }
}
```

Result

- The `any-pointer` media feature

prefers-color-scheme CSS media feature

The **`prefers-color-scheme`** CSS media feature is used to detect if a user has requested light or dark color themes. A user indicates their preference through an operating system setting (e.g., light or dark mode) or a user agent setting.

Embedded elements

For SVG and iframes, `prefers-color-scheme` lets you set a CSS style for the SVG or iframe based on the `color-scheme` of the parent element in the web page. SVGs must be used embedded (i.e., `<img src="circle.svg" alt="circle" />`) as opposed to inlined in HTML. An example of using `prefers-color-scheme` in SVGs can be found in the "Inherited color scheme in embedded elements" section.

Using `prefers-color-scheme` is allowed in cross-origin `<svg>` and `<iframe>` elements. Cross-origin elements are elements retrieved from a different host than the page that is referencing them. To learn more about SVGs, see the SVG documentation and for more information about iframes, see the iframe documentation.

Syntax

`light`

Indicates that user has notified that they prefer an interface that has a light theme, or has not expressed an active preference.

`dark`

Indicates that user has notified that they prefer an interface that has a dark theme.

Examples

Detecting a dark or light theme

A common usage is to use a light color scheme by default, and then use `prefers-color-scheme: dark` to override the colors to a darker variant. It is also possible to do it the other way around.

This example shows both options: Theme A uses light colors, but can be overridden to dark colors. Theme B uses dark colors, but can be overridden to light colors. In the end, if the browser supports `prefers-color-scheme`, both themes will be light or dark.

HTML

```
<div class="box theme-a">Theme A (initial)</div>
<div class="box theme-a adaptive">Theme A (changed if dark preferred)</div>
<br />
```

```
<div class="box theme-b">Theme B (initial)</div>
<div class="box theme-b adaptive">Theme B (changed if light preferred)</div>
```

CSS

```
div.box {
  display: inline-block;
  padding: 1em;
  margin: 6px;
  outline: 2px solid black;
  width: 12em;
  height: 2em;
  vertical-align: middle;
}
```

Theme A (brown) uses a light color scheme by default, but will switch to a dark scheme based on the media query:

```
.theme-a {
  background: #ddccaa;
  color: #773311;
}
@media (prefers-color-scheme: dark) {
  .theme-a.adaptive {
    background: #775533;
    color: #ddccbb;
    outline: 5px dashed black;
  }
}
```

Theme B (blue) uses a dark color scheme by default, but will switch to a light scheme based on the media query:

```
.theme-b {
  background: #444477;
  color: #bbbbdd;
}
@media (prefers-color-scheme: light) {
  .theme-b.adaptive {
    background: #bbccdd;
    color: #333344;
    outline: 5px dotted black;
  }
}
```

Result

The left boxes shows Theme A and Theme B as they would appear without the `prefers-color-scheme` media query. The right boxes show the same themes, but one of them will be changed to a darker or lighter variant based on the user's active color scheme. The outline of one box will be dashed or dotted if it was changed based on your browser or operating systems settings.

Inherited color scheme in embedded elements

The following example shows how to use the `prefers-color-scheme` media feature in an embedded element to inherit a color scheme from a parent element. A script is used to set the source of the `<img>` elements and their `alt` attributes. This would normally be done in HTML as `<img src="circle.svg" alt="circle" />`.

You should see three circles, with one drawn in a different color. The first circle inherits the `color-scheme` from the OS and can be toggled using the system OS's theme switcher.

The second and third circles inherit the `color-scheme` from the embedding element; the `@media` query allows setting styles of the SVG content based on the parent element's `color-scheme`. In this case, the parent element with a `color-scheme` CSS property is a `<div>`.

```
<div>
  <img alt="circle" src="" />
</div>
<div class="light">
  <img alt="circle" src="" />
</div>
<div class="dark">
  <img alt="circle" src="" />
</div>
```

```
.light {
  color-scheme: light;
}

.dark {
  color-scheme: dark;
}
```

```
// Embed an SVG for all <img> elements
for (const img of document.querySelectorAll("img")) {
  img.src = `${window.btoa(`
    <svg width="32" height="32" viewBox="0 0 32 32" xmlns="http://www.w3.org/2000/svg">
      <style>
        :root { color: blue }
        @media (prefers-color-scheme: dark) {
          :root { color: purple }
        }
      </style>
      <circle fill="currentColor" cx="16" cy="16" r="16"/>
    </svg>
  `)}`;
}
```

prefers-contrast CSS media feature

The **`prefers-contrast`** CSS media feature is used to detect whether the user has requested the web content to be presented with a lower or higher contrast.

Syntax

`no-preference`

Indicates that the user has made no preference known to the system. This keyword value evaluates as false in the Boolean context.

`more`

Indicates that user has notified the system that they prefer an interface that has a higher level of contrast.

`less`

Indicates that user has notified the system that they prefer an interface that has a lower level of contrast.

`custom`

Indicates that user has notified the system for using a specific set of colors, and the contrast implied by these colors matches neither `more` nor `less`. This value will match the color palette specified by users of `forced-colors: active`.

User preferences

Various operating systems do support such preferences and user agents are likely to rely on the settings provided by the operating system.

Examples

This example includes a box with a dashed `outline` set on it by default. When the `prefers-contrast: more` media query matches, the applied outline is given a higher contrast `solid` style instead.

HTML

```
<div class="contrast">low contrast box</div>
```

CSS

```
.contrast {
  margin: 5px;
  width: 100px;
  height: 100px;
  outline: 2px dashed black;
}

@media (prefers-contrast: more) {
  .contrast {
    outline: 2px solid black;
  }
}
```

Result

prefers-reduced-data CSS media feature

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

> **Warning:** This feature is not supported by any user agent and its specifics are subject to change.

The **`prefers-reduced-data`** CSS media feature is used to detect if the user has requested web content that consumes less internet traffic.

The browser typically achieves this by querying the underlying operating system's preferences for reduced data.

Syntax

`no-preference`

Indicates that the user has made no preference known to the system. This keyword evaluates to false in the Boolean context.

`reduce`

Indicates that the user has expressed a preference for lightweight alternate content.

Examples

Basic usage

In this example, the `montserrat-regular.woff2` font file will neither be preloaded nor downloaded if the user prefers reduced data; in this case, the "system font stack" will serve as the fallback font:

HTML

```
<head>
  <link
    rel="preload"
    href="fonts/montserrat-regular.woff2"
    as="font"
    media="(prefers-reduced-data: no-preference)"
    crossorigin />
```

```
  <link rel="stylesheet" href="style.css" />
</head>
```

CSS

```
@media (prefers-reduced-data: no-preference) {
  @font-face {
    font-family: "Montserrat";
    font-style: normal;
    font-weight: normal;
    font-display: swap;
    /* latin */
    src:
      local("Montserrat Regular"),
      local("Montserrat-Regular"),
      url("fonts/montserrat-regular.woff2") format("woff2");
    unicode-range:
      U+0000-00FF, U+0131, U+0152-0153, U+02BB-02BC, U+02C6, U+02DA, U+02DC,
      U+2000-206F, U+2074, U+20AC, U+2122, U+2191, U+2193, U+2212, U+2215,
      U+FEFF, U+FFFD;
  }
}

body {
  font-family:
    "Montserrat",
    -apple-system,
    BlinkMacSystemFont,
    "Segoe UI",
    "Roboto",
    "Helvetica",
    "Arial",
    sans-serif;
}
```

- `Save-Data` HTTP header

prefers-reduced-motion CSS media feature

> **Warning:** An embedded example at the bottom of this page has a scaling movement that may be problematic for some readers. Readers with vestibular motion disorders may wish to enable the reduce motion feature on their device before viewing the animation.

The **`prefers-reduced-motion`** CSS media feature is used to detect if a user has enabled a setting on their device to minimize the amount of non-essential motion. The setting is used to convey to the browser on the device that the user prefers an interface that removes, reduces, or replaces motion-based animations.

Such animations can trigger discomfort for those with vestibular motion disorders. Animations such as scaling or panning large objects can be vestibular motion triggers.

Syntax

`no-preference`

Indicates that a user has made no preference known on the device. This keyword value evaluates as false.

`reduce`

Indicates that a user has enabled the setting on their device for reduced motion. The `reduce` keyword value evaluates as true; therefore, `@media (prefers-reduced-motion)` is equivalent to `@media (prefers-reduced-motion: reduce)`.

User preferences

Use the following settings to honor the `reduce` request:

- In GTK/GNOME: Settings > Accessibility > Seeing > turn on "Reduced animation".
  - In older versions of GNOME, GNOME Tweaks > General tab (or Appearance, depending on version) > Animations is turned off.
  - Alternatively, add `gtk-enable-animations = false` to the `[Settings]` block of the GTK 3 configuration file.
  - Additionally, try running `gsettings set org.gnome.desktop.interface enable-animations false` to make Firefox (and other programs relying on GTK version 4) respect the `reduce` setting.
- In Plasma/KDE: System Settings > Workspace Behavior > General Behavior > set "Animation speed" to "Instant".
  - Alternatively, add `AnimationDurationFactor=0` to the `[KDE]` block of `~/.config/kdeglobals`.
  - Or just run `kwriteconfig6 --key AnimationDurationFactor 0` in your terminal.
- In Windows 10: Settings > Ease of Access > Display > Show animations in Windows.
- In Windows 11: Settings > Accessibility > Visual Effects > Animation Effects.
- In macOS up to 15 (Sequoia): System Settings > Accessibility > Display > Reduce motion.
- In macOS 25 (Tahoe) onwards: System Settings > Accessibility > Motion > Reduce motion.
- In iOS: Settings > Accessibility > Motion.
- In Android 9+: Settings > Accessibility > Remove animations.
- In Firefox `about:config`: Add a number preference called `ui.prefersReducedMotion` and set its value to either `0` for full animation or to `1` to indicate a preference for reduced motion. Changes to this preference take effect immediately.

Examples

This example uses a scaling animation to demonstrate `prefers-reduced-motion`. If you enable the setting for reducing motion in the accessibility preferences on your device, the `prefers-reduced-motion` media query will detect your preference and the CSS within the reduced motion rules, with the same specificity but coming later in the CSS source order, will take precedence. As a result, the animation on the box will tone down to the `dissolve` animation, which is a more muted animation that is not a vestibular motion trigger.

Toning down the animation scaling

HTML

```
<div class="animation">animated box</div>
```

CSS

```
.animation {
  animation: pulse 1s linear infinite both;
  background-color: purple;
}

/* Tone down the animation to avoid vestibular motion triggers. */
@media (prefers-reduced-motion: reduce) {
  .animation {
    animation: dissolve 4s linear infinite both;
    background-color: green;
    text-decoration: overline;
  }
}
```

```
.animation {
  color: white;
  font: 1.2em sans-serif;
  width: 10em;
  padding: 1em;
  border-radius: 1em;
  text-align: center;
}

@keyframes pulse {
  0% {
    transform: scale(1);
  }
  25% {
    transform: scale(0.9);
  }
  50% {
    transform: scale(1);
  }
  75% {
    transform: scale(1.1);
  }
  100% {
    transform: scale(1);
  }
}

@keyframes dissolve {
  0% {
    opacity: 1;
  }
  50% {
    opacity: 0.3;
  }
  100% {
    opacity: 1;
  }
}
```

Result

You can enable the setting for reducing motion on your device to view the change in animation scaling. This example uses the background color and the line over the text to visually highlight when the keyframe animation switches in response to the setting being enabled or disabled.

prefers-reduced-transparency CSS media feature

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`prefers-reduced-transparency`** CSS media feature is used to detect if a user has enabled a setting on their device to reduce the transparent or translucent layer effects used on the device. Switching on such a setting can help improve contrast and readability for some users.

Syntax

`no-preference`

Indicates that a user has made no preference known on the device. This keyword value evaluates as false in the boolean context.

`reduce`

Indicates that a user has enabled the setting on their device to minimize the amount of transparent or translucent layer effects.

User preferences

Various operating systems provide a preference for reducing transparency, and user agents are likely to rely on these system settings. They may also rely on less explicit signals on platforms which don't offer a specific setting.

- In Windows 10/11: Settings > Personalization > Colors > Transparency effects.
- In macOS: System Settings > Accessibility > Display > Reduce transparency.
- In iOS: Settings > Accessibility > Display & Text Size > Reduce Transparency.

Examples

This example has a translucent box by default. If the setting to reduce transparency is enabled in the accessibility preferences on your device, the translucent box becomes more opaque.

HTML

```
<div class="translucent">translucent box</div>
```

CSS

```
.translucent {
  opacity: 0.4;
}

@media (prefers-reduced-transparency) {
  .translucent {
    opacity: 0.8;
  }
}
```

- CSS prefers-reduced-motion media query
- Using media queries

resolution CSS media feature

The **`resolution`** CSS media feature can be used to test the pixel density of the output device.

Syntax

The `resolution` feature is specified as a `<resolution>` value representing the pixel density of the output device. It is a range feature, meaning that you can also use the prefixed **`min-resolution`** and **`max-resolution`** variants to query minimum and maximum values, respectively.

Examples

HTML

```
<p>This is a test of your device's pixel density.</p>
```

CSS

```
/* Exact resolution with unit `dpi` */
@media (resolution: 150dpi) {
  p {
    color: red;
  }
}

/* Minimum resolution synonym units: `dppx` and `x` */
@media (min-resolution: 2dppx) {
  p {
    text-decoration: underline;
  }
}

@media (min-resolution: 2x) {
  p {
    text-decoration: underline;
  }
}

/* Maximum resolution with unit `dpcm` */
@media (max-resolution: 2dpcm) {
  p {
    background: yellow;
  }
}
```

Result

See also

- `window.devicePixelRatio`
- The `image-resolution` property

scan CSS media feature

The **`scan`** CSS media feature is used to apply CSS styles based on the scanning process of the output device.

Syntax

The `scan` feature is specified as one of the following keyword values:

`interlace`

> The output device uses "interlaced" rendering, where video frames alternate between specifying only the "even" lines on the screen and only the "odd" lines.

`progressive`

> The output device renders content to the screen with no special treatment.

Description

Most modern screens (and all computer screens) use progressive rendering, displaying each screen fully with no special treatment.

Interlacing was used by CRT monitors and some plasma TVs to enable the appearance of faster frames per second (FPS) while reducing bandwidth. With interlacing, video frames alternate between rendering the even lines and the odd lines on the screen, downloading and rendering only half the screen for each frame, exploiting the human image-smoothing ability so the brain simulates a higher FPS broadcast at half the bandwidth cost.

When targeting interlaced screens, avoid very fast movement across the screen and ensure animated details are wider than 1px to reduce flickering.

Examples

HTML

```
<p>This is a test.</p>
```

CSS

```
p {
  padding: 10px;
  border: solid;
}

@media screen and (scan: interlace) {
  p {
    background: #f4ae8a;
  }
}
@media screen and (scan: progressive) {
  p {
    text-decoration: underline;
  }
}
@media not screen and (scan: progressive) {
  p {
    border-style: dashed;
  }
}
@media not screen and (scan: interlace) {
  p {
    color: purple;
  }
}
```

scripting CSS media feature

The **`scripting`** CSS media feature can be used to test whether scripting (such as JavaScript) is available.

> **Note:** The detection is done by the browsers based on the user settings. Some browser extensions can implement script blocking using different techniques. In such cases the `scripting` media feature may not work as expected.

Syntax

The `scripting` feature is specified as a keyword value chosen from the list below.

`none`

Scripting is completely unavailable on the current document.

`initial-only`

Scripting is enabled during the initial page load, but not afterwards.

`enabled`

Scripting is supported and active on the current document.

Examples

HTML

```
<p class="script-none">You do not have scripting available. :-(</p>
<p class="script-initial-only">
  Your scripting is only enabled during the initial page load. Weird.
</p>
<p class="script-enabled">You have scripting enabled! :-)</p>
```

CSS

```
p {
  color: lightgray;
}

@media (scripting: none) {
  .script-none {
    color: red;
  }
}

@media (scripting: initial-only) {
  .script-initial-only {
    color: red;
  }
}

@media (scripting: enabled) {
  .script-enabled {
    color: red;
  }
}
```

shape CSS media feature

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The `shape` CSS media feature can be used to test the shape of the device to distinguish rectangular and round displays.

Syntax

The `shape` discrete feature is specified as one of two acceptable strings, either `rect` representing a rectangular screen or `round` representing a circular, oval or elliptical screen.

`rect`

The shape is an axis aligned rectangle or square, or a similar shape such as rounded rectangle for which the traditional designs are appropriate.

`round`

The shape is rounded or a similar shape to the circle such as an oval, an ellipse for which distinctively rounded designs are appropriate.

Examples

Basic example

HTML

```
<h1>Hello World!</h1>
```

CSS

```
h1 {
  text-align: left;
}

@media (shape: rect) {
  h1 {
    text-align: left;
  }
}

@media (shape: round) {
  h1 {
    text-align: center;
  }
}
```

Custom stylesheet

This HTML will apply a special stylesheet for devices that have round screens.

```
<head>
  <link rel="stylesheet" href="default.css" />
  <link
    media="screen and (shape: rect)"
    rel="stylesheet"
    href="rectangle.css" />
  <link media="screen and (shape: round)" rel="stylesheet" href="round.css" />
</head>
```

Browser compatibility

Currently, no browsers support this feature.

update CSS media feature

The **`update`** CSS media feature can be used to test how frequently (if at all) the output device is able to modify the appearance of content once rendered.

Syntax

`none`

Once it has been rendered, the layout can no longer be updated. Example: documents printed on paper.

`slow`

The layout may change dynamically according to the usual rules of CSS, but the output device is not able to render or display changes quickly enough for them to be perceived as a smooth animation. Examples: e-book readers or severely underpowered devices.

`fast`

The layout may change dynamically according to the usual rules of CSS, and the output device is not unusually constrained in speed, so regularly-updating things like CSS Animations can be used. Example: computer screens.

Examples

HTML

```
<p>
  If this text animates for you, your browser supports `update` and you are
  using a fast-updating device.
</p>
```

CSS

```
@keyframes jiggle {
  from {
    transform: translateY(0);
  }

  to {
    transform: translateY(25px);
  }
}

@media (update: fast) {
  p {
    animation: 1s jiggle linear alternate infinite;
  }
}
```

vertical-viewport-segments CSS media feature

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`vertical-viewport-segments`** CSS media feature detects whether the device has a specified number of viewport segments laid out vertically (top to bottom).

Related to the Viewport Segments API, the `vertical-viewport-segments` feature can be used to create responsive designs that work well on multi-viewport devices — devices with a display that is divided into logically separate viewport segments, such as foldable or hinged devices.

Syntax

The `vertical-viewport-segments` feature is specified as an `<integer>` value of `1` or greater, representing the number of vertical viewport segments the device has.

- The value will be `1` for:
  - A non-foldable device (for example, a standard single-screen smartphone or tablet).
  - A foldable device that is either unfolded or closed (in the `continuous` device posture).
  - A two-screen hinged device or a foldable device that is currently folded and is oriented horizontally so the segments are side by side.
- The value will be `2` for a two-screen hinged device or a foldable device that is currently folded (in the `folded` device posture) and is oriented vertically so the segments are on top of one another.
- The value may be greater than `2` for foldable devices with more than one fold.

Examples

Basic <code>vertical-viewport-segments</code> usage

In this snippet we use a `vertical-viewport-segments` media query to handle the case of foldable devices where the segments are top-to-bottom.

We set the top container to have a height equal to the top segment height (`env(viewport-segment-height 0 0)`), and the bottom container to have a height equal to the bottom segment height (`env(viewport-segment-height 0 1)`).

To calculate how much height the fold takes up in between the two, we subtract the bottom edge offset of the top container from the top edge offset of the bottom container (`calc(env(viewport-segment-top 0 1) - env(viewport-segment-bottom 0 0));`).

```
.wrapper {
  height: 100%;
  display: flex;
}

@media (vertical-viewport-segments: 2) {
  .wrapper {
    flex-direction: column;
  }

  .list-view {
    height: env(viewport-segment-height 0 0);
  }

  .fold {
    width: 100%;
    height: calc(
      env(viewport-segment-top 0 1) - env(viewport-segment-bottom 0 0)
    );
    background-color: black;
  }

  .detail-view {
    height: env(viewport-segment-height 0 1);
  }
}
```

See our Viewport segment API demo for a full working demo (source code). Also check out Using the Viewport Segments API for a full demo explanation.

video-dynamic-range CSS media feature

The **`video-dynamic-range`** CSS media feature can be used to test the combination of brightness, contrast ratio, and color depth that are supported by the video plane of the user agent and the output device.

Some user agents, including many TVs, render video and graphics in two separate planes (bi-plane) with distinct screen characteristics. The `video-dynamic-range` feature is used to test the characteristics in the video plane.

Syntax

The `video-dynamic-range` feature is specified as a keyword value chosen from the list below.

`standard`

This value matches any visual device and excludes devices lacking visual capabilities. A user agent or an output device that matches `high` will also match the `standard` value.

`high`

This value matches user agents and output devices that support high peak brightness, high contrast ratio, and color depth greater than 24 bit or 8 bit per color component of RGB. **Peak brightness** refers to how bright the brightest point a light-emitting device, such as an LCD screen, can produce. In the case of a light-reflective device, such as paper or e-ink, peak brightness refers to the point that at least absorbs light. **Contrast ratio** refers to the ratio of the luminance of the brightest color to that of the darkest color that the system is capable of producing. Currently, there is no precise way to measure peak brightness and contrast ratio, and the determination of what counts as high peak brightness and high contrast ratio depends on the user agent.

width CSS media feature

The **`width`** CSS media feature can be used to test the width of the viewport (or the page box, for paged media).

Syntax

The `width` feature is specified as a `<length>` value representing the viewport width. It is a range feature, meaning that you can also use the prefixed **`min-width`** and **`max-width`** variants to query minimum and maximum values, respectively.

Examples

HTML

```
<div>Watch this element as you resize your viewport's width.</div>
```

CSS

```
/* Exact width */
@media (width: 360px) {
  div {
    color: red;
  }
}

/* Minimum width */
@media (min-width: 35rem) {
  div {
    background: yellow;
  }
}

/* Maximum width */
@media (max-width: 50rem) {
  div {
    border: 2px solid blue;
  }
}
```

@namespace CSS at-rule

`@namespace` is an at-rule that defines XML namespaces to be used in a CSS style sheet.

Try it

```
@namespace svg url("http://www.w3.org/2000/svg");

a {
  color: orangered;
  text-decoration: underline dashed;
  font-weight: bold;
}

svg|a {
  fill: blueviolet;
  text-decoration: underline solid;
  text-transform: uppercase;
}
```

```
<p>
  <a href="#">This is an ordinary HTML link</a>
</p>

<svg width="250px" viewBox="0 0 250 20" xmlns="http://www.w3.org/2000/svg">
  <a href="#">
    <text x="0" y="15">This is a link created in SVG</text>
  </a>
</svg>
```

Syntax

```
/* Default namespace */
@namespace url("XML-namespace-URL");
@namespace "XML-namespace-URL";

/* Prefixed namespace */
@namespace prefix url("XML-namespace-URL");
@namespace prefix "XML-namespace-URL";
```

Description

The defined namespaces can be used to restrict the universal, type, and attribute selectors to only select elements within that namespace. The `@namespace` rule is generally only useful when dealing with documents containing multiple namespaces—such as HTML with inline SVG or MathML, or XML that mixes multiple vocabularies.

Any `@namespace` rules must follow all `@charset` and `@import` rules, and precede all other at-rules and style declarations in a style sheet.

`@namespace` can be used to define the **default namespace** for the style sheet. When a default namespace is defined, all universal and type selectors (but not attribute selectors, see note below) apply only to elements in that namespace.

The `@namespace` rule can also be used to define a **namespace prefix**. When a universal, type, or attribute selector is prefixed with a namespace prefix, then that selector only matches if the namespace *and* name of the element or attribute matches.

In HTML, known foreign elements will automatically be assigned namespaces. This means that HTML elements will act as though they are in the XHTML namespace (`http://www.w3.org/1999/xhtml`), even if there is no `xmlns` attribute anywhere in the document, and the `<svg>` and `<math>` elements will be assigned their proper namespaces (`http://www.w3.org/2000/svg` and `http://www.w3.org/1998/Math/MathML`, respectively).

> **Note:** In XML, unless a prefix is defined directly on an attribute (*e.g.*, `xlink:href`), that attribute has no namespace. In other words, attributes do not inherit the namespace of the element they're on. To match this behavior, the default namespace in CSS does not apply to attribute selectors.

Formal syntax

```
@namespace =
  @namespace <namespace-prefix>? [ <string> | <url> ] ;

<namespace-prefix> =
  <ident>
```

This syntax reflects the latest standard as per CSS Namespaces Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Specifying default and prefixed namespaces

```
@namespace url("http://www.w3.org/1999/xhtml");
@namespace svg url("http://www.w3.org/2000/svg");

/* This matches all XHTML <a> elements, as XHTML is the default unprefixed namespace */
a {
}

/* This matches all SVG <a> elements */
svg|a {
}

/* This matches both XHTML and SVG <a> elements */
*|a {
}
```

@page CSS at-rule

The **`@page`** at-rule is a CSS at-rule used to modify different aspects of printed pages. It targets and modifies the page's dimensions, orientation, and margins. The `@page` at-rule can be used to target all pages in a print-out or a subset using its various pseudo-classes.

Syntax

```
/* Targets all the pages */
@page {
  size: 8.5in 9in;
  margin-top: 4in;
}

/* Targets all even-numbered pages */
@page :left {
  margin-top: 4in;
}

/* Targets all odd-numbered pages */
@page :right {
  size: 11in;
  margin-top: 4in;
}

/* Targets all selectors with `page: wide;` set */
```

```
@page wide {
  size: a4 landscape;
}

@page {
  /* margin box at top right showing page number */
  @top-right {
    content: "Page " counter(pageNumber);
  }
}
```

Page properties

The `@page` at-rule can contain only page descriptors and margin at-rules. The following descriptors have been implemented by at least one browser:

`margin`

Specifies the page margins. Individual margin properties `margin-top`, `margin-right`, `margin-bottom`, and `margin-left` can also be used.

`page-orientation`

Specifies the orientation of the page. This does not affect the layout of the page; the rotation is applied after the layout in the output medium.

`size`

Specifies the target size and orientation of the page box's containing block. In the general case, where one page box is rendered onto one page sheet, it also indicates the size of the destination page sheet.

The specification mentions following CSS properties to be applicable to page boxes via @page at-rule. But these have *not been supported* by any user agent yet.

Description

The @page rule defines properties of the page box. The `@page` at-rule can be accessed via the CSS object model interface `CSSPageRule`.

> **Note:** The W3C is discussing how to handle viewport-related `<length>` units, `vh`, `vw`, `vmin`, and `vmax`. Meanwhile do not use them within a `@page` at-rule.

Related properties

The `@page` at-rule, allows the user to assign a name to the rule, which is then called in a declaration using the `page` property.

`page`

Allows a selector to use a user-defined **named page**

Formal syntax

```
@page =
  @page <page-selector-list>? { <declaration-rule-list> }

<page-selector-list> =
  <page-selector>#

<page-selector> =
  [ <ident-token>? <pseudo-page>* ]!

<pseudo-page> =
  : [ left | right | first | blank ]
```

This syntax reflects the latest standard as per CSS Paged Media Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Where the `<page-body>` includes:

- page-properties
- page-margin properties

and `<pseudo-page>` represents these pseudo-classes:

- `:blank`
- `:first`
- `:left`
- `:right`

Margin at-rules

The margin at-rules are used inside of the `@page` at-rule. They each target a different section of the document printed page, styling the area of the printed page based on the property values set in the style block:

```
@page {
  @top-left {
    /* page-margin-properties */
  }
}
```

`@top-left` targets the top-left of the document and applies the changes based on the page-margin-properties set.

Other margin-at rules include:

```
@top-left-corner
@top-left
@top-center
@top-right
@top-right-corner
@bottom-left-corner
@bottom-left
@bottom-center
@bottom-right
@bottom-right-corner
@left-top
@left-middle
@left-bottom
@right-top
```

```
@right-middle
@right-bottom
```

Page-margin properties

The page-margin properties are the set of CSS properties can be set in any individual margin at-rule. They include:

Named pages

Named pages enable performing per-page layout and adding page-breaks in a declarative manner when printing.

Named pages can be applied using the `page` property. This allows the user to create different page configurations for use in print layouts.

An example of this can be found on the `page` examples.

Examples

Using the size property to change the page orientation

This example shows how to split the `<section>`s into individual pages in `landscape` format with each page having a 20% margin when printed. Clicking the print button will launch a print dialog with the HTML sections split into individual pages.

```
<button>Print page</button>
<article>
  <section>
    <h2>Header one</h2>
    <p>Paragraph one.</p>
  </section>
  <section>
    <h2>Header two</h2>
    <p>Paragraph two.</p>
  </section>
  <section>
    <h2>Header three</h2>
    <p>Paragraph three.</p>
  </section>
</article>
```

```
const button = document.querySelector("button");

button.addEventListener("click", () => {
  window.print();
});
```

```
@page {
  size: landscape;
  margin: 2cm;
}

section {
  page-break-after: always;
  break-after: page;
}

@media print {
  button {
    display: none;
  }
}
```

```
body {
  font-family: "Helvetica", sans-serif;
  background-color: silver;
}

article {
  width: 100%;
}

section {
  display: grid;
  background-color: white;
  border-radius: 0.6rem;
  justify-items: center;
  padding: 1rem;
  width: 50%;
  print-color-adjust: exact;
  -webkit-print-color-adjust: exact;
  margin: 0 auto;
  margin-block-end: 1rem;
  border: 1px dashed;
}
```

@page pseudo-class examples

See the various pseudo-classes of `@page` for examples.

- `:blank`
- `:first`
- `:left`
- `:right`

See also

- The `page` property
- The `@page` `size` descriptor
- CSS paged media module
- [META] CSS Paged Media Module Level 3 Bugzilla for tracking progress on the subject (page-based counters, etc.)

page-orientation CSS at-rule descriptor

The **`page-orientation`** CSS descriptor for the `@page` at-rule controls the rotation of a printed page. It handles the flow of content across pages when the orientation of a page is changed. This behavior differs from the `size` descriptor in that a user can define the direction in which to rotate the page.

This descriptor helps with the layout and orientation of printed documents, especially when documents are printed double-sided. A user can specify how the pages will be rotated when printed. This is particularly useful to lay out content such as tables, which may be wider than the rest of the content, in a different orientation.

> **Note:** Margin boxes and other positional elements have no special interaction with this descriptor. Margins are laid out as normal in the unrotated page, then rotated along with everything else.

Syntax

```
/* Displays the print content in an upright position */
@page {
  page-orientation: upright;
}

/* Displays the print content rotated counter-clockwise */
@page {
  page-orientation: rotate-left;
}

/* Displays the print content rotated clockwise */
@page {
  page-orientation: rotate-right;
}
```

Values

`upright`

No orientation is applied and the page is laid out and formatted as normal.

`rotate-left`

After a page is laid out, the page must be displayed rotated a quarter turn to the left (counter-clockwise).

`rotate-right`

After the page is laid out, the page must be displayed rotated a quarter turn to the right (clockwise).

Formal definition

Related at-rule	`@page`
Initial value	`upright`
Computed value	as specified

Formal syntax

```
page-orientation =
  upright       |
  rotate-left   |
  rotate-right
```

This syntax reflects the latest standard as per CSS Paged Media Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Rotating printed pages

This example shows how the contents of a print document can be rotated to suit the page content and the page position. In this first part of the CSS code, named pages are set up to define the direction in which to rotate the content.

```
@page upright {
  size: portrait;
  page-orientation: upright;
}

@page left {
  size: landscape;
  page-orientation: rotate-left;
}

@page right {
  size: landscape;
  page-orientation: rotate-right;
}
```

```
fieldset {
  display: flex;
  flex-direction: row;
  justify-content: space-between;
  gap: 1rem;
  width: fit-content;
}
p {
  max-width: 60ch;
}
@media print {
  fieldset {
    display: none;
  }
  section {
    font-family: "Roboto", sans-serif;
    font-size: 1.5rem;
  }
}
```

The second part of the CSS code declares a named page rule defined above for the selectors, such as `<section class="left">…</section>`.

```
@media print {
  .upright {
    page: upright;
  }
  .left {
    page: left;
  }
  .right {
    page: right;
  }
}
```

```
<fieldset id="printStyle">
  <legend>
    Click Print. The page will be laid out in the defined orientation.
  </legend>
  <button id="print">Print</button>
</fieldset>
<div id="print-area">
  <section class="upright">
    <h2>Section in Portrait/Upright</h2>
    <p>This section will be printed in portrait and upright with:</p>
    <pre>
.upright {
  size: portrait;
  page-orientation: upright;
}
    </pre>
    <p>Paragraph one.</p>
    <p>Paragraph two.</p>
  </section>
  <section class="left">
    <h2>Section in Landscape/Left</h2>
    <p>This section will be printed in landscape and rotated left with:</p>
    <pre>
.left {
  size: landscape;
  page-orientation: rotate-left;
}
    </pre>
    <table>
      <thead>
        <tr>
          <th></th>
          <th>100m</th>
          <th>1500m</th>
          <th>Hurdles</th>
          <th>Long Jump</th>
          <th>High Jump</th>

const printButton = document.querySelector("#print");
printButton.addEventListener("click", () => {
  window.print();
});
```

Click the print button to see the page orientation on print.

size CSS at-rule descriptor

The **`size`** CSS at-rule descriptor, used with the `@page` at-rule, defines the size and orientation of the box which is used to represent a page. Most of the time, this size corresponds to the target size of the printed page if applicable.

Size may either be defined with a "scalable" keyword (in this case the page will fill the available dimensions) or with absolute dimensions.

Syntax

```
/* Keyword values for scalable size */
size: auto;
size: portrait;
size: landscape;

/* <length> values */
/* 1 value: height = width */
size: 6in;

/* 2 values: width then height */
size: 4in 6in;

/* Keyword values for absolute size */
size: A4;
size: B5;
size: JIS-B4;
size: letter;

/* Mixing size and orientation */
size: A4 portrait;
```

Values

`auto`

The user agent decides the size of the page. In most cases, the dimensions and orientation of the target sheet are used.

`landscape`

The content of the page is displayed in landscape mode (i.e., the longest side of the box is horizontal).

`portrait`

The content of the page is displayed in portrait mode (i.e., the longest side of the box is vertical). This is the default orientation.

`<length>`

Any length value (see `<length>`). The first value corresponds to the width of the page box and the second one corresponds to its height. If only one value is provided, it is used for both width and height.

`<page-size>`

A keyword which may be any of the following values:

A5

This matches the standard, ISO dimensions: 148mm x 210mm.

A4

This matches the standard, ISO dimensions: 210mm x 297mm. (most frequently used dimensions for personal printing.)

A3

This matches the standard, ISO dimensions: 297mm x 420mm.

B5

This matches the standard, ISO dimensions: 176mm x 250mm.

B4

This matches the standard, ISO dimensions: 250mm x 353mm.

JIS-B5

This correspond to the JIS standard dimensions: 182mm x 257mm.

JIS-B4

This correspond to the JIS standard dimensions: 257mm x 364mm.

letter

This keyword is an equivalent to the dimensions of letter paper in North America i.e., 8.5in x 11in.

legal

This keyword is an equivalent to the dimensions of legal papers in North America i.e., 8.5in x 14in.

ledger

This keyword is an equivalent to the dimensions of ledger pages in North America i.e., 11in x 17in.

Formal definition

Related at-rule	`@page`
Initial value	`auto`
Computed value	as specified, but with relative lengths converted into absolute lengths

Formal syntax

```
size =
  <length [0,∞]>{1,2}                        |
  auto                                       |
  [ <page-size> || [ portrait | landscape ] ]

<page-size> =
  A5      |
  A4      |
  A3      |
  B5      |
  B4      |
  JIS-B5  |
  JIS-B4  |
  letter  |
  legal   |
  ledger
```

This syntax reflects the latest standard as per CSS Paged Media Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Specifying size and orientation

```
@page {
  size: A4 landscape;
}
```

Specifying a custom size

```
@page {
  size: 4in 6in;
}
```

Nesting inside a @media rule

```
@media print {
  @page {
    size: 50mm 150mm;
  }
}
```

@position-try CSS at-rule

The **`@position-try`** CSS at-rule is used to define a custom position try fallback option, which can be used to define positioning and alignment for anchor-positioned elements. One or more sets of position try fallback options can be applied to the anchored element via the `position-try-fallbacks` property or `position-try` shorthand. When the positioned element is moved to a position where it starts to overflow its containing block or the viewport, the browser will select the first position try fallback option it finds that places the positioned element fully back on-screen.

Each position option is named with a `<dashed-ident>` and contains a descriptor list specifying declarations that define information such as inset position, margin, sizing, and self-alignment. The `<dashed-ident>` is used to reference the custom position option in the `position-try-fallbacks` property and `position-try` shorthand.

For detailed information on anchor features and position try fallback usage, see the CSS anchor positioning module and the Fallback options and conditional hiding for overflow guide.

Syntax

```
@position-try --try-option-name {
  descriptor-list
}
```

> **Note:** The `--try-option-name` is a `<dashed-ident>` specifying an identifying name for the custom position option, which can then be used to add that fallback option to the `position-try-fallbacks` list.

Descriptors

The descriptors specify property values that define the behavior of the custom position option, i.e., where it will result in the positioned element being placed.

`position-anchor`

Specifies a `position-anchor` property value that defines the anchor element that the positioned element is tethered to, by specifying a `<dashed-ident>` value equal to the anchor element's `anchor-name` property value.

`position-area`

Specifies a `position-area` property value that defines the position of the anchor-positioned element relative to the anchor.

Inset property descriptors

Specify `anchor()` function values that define the position of the anchor-positioned element's edges relative to the anchor element's edge. Inset property descriptors can be set that represent the following properties:

- `top`
- `left`
- `bottom`
- `right`.
- `inset-block-start`
- `inset-block-end`
- `inset-inline-start`
- `inset-inline-end`
- `inset-block`
- `inset-inline`
- `inset`

Margin property descriptors

Specify the margin set on the anchor-positioned element. Margin property descriptors can be set that represent the following properties:

- `margin-top`
- `margin-left`
- `margin-bottom`
- `margin-right`
- `margin-block-start`
- `margin-block-end`
- `margin-inline-start`
- `margin-inline-end`
- `margin`
- `margin-block`
- `margin-inline`

Sizing property descriptors

Specify `anchor-size()` function values that define the size of the anchor-positioned element relative to the anchor element size. Sizing property descriptors can be set that represent the following properties:

- `width`
- `height`
- `min-width`
- `min-height`
- `max-width`
- `max-height`
- `block-size`
- `inline-size`
- `min-block-size`
- `min-inline-size`
- `max-block-size`
- `max-inline-size`

Self-alignment property descriptors

Specify the `anchor-center` value to align the anchor-positioned element relative to the anchor element's center, in the block or inline direction. `align-self` and `justify-self` property descriptors can take the `anchor-center` value.

> **Note:** When a custom position option is applied to an element, the property values defined in the `@position-try` at-rule descriptor takes precedence over the values set on the element via standard CSS properties.

Formal syntax

```
@position-try =
  @position-try <dashed-ident> { <declaration-list> }
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Custom position option usage

In this example, we define an anchor element and an anchor-positioned element, then create four named custom position try fallback options. These options are applied to the positioned element to ensure its contents are always visible no matter where the anchor element is within the viewport.

HTML

We include two `<div>` elements that will become an anchor and an anchor-positioned element:

```
<div class="anchor">⚓</div>

<div class="infobox">
  <p>This is an information box.</p>
</div>
```

CSS

We first style the `<body>` element to be very large, so that we can scroll the anchor and the positioned element around in the viewport, both horizontally and vertically:

```
body {
  width: 1500px;
  height: 500px;
}
```

```
.anchor {
  font-size: 1.8rem;
  color: white;
```

```
  text-shadow: 1px 1px 1px black;
  background-color: hsl(240 100% 75%);
  width: fit-content;
  border-radius: 10px;
  border: 1px solid black;
  padding: 3px;
}
```

The anchor is given an `anchor-name` and has a `position` value of `absolute` set on it. We then position it somewhere near the center of the initial `<body>` rendering using `top` and `left` values:

```
.anchor {
  anchor-name: --my-anchor;
  position: absolute;
  top: 100px;
  left: 350px;
}
```

```
.infobox {
  color: darkblue;
  background-color: azure;
  border: 1px solid #dddddd;
  padding: 10px;
  border-radius: 10px;
  font-size: 1rem;
}
```

Next, we use the `@position-try` at-rule to define four custom position options, with descriptive `<dashed-ident>` names to identify them and describe their purpose. Each one places the positioned element in a specific position around the anchor element and gives it an appropriate `10px` margin between the positioned element and its anchor. The positioning is handled in a variety of ways, to demonstrate the different techniques available:

- The first and last position options use a `position-area`.
- The second position option uses `top` with an `anchor()` value and `justify-self: anchor-center` to center the positioned element on the anchor in the inline direction.
- The third position option uses `left` with an `anchor()` value, wrapped inside a `calc()` function that adds `10px` of spacing (rather than creating the spacing with `margin` like the other options do). It then uses `align-self: anchor-center` to center the positioned element on the anchor in the block direction.

Finally, the left and right position options are given a narrower `width`

```
@position-try --custom-left {
  position-area: left;
  width: 100px;
  margin-right: 10px;
}

@position-try --custom-bottom {
  top: anchor(bottom);
  justify-self: anchor-center;
  margin-top: 10px;
  position-area: none;
}

@position-try --custom-right {
  left: calc(anchor(right) + 10px);
  align-self: anchor-center;
  width: 100px;
  position-area: none;
}

@position-try --custom-bottom-right {
  position-area: bottom right;
  margin: 10px 0 0 10px;
}
```

The infobox is given fixed positioning, a `position-anchor` property that references the anchor's `anchor-name` to associate the two together, and it is tethered to the anchor's top edge using a `position-area`. We also give it a fixed `width` and some bottom `margin`. The custom position options are then referenced in the `position-try-fallbacks` property to prevent the positioned element from overflowing, or being scrolled out of view, when the anchor gets near the edge of the viewport.

```
.infobox {
  position: fixed;
  position-anchor: --my-anchor;
  position-area: top;
  width: 200px;
  margin-bottom: 10px;
  position-try-fallbacks:
    --custom-left, --custom-bottom, --custom-right, --custom-bottom-right;
}
```

Result

Scroll the page and notice the change in the positioned element's placement as the anchor nears the different edges of the viewport. This is due to different fallback position options being applied.

Let's talk through how these position options work:

- First of all, note that our default position is defined by `position-area: top`. When the infobox isn't overflowing the page in any direction, the infobox sits above the anchor, and the position try fallback options set in the `position-try-fallbacks` property are ignored. Also note that the infobox has a fixed width and bottom margin set. These values will change as different position try fallback options are applied.
- If the infobox starts to overflow, the browser first tries the `--custom-left` position. This moves the infobox to the left of the anchor using `position-area: left`, adjusts the margin to suit, and also gives the infobox a different width.
- Next, the browser tries the `--custom-bottom` position. This moves the infobox to the bottom of the anchor using `top` and `justify-self` instead of a `position-area`, and sets an appropriate margin. It doesn't include a `width` descriptor, so the infobox returns to its default width of `200px` set by the `width` property.
- The browser next tries the `--custom-right` position. This works much the same as the `--custom-left` position, with the same `width` descriptor value applied. However, we are using `left` and `align-self` to place the positioned element instead of a `position-area`. And we are wrapping the `left` value in a `calc()` function inside which we are adding `10px` to create spacing, instead of using `margin`.
- If none of the other try fallback options succeed in stopping the positioned element from overflowing, the browser tries the `--custom-bottom-right` position as a last resort. This places the positioned element to the bottom-right of the anchor using `position-area: bottom right`.

When a position option is applied, its values override the initial values set on the positioned element. For example, the `width` initially set on the positioned element is `200px`, but when the `--custom-right` position option is applied, its width is set to `100px`.

In some cases, we need to set values inside the custom position options to turn off the initial values. The `--custom-bottom` and `--custom-right` options use inset property and `*-self: anchor-center` values to place the positioned element, therefore we remove the previously-set `position-area` value in each case by setting `position-area: none`. If we didn't do this, the initially set `position-area: top` value would still take effect and interfere with the other positioning information.

@property CSS at-rule

The **`@property`** CSS at-rule is used to explicitly define CSS custom properties, allowing for property type checking and constraining, setting default values, and defining whether a custom property can inherit values or not.

> **Note:** The JavaScript `registerProperty()` method is equivalent to the `@property` at-rule.

Syntax

```
@property --canBeAnything {
  syntax: "*";
  inherits: true;
}

@property --rotation {
  syntax: "<angle>";
  inherits: false;
  initial-value: 45deg;
}

@property --defaultSize {
  syntax: "<length> | <percentage>";
  inherits: true;
  initial-value: 200px;
}
```

The custom property name is a `<dashed-ident>` that starts with `--` and is followed by a valid, user-defined identifier. It is case-sensitive.

Descriptors

`syntax`

A string that describes the allowed value types for the registered custom property.

`inherits`

A boolean value that controls whether the custom property registration specified by `@property` inherits by default.

`initial-value`

A value that sets the starting value for the property.

Description

The `@property` at-rule is part of the CSS Houdini set of APIs. It allows developers to explicitly define CSS custom properties, allowing for property type checking and constraining, setting default values, and defining whether a custom property can inherit values or not.

The `@property` rule enables custom property registration directly inside stylesheets without requiring any JavaScript. Valid `@property` rules produce registered custom properties, producing the same effect as calling `registerProperty()` with equivalent parameters.

The following conditions must be met for the `@property` rule to be valid:

- The `@property` rule must include both the `syntax` and `inherits` descriptors. If either is missing, the entire `@property` rule is invalid and ignored.
- The `syntax` may be a data type name (such as `<color>`, `<length>`, or `<number>`, etc.), with multipliers (`+` to accept a space-separated list, or `#` to accept a comma-separated list) and combinators (`|` to accept one data type or another), a custom ident, or the universal syntax definition (`*`), meaning the syntax can be any valid token stream. The value is a `<string>`. As such, it must be in quotes.
- The `initial-value` descriptor is optional if the value of the `syntax` descriptor is the universal syntax definition (`syntax: "*"`). If the `initial-value` descriptor is required but omitted, the entire `@property` rule is invalid and ignored.
- If the value of the `syntax` descriptor is not the universal syntax definition, the `initial-value` descriptor has to be a computationally independent value. This means the value can be converted into a computed value without depending on other values, except for "global" definitions independent of CSS. For example, `10px` is computationally independent—it doesn't change when converted to a computed value. `2in` is also valid, because `1in` is always equivalent to `96px`. However, `3em` is not valid, because the value of an `em` is dependent on the parent's `font-size`.
- Unknown descriptors are invalid and ignored, but do not invalidate the `@property` rule.

If multiple valid `@property` rules are defined using the same name, the last one in stylesheet order "wins". If custom properties are registered with the same name using `@property` in CSS and `CSS.registerProperty()` in JavaScript, the JavaScript registration wins.

Formal syntax

```
@property =
  @property <custom-property-name># { <declaration-list> }
```

This syntax reflects the latest standard as per CSS Properties and Values API Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

In this example, we use the `@property` at-rule to declare two custom properties, and then use those properties in our style declarations.

HTML

```
<p>Hello world!</p>
```

CSS

```
@property --myColor {
  syntax: "<color>";
  inherits: true;
  initial-value: rebeccapurple;
}

@property --myWidth {
  syntax: "<length> | <percentage>";
  inherits: true;
  initial-value: 200px;
}

p {
  background-color: var(--myColor);
  width: var(--myWidth);
  color: white;
}
```

Results

The paragraph should be `200px` wide, with a purple background and white text.

Animating a custom property value

In this example, we define a custom property called `--progress` using `@property`: this accepts `<percentage>` values and has an initial value of `25%`. We use `--progress` to define the position value of the color stops in a `linear-gradient()`, specifying where a green color stops, and black starts. We then animate the value of `--progress` to `100%` over 2.5 seconds, giving the effect of animating a progress bar.

HTML

```
<div class="bar"></div>
```

CSS

```
@property --progress {
  syntax: "<percentage>";
  inherits: false;
  initial-value: 25%;
}

.bar {
  display: inline-block;
  --progress: 25%;
  width: 100%;
  height: 5px;
  background: linear-gradient(
    to right,
    #00d230 var(--progress),
    black var(--progress)
  );
  animation: progressAnimation 2.5s ease infinite;
}

@keyframes progressAnimation {
  to {
    --progress: 100%;
  }
}
```

inherits CSS at-rule descriptor

The **`inherits`** CSS descriptor of the `@property` at-rule controls whether or not the registered CSS custom property inherits by default. It is a required descriptor; if missing or invalid, the entire `@property` rule is invalid and ignored.

Syntax

```
/* Custom property does not inherit values */
inherits: false;

/* Custom property inherits values */
inherits: true;
```

Values

`true`

The property inherits by default.

`false`

The property does not inherit by default.

Formal definition

Related at-rule	`@property`
Initial value	`auto`
Computed value	as specified

Formal syntax

```
inherits =
  true  |
  false
```

This syntax reflects the latest standard as per CSS Properties and Values API Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting inheritance behavior of a custom property

This example shows how to define a custom property `--my-color` that does not inherit its value from its parent elements:

```
@property --my-color {
  syntax: "<color>";
  inherits: false;
  initial-value: #c0ffee;
}
```

Using JavaScript `CSS.registerProperty()`:

```
window.CSS.registerProperty({
  name: "--my-color",
  syntax: "<color>",
  inherits: false,
  initialValue: "#c0ffee",
});
```

initial-value CSS at-rule descriptor

The **`initial-value`** descriptor of the `@property` at-rule specifies the initial value for the registered CSS custom property. It is a required descriptor unless the `syntax` descriptor value is the universal syntax (`*`). If required but missing or invalid, the entire `@property` rule is invalid and ignored.

Syntax

```
/* Set initial color value */
initial-value: rebeccapurple;

/* Set initial length value */
initial-value: 16px;
```

Values

A value that matches the type specified in the `syntax` descriptor. For example, if `syntax` is `<color>`, then the `initial-value` must be a valid `color` value.

If the value of the `syntax` descriptor is not the universal syntax definition, the `initial-value` descriptor has to be a computationally independent value. This means the value can be converted into a computed value without depending on other values, except for "global" definitions independent of CSS. For example, `10px` is computationally independent—it doesn't change when converted to a computed value. `2in` is also valid, because `1in` is always equivalent to `96px`. However, `3em` is not valid, because the value of an `em` is dependent on the parent's `font-size`.

Formal definition

Related at-rule	`@property`
Initial value	`n/a (required)`
Computed value	as specified

Formal syntax

```
initial-value =
  <declaration-value>?
```

This syntax reflects the latest standard as per CSS Properties and Values API Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting an initial value for a custom property

This example shows how to define a custom property `--my-color` with an initial color value of `#c0ffee`. This initial value will be used when the property is not inherited (`inherits: false`) and no other value is set on the element.

```
@property --my-color {
  syntax: "<color>";
  inherits: false;
  initial-value: #c0ffee;
}
```

Using JavaScript `CSS.registerProperty()`:

```
window.CSS.registerProperty({
  name: "--my-color",
  syntax: "<color>",
  inherits: false,
  initialValue: "#c0ffee",
});
```

syntax CSS at-rule descriptor

The **`syntax`** descriptor of the `@property` at-rule defines the allowed value types for the registered CSS custom property. It controls how the property's specified value is processed to derive the computed value. It is a required descriptor; if missing or invalid, the entire `@property` rule is invalid and ignored.

Syntax

```
/* A data type name */
syntax: "<color>";

/* A '|' combinator for multiple data types */
syntax: "<length> | <percentage>";

/* Space-separated list of values */
syntax: "<color>+";

/* Comma-separated list of values */
syntax: "<length>#";

/* Keywords */
syntax: "small | medium | large";

/* Combination of data type and keyword */
syntax: "<length> | auto";

/* Universal syntax value */
syntax: "*";
```

Values

A string (known as the syntax string) that defines the allowed values. It can be one of the following:

- One or more syntax component names, which can be:
  - Data type names (written with angle brackets, such as `<color>` or `<length>`)
  - Keywords (written without angle brackets, such as `auto` or `none`)
- The universal syntax `*`, which accepts any valid CSS value. It cannot be multiplied or combined with other syntax components.

The syntax component names can be used alone or multiplied and combined in different ways:

- The `+` (space-separated) and `#` (comma-separated) multipliers indicate that a list of values is expected. For example, `<color>#` means a comma-separated list of `<color>` values is the expected syntax.
- The vertical line (`|`) combinator can create "or" conditions for the expected syntax. For example, `<length> | auto` accepts `<length>` or `auto`, and `<color># | <integer>#` expects a comma-separated list of `<color>` values or a comma-separated list of `<integer>` values.

The following syntax component names are supported:

`"<angle>"`

Accepts any valid `<angle>` value.

`"<color>"`

Accepts any valid `<color>` value.

`"<custom-ident>"`

Accepts any valid `<custom-ident>` value.

`"<image>"`

Accepts any valid `<image>` value.

`"<integer>"`

Accepts any valid `<integer>` value.

`"<length>"`

Accepts any valid `<length>` value.

`"<length-percentage>"`

Accepts any valid `<length>` or `<percentage>` value and any valid `calc()` expression combining `<length>` and `<percentage>` values.

`"<number>"`

Accepts any valid `<number>` value.

`"<percentage>"`

Accepts any valid `<percentage>` value.

`"<resolution>"`

Accepts any valid `<resolution>` value.

`"<string>"`

Accepts any valid `<string>` value.

`"<time>"`

Accepts any valid `<time>` value.

`"<transform-function>"`

Accepts any valid `<transform-function>` value.

`"<transform-list>"`

Accepts a list of valid `<transform-function>` values. It is equivalent to `"<transform-function>+"`.

`"<url>"`

Accepts any valid `<url>` value.

Formal definition

Related at-rule	`@property`
Initial value	`n/a (required)`
Computed value	as specified

Formal syntax

```
syntax =
  <string>
```

This syntax reflects the latest standard as per CSS Properties and Values API Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Registering a custom property with type checking

This example shows how to define a custom property `--my-color` that allows only `<color>` values:

```
@property --my-color {
  syntax: "<color>";
  inherits: false;
  initial-value: #c0ffee;
}
```

Using JavaScript `CSS.registerProperty()`:

```
window.CSS.registerProperty({
  name: "--my-color",
  syntax: "<color>",
  inherits: false,
  initialValue: "#c0ffee",
});
```

@scope CSS at-rule

The **`@scope`** CSS at-rule enables you to select elements in specific DOM subtrees, targeting elements precisely without writing overly-specific selectors that are hard to override, and without coupling your selectors too tightly to the DOM structure.

In JavaScript, `@scope` can be accessed via the CSS object model interface `CSSScopeRule`.

Syntax

The `@scope` at-rule contains one or more rulesets (termed **scoped style rules**) and defines a scope in which to apply them to selected elements. `@scope` can be used in two ways:

1. As a standalone block inside your CSS, in which case it includes a prelude section that includes **scope root** and optional **scope limit** selectors — these define the upper and lower bounds of the scope.

   ```
   @scope (scope root) to (scope limit) {
     /* … */
   }
   ```

2. As inline styles included inside a `<style>` element in your HTML, in which case the prelude is omitted, and the enclosed ruleset is automatically scoped to the `<style>` element's enclosing parent element.

   ```
   <parent-element>
     <style>
       @scope {
         /* rulesets */
       }
     </style>
   </parent-element>
   ```

   It is also possible to combine an inline `@scope` with a scope limit selector, as in `@scope to (scope limit) { ... }`.

Description

A complex web document might include components such as headers, footers, news articles, maps, media players, ads, and others. As complexity increases, effectively managing the styling for these components becomes more of a concern, and effective scoping of styles helps us manage this complexity. Let's consider the following DOM tree:

```
body
└ article.feature
   ├ section.article-hero
   │  ├ h2
   │  └ img
   │
   ├ section.article-body
   │  ├ h3
   │  ├ p
   │  ├ img
   │  ├ p
   │  └ figure
   │     ├ img
   │     └ figcaption
   │
   └ footer
      ├ p
      └ img
```

If you wanted to select the `<img>` element inside the `<section>` with a class of `article-body`, you could do the following:

- Write a selector like `.feature > .article-body > img`. However, that has high specificity so is hard to override, and is also tightly coupled to the DOM structure. If your markup structure changes in the future, you might need to rewrite your CSS.
- Write something less specific like `.article-body img`. However, that will select all images inside the `section`.

This is where `@scope` is useful. It allows you to define a precise scope inside which your selectors are allowed to target elements. For example, you could solve the above problem using a standalone `@scope` block like the following:

```
@scope (.article-body) to (figure) {
  img {
    border: 5px solid black;
    background-color: goldenrod;
  }
}
```

The `.article-body` scope root selector defines the upper bound of the DOM tree scope in which the ruleset will be applied, and the `figure` scope limit selector defines the lower bound. As a result, only `<img>` elements inside a `<section>` with a class of `article-body`, but not inside `<figure>` elements, will be selected.

> **Note:** This kind of scoping — with an upper and lower bound — is commonly referred to as a **donut scope**.

The scope's upper bound is inclusive and its lower bound is exclusive. To change this behavior, you can combine either selector with a universal child selector. For example, `@scope (scope root) to (scope limit > *)` would make both bounds inclusive, `@scope (scope root > *) to (scope limit)` would make both bounds exclusive, while `@scope (scope root > *) to (scope limit > *)` would give an exclusive upper bound and an inclusive lower bound.

If you want to select all images inside a `<section>` with a class of `article-body`, you can omit the scope limit:

```
@scope (.article-body) {
  img {
    border: 5px solid black;
    background-color: goldenrod;
  }
}
```

Or you could include your `@scope` block inline inside a `<style>` element, which in turn is inside the `<section>` with a class of `article-body`:

```
<section class="article-body">
  <style>
    @scope {
      img {
        border: 5px solid black;
        background-color: goldenrod;
      }
    }
  </style>

  <!-- ... -->
</section>
```

> **Note:** It is important to understand that, while `@scope` allows you to isolate the application of selectors to specific DOM subtrees, it does not completely isolate the applied styles to within those subtrees. This is most noticeable with inheritance — properties that are inherited by children (for example `color` or `font-family`) will still be inherited, beyond any set scope limit.

<code>:scope</code> pseudo-class within <code>@scope</code> blocks

In the context of an `@scope` block, the `:scope` pseudo-class provides a convenient way to directly apply styles to the scope root, like so:

```
@scope (.feature) {
  :scope {
    background: rebeccapurple;
    color: antiquewhite;
    font-family: sans-serif;
  }
}
```

Here's some considerations for `:scope` within `@scope` blocks:

- `:scope` adds class-level specificity (see Specificity in @scope for details).
- A scope limit can use `:scope` to specify a specific relationship requirement between the scope limit and root. For example:

```
/* figure is only a limit when it is a direct child of the :scope */
@scope (.article-body) to (:scope > figure) {
  /* … */
}
```

- A scope limit can reference elements outside the scope root using `:scope`. For example:

```
/* figure is only a limit when the :scope is inside .feature */
@scope (.article-body) to (.feature :scope figure) {
  /* … */
}
```

- Scoped style rules can't escape the subtree. Selections like `:scope + p` are invalid because that selection would be outside the subtree.
- It is perfectly valid to define the scope root and limit as a selector list, in which case multiple scopes will be defined. In the following example the styles are applied to any `<img>` inside a `<section>` with a class of `article-hero` or `article-body`, but not if it is nested inside a `<figure>`:

```
@scope (.article-hero, .article-body) to (figure) {
  img {
    border: 5px solid black;
    background-color: goldenrod;
  }
}
```

Specificity in <code>@scope</code>

Inside an `@scope` rule, both bare selectors and the `&` nesting selector behave as if `:where(:scope)` were prepended to the selector. Because `:where()` has zero specificity, bare selectors and `&` add zero weight. The specificity weight is determined by the rest of the selector. For example, the specificity of the `& img` selector is equivalent to the specificity of `:where(:scope) img` (0-0-1).

> **Warning:** The specificity of `&` inside `@scope` blocks is handled differently according to the browser engine and release version. Check Browser compatibility for details.

In both cases in the following code block, the only specificity comes from `img`:

```
@scope (.article-body) {
  /* img has a specificity of 0-0-1, as expected */
  img {
    /* … */
  }

  /* & img also has a specificity of 0-0-1 */
  & img {
    /* … */
  }
}
```

By contrast, using `:scope` explicitly selects the scope root and adds class-level specificity (0-1-0), since `:scope` is a pseudo-class. In the following code block, `:scope img` has a specificity of 0-1-1:

```
@scope (.article-body) {
  /* :scope img has a specificity of 0-1-0 + 0-0-1 = 0-1-1 */
  :scope img {
    /* … */
  }
}
```

How <code>@scope</code> conflicts are resolved

`@scope` adds a new criterion to the CSS cascade: **scoping proximity**. This states that when two scopes have conflicting styles, the style that has the smallest number of hops up the DOM tree hierarchy to the scope root is applied. Let's look at an example to see what this means.

Take the following HTML snippet, where different-themed cards are nested inside one another:

```
<div class="light-theme">
  <p>Light theme text</p>
  <div class="dark-theme">
    <p>Dark theme text</p>
    <div class="light-theme">
      <p>Light theme text</p>
    </div>
  </div>
</div>
```

If you wrote the theme CSS like so, you'd run into trouble:

```
.light-theme {
  background: #cccccc;
}

.dark-theme {
  background: #333333;
}

.light-theme p {
  color: black;
}

.dark-theme p {
  color: white;
}
```

The innermost paragraph is supposed to be colored black because it is inside a light theme card. However, it's targeted by both `.light-theme p` and `.dark-theme p`. Because the `.dark-theme p` rule appears later in the source order, it is applied, and the paragraph ends up being wrongly colored white.

To fix this, you can use `@scope` as follows:

```
@scope (.light-theme) {
  :scope {
    background: #cccccc;
  }
  p {
    color: black;
  }
}

@scope (.dark-theme) {
  :scope {
    background: #333333;
  }
  p {
    color: white;
  }
}
```

Now the innermost paragraph is correctly colored black. This is because it is only one DOM tree hierarchy level away from the `.light-theme` scope root, but two levels away from the `.dark-theme` scope root. Therefore, the light style wins.

> **Note:** Scoping proximity overrules source order but is itself overridden by other, higher-priority criteria such as importance, layers, and specificity.

Formal syntax

```
@scope =
  @scope <scope-boundaries>? { <block-contents> }

<scope-boundaries> =
  [ [ ( <scope-start> ) ]? [ to ( <scope-end> ) ]? ]!

<scope-start> =
  <selector-list>

<scope-end> =
  <selector-list>

<selector-list> =
  <complex-selector-list>

<complex-selector-list> =
  <complex-selector>#

<complex-selector> =
  <complex-selector-unit> [ <combinator>? <complex-selector-unit> ]*

<complex-selector-unit> =
  [ <compound-selector>? <pseudo-compound-selector>* ]!

<combinator> =
  '>'               |
  '+'               |
  '~'               |
  [ '|' '|' ]       |
  [ / <wq-name> / ]

<compound-selector> =
  [ <type-selector>? <subclass-selector>* ]!

<pseudo-compound-selector> =
  <pseudo-element-selector> <pseudo-class-selector>*

<wq-name> =
  <ns-prefix>? <ident-token>

<type-selector> =
  <wq-name>         |
  <ns-prefix>? '*'

<subclass-selector> =
  <id-selector>           |
  <class-selector>        |
  <attribute-selector>    |
  <pseudo-class-selector>

<pseudo-element-selector> =
  : <pseudo-class-selector>        |
  <legacy-pseudo-element-selector>

<pseudo-class-selector> =
  : <ident-token>                  |
  : <function-token> <any-value> )

<ns-prefix> =
  [ <ident-token> | '*' ]? '|'

<id-selector> =
  <hash-token>

<class-selector> =
  '.' <ident-token>

<attribute-selector> =
  '[' <wq-name> ']'                                |
  '[' <wq-name> <attr-matcher> [ <string-token> | <ident-token> ] <attr-modifier>? ']'

<legacy-pseudo-element-selector> =
  : [ before | after | first-line | first-letter ]

<attr-matcher> =
  [ '~' | '|' | '^' | '$' | '*' ]? '='

<attr-modifier> =
```

```
  i  |
  s
```

This syntax reflects the latest standard as per CSS Cascading and Inheritance Level 6, Selectors Level 4, Selectors Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic style inside scope roots

In this example, we use two separate `@scope` blocks to match links inside elements with a `.light-scheme` and `.dark-scheme` class respectively. Note how `:scope` is used to select and provide styling to the scope roots themselves. In this example, the scope roots are the `<div>` elements that have the classes applied to them.

HTML

```
<div class="light-scheme">
  <p>
    MDN contains lots of information about
    <a href="/en-US/docs/Web/HTML">HTML</a>,
    <a href="/en-US/docs/Web/CSS">CSS</a>, and
    <a href="/en-US/docs/Web/JavaScript">JavaScript</a>.
  </p>
</div>

<div class="dark-scheme">
  <p>
    MDN contains lots of information about
    <a href="/en-US/docs/Web/HTML">HTML</a>,
    <a href="/en-US/docs/Web/CSS">CSS</a>, and
    <a href="/en-US/docs/Web/JavaScript">JavaScript</a>.
  </p>
</div>
```

CSS

```
div {
  padding: 10px;
}
```

```
@scope (.light-scheme) {
  :scope {
    background-color: plum;
  }

  a {
    color: darkmagenta;
  }
}

@scope (.dark-scheme) {
  :scope {
    background-color: darkmagenta;
    color: antiquewhite;
  }

  a {
    color: plum;
  }
}
```

Result

The above code renders like this:

Scope roots and scope limits

In this example, we have an HTML snippet that matches the DOM structure we talked about earlier in the Description section. This structure represents a typical article summary. The key features to note are the `<img>` elements, which are nested at various levels in the structure.

The aim of this example is to show how to use a scope root and limit to style `<img>` elements starting at the top of the hierarchy, but only down as far as (and not including) the `<img>` inside the `<figure>` element — in effect creating a donut scope.

HTML

```
<article class="feature">
  <section class="article-hero">
    <h2>Article heading</h2>
    <img alt="image" src="" />
  </section>

  <section class="article-body">
    <h3>Article subheading</h3>
    <p>
      Lorem ipsum dolor sit amet, consectetur adipiscing elit. Nam euismod
      consectetur leo, nec eleifend quam volutpat vitae. Duis quis felis at
      augue imperdiet aliquam. Morbi at felis et massa mattis lacinia. Cras
      pharetra velit nisi, ac efficitur magna luctus nec.
    </p>

    <img alt="image" src="" />

    <p>Lorem ipsum dolor sit amet, consectetur adipiscing elit.</p>

    <figure>
      <img alt="image" src="" />
      <figcaption>My infographic</figcaption>
    </figure>
  </section>

  <footer>
    <p>Written by Chris Mills.</p>
    <img alt="image" src="" />
```

```
  </footer>
</article>
```

CSS

```
* {
  box-sizing: border-box;
}

article {
  margin-bottom: 20px;
  padding: 10px;
  border: 2px solid gray;
}

.article-hero,
.article-body,
article footer {
  padding: 20px;
  margin: 10px;
  border: 2px solid lightgray;
}

img {
  height: 100px;
  width: 100%;
  display: block;
  background-color: lightgray;
  color: black;
  padding: 10px;
}
```

In our CSS, we have two `@scope` blocks:

- The first `@scope` block defines its scope root as elements with a class of `.feature` (in this case, the outer `<article>` only), demonstrating how `@scope` can be used to theme a specific HTML subset.
- The second `@scope` block also defines its scope root as elements with a class of `.feature`, but also defines a scope limit of `figure`. This ensures that contained rulesets will only be applied to matching elements within the scope root (`<article class="feature"> ... </article>` in this case) that **are not** nested inside descendant `<figure>` elements. This `@scope` block contains a single ruleset that styles `<img>` elements with a thick black border and a golden background color.

```
/* Scoped CSS */

@scope (.feature) {
  :scope {
    background: rebeccapurple;
    color: antiquewhite;
    font-family: sans-serif;
  }

  figure {
    background-color: white;
    border: 2px solid black;
    color: black;
    padding: 10px;
  }
}

/* Donut scope */

@scope (.feature) to (figure) {
  img {
    border: 5px solid black;
    background-color: goldenrod;
  }
}
```

Result

In the rendered code, note how all of the `<img>` elements are styled with the thick border and golden background, except for the one inside the `<figure>` element (labeled "My infographic").

@starting-style CSS at-rule

The **`@starting-style`** CSS at-rule is used to define starting values for properties set on an element that you want to transition from when the element receives its first style update, i.e., when an element is first displayed on a previously loaded page.

Syntax

The `@starting-style` at rule can be used in two ways:

1. As a standalone block, in which case it contains one or more rulesets defining starting style declarations and selecting the elements they apply to:

   ```
   @starting-style {
     /* rulesets */
   }
   ```

2. Nested within an existing ruleset, in which case it contains one or more declarations defining starting property values for the elements already selected by that ruleset:

   ```
   selector {
     /* existing ruleset */
     /* ... */
   ```

```
  @starting-style {
    /* declarations */
  }
}
```

Description

To avoid unexpected behavior, CSS transitions are by default not triggered on an element's initial style update, or when its `display` type changes from `none` to another value. To enable first-style transitions, `@starting-style` rules are needed. They provide starting styles for elements that do not have a previous state, defining the property values to transition from.

`@starting-style` is especially useful when creating entry and exit transitions for elements displayed in the top layer (such as popovers and modal `<dialog>`s), elements that are changing to and from `display: none`, and elements when first added to or removed from the DOM.

> **Note:** `@starting-style` is only relevant to CSS transitions. When using CSS animations to implement such effects, `@starting-style` is not needed. See Using CSS animations for an example.

There are two ways to use `@starting-style`: as a standalone rule or nested within a ruleset.

Let's consider a scenario where we want to animate a popover when shown (that is, when added to the top layer). The "original rule" specifying the styles for the open popover could look something like this (see the popover example below):

```
[popover]:popover-open {
  opacity: 1;
  transform: scaleX(1);
}
```

To specify the starting values of the popover's properties that will be animated using the first method, you include a standalone `@starting-style` block in your CSS:

```
@starting-style {
  [popover]:popover-open {
    opacity: 0;
    transform: scaleX(0);
  }
}
```

> **Note:** The `@starting-style` at-rule and the "original rule" have the same specificity. To ensure that starting styles get applied, include the `@starting-style` at-rule *after* the "original rule". If you specify the `@starting-style` at-rule before the "original rule", the original styles will override the starting styles.

To specify the starting style for the popover using the nested method, you can nest the `@starting-style` block inside the "original rule":

```
[popover]:popover-open {
  opacity: 1;
  transform: scaleX(1);

  @starting-style {
    opacity: 0;
    transform: scaleX(0);
  }
}
```

When exactly are starting styles used?

It is important to understand that an element will transition from its `@starting-style` styles when it is first rendered in the DOM, or when it transitions from `display: none` to a visible value. When it transitions back from its initial visible state, it will no longer use the `@starting-style` styles as it is now visible in the DOM. Instead, it will transition back to whatever styles exist for that element's default state.

In effect, there are three style states to manage in these situations — starting-style state, transitioned state, and default state. It is possible for the "to" and "from" transitions to be different in such cases. You can see a proof of this in our Demonstration of when starting styles are used example, below.

Formal syntax

```
@starting-style =
  @starting-style { <rule-list> }
```

Examples

Basic @starting-style usage

Transition an element's `background-color` from transparent to green when it is initially rendered:

```
#target {
  transition: background-color 1.5s;
  background-color: green;
}

@starting-style {
  #target {
    background-color: transparent;
  }
}
```

Transition the `opacity` of an element when it changes its `display` value to or from `none`:

```
#target {
  transition-property: opacity, display;
  transition-duration: 0.5s;
  display: block;
  opacity: 1;
  @starting-style {
    opacity: 0;
  }
}

#target.hidden {
  display: none;
```

```
  opacity: 0;
}
```

Demonstration of when starting styles are used

In this example, a button is pressed to create a `<div>` element, give it a `class` of `showing`, and add it to the DOM.

`showing` is given a `@starting-style` of `background-color: red` and a style of `background-color: blue` to transition to. The default `div` ruleset contains `background-color: yellow`, and is also where the `transition` is set.

When the `<div>` is first added to the DOM, you'll see the background transition from red to blue. After a timeout, we remove the `showing` class from the `<div>` via JavaScript. At that point it transitions from blue back to yellow, not red. This proves that the starting styles are only used when the element is first rendered in the DOM. Once it has appeared, the element transitions back to the default style set on it.

After another timeout, we then remove the `<div>` from the DOM altogether, resetting the initial state of the example so it can be run again.

HTML

```
<button>Display <code>&lt;div&gt;</code></button>
```

CSS

```
div {
  width: 200px;
  height: 100px;
  border: 1px solid black;
  margin-top: 10px;
}

div::after {
  content: "class: " attr(class);
  position: relative;
  top: 3px;
  left: 3px;
}
```

```
div {
  background-color: yellow;
  transition: background-color 3s;
}

div.showing {
  background-color: skyblue;
}

@starting-style {
  div.showing {
    background-color: red;
  }
}
```

JavaScript

```
const btn = document.querySelector("button");

btn.addEventListener("click", () => {
  btn.disabled = true;
  const divElem = document.createElement("div");
  divElem.classList.add("showing");
  document.body.append(divElem);

  setTimeout(() => {
    divElem.classList.remove("showing");

    setTimeout(() => {
      divElem.remove();
      btn.disabled = false;
    }, 3000);
  }, 3000);
});
```

Result

The code renders as follows:

Animating a popover

In this example, a popover is animated using CSS transitions. Basic entry and exit animations are provided using the `transition` property.

HTML

The HTML contains a `<div>` element declared as a popover using the popover attribute and a `<button>` element designated as the popover's display control using its popovertarget attribute.

```
<button popovertarget="mypopover">Show the popover</button>
<div popover="auto" id="mypopover">I'm a Popover! I should animate.</div>
```

CSS

In this example, we want to animate two properties, `opacity` and `transform` (specifically, a horizontally scaling transform), to make the popover fade in and out as well as grow and shrink horizontally.

```
html {
  font-family: "Helvetica", "Arial", sans-serif;
}

[popover]:popover-open {
  opacity: 1;
  transform: scaleX(1);
}

[popover] {
  font-size: 1.2rem;
```

```
  padding: 10px;

  /* Final state of the exit animation */
  opacity: 0;
  transform: scaleX(0);

  transition:
    opacity 0.7s,
    transform 0.7s,
    overlay 0.7s allow-discrete,
    display 0.7s allow-discrete;
  /* Equivalent to
  transition: all 0.7s allow-discrete; */
}

/* Include after the [popover]:popover-open rule */
@starting-style {
  [popover]:popover-open {
    opacity: 0;
    transform: scaleX(0);
  }
}

/* Transition for the popover's backdrop */
[popover]::backdrop {
  background-color: transparent;
  transition:
    display 0.7s allow-discrete,
    overlay 0.7s allow-discrete,
    background-color 0.7s;
  /* Equivalent to
  transition: all 0.7s allow-discrete; */
}

[popover]:popover-open::backdrop {
  background-color: rgb(0 0 0 / 25%);
}

/* Nesting (&) is not supported for pseudo-elements
so specify a standalone starting-style block. */
@starting-style {
  [popover]:popover-open::backdrop {
    background-color: transparent;
  }
}
```

To achieve this, we have set a starting state for these properties on the default hidden state of the popover element (selected via `[popover]`), and an ending state on the open state of the popover (selected via the `:popover-open` pseudo-class).

We then set a `transition` property to animate between the two states. A starting state for the animation is included inside a `@starting-style` at-rule to enable the entry animation.

Because the animated element is being promoted to the top layer when shown and removed from the top layer when hidden (with `display: none`), some extra steps are required to ensure the animation works in both directions:

- `display` is added to the list of transitioned elements to ensure the animated element is visible (set to `display: block` or another visible `display` value) throughout both the entry and exit animations. Without this, the exit animation would not be visible; in effect, the popover would just disappear. Note that the `transition-behavior: allow-discrete` value is also set in the shorthand to activate the animation.
- `overlay` is added to the list of transitioned elements to ensure that the removal of the element from the top layer is deferred until the animation ends. This doesn't make a huge difference for animations such as this one, but in more complex cases, not doing this can result in the element being removed from the overlay too quickly, meaning the animation is not smooth or effective. Again, `transition-behavior: allow-discrete` is required in this case for the animation to occur.

> **Note:** We've also included a transition on the `::backdrop` that appears behind the popover when it opens, to provide a nice darkening animation. `[popover]:popover-open::backdrop` is used to select the backdrop when the popover is open.

Result

The code renders as follows:

> **Note:** Because popovers change from `display: none` to `display: block` each time they are shown, the popover transitions from its `@starting-style` styles to its `[popover]:popover-open` styles every time the entry transition occurs. When the popover closes, it transitions from its `[popover]:popover-open` state to the default `[popover]` state.

> **Note:** You can find an example that demonstrates transitioning a `<dialog>` element and its backdrop as it is shown and hidden on the `<dialog>` reference page — see Transitioning dialog elements.

Transitioning elements on DOM addition and removal

This example contains a button which, when pressed, appends new elements to a `<section>` container. Each element, in turn, contains a nested button, which when pressed, removes the element. This example demonstrates how to use transitions to animate elements when they are added to or removed from the DOM.

HTML

```
<button>Create new column</button>
<section></section>
```

JavaScript

JavaScript enables the addition and removal of elements:

```
const btn = document.querySelector("button");
const sectionElem = document.querySelector("section");

btn.addEventListener("click", createColumn);

function randomBackground() {
  function randomNum() {
    return Math.floor(Math.random() * 255);
```

```
  }
  const baseColor = `${randomNum()} ${randomNum()} ${randomNum()}`;

  return `linear-gradient(to right, rgb(${baseColor} / 0), rgb(${baseColor} / 0.5))`;
}

function createColumn() {
  const divElem = document.createElement("div");
  divElem.style.background = randomBackground();

  const closeBtn = document.createElement("button");
  closeBtn.textContent = "✕";
  closeBtn.setAttribute("aria-label", "close");
  divElem.append(closeBtn);
  sectionElem.append(divElem);

  closeBtn.addEventListener("click", () => {
    divElem.classList.add("fade-out");

    setTimeout(() => {
      divElem.remove();
    }, 1000);
  });
}
```

When the "Create new column" button is clicked, the `createColumn()` function is called. This creates a `<div>` element with a randomly generated background color and a `<button>` element to close the `<div>`. It then appends the `<button>` to the `<div>` and the `<div>` to the `<section>` container.

We then add an event listener to the close button via `addEventListener()`. Clicking the close button does two things:

- Adds the `fade-out` class to the `<div>`. Adding the class triggers the exit animation set on that class.
- Removes the `<div>` after a 1000ms delay. The `setTimeout()` delays removal of the `<div>` from the DOM (via `Element.remove()`) until after the animation ends.

CSS

We include a `transition` that animates the `opacity` and `scale` of each column as they are added and removed:

```
html * {
  box-sizing: border-box;
  font-family: sans-serif;
}

body {
  margin: 0;
  display: flex;
  flex-direction: column;
  height: 100vh;
  gap: 10px;
}

body > button {
  margin: 10px 10px 0 10px;
}

section {
  display: flex;
  flex: 1;
  gap: 10px;
  margin: 10px;
}
```

```
div {
  flex: 1;
  border: 1px solid gray;
  position: relative;
  opacity: 1;
  scale: 1 1;

  transition:
    opacity 0.7s,
    scale 0.7s,
    display 0.7s allow-discrete,
    all 0.7s allow-discrete;
  /* Equivalent to
  transition: all 0.7s allow-discrete; */
}

/* Include after the `div` rule */
@starting-style {
  div {
    opacity: 0;
    scale: 1 0;
  }
}

.fade-out {
  opacity: 0;
  display: none;
  scale: 1 0;
}

div > button {
  font-size: 1.6rem;
  background: none;
  border: 0;
  text-shadow: 2px 1px 1px white;
  border-radius: 15px;
  position: absolute;
  top: 1px;
  right: 1px;
```

```
  cursor: pointer;
}
```

To animate the `opacity` and `scale` of each `<div>` as it is added to the DOM and then reverse the animation as it is removed from the DOM, we:

- Specify the ending state of the properties we want to transition on the `div { ... }` rule.
- Specify the starting state from which to transition the properties inside a `@starting-style` block.
- Specify the exit animation inside the `.fade-out` rule — this is the class that the JavaScript assigns to the `<div>` elements when their close buttons are pressed. Besides setting the `opacity` and `scale` ending states, we also set `display: none` on the `<div>`s — we want them to become immediately unavailable when removed from the UI.
- Specify the `transition` list inside the `div { ... }` rule to animate `opacity`, `scale`, and `display`. Note that for `display`, the `transition-behavior: allow-discrete` value is also set in the shorthand so that it will animate.

Result

The final result looks like this:

@supports CSS at-rule

The **`@supports`** CSS at-rule lets you specify CSS declarations that depend on a browser's support for CSS features. Using this at-rule is commonly called a *feature query*. The rule must be placed at the top level of your code or nested inside any other conditional group at-rule.

In JavaScript, `@supports` can be accessed via the CSS object model interface `CSSSupportsRule`.

Try it

```
.flex-container > * {
  padding: 0.3em;
  list-style-type: none;
  text-shadow: 0 0 2px red;
  float: left;
}

@supports (display: flex) {
  .flex-container > * {
    text-shadow: 0 0 2px blue;
    float: none;
  }

  .flex-container {
    display: flex;
  }
}
```

```
<ul class="flex-container">
  <li><a href="#">Index</a></li>
  <li><a href="#">About me</a></li>
  <li><a href="#">Contact</a></li>
</ul>
```

Syntax

```
@supports (<supports-condition>) {
  /* If the condition is true, use the CSS in this block. */
}

@supports (<supports-condition>) and (<supports-condition>) {
  /* If both conditions are true, use the CSS in this block. */
}
```

The `@supports` at-rule consists of a block of statements with a *supports condition*. The conditions can be combined by conjunctions (`and`), disjunctions (`or`), and/or negations (`not`). The precedence of operators can be defined with parentheses.

Supports conditions can use either a `<property>: <value>` declaration syntax or a `<function()>` syntax. The following sections describe the use of each type of supports condition.

Declaration syntax

The declaration syntax checks if a browser supports the specified `<property>: <value>` declaration. The declaration must be surrounded by parentheses. The following example returns true if the browser supports the expression `transform-origin: 5% 5%`:

```
@supports (transform-origin: 5% 5%) {
}
```

Function syntax

The function syntax checks if a browser supports values or expressions within the function. The functions supported in the function syntax are described in the following sections.

`at-rule()`

This function checks if a browser supports the specified at-rule. The following example returns true and applies the contained CSS styles if the browser supports the `@keyframes` at-rule:

```
@supports at-rule(@keyframes) {
}
```

`selector()`

This function evaluates if a browser supports the specified selector syntax. The following example returns true and applies the contained CSS styles if the browser supports the child combinator:

```
@supports selector(h2 > p) {
}
```

`font-tech()`

This function checks if a browser supports the specified font technology for layout and rendering. The following example returns true and applies the contained CSS styles if the browser supports the `COLRv1` font technology:

```
@supports font-tech(color-COLRv1) {
}
```

The table below describes the font technologies (`<font-tech>`), including color font technologies (`<color-font-tech>`), font feature technologies (`<font-features-tech>`), and other available font technologies that can be queried using the `font-tech()` function:

Technology	Supports
`<color-font-tech>`	
`color-colrv0`	Multi-colored glyphs via COLR version 0 table
`color-colrv1`	Multi-colored glyphs via COLR version 1 table
`color-svg`	SVG multi-colored tables
`color-sbix`	Standard bitmap graphics tables
`color-cbdt`	Color bitmap data tables
`<font-features-tech>`	
`features-opentype`	OpenType `GSUB` and `GPOS` tables
`features-aat`	TrueType `morx` and `kerx` tables
`features-graphite`	Graphite features, namely `Silf`, `Glat`, `Gloc`, `Feat`, and `Sill` tables
Other `<font-tech>` values	
`incremental-patch`	Incremental font loading using the patch subset method
`incremental-range`	Incremental font loading using the range request method
`incremental-auto`	Incremental font loading using method negotiation
`variations`	Font variations in TrueType and OpenType fonts to control the font axis, weight, glyphs, etc.
`palettes`	Font palettes by means of `font-palette` to select one of many color palettes in the font

`font-format()`

This function checks if a browser supports the specified font format for layout and rendering. The following example returns true and applies the contained CSS styles if the browser supports the `opentype` font format:

```
@supports font-format(opentype) {
}
```

The following table describes the available formats (`<font-format>` values) that can be queried with this function:

Format	Description	File extensions
`collection`	OpenType Collection	`.otc`, `.ttc`
`embedded-opentype`	Embedded OpenType	`.eot`
`opentype`	OpenType	`.ttf`, `.otf`
`svg`	SVG Font (deprecated)	`.svg`, `.svgz`
`truetype`	TrueType	`.ttf`
`woff`	WOFF 1.0 (Web Open Font Format)	`.woff`
`woff2`	WOFF 2.0 (Web Open Font Format)	`.woff2`

`named-feature()`

This function takes one predefined keyword and evaluates if a browser supports the specified named feature. This is to allow for feature support that cannot be tested for using the other `@supports` functions.

```
@supports named-feature(anchor-position-follows-transform) {
}
```

> **Note:** More features will be added rarely and only when there is real demand for feature testing something specific that would not be covered by more general testing methods.

`anchor-position-follows-transforms`

This `named-feature()` checks if the browser supports transform-aware anchor positioning.

`single-axis-scroll-container`

This `named-feature()` checks if the browser supports the ability to have single-axis scroll containers, where one axis is either `scroll`, or `auto`, or `hidden` and the other is `clip`.

The not operator

The `not` operator precedes an expression resulting in the negation of the expression. The following returns true if the browser's `transform-origin` property considers `10em 10em 10em` **to be invalid:**

```
@supports not (transform-origin: 10em 10em 10em) {
}
```

As with any operator, the `not` operator can be applied to a declaration of any complexity. The following examples are both valid:

```
@supports not (not (transform-origin: 2px)) {
}
@supports (display: grid) and (not (display: inline-grid)) {
}
```

> **Note:** There is no need to enclose the `not` operator between two parentheses at the top level. To combine it with other operators, like `and` and `or`, the parentheses are required.

The and operator

The `and` operator creates a new expression from the conjunction of two shorter expressions. It returns true only if **both** of the shorter expressions are also true. The following example returns true if and only if the two shorter expressions are simultaneously true:

```
@supports (display: table-cell) and (display: list-item) {
}
```

Multiple conjunctions can be juxtaposed without the need of more parentheses. The following are both equivalent:

```
@supports (display: table-cell) and (display: list-item) and (display: contents) {
}
@supports (display: table-cell) and
  ((display: list-item) and (display: contents)) {
}
```

The or operator

The `or` operator creates a new expression from the disjunction of two shorter expressions. It returns true if **one or both** of the shorter expressions is also true. The following example returns true if at least one of the two shorter expressions is true:

```
@supports (transform-style: preserve) or (-moz-transform-style: preserve) {
}
```

Multiple disjunctions can be juxtaposed without the need of more parentheses. The following are both equivalent:

```
@supports (transform-style: preserve) or (-moz-transform-style: preserve) or
  (-webkit-transform-style: preserve) {
}

@supports (transform-style: preserve-3d) or
  (
    (-moz-transform-style: preserve-3d) or
      (-webkit-transform-style: preserve-3d)
  ) {
}
```

> **Note:** When using both `and` and `or` operators, the parentheses must be used to define the order in which they apply. Otherwise, the condition is invalid and the whole rule is ignored.

Formal syntax

```
@supports =
  @supports <supports-condition> { <rule-list> }

<supports-condition> =
  not <supports-in-parens>                          |

<attr-matcher> =
  [ '~' | '|' | '^' | '$' | '*' ]? '='

<attr-modifier> =
  i  |
  s
```

This syntax reflects the latest standard as per CSS Conditional Rules Module Level 3, CSS Conditional Rules Module Level 4, CSS Conditional Rules Module Level 5, CSS Fonts Module Level 5, Media Queries Level 5, Selectors Level 4, Selectors Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Testing for the support of a CSS property

```
@supports (animation-name: test) {
  /* CSS applied when animations are supported without a prefix */
  @keyframes {
    /* Other at-rules can be nested inside */
  }
}
```

Testing for the support of a given CSS property or a prefixed version

```
@supports (text-stroke: 10px) or (-webkit-text-stroke: 10px) {
  /* CSS applied when text-stroke, prefixed or not, is supported */
}
```

Testing for the non-support of a specific CSS property

```
@supports not ((text-align-last: justify) or (-moz-text-align-last: justify)) {
  /* CSS to provide fallback alternative for text-align-last: justify */
```

```
}
```

Testing for the support of a selector

CSS conditional rules provide the ability to test for the support of a selector such as `:has()`.

```
/* This rule won't be applied in browsers that don't support :has() */
ul:has(> li li) {
  /* CSS is applied when the :has(…) pseudo-class is supported */
}

@supports not selector(:has(a, b)) {
  /* Fallback for when :has() is unsupported */
  ul > li,
  ol > li {
    /* The above expanded for browsers that don't support :has(…) */
  }
}

/* Note: So far, there's no browser that supports the `of` argument of :nth-child(…) */
@supports selector(:nth-child(1n of a, b)) {
  /* This rule needs to be inside the @supports block, otherwise
     it will be partially applied in browsers which don't support
     the `of` argument of :nth-child(…) */
  :is(:nth-child(1n of ul, ol) a, details > summary) {
    /* CSS applied when the :is(…) selector and
       the `of` argument of :nth-child(…) are both supported */
  }
}
```

Testing for the support of a font technology

The following example applies the Bungee Spice color font if the browser supports the `COLRv1` font technology:

```
@supports font-tech(color-COLRv1) {
  body {
    font-family: "Bungee Spice", fantasy;
  }
}
```

It's also possible to test for the support of a font technology by using the `tech` function inside the `@font-face` at-rule. In the following example, if a browser doesn't support the color font technology in the `bungee-spice.woff2` font, a regular `bungee.woff2` font will be used instead.

```
@font-face {
  font-family: "Bungee Spice";
  src:
    url("bungee-spice.woff2") tech(color-COLRv1) format("woff2"),
    url("bungee.woff2") format("woff2");
}
```

Testing for the support of a font format

The following example uses the WOFF2 version of the font if the browser supports this font format, otherwise it falls back to the previously specified WOFF version:

```
@font-face {
  font-family: "Open Sans WOFF";
  src: url("open-sans.woff") format("woff");
}

@font-face {
  font-family: "Open Sans WOFF2";
  src: url("open-sans.woff2") format("woff2");
}

body {
  font-family: "Open Sans WOFF", sans-serif;
}

@supports font-format(woff2) {
  body {
    font-family: "Open Sans WOFF2", sans-serif;
  }
}
```

However, a more efficient way to specify multiple font formats is to list them in the `src` descriptor of a single `@font-face` at-rule in the order from the most preferred format to the least preferred:

```
@font-face {
  font-family: "Open Sans";
  src:
    url("open-sans.woff2") format("woff2"),
    url("open-sans.woff") format("woff");
}

body {
  font-family: "Open Sans", sans-serif;
}
```

Testing for the support of an at-rule

The following example applies a set of scoped color scheme styles if the browser supports the `@scope` at-rule:

```
@supports at-rule(@scope) {
  @scope (.light-scheme) {
    :scope {
      background-color: plum;
    }

    a {
      color: darkmagenta;
```

```
    }
  }

  @scope (.dark-scheme) {
    :scope {
      background-color: darkmagenta;
      color: antiquewhite;
    }

    a {
      color: plum;
    }
  }
}
```

- `CSS.supports()` method

@view-transition CSS at-rule

The **`@view-transition`** CSS at-rule is used to opt in the current and destination documents to undergo a view transition, in the case of a cross-document navigation.

For a cross-document view transition to work, the current and destination documents of the navigation need to be on the same origin.

Syntax

```
@view-transition {
  navigation: auto | none;
  types: none | <custom-ident>#;
}
```

Descriptors

`navigation`

A keyword specifying the effect this at-rule will have on the document's view transition behavior. Possible values are:

`auto`

The document will undergo a view transition when taking part in a navigation, provided the navigation is same-origin, without cross-origin redirects, and its `navigationType` is `traverse`, `push`, or `replace`. In the case of `push` or `replace`, the navigation must be initiated by a user interacting with the page content, not by a browser UI feature.

`none`

The document will not undergo a view transition.

`types`

Specifies the view transition types to set on the active view transition for the current and destination documents. Possible values are:

`<custom-ident>+`

One or more space-separated `<custom-ident>` values representing the types to set.

`none`

No types are set.

Formal syntax

```
@view-transition =
  @view-transition { <declaration-list> }
```

This syntax reflects the latest standard as per CSS View Transitions Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Transitioning page view

The following code snippets show key concepts used in a page transition demo. The demo uses cross-document view-transitions; a half second transition that occurs when navigating between two pages of a site. For the full demo, see the View transitions multi-page app demo.

The `@view-transition` at-rule is specified in the CSS for both your current and destination documents of a navigation to opt them both in to the view transition:

```
@view-transition {
  navigation: auto;
}
```

In addition to the `@view-transition` at-rule, we use the `@keyframes` at-rule to define two keyframe animations and use the `animation` shorthand property to apply those keyframe animations to the elements in the outbound (`::view-transition-old()`) and inbound (`::view-transition-new()`) pages that we want to animate.

```
/* Create a custom animation */
@keyframes move-out {
  from {
    transform: translateY(0%);
  }

  to {
    transform: translateY(-100%);
  }
}

@keyframes move-in {
  from {
    transform: translateY(100%);
  }
```

```
  to {
    transform: translateY(0%);
  }
}

/* Apply the custom animation to the old and new page states */
::view-transition-old(root) {
  animation: 0.4s ease-in both move-out;
}

::view-transition-new(root) {
  animation: 0.4s ease-in both move-in;
}
```

See this transitions multi-page app demo live.

Using view transition types

Our MPA transition types example (source code) demonstrates how to use `types` via `@view-transition`:

```
@view-transition {
  navigation: auto;
  types: slide;
}
```

See Using types with cross-document view transitions via `@view-transition` for a walkthrough of the referenced example.

- CSS at-rule functions

CSS at-rule functions

CSS at-rule functions are at-rule statements that represent complex rules or can invoke special data processing or calculations.

Syntax

```
@identifier function([argument]? [, argument]!) {
}
```

The syntax begins with the at symbol `@` and an at-rule identifier, such as `import`. This is followed by the **name of the at-rule function**, such as `url`, followed by a pair of opening and closing parentheses. One or more arguments are specified inside the parentheses.

Some at-rule functions can take multiple arguments, which are formatted similar to CSS property values. White space is allowed, but it is optional inside the parentheses. Multiple arguments can be separated using a comma or a space.

@import functions

The `@import` at-rule is used to import styles from other stylesheets.

`@import url()`

: Imports a stylesheet file from the specified URL.

`@import supports()`

: Imports a stylesheet file based on browser support.

`@import layer()`

: Imports a stylesheet file into the specified cascade layer.

@supports functions

The `@supports` at-rule checks for a browser's support for the specified CSS feature and then applies the CSS styling.

`@supports selector()`

: Applies CSS rules after checking browser's support for the specified selector syntax.

`@supports font-tech()`

: Applies CSS rules after checking browser's support for the specified font technology.

`@supports font-format()`

: Applies CSS rules after checking browser's support for the specified font format.

@namespace functions

The `@namespace` at-rule is used to specify XML namespaces to be used in a CSS stylesheet.

`@namespace url()`

: Defines XML namespace from the specified URL.

@container functions

The `@container` at-rule is used to specify styles for a containment context.

`@container style()`

Defines the containment context style.

Firefox (-moz-) vendor-prefixed CSS extensions

A vendor prefix is used to indicate that a feature is specific to a certain browser. Firefox supports several extensions to CSS, which are prefixed with `-moz-`.

-moz-prefixed properties without standard equivalents

> **Note:** These extensions are mostly experimental or deprecated but kept for backward compatibility. You should avoid using them on production websites.

- `-moz-float-edge`
- `-moz-force-broken-image-icon` : Use `alt` text instead.
- `-moz-orient`
- `-moz-osx-font-smoothing`: A similar `font-smooth` equivalent exists.
- `-moz-user-focus`
- `-moz-user-input`
- `-moz-user-modify`: A non-prefixed `user-modify` equivalent exists, but the HTML `contenteditable` attribute is recommended instead.

-moz-prefixed properties with standard equivalents

The following properties were implemented first using the `-moz-` vendor prefix, but are now supported in Firefox using the standard (non-prefixed) syntax. Support for the prefixed version is typically dropped eventually, so use the standard property instead.

A

- `-moz-animation` : Prefixed version still supported.
- `-moz-animation-delay` : Prefixed version still supported.
- `-moz-animation-direction` : Prefixed version still supported.
- `-moz-animation-duration` : Prefixed version still supported.
- `-moz-animation-fill-mode` : Prefixed version still supported.
- `-moz-animation-iteration-count` : Prefixed version still supported.
- `-moz-animation-name` : Prefixed version still supported.
- `-moz-animation-play-state` : Prefixed version still supported.
- `-moz-animation-timing-function` : Prefixed version still supported.
- `-moz-appearance`: The prefixed version of `appearance` is still supported.

B

- `-moz-backface-visibility` : Prefixed version still supported.
- `-moz-background-clip` : Not supported; use `background-clip`.
- `-moz-background-origin` : Not supported; use `background-origin`.
- `-moz-box-align` : Use CSS flexbox with `align-items`.
- `-moz-background-inline-policy` : Not supported; use `box-decoration-break`.
- `-moz-box-direction` : Use CSS flexbox with `flex-direction`.
- `-moz-box-flex` : Use CSS flexbox with `flex-grow`.
- `-moz-box-ordinal-group` : Use CSS flexbox with `order`.
- `-moz-box-orient` : Use CSS flexbox with `flex-direction`.
- `-moz-box-pack` : Use CSS flexbox with `justify-content`.
- `-moz-background-size` : Not supported; use `background-size`.
- `-moz-border-end` : Not supported; use `border-inline-end`.
- `-moz-border-end-color` : Not supported; use `border-inline-end-color`.
- `-moz-border-end-style` : Not supported; use `border-inline-end-style`.
- `-moz-border-end-width` : Not supported; use `border-inline-end-width`.
- `-moz-border-image` : Not supported; use `border-inline-end-width`.
- `-moz-border-start` : Not supported; use `border-inline-start`.
- `-moz-border-start-color` : Not supported; use `border-inline-start-color`.
- `-moz-border-start-style` : Not supported; use `border-inline-start-style`.
- `-moz-border-start-width` : Not supported; use `border-inline-start-width`.
- `-moz-box-sizing` : Prefixed version still supported.

C

- `-moz-column-count` : Not supported; use `column-count`.
- `-moz-column-fill` : Not supported; use `column-fill`.
- `-moz-column-gap` : Not supported; use `column-gap`.
- `-moz-column-width` : Not supported; use `column-width`.
- `-moz-column-rule` : Not supported; use `column-rule`.
- `-moz-column-rule-width` : Not supported; use `column-rule-width`.
- `-moz-column-rule-style` : Not supported; use `column-rule-style`.
- `-moz-column-rule-color` : Not supported; use `column-rule-color`.

F–M

- `-moz-font-feature-settings` : Prefixed version still supported.
- `-moz-font-language-override` : Prefixed version still supported.
- `-moz-hyphens` : Prefixed version still supported.
- `-moz-margin-end` : Not supported; use `margin-inline-end`.
- `-moz-margin-start` : Not supported; use `margin-inline-start`.

O-P

- `-moz-opacity` : Not supported; use `opacity`.
- `-moz-outline` : Not supported; use `outline`.
- `-moz-outline-color` : Not supported; use `outline-color`.
- `-moz-outline-offset` : Not supported; use `outline-offset`.

- `-moz-outline-style` : Not supported; use `outline-style`.
- `-moz-outline-width` : Not supported; use `outline-width`.
- `-moz-padding-end` : Not supported; use `padding-inline-end`.
- `-moz-padding-start` : Not supported; use `padding-inline-start`.
- `-moz-perspective` : Prefixed version still supported.
- `-moz-perspective-origin` : Prefixed version still supported.

T–Z

- `-moz-tab-size`: Use `tab-size`
- `-moz-text-align-last` : Not supported; use `text-align-last`.
- `-moz-text-decoration-color` : Not supported; use `text-decoration-color`.
- `-moz-text-decoration-line` : Not supported; use `text-decoration-line`.
- `-moz-text-decoration-style` : Not supported; use `text-decoration-style`.
- `-moz-text-size-adjust`: See `text-size-adjust` .
- `-moz-transform` : Prefixed version still supported.
- `-moz-transform-origin` : Prefixed version still supported.
- `-moz-transform-style` : Prefixed version still supported.
- `-moz-transition` : Not supported; use `transition`.
- `-moz-transition-delay` : Not supported; use `transition-delay`.
- `-moz-transition-duration` : Not supported; use `transition-duration`.
- `-moz-transition-property` : Not supported; use `transition-property`.
- `-moz-transition-timing-function` : Not supported; use `transition-timing-function`.
- `-moz-user-select`: Use `user-select`.

-moz-prefixed property values

Global values

- `-moz-initial`: See `initial`.

background-image

Property: `background-image`

- `-moz-linear-gradient` : Use `linear-gradient()`.
- `-moz-radial-gradient` : Use `radial-gradient()`.
- `-moz-element` : Use `element()`.
- `-moz-image-rect()`

border-style and outline-style

Properties: `border-style` and `outline-style`.

- `-moz-bg-inset`
- `-moz-bg-outset`
- `-moz-bg-solid`

<color> keywords

Type: `<color>`

- `-moz-activehyperlinktext`
- `-moz-hyperlinktext`
- `-moz-visitedhyperlinktext`
- `-moz-buttonhoverface`
- `-moz-buttonhovertext`
- `-moz-default-background-color`
- `-moz-default-color`
- `-moz-cellhighlight`
- `-moz-cellhighlighttext`
- `-moz-field`
- `-moz-fieldtext`
- `-moz-dialog`
- `-moz-dialogtext`
- `-moz-menuhover`
- `-moz-menuhovertext`

empty-cells

Property: `empty-cells`

- `-moz-show-background` (default value in quirks mode)

font-family

Property: `font-family`

- `-moz-fixed`

image-rendering

Property: `image-rendering`

- `-moz-crisp-edges` : Use `crisp-edges`.

<length>

Type: `<length>`

- `-moz-calc`: Use `calc()`.

list-style-type

Property: `list-style-type`

Several vendor-prefixed values for `list-style-type` are now supported as standard values without a `-moz-` prefix, except for those in the following list. See Browser Compatibility for details.

- `-moz-ethiopic-halehame`
- `-moz-ethiopic-halehame-am`
- `-moz-ethiopic-halehame-ti-er`
- `-moz-ethiopic-halehame-ti-et`
- `-moz-hangul`
- `-moz-hangul-consonant`
- `-moz-urdu`

text-align

Property: `text-align`

- `-moz-center` : Use `text-align: center`.
- `-moz-left` : Use `text-align: left`.
- `-moz-right` : Use `text-align: right`.

width, min-width, and max-width

Properties: `width`, `min-width`, and `max-width`

- `-moz-min-content`: See `min-content`.
- `-moz-fit-content`: See `fit-content`.
- `-moz-max-content`: See `max-content`.
- `-moz-available`: See `stretch`.

Pseudo-classes

- `:-moz-any` : Use `:is`.
- `:-moz-any-link` : Use `:any-link`.
- `:-moz-broken`
- `:-moz-drag-over`
- `:-moz-first-node`
- `:-moz-full-screen` : Not supported; use `:fullscreen`.
- `:-moz-full-screen-ancestor` : Not supported; use `:fullscreen`.
- `:-moz-handler-blocked`
- `:-moz-handler-crashed`
- `:-moz-handler-disabled`
- `:-moz-last-node`
- `:-moz-loading`
- `:-moz-locale-dir(ltr)`
- `:-moz-locale-dir(rtl)`
- `:-moz-native-anonymous`
- `:-moz-placeholder` : Use `:placeholder-shown`.
- `:-moz-only-whitespace`
- `:-moz-read-only` : Use `:read-only`.
- `:-moz-read-write` : Use `:read-write`.
- `:-moz-submit-invalid`: See `:invalid`.
- `:-moz-suppressed`
- `:-moz-ui-invalid` : Use `:user-invalid`.
- `:-moz-ui-valid` : Use `:user-valid`.
- `:-moz-user-disabled`
- `:-moz-window-inactive`

Pseudo-elements

- `::-moz-canvas`
- `::-moz-cell-content`
- `::-moz-color-swatch`
- `::-moz-focus-inner`
- `::-moz-focus-outer`
- `::-moz-inline-table`
- `::-moz-list-bullet`
- `::-moz-list-number`
- `::-moz-meter-bar`
- `::-moz-pagebreak`
- `::-moz-pagecontent`
- `::-moz-placeholder` : Use `::placeholder`.
- `::-moz-progress-bar`
- `::-moz-range-progress`
- `::-moz-range-thumb`
- `::-moz-range-track`
- `::-moz-scrolled-canvas`
- `::-moz-scrolled-content`
- `::-moz-selection` : Use `::selection`.
- `::-moz-svg-foreign-content`
- `::-moz-table`
- `::-moz-table-cell`
- `::-moz-table-column`
- `::-moz-table-column-group`
- `::-moz-table-outer`
- `::-moz-table-row`
- `::-moz-table-row-group`
- `::-moz-viewport`
- `::-moz-viewport-scroll`

At-rules

- `@-moz-document`

Media features

- `-moz-device-pixel-ratio`
- `-moz-platform`
- `-moz-windows-glass`

Other

- `-moz-alt-content`: See Firefox bug 11011

- Vendor Prefix glossary entry

CSS properties

A CSS ***property*** is a parameter used in a CSS declaration that lets you style certain aspects of selected elements. For example, the `opacity` property is used to set the opacity of a selected element, allowing you to control if content behind that element is visible:

```
/* Set 0.8 opacity on <img> elements */
img {
  opacity: 0.8;
}
```

Each property has a name (e.g., `opacity`), a value (e.g., `0.8`), and a defined behavior on the rendering of the document. CSS also defines shorthand properties, so you can specify multiple related properties in a single declaration. For example, the `margin` property is a shorthand for `margin-top`, `margin-right`, `margin-bottom`, and `margin-left`, setting the margin of all four sides of an element:

```
/* Give <img> elements 1rem of margin */
img {
  margin: 1rem;
}
```

Syntax

```
selector {
  property: value;
}
```

Alphabetical index of properties

Standard properties defined by CSS specifications include the following:

Misc

- Custom properties (`--*`): CSS variables

A

- `accent-color`
- `align-content`
- `align-items`
- `align-self`
- `alignment-baseline`
- `all` (shorthand)
- `anchor-name`
- `anchor-scope`
- `animation-composition`
- `animation-delay`
- `animation-direction`
- `animation-duration`
- `animation-fill-mode`
- `animation-iteration-count`
- `animation-name`
- `animation-play-state`
- `animation-range-end`
- `animation-range-start`
- `animation-range` (shorthand)
- `animation-timeline`
- `animation-timing-function`
- `animation` (shorthand)
- `appearance`
- `aspect-ratio`

B

- `backdrop-filter`
- `backface-visibility`
- `background-attachment`
- `background-blend-mode`
- `background-clip`
- `background-color`
- `background-image`
- `background-origin`
- `background-position-x`
- `background-position-y`
- `background-position`
- `background-repeat` (shorthand)

- background-repeat-x
- background-repeat-y
- background-size
- background (shorthand)
- baseline-shift
- baseline-source
- block-size

Border-*

- border-block-color
- border-block-end-color
- border-block-end-style
- border-block-end-width
- border-block-end (shorthand)
- border-block-start-color
- border-block-start-style
- border-block-start-width
- border-block-start (shorthand)
- border-block-style
- border-block-width
- border-block (shorthand)
- border-bottom-color
- border-bottom-left-radius
- border-bottom-right-radius
- border-bottom-style
- border-bottom-width
- border-bottom (shorthand)
- border-collapse
- border-color (shorthand)
- border-end-end-radius
- border-end-start-radius
- border-image-outset
- border-image-repeat
- border-image-slice
- border-image-source
- border-image-width
- border-image (shorthand)
- border-inline-color
- border-inline-end-color
- border-inline-end-style
- border-inline-end-width
- border-inline-end (shorthand)
- border-inline-start-color
- border-inline-start-style
- border-inline-start-width
- border-inline-start (shorthand)
- border-inline-style
- border-inline-width
- border-inline (shorthand)
- border-left-color
- border-left-style
- border-left-width
- border-left (shorthand)
- border-radius (shorthand)
- border-right-color
- border-right-style
- border-right-width
- border-right (shorthand)
- border-spacing
- border-start-end-radius
- border-start-start-radius
- border-style (shorthand)
- border-top-color
- border-top-left-radius
- border-top-right-radius
- border-top-style
- border-top-width
- border-top (shorthand)
- border-width (shorthand)
- border (shorthand)

B - C

- bottom
- box-align
- box-decoration-break
- box-direction
- box-flex-group
- box-flex
- box-lines
- box-ordinal-group
- box-orient
- box-pack
- box-shadow
- box-sizing

- break-after
- break-before
- break-inside
- caption-side
- caret-animation
- caret-color
- caret-shape
- caret (shorthand)
- clear
- clip-path
- clip-rule
- clip
- color-interpolation-filters
- color-interpolation
- color-scheme
- color
- column-count
- column-fill
- column-gap
- column-height
- column-rule-color
- column-rule-style
- column-rule-width
- column-rule (shorthand)
- column-span
- column-width
- column-wrap
- columns (shorthand)
- contain-intrinsic-block-size
- contain-intrinsic-height
- contain-intrinsic-inline-size
- contain-intrinsic-size (shorthand)
- contain-intrinsic-width
- contain
- container-name
- container-type
- container (shorthand)
- content-visibility
- content
- corner-block-end-shape
- corner-block-start-shape
- corner-bottom-left-shape
- corner-bottom-right-shape
- corner-bottom-shape (shorthand)
- corner-end-end-shape
- corner-end-start-shape
- corner-inline-end-shape
- corner-inline-start-shape
- corner-left-shape (shorthand)
- corner-right-shape (shorthand)
- corner-shape (shorthand)
- corner-start-end-shape
- corner-start-start-shape
- corner-top-left-shape
- corner-top-right-shape
- corner-top-shape (shorthand)
- counter-increment
- counter-reset
- counter-set
- cursor
- cx
- cy

D - F

- d
- direction
- display
- dominant-baseline
- dynamic-range-limit
- empty-cells
- field-sizing
- fill-opacity
- fill-rule
- fill
- filter
- flex-basis
- flex-direction
- flex-flow (shorthand)
- flex-grow
- flex-shrink
- flex-wrap

- mask-clip
- mask-composite
- mask-image
- mask-mode
- mask-origin
- mask-position
- mask-repeat
- mask-size
- mask-type
- mask (shorthand)
- math-depth
- math-shift
- math-style
- max-block-size
- max-height
- max-inline-size
- max-width
- min-block-size
- min-height
- min-inline-size
- min-width
- mix-blend-mode

O - P

- object-fit
- object-position
- object-view-box
- offset-anchor
- offset-distance
- offset-path
- offset-position
- offset-rotate
- offset (shorthand)
- opacity
- order
- orphans
- outline-color
- outline-offset
- outline-style
- outline-width
- outline (shorthand)
- overflow-anchor
- overflow-block
- overflow-clip-margin
- overflow-inline
- overflow-wrap
- overflow-x
- overflow-y
- overflow (shorthand)
- overlay
- overscroll-behavior-block
- overscroll-behavior-inline
- overscroll-behavior-x
- overscroll-behavior-y

- overscroll-behavior (shorthand)
- padding-block-end
- padding-block-start
- padding-block (shorthand)
- padding-bottom
- padding-inline-end
- padding-inline-start
- padding-inline (shorthand)
- padding-left
- padding-right
- padding-top
- padding (shorthand)
- page-break-after
- page-break-before
- page-break-inside
- page
- paint-order
- path-length
- perspective-origin
- perspective
- place-content (shorthand)
- place-items (shorthand)
- place-self (shorthand)
- pointer-events
- position-anchor
- position-area
- position-try-fallbacks
- position-try-order
- position-try (shorthand)
- position-visibility
- position
- print-color-adjust

Q - S

Custom properties (--*): CSS variables

Property names that are prefixed with `--`, like `--example-name`, represent *custom properties* that contain a value that can be used in other declarations using the `var()` function.

Custom properties are scoped to the element(s) they are declared on, and participate in the cascade: the value of such a custom property is that from the declaration decided by the cascading algorithm.

Initial value	see prose
Applies to	all elements
Inherited	yes
Computed value	as specified with variables substituted
Animation type	discrete

Syntax

```
--some-keyword: left;
--some-color: #123456;
--some-complex-value: 3px 6px rgb(20 32 54);
```

`<declaration-value>`

This value matches any sequence of one or more tokens, so long as the sequence does not contain any disallowed token. It represents the entirety of what a valid declaration can have as its value.

> **Note:** Custom property names are case sensitive — `--my-color` will be treated as a separate custom property to `--My-color`.

Example

Basic example

HTML

```
<p id="firstParagraph">
  This paragraph should have a blue background and yellow text.
</p>
<p id="secondParagraph">
  This paragraph should have a yellow background and blue text.
</p>
<div id="container">
  <p id="thirdParagraph">
    This paragraph should have a green background and yellow text.
  </p>
</div>
```

CSS

```
:root {
  --first-color: #1166ff;
```

```
  --second-color: #ffff77;
}

#firstParagraph {
  background-color: var(--first-color);
  color: var(--second-color);
}

#secondParagraph {
  background-color: var(--second-color);
  color: var(--first-color);
}

#container {
  --first-color: #229900;
}

#thirdParagraph {
  background-color: var(--first-color);
  color: var(--second-color);
}
```

Result

Registering custom properties with @property

In this example, we use the `@property` at-rule to register a custom property.

HTML

Our HTML includes an ordered list (`<ol>`) containing three list items (`<li>`).

```
<ol>
  <li class="one">Item one</li>
  <li class="two">Item two</li>
  <li class="three">Item three</li>
</ol>
```

CSS

We use the `@property` at-rule to register two custom properties.

```
@property --itemSize {
  syntax: "<length> | <percentage>";
  inherits: true;
  initial-value: 200px;
}

@property --borderWidth {
  syntax: "<length>";
  inherits: false;
  initial-value: 10px;
}
```

We try to override the custom property values. The values set on `.two` are valid while the values set on `.three` are invalid.

```
ol {
  --itemSize: 100px;
  --borderWidth: 1px;
}
.two {
  --itemSize: initial;
  --borderWidth: inherit;
}
.three {
  --itemSize: large;
  --borderWidth: 3%;
}
```

We use the two custom properties to style the items, setting the border and width for all the items at once:

```
li {
  width: var(--itemSize);
  border: var(--borderWidth) solid red;
  background-color: yellow;
  margin-bottom: 10px;
}
```

Results

The `--itemSize` property is inheritable; the `--borderWidth` is not. The properties are set on the `ol` parent, overriding the default values defined in their registration. Item one inherits the size but not the border width from the OL. The global keywords, declared for `.two`, are valid for `<length>`, so are used. The values in `.three` are invalid ("large" is not a `<length-percentage>` and `3%` is not a `<length>`). See

-moz-float-edge CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The non-standard **`-moz-float-edge`** CSS property specifies whether the height and width properties of the element include the margin, border, or padding thickness.

Syntax

```
/* Keyword values */
-moz-float-edge: content-box;
-moz-float-edge: margin-box;

/* Global values */
-moz-float-edge: inherit;
-moz-float-edge: initial;
-moz-float-edge: revert;
-moz-float-edge: revert-layer;
-moz-float-edge: unset;
```

Values

This property is specified as one of the following keyword values:

`content-box`

The height and width properties include the content, but not the padding, border or margin.

`margin-box`

The height and width properties include the content, padding, border and margin.

Formal definition

Initial value	`content-box`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
-moz-float-edge =
  content-box  |
  margin-box
```

Examples

HTML

```
<div class="box">
  <p>Lorem ipsum dolor sit amet, consectetur adipiscing elit.</p>
</div>
```

CSS

```
.box {
  display: block;
  height: 5px;
  margin: 0.5em auto;
  color: gray;
  -moz-float-edge: margin-box;
  box-sizing: border-box;
}
```

Result

Specifications

Not part of any standard.

See also

- Firefox bug 432891

-moz-force-broken-image-icon CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`-moz-force-broken-image-icon`** extended CSS property can be used to force the broken image icon to be shown even when a broken image has an `alt` attribute.

Syntax

```
-moz-force-broken-image-icon: 1;
-moz-force-broken-image-icon: 0;

/* Global values */
-moz-force-broken-image-icon: inherit;
-moz-force-broken-image-icon: initial;
-moz-force-broken-image-icon: revert;
-moz-force-broken-image-icon: revert-layer;
-moz-force-broken-image-icon: unset;
```

Values

This property is specified as the following value:

`<integer>`

A value of `1` means that the broken image icon is shown even if the image has an `alt` attribute. When the value `0` is used, the image will act as usual and only display the `alt` attribute.

> **Note:** Even if the value is set to `1` the `alt` attribute will still be displayed, alongside the broken image icon.

Formal definition

Initial value	`0`
Applies to	images
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
-moz-force-broken-image-icon =
  <integer>

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<img src="/broken/image/link.png" alt="Broken image link" />
```

CSS

```
img {
  -moz-force-broken-image-icon: 1;
  height: 100px;
  width: 100px;
}
```

Result

> **Note:** The alt text may not be visible if `-moz-force-broken-image-icon` is set to `1` and the image has no (or too small) `height` or `width` set.

Notes

- This property will only work in Gecko-based browsers.
- The use of this property is not recommended. A proper `alt` attribute should be used instead.

Specifications

Not part of any standard.

See also

- Firefox bug 58646

-moz-orient CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`-moz-orient`** CSS property specifies the orientation of the element to which it's applied.

Syntax

```
-moz-orient: inline;

/* Global values */
-moz-orient: inherit;
-moz-orient: initial;
-moz-orient: revert;
-moz-orient: revert-layer;
-moz-orient: unset;
```

Values

This property is specified as one of the following keyword values:

`inline`

The element is rendered in the same direction as the axis of the text: horizontally for horizontal writing modes, vertically for vertical writing modes.

`block`

The element is rendered orthogonally to the axis of the text: vertically for horizontal writing modes, horizontal for vertical writing modes.

`horizontal`

The element is rendered horizontally.

`vertical`

The element is rendered vertically.

Formal definition

Initial value	`inline`

Applies to	any element; it has an effect on `<progress>` and `<meter>`, but not on <input type="range"> or other elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
-moz-orient =
  inline     |
  block      |
  horizontal |
  vertical
```

Examples

HTML

```
<p>The following progress meter is horizontal (the default):</p>
<progress max="100" value="75"></progress>

<p>The following progress meter is vertical:</p>
<progress class="vert" max="100" value="75"></progress>
```

CSS

```
.vert {
  -moz-orient: vertical;
  width: 16px;
  height: 150px;
}
```

Result

Specifications

Not part of any standard. Though submitted to the W3C, with positive initial feedback, this property is not yet part of any specification; currently, this is a Mozilla-specific extension (that is, `-moz-orient`).

See also

- `box-orient`

-moz-user-focus CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`-moz-user-focus`** CSS property is used to indicate whether an element can have the focus.

By setting its value to `ignore`, you can disable focusing the element, which means that the user will not be able to activate the element, and the element will be skipped in the tab sequence. The default is `none`, which disables focussing on the element and removes focus on other elements if there is an attempt to select the element.

Syntax

```
/* Keyword values */
-moz-user-focus: none;
-moz-user-focus: normal;
-moz-user-focus: ignore;

/* Global values */
-moz-user-focus: inherit;
-moz-user-focus: initial;
-moz-user-focus: unset;
```

Values

This property is specified as one of the following keyword values:

`ignore`

The element does not accept keyboard focus and will be skipped in the tab order.

`normal`

The element can accept keyboard focus.

`none`

The element does not accept keyboard focus. Attempting to select the element removes focus from any other element.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
-moz-user-focus =
  ignore  |
  normal  |
  none
```

Examples

HTML

```
<input class="ignored" value="The user cannot focus on this element." />
```

CSS

```
.ignored {
  -moz-user-focus: ignore;
}
```

Specifications

Not part of any standard.

See also

- `-moz-user-input`
- `user-modify`
- `-moz-user-select`

-moz-user-input CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

In Mozilla applications, **`-moz-user-input`** determines if an element will accept user input.

As of Firefox 60, this property can no longer grant an element the ability to accept user input if it normally does not. It may only be used to disable user input.

The `user-input` property is currently not on a standards track.

Syntax

```
/* Keyword values */
-moz-user-input: auto;
-moz-user-input: none;

/* Global values */
-moz-user-input: inherit;
-moz-user-input: initial;
-moz-user-input: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

The element will respond to user input if it normally takes user input, such as a `<textarea>`.

`none`

The element does not respond to user input, and it does not become `:active`.

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
-moz-user-input =
  auto  |
  none
```

Examples

Disabling user input for an element

```
input.example {
  /* The user will be able to select the text, but not change it. */
  -moz-user-input: none;
}
```

Specifications

Not part of any standard.

See also

- `-moz-user-focus`
- `-moz-user-modify`
- `-moz-user-select`

-webkit-border-before CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they

> can be a suitable alternative in specific cases where no standard option exists.

The **`-webkit-border-before`** CSS shorthand property sets the individual logical block start border property values in a single place in the style sheet.

Constituent properties

This property is a shorthand for the following CSS properties:

- `-webkit-border-before-color`
- `-webkit-border-before-style`
- `-webkit-border-before-width`

Syntax

```
/* Border values */
-webkit-border-before: 1px;
-webkit-border-before: 2px dotted;
-webkit-border-before: medium dashed blue;

/* Global values */
-webkit-border-before: inherit;
-webkit-border-before: initial;
-webkit-border-before: revert;
-webkit-border-before: revert-layer;
-webkit-border-before: unset;
```

Values

This property is specified as a space-separated list of one to three of the following values:

`<'border-width'>`

See `border-width`

`<'border-style'>`

See `border-style`

`<'color'>`

See `color`

Description

The `-webkit-border-before` property maps to a physical border depending on the element's writing mode, directionality, and text orientation. It corresponds to the `border-top`, `border-right`, `border-bottom`, or `border-left` property depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

It relates to `-webkit-border-after`, `-webkit-border-start`, and `-webkit-border-end`, which define the other borders of the element.

The standard-track equivalent of this property is `border-block-start`.

Formal definition

Initial value	as each of the properties of the shorthand: • `border-block-start-width`: `medium` • `border-block-start-style`: `none` • `border-block-start-color`: `currentcolor`
Applies to	all elements
Inherited	no
Computed value	as each of the properties of the shorthand: • `border-block-start-width`: the absolute `<length>`, snapped as a line width • `border-block-start-style`: as specified • `border-block-start-color`: computed color
Animation type	as each of the properties of the shorthand: • `border-block-start-width`: by computed value type • `border-block-start-style`: discrete • `border-block-start-color`: by computed value type

Formal syntax

```
-webkit-border-before =
  <'border-width'>  ||
  <'border-style'>  ||
  <color>

<border-width> =
  <'border-top-width'>{1,4}

<border-style> =
  <'border-top-style'>{1,4}

<border-top-width> =
  <line-width>

<border-top-style> =
  <line-style>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

```
<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Applying a border with vertical text

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-rl;
  -webkit-border-before: 5px dashed blue;
}
```

Result

Specifications

Not part of any standard, but it relates to the standards-track `border-block-start` property.

See also

- `border-block-start`
- The mapped physical properties: `border-top`, `border-right`, `border-bottom`, and `border-left`
- `writing-mode`, `direction`, `text-orientation`

-webkit-box-reflect CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`-webkit-box-reflect`** CSS property lets you reflect the content of an element in one specific direction.

Syntax

```
/* Direction values */
-webkit-box-reflect: above;
-webkit-box-reflect: below;
-webkit-box-reflect: left;
-webkit-box-reflect: right;

/* Offset value */
-webkit-box-reflect: below 10px;

/* Mask value */
-webkit-box-reflect: below 0 linear-gradient(transparent, white);

/* Global values */
-webkit-box-reflect: inherit;
-webkit-box-reflect: initial;
-webkit-box-reflect: revert;
-webkit-box-reflect: revert-layer;
-webkit-box-reflect: unset;
```

Values

This property is specified as a space-separated list of the following values:

`above`, `below`, `right`, `left`

Are keywords indicating in which direction the reflection is to happen.

`<length>`

Indicates the size of the reflection.

`<image>`

Describes the mask to be applied to the reflection.

Formal definition

Initial value	none
Applies to	all elements

Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
-webkit-box-reflect =
  [ above | below | right | left ]? <length>? <image>?

<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
  <gradient>

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-set()> =
  image-set( <image-set-option># )

<cross-fade()> =
  cross-fade( <cf-image># )

<element()> =
  element( <id-selector> )

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Images Module Level 4, CSS Images Module Level 5, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Specifications

Not part of any standard. The standard way to do reflection in CSS is to use the CSS `element()` function.

See also

- The Apple documentation.
- The WebKit specification.

-webkit-mask-box-image CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The non-standard prefixed **`-webkit-mask-box-image`** CSS shorthand property sets the mask image for an element's border box.

> **Note:** This property is not standard and is not on any standards track. Consider using the `mask-border` property instead.

Constituent properties

This property is a shorthand for the following CSS properties:

- `-webkit-mask-border-source`
- `-webkit-mask-border-outset`
- `-webkit-mask-border-repeat`

The values includes the `<image>` to be used as the mask border, and optionally four border outset values and up to two border repeat styles.

Syntax

```
/* default */
-webkit-mask-box-image: none;

/* image */
-webkit-mask-box-image: url("image.png");

/* image edge-offset */
-webkit-mask-box-image: url("image.png") 10 20 20 10;
-webkit-mask-box-image: url("image.png") 10px 20px 20px 10px;

/* image repeat-style */
-webkit-mask-box-image: url("image.png") space repeat;

/* image edge-offset repeat-style */
-webkit-mask-box-image: url("image.png") 10px 20px 20px 10px space repeat;

/* Global values */
-webkit-mask-box-image: inherit;
```

```
-webkit-mask-box-image: initial;
-webkit-mask-box-image: revert;
-webkit-mask-box-image: revert-layer;
-webkit-mask-box-image: unset;
```

Values

`<image>`

The location of the image resource to be used as a mask image, `<gradient>`, or other `<image>` value.

`none`

Used to specify that a border box is to have no mask image.

`<length>`

The size of the mask image's offset. See `<length>` for possible units.

`<percentage>`

The mask image's offset has a percentage value relative to the border box's corresponding dimension (width or height).

`<number>`

The size of the mask image's offset in pixels.

`repeat`

The mask image is repeated as many times as is necessary to span the border box. May include a partial image if the mask image does not divide evenly into the border box.

`stretch`

The mask image is stretched to contain the border box exactly.

`round`

The mask image is stretched somewhat and repeated such that there is no partial mask image at the end of the border box.

`space`

The mask image is repeated as many times as possible without stretching. There is no partial mask image at the end of the border box.

The outset values, or edge offsets, define the distances from the top, right, bottom, and left edges of the image, in that order. The values can be set as `<length>`, `<number>`, or `<percentage>`, with numbers interpreted as pixel lengths.

Border repeat styles, when included, are interpreted in the order of `<repeat-x> <repeat-y>`. If only one value is declared, the value is the same for both axes. While similar to `background-repeat`, the `cover` and `contain` values are not supported.

Formal definition

- Initial value: `none`
- Applies to: all elements
- Inherited: no
- Computed value: as specified

Formal syntax

```
-webkit-mask-box-image =
  <mask-image-source> [ <mask-image-offset>{4} <mask-border-repeat>{1,2} ]
```

Examples

Setting an image

```
.example-one {
  -webkit-mask-box-image: url("mask.png");
}
```

Offsetting and filling an image

```
.example-two {
  -webkit-mask-box-image: url("logo.png") 100px 100px 0px 0px round round;
}
```

Specifications

Not part of any standard.

- Safari CSS reference: `-webkit-mask-box-image`

-webkit-mask-composite CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`-webkit-mask-composite`** property specifies the manner in which multiple mask images applied to the same element are composited with one another. Mask images are composited in the opposite order that they are declared with the `-webkit-mask-image` property.

> **Note:** There is a standardized `mask-composite` property covering parts of this non-standard property using different keywords.

Syntax

```
/* Keyword values */
-webkit-mask-composite: clear;
-webkit-mask-composite: copy;
-webkit-mask-composite: source-over;
-webkit-mask-composite: source-in;
-webkit-mask-composite: source-out;
-webkit-mask-composite: source-atop;
-webkit-mask-composite: destination-over;
-webkit-mask-composite: destination-in;
-webkit-mask-composite: destination-out;
-webkit-mask-composite: destination-atop;
-webkit-mask-composite: xor;

/* Global values */
-webkit-mask-composite: inherit;
-webkit-mask-composite: initial;
-webkit-mask-composite: revert;
-webkit-mask-composite: revert-layer;
-webkit-mask-composite: unset;
```

Values

This property is specified as one of the following keyword values:

`clear`

Overlapping pixels in the source mask image and the destination mask image are cleared.

`copy`

The source mask image replaces the destination mask image.

`source-over`

The source mask image is rendered over the destination mask image.

`source-in`

Overlapping pixels in the source mask image and the destination mask image are replaced by the pixels of the source mask image; all other pixels are cleared.

`source-out`

Overlapping pixels in the source mask image and the destination mask image are cleared; all remaining pixels of the source mask image are rendered.

`source-atop`

The pixels of the destination mask image are rendered. The pixels of the source mask image are rendered only if they overlap a nontransparent portion of the destination mask image. This causes the source mask image to have no effect.

`destination-over`

The destination mask image is rendered over the source mask image.

`destination-in`

Overlapping pixels in the source mask image and the destination mask image remain the pixels of the destination mask image; all other pixels are cleared.

`destination-out`

Overlapping pixels in the source mask image and the destination mask image are cleared; all remaining pixels of the source mask image are rendered.

`destination-atop`

The pixels of the source mask image are rendered. The pixels of the destination mask image are rendered only if they overlap a nontransparent portion of the destination mask image. This causes the destination mask image to have no effect.

`xor`

Overlapping pixels in the source mask image and the destination mask image become fully transparent if they are both fully opaque.

Formal definition

Initial value	`source-over`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
-webkit-mask-composite =
  <composite-style>#
```

Examples

Compositing with XOR

```
.example {
  -webkit-mask-image: url("mask1.png"), url("mask2.png");
  -webkit-mask-composite: xor, source-over;
}
```

Specifications

Not part of any standard. This property is specified as `mask-composite` using different values.

-webkit-mask-position-x CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The `-webkit-mask-position-x` CSS property sets the initial horizontal position of a mask image.

Syntax

```
/* Keyword values */
-webkit-mask-position-x: left;
-webkit-mask-position-x: center;
-webkit-mask-position-x: right;

/* <percentage> values */
-webkit-mask-position-x: 100%;
-webkit-mask-position-x: -50%;

/* <length> values */
-webkit-mask-position-x: 50px;
-webkit-mask-position-x: -1cm;

/* Multiple values */
-webkit-mask-position-x:
  50px,
  25%,
  -3em;

/* Global values */
-webkit-mask-position-x: inherit;
-webkit-mask-position-x: initial;
-webkit-mask-position-x: revert;
-webkit-mask-position-x: revert-layer;
-webkit-mask-position-x: unset;
```

Values

This property is specified as one or more comma-separated values:

`<length-percentage>`

A length indicating the position of the left edge of the image relative to the box's left padding edge. Percentages are calculated against the horizontal dimension of the box padding area. That means, a value of `0%` means the left edge of the image is aligned with the box's left padding edge and a value of `100%` means the right edge of the image is aligned with the box's right padding edge.

`left`

Equivalent to `0%`.

`center`

Equivalent to `50%`.

`right`

Equivalent to `100%`.

Formal definition

Initial value	`0%`
Applies to	all elements
Inherited	no
Percentages	refer to the size of the box itself
Computed value	for `<length>` the absolute value, otherwise a percentage
Animation type	discrete

Formal syntax

```
-webkit-mask-position-x =
  [ <length-percentage> | left | center | right ]#

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Horizontally positioning a mask image

```
.exampleOne {
  -webkit-mask-image: url("mask.png");
  -webkit-mask-position-x: right;
}

.exampleTwo {
  -webkit-mask-image: url("mask.png");
  -webkit-mask-position-x: 25%;
}
```

Specifications

Not part of any standard.

-webkit-mask-position-y CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The `-webkit-mask-position-y` CSS property sets the initial vertical position of a mask image.

Syntax

```
/* Keyword values */
-webkit-mask-position-y: top;
-webkit-mask-position-y: center;
-webkit-mask-position-y: bottom;

/* <percentage> values */
-webkit-mask-position-y: 100%;
-webkit-mask-position-y: -50%;

/* <length> values */
-webkit-mask-position-y: 50px;
-webkit-mask-position-y: -1cm;

/* Multiple values */
-webkit-mask-position-y:
  50px,
  25%,
  -3em;

/* Global values */
-webkit-mask-position-y: inherit;
-webkit-mask-position-y: initial;
-webkit-mask-position-y: revert;
-webkit-mask-position-y: revert-layer;
-webkit-mask-position-y: unset;
```

Values

This property is specified as one or more comma-separated values:

`<length-percentage>`

A length indicating the position of the top side of the image relative to the box's top padding edge. Percentages are calculated against the vertical dimension of the box padding area. A value of `0%` means the top edge of the image is aligned with the box's top padding edge and a value of `100%` means the bottom edge of the image is aligned with the box's bottom padding edge.

`top`

Equivalent to `0%`.

`bottom`

Equivalent to `100%`.

`center`

Equivalent to `50%`.

Formal definition

Initial value	`0%`
Applies to	all elements
Inherited	no
Percentages	refer to the size of the box itself
Computed value	for `<length>` the absolute value, otherwise a percentage
Animation type	discrete

Formal syntax

```
-webkit-mask-position-y =
  [ <length-percentage> | top | center | bottom ]#

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Vertically positioning a mask image

```
.exampleOne {
  -webkit-mask-image: url("mask.png");
  -webkit-mask-position-y: bottom;
}

.exampleTwo {
```

```
  -webkit-mask-image: url("mask.png");
  -webkit-mask-position-y: 25%;
}
```

Specifications

Not part of any standard.

See also

- `-webkit-mask-position`

-webkit-mask-repeat-x CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The `-webkit-mask-repeat-x` property specifies whether and how a mask image is repeated (tiled) horizontally.

Syntax

```
/* Keyword values */
-webkit-mask-repeat-x: repeat;
-webkit-mask-repeat-x: no-repeat;
-webkit-mask-repeat-x: space;
-webkit-mask-repeat-x: round;

/* Multiple values */
-webkit-mask-repeat-x: repeat, no-repeat, space;

/* Global values */
-webkit-mask-repeat-x: inherit;
-webkit-mask-repeat-x: initial;
-webkit-mask-repeat-x: revert;
-webkit-mask-repeat-x: revert-layer;
-webkit-mask-repeat-x: unset;
```

Values

This property is specified as one or more comma-separated values:

`repeat`

The mask image is repeated both horizontally and vertically.

`no-repeat`

The mask image is not repeated horizontally; only one copy of the mask image is drawn in that direction. The remainder of the masked element's content is not displayed.

`space`

The image is repeated as much as possible without clipping. The first and last images are pinned to either side of the element, and whitespace is distributed evenly between the images. The `mask-position` property is ignored unless only one image can be displayed without clipping. The only case where clipping happens using space is when there isn't enough room to display one image.

`round`

As the allowed space increases in size, the repeated images will stretch (leaving no gaps) until there is room for another one to be added. When the next image is added, all of the current ones compress to allow room. Example: An image with an original width of 260px, repeated three times, might stretch until each repetition is 300px wide, and then another image will be added. They will then compress to 225px.

Formal definition

Initial value	`repeat`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
-webkit-mask-repeat-x =
  [ repeat | no-repeat | space | round ]#
```

Examples

Using a repeating or non-repeating mask image

```
.example-one {
  -webkit-mask-image: url("mask.png");
  -webkit-mask-repeat-x: repeat;
}

.example-two {
  -webkit-mask-image: url("mask.png");
  -webkit-mask-repeat-x: no-repeat;
}
```

Using multiple mask images

You can specify a different `<repeat-style>` for each mask image, separated by commas:

```
.example-three {
  -webkit-mask-image: url("mask1.png"), url("mask2.png");
```

```
  -webkit-mask-repeat-x: repeat, space;
}
```

Each image is matched with the corresponding repeat style, from first specified to last.

Specifications

Not part of any standard.

-webkit-mask-repeat-y CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The `-webkit-mask-repeat-y` property sets whether and how a mask image is repeated (tiled) vertically.

Syntax

```
/* Keyword values */
-webkit-mask-repeat-y: repeat;
-webkit-mask-repeat-y: no-repeat;
-webkit-mask-repeat-y: space;
-webkit-mask-repeat-y: round;

/* Multiple values */
-webkit-mask-repeat-y: repeat, no-repeat, space;

/* Global values */
-webkit-mask-repeat-y: inherit;
-webkit-mask-repeat-y: initial;
-webkit-mask-repeat-y: revert;
-webkit-mask-repeat-y: revert-layer;
-webkit-mask-repeat-y: unset;
```

Values

This property is specified as one or more comma-separated values:

`repeat`

The mask image is repeated vertically.

`no-repeat`

The mask image is not repeated vertically; only one copy of the mask image is drawn in that direction. The vertical remainder of the masked element's content is not displayed.

`space`

The image is repeated as much as possible without clipping. The first and last images are pinned to the top and bottom edge of the element, and whitespace is distributed evenly between the images. The `mask-position` property is ignored unless only one image can be displayed without clipping. The only case where clipping happens using space is when there isn't enough room to display one image.

`round`

As the allowed vertical space increases in size, the repeated images will stretch (leaving no gaps) until there is room for another one to be added. When the next image is added, all of the current ones compress to allow room. Example: An image with an original height of 260px, repeated three times, might stretch until each repetition is 300px high, and then another image will be added. They will then compress to a height of 225px.

Formal definition

Initial value	`repeat`
Applies to	all elements
Inherited	no
Computed value	for `<length>` the absolute value, otherwise a percentage
Animation type	discrete

Formal syntax

```
-webkit-mask-repeat-y =
  [ repeat | no-repeat | space | round ]#
```

Examples

Using a repeating or non-repeating mask image

```
.example-one {
  -webkit-mask-image: url("mask.png");
  -webkit-mask-repeat-y: repeat;
}

.example-two {
  -webkit-mask-image: url("mask.png");
  -webkit-mask-repeat-y: no-repeat;
}
```

Using multiple mask images

You can specify a different `<repeat-style>` for each mask image, separated by commas:

```
.example-three {
  -webkit-mask-image: url("mask1.png"), url("mask2.png");
```

```
  -webkit-mask-repeat-y: repeat, space;
}
```

Each image is matched with the corresponding repeat style, from first specified to last.

Specifications

Not part of any standard.

-webkit-tap-highlight-color CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

`-webkit-tap-highlight-color` is a non-standard CSS property that sets the color of the highlight that appears over a link while it's being tapped. The highlighting indicates to the user that their tap is being successfully recognized, and indicates which element they're tapping on.

Syntax

```
-webkit-tap-highlight-color: red;
-webkit-tap-highlight-color: transparent; /* for removing the highlight */

/* Global values */
-webkit-tap-highlight-color: inherit;
-webkit-tap-highlight-color: initial;
-webkit-tap-highlight-color: revert;
-webkit-tap-highlight-color: revert-layer;
-webkit-tap-highlight-color: unset;
```

Values

This property is specified as the following value:

`<color>`

Defines the color of the highlight.

Formal definition

Initial value	`black`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
-webkit-tap-highlight-color =
  <color>
```

Specifications

Not part of any standard. Apple has a description in the Safari Web Content Guide.

  - `:hover`
  - `:active`
  - `:visited`

-webkit-text-fill-color CSS property

The **`-webkit-text-fill-color`** CSS property specifies the fill color of characters of text. If this property is not set, the value of the `color` property is used.

Syntax

```
/* <color> values */
-webkit-text-fill-color: red;
-webkit-text-fill-color: #123456;
-webkit-text-fill-color: rgb(100 200 0);

/* Global values */
-webkit-text-fill-color: inherit;
-webkit-text-fill-color: initial;
-webkit-text-fill-color: revert;
-webkit-text-fill-color: revert-layer;
-webkit-text-fill-color: unset;
```

Values

This property is specified as one `<color>` value:

`<color>`

The foreground fill color of the element's text content.

Formal definition

Initial value	`currentcolor`
Applies to	all elements
Inherited	yes
Computed value	computed color
Animation type	a color

Formal syntax

```
-webkit-text-fill-color =
  <color>
```

This syntax reflects the latest standard as per Compatibility. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Changing the fill color

CSS

```
p {
  margin: 0;
  font-size: 3em;
  -webkit-text-fill-color: green;
}
```

HTML

```
<p>This text is green.</p>
```

-webkit-text-security CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

`-webkit-text-security` is a non-standard CSS property that obfuscates characters in a `<form>` field (such as `<input>` or `<textarea>`) by replacing them with a shape. It only affects fields that are *not* of `type=password`.

Syntax

```
-webkit-text-security: circle;
-webkit-text-security: disc;
-webkit-text-security: square;
-webkit-text-security: none;

/* Global values */
-webkit-text-security: inherit;
-webkit-text-security: initial;
-webkit-text-security: revert;
-webkit-text-security: revert-layer;
-webkit-text-security: unset;
```

Formal syntax

```
-webkit-text-security =
  circle  |
  disc    |
  square  |
  none
```

Examples

Obscuring a text input

Try typing in the field below. If your browser supports this property, the characters should be visually replaced with squares.

HTML

```
<label for="name">Name:</label> <input type="text" name="name" id="name" />
```

CSS

```
input {
  -webkit-text-security: square;
}
```

Result

Specifications

Not part of any standard.

-webkit-text-stroke CSS property

The **`-webkit-text-stroke`** CSS shorthand property specifies the width and color of strokes for text characters.

Constituent properties

This property is a shorthand for the following CSS properties:

- `-webkit-text-stroke-color`
- `-webkit-text-stroke-width`

Syntax

```
/* Width and color values */
-webkit-text-stroke: 4px navy;

/* Global values */
-webkit-text-stroke: inherit;
-webkit-text-stroke: initial;
-webkit-text-stroke: revert;
-webkit-text-stroke: revert-layer;
-webkit-text-stroke: unset;
```

Values

This property is specified as two space-separated values:

`<length>`

The width of the stroke.

`<color>`

The color of the stroke.

Formal definition

Initial value	as each of the properties of the shorthand: • `-webkit-text-stroke-width`: `0` • `-webkit-text-stroke-color`: `currentcolor`
Applies to	all elements
Inherited	yes
Computed value	as each of the properties of the shorthand: • `-webkit-text-stroke-width`: absolute `<length>` • `-webkit-text-stroke-color`: computed color
Animation type	as each of the properties of the shorthand: • `-webkit-text-stroke-width`: discrete • `-webkit-text-stroke-color`: a color

Formal syntax

```
-webkit-text-stroke =
  <line-width>  ||
  <color>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, Compatibility. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Adding a red text stroke

HTML

```
<p id="example">The stroke of this text is red.</p>
```

CSS

```
#example {
  font-size: 3em;
  margin: 0;
  -webkit-text-stroke: 2px red;
}
```

Result

- `-webkit-text-stroke-color`
- `-webkit-text-fill-color`

-webkit-text-stroke-color CSS property

The **`-webkit-text-stroke-color`** CSS property specifies the stroke color of characters of text. If this property is not set, the value of the `color` property is used.

Syntax

```
/* <color> values */
-webkit-text-stroke-color: red;
-webkit-text-stroke-color: #e08ab4;
-webkit-text-stroke-color: rgb(200 100 0);

/* Global values */
-webkit-text-stroke-color: inherit;
-webkit-text-stroke-color: initial;
-webkit-text-stroke-color: revert;
-webkit-text-stroke-color: revert-layer;
-webkit-text-stroke-color: unset;
```

Values

This property is specified as one `<color>` value:

`<color>`

The color of the stroke.

Formal definition

Initial value	`currentcolor`
Applies to	all elements
Inherited	yes
Computed value	computed color
Animation type	a color

Formal syntax

```
-webkit-text-stroke-color =
  <color>
```

This syntax reflects the latest standard as per Compatibility. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Varying the stroke color

HTML

```
<p>Text with stroke</p>
<input type="color" value="#ff0000" />
```

CSS

```
p {
  margin: 0;
  font-size: 4em;
  -webkit-text-stroke-width: 3px;
  -webkit-text-stroke-color: red; /* Can be changed in the live sample */
}
```

```
const colorPicker = document.querySelector("input");
colorPicker.addEventListener("change", (evt) => {
  document.querySelector("p").style.webkitTextStrokeColor = evt.target.value;
});
```

Results

- `-webkit-text-stroke-width`
- `-webkit-text-stroke`

-webkit-text-stroke-width CSS property

The **`-webkit-text-stroke-width`** CSS property specifies the width of the stroke for text.

Syntax

```
/* Keyword values */
-webkit-text-stroke-width: thin;
-webkit-text-stroke-width: medium;
-webkit-text-stroke-width: thick;

/* <length> values */
-webkit-text-stroke-width: 2px;
-webkit-text-stroke-width: 0.1em;
-webkit-text-stroke-width: 1mm;
-webkit-text-stroke-width: 5pt;

/* Global values */
-webkit-text-stroke-width: inherit;
```

```
-webkit-text-stroke-width: initial;
-webkit-text-stroke-width: revert;
-webkit-text-stroke-width: revert-layer;
-webkit-text-stroke-width: unset;
```

Values

This property is specified as the following value:

`<line-width>`

The width of the stroke.

Formal definition

Initial value	`0`
Applies to	all elements
Inherited	yes
Computed value	absolute `<length>`
Animation type	discrete

Formal syntax

```
-webkit-text-stroke-width =
  <line-width>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, Compatibility. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Varying stroke widths

CSS

```
p {
  margin: 0;
  font-size: 4em;
  -webkit-text-stroke-color: red;
}

#thin {
  -webkit-text-stroke-width: thin;
}

#medium {
  -webkit-text-stroke-width: 3px;
}

#thick {
  -webkit-text-stroke-width: 1.5mm;
}
```

HTML

```
<p id="thin">Thin stroke</p>
<p id="medium">Medium stroke</p>
<p id="thick">Thick stroke</p>
```

-webkit-touch-callout CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The `-webkit-touch-callout` CSS property controls the display of the default callout shown when you touch and hold a touch target.

When a target is touched and held on iOS, Safari displays a callout information about the link. This property allows disabling that behavior.

Syntax

```
/* Keyword values */
-webkit-touch-callout: default;
-webkit-touch-callout: none;

/* Global values */
-webkit-touch-callout: initial;
-webkit-touch-callout: inherit;
-webkit-touch-callout: revert;
```

```
-webkit-touch-callout: revert-layer;
-webkit-touch-callout: unset;
```

Values

This property is specified as one of the following keyword values:

`default`

The default callout is displayed.

`none`

The callout is disabled.

Formal definition

Initial value	`default`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
-webkit-touch-callout =
  default  |
  none
```

Examples

Turn off touch callout

```
.example {
  -webkit-touch-callout: none;
}
```

Specifications

Not part of any standard. Apple has a description in the Safari CSS Reference.

See also

- WebKit CSS extensions
- -webkit-touch-callout in the Apple developer documentation

accent-color CSS property

The **`accent-color`** CSS property sets the accent color for user-interface controls generated by some elements.

Try it

```
accent-color: red;
```

```
accent-color: #74992e;
```

```
accent-color: rgb(255 255 128);
```

```
accent-color: hsl(250 100% 34%);
```

```
<section class="default-example container" id="default-example">
  <div>
    <input checked id="example-element" type="checkbox" />
    <label for="example-element" id="example-label">Example Label</label>
  </div>
</section>
```

```
.container > div {
  display: flex;
  align-items: center;
}

#example-element {
  width: 40px;
  height: 40px;
}

#example-label {
  margin-left: 10px;
  font-size: x-large;
}
```

Syntax

```
/* Keyword value */
accent-color: auto;

/* <color> values */
accent-color: darkred;
accent-color: #5729e9;
accent-color: rgb(0 200 0);
accent-color: hsl(228 4% 24%);

/* Global values */
accent-color: inherit;
accent-color: initial;
```

```
accent-color: revert;
accent-color: revert-layer;
accent-color: unset;
```

Values

This property is specified as the keyword `auto` or one `<color>` value:

`auto`

Represents a UA-chosen color, which should match the accent color of the platform, if any.

`<color>`

Specifies the color to be used as the accent color.

Description

Browsers that support `accent-color` currently apply it to the following HTML elements:

- `<input type="checkbox">`
- `<input type="radio">`
- `<input type="range">`
- `<progress>`

Each user agent has an accent color, with variations to ensure legibility and contrast. That accent color is not used by every user-interface control nor in every state of the control. The `accent-color` is only applied to user-interface controls that use an accent color in the states where it is applicable.

> **Note:** To reduce the risk of fingerprinting, some browsers return a fixed value for `accent-color: auto` unless it is used in certain restricted circumstances. See browser compatibility for details.

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	yes
Computed value	`auto` is computed as specified and `<color>` values are computed as defined for the `color` property.
Animation type	by computed value type

Formal syntax

```
accent-color =
  auto     |
  <color>
```

This syntax reflects the latest standard as per CSS Basic User Interface Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting a custom accent color

HTML

```
<input type="checkbox" checked />
<input type="checkbox" class="custom" checked />
```

CSS

```
input {
  accent-color: auto;
  display: block;
  width: 30px;
  height: 30px;
}

input.custom {
  accent-color: rebeccapurple;
}
```

- `<input>`: Related HTML element

align-content CSS property

The CSS **`align-content`** property sets the distribution of space between and around content items along a flexbox's cross axis, or a grid or block-level element's block axis.

This property has no effect on single line flex containers (i.e., ones with `flex-wrap: nowrap`).

The interactive example below uses grid layout to demonstrate some of the values of this property.

Try it

```
align-content: start;
```

```
align-content: center;
```

```
align-content: space-between;
```

```
align-content: space-around;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">
      <div>One</div>
      <div>Two</div>
      <div>Three</div>
    </div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-template-columns: 60px 60px;
  grid-auto-rows: 40px;
  column-gap: 10px;
  height: 180px;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}
```

Syntax

```
/* Normal alignment */
align-content: normal;

/* Basic positional alignment */
/* align-content does not take left and right values */
align-content: start;
align-content: center;
align-content: end;
align-content: flex-start;
align-content: flex-end;

/* Baseline alignment */
align-content: baseline;
align-content: first baseline;
align-content: last baseline;

/* Distributed alignment */
align-content: space-between;
align-content: space-around;
align-content: space-evenly;
align-content: stretch;

/* Overflow alignment */
align-content: safe center;
align-content: unsafe center;

/* Global values */
align-content: inherit;
align-content: initial;
align-content: revert;
align-content: revert-layer;
align-content: unset;
```

Values

This property is specified as one or two of the following keyword values:

`normal`

> The items are packed in their default position as if no `align-content` value was set.

`start`

> The items are packed flush to each other against the start edge of the alignment container in the cross axis.

`center`

> The items are packed flush to each other in the center of the alignment container along the cross axis.

`end`

> The items are packed flush to each other against the end edge of the alignment container in the cross axis.

`flex-start`

> The items are packed flush to each other against the edge of the alignment container depending on the flex container's cross-start side. This only applies to flex layout items. For items that are not children of a flex container, this value is treated like `start`.

`flex-end`

> The items are packed flush to each other against the edge of the alignment container depending on the flex container's cross-end side. This only applies to flex layout items. For items that are not children of a flex container, this value is treated like `end`.

`baseline`, `first baseline`, `last baseline`

> Specifies participation in first- or last-baseline alignment: aligns the alignment baseline of the box's first or last baseline set with the corresponding baseline in the shared first or last baseline set of all the boxes in its baseline-sharing group.

The fallback alignment for `first baseline` is `start`, the one for `last baseline` is `end`.

`space-between`

The items are evenly distributed within the alignment container along the cross axis. The spacing between each pair of adjacent items is the same. The first item is flush with the start edge of the alignment container in the cross axis, and the last item is flush with the end edge of the alignment container in the cross axis.

`space-around`

The items are evenly distributed within the alignment container along the cross axis. The spacing between each pair of adjacent items is the same. The empty space before the first and after the last item equals half of the space between each pair of adjacent items.

`space-evenly`

The items are evenly distributed within the alignment container along the cross axis. The spacing between each pair of adjacent items, the start edge and the first item, and the end edge and the last item, are all exactly the same.

`stretch`

If the combined size of the items along the cross axis is less than the size of the alignment container, any `auto`-sized items have their size increased equally (not proportionally), while still respecting the constraints imposed by `max-height`/`max-width` (or equivalent functionality), so that the combined size exactly fills the alignment container along the cross axis.

`safe`

Used alongside an alignment keyword. If the chosen keyword means that the item overflows the alignment container causing data loss, the item is instead aligned as if the alignment mode were `start`.

`unsafe`

Used alongside an alignment keyword. Regardless of the relative sizes of the item and alignment container and whether overflow which causes data loss might happen, the given alignment value is honored.

> **Note:** The `<content-distribution>` values (`space-between`, `space-around`, `space-evenly`, and `stretch`) have no effect in block layout as all the content in that block is treated as a single alignment-subject.

Formal definition

Initial value	`normal`
Applies to	Block-containers, multi-column containers, flex containers
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
align-content =
  normal                                |
  <baseline-position>                   |
  <content-distribution>                |
  <overflow-position>? <content-position>

<baseline-position> =
  [ first | last ]?  &&
  baseline

<content-distribution> =
  space-between  |
  space-around   |
  space-evenly   |
  stretch

<overflow-position> =
  unsafe  |
  safe

<content-position> =
  center      |
  start       |
  end         |
  flex-start  |
  flex-end
```

This syntax reflects the latest standard as per CSS Box Alignment Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Effects of different align-content values

In this example, you can switch between three different `display` property values, including `flex`, `grid`, and `block`. You can also switch between the different values for `align-content`.

HTML

```
<section>
  <div class="olive">Olive</div>
  <div class="coral">Coral</div>
  <div class="deepskyblue">Deep<br />sky<br />blue</div>
  <div class="orchid">Orchid</div>
  <div class="slateblue">Slateblue</div>
  <div class="maroon">Maroon</div>
</section>
```

```
<fieldset class="controls">
  <legend>Controls</legend>
  <div class="row">
    <label for="display">display: </label>
    <select id="display">
      <option value="block" selected>block</option>
      <option value="flex">flex</option>
      <option value="grid">grid</option>
    </select>
  </div>
  <div class="row">
    <label for="alignContent">align-content: </label>
    <select id="alignContent">
      <option value="normal" selected>normal</option>
      <option value="start">start</option>
      <option value="center">center</option>
      <option value="end">end</option>
      <option value="flex-start">flex-start</option>
      <option value="flex-end">flex-end</option>
      <option value="space-between">space-between</option>
      <option value="space-around">space-around</option>
      <option value="space-evenly">space-evenly</option>
    </select>
  </div>
  <p>CSS applied</p>
  <pre>
section {
  display: <span id="displayStyle">block</span>;
  align-content: <span id="align">normal</span>
}
  </pre>
</fieldset>
```

CSS

```
body {
  font-size: 1.25rem;
  display: flex;
  gap: 1rem;
}
section div {
  font-family: monospace;
  padding: 3px;
}
```

```
section {
  border: solid 1.5px tomato;
  height: 300px;
  width: 300px;
  flex-wrap: wrap; /* used by flex only */
  gap: 0.2rem; /* not used by block */
}
.olive {
  background-color: olive;
}
.coral {
  background-color: coral;
}
.deepskyblue {
  background-color: deepskyblue;
}
.orchid {
  background-color: orchid;
}
.slateblue {
  background-color: slateblue;
  color: white;
}
.maroon {
  background-color: maroon;
  color: white;
}
```

```
const alignContent = document.querySelector("#alignContent");
const display = document.querySelector("#display");
const container = document.querySelector("section");
const displayStyle = document.querySelector("#displayStyle");
const alignStyle = document.querySelector("#align");

alignContent.addEventListener("change", () => {
  updatePage();
});
display.addEventListener("change", () => {
  updatePage();
});
function updatePage() {
  const alVal = alignContent.value;
  const dVal = display.value;
  container.style.alignContent = alVal;
  container.style.display = dVal;
  alignStyle.innerText = alVal;
  displayStyle.innerText = dVal;
}
updatePage();
```

Result

Try changing the `display` value and the `align-content` value.

In block layout, child elements are treated as a single element, meaning `space-between`, `space-around`, and `space-evenly` behave differently.

- Block-level content
- `display`

align-items CSS property

The CSS **`align-items`** property sets the `align-self` value on all direct children as a group. In flexbox, it controls the alignment of items on the cross axis. In grid layout, it controls the alignment of items on the block axis within their grid areas.

The interactive example below uses grid layout to demonstrate some of the values of this property.

Try it

```
align-items: stretch;
```

```
align-items: center;
```

```
align-items: start;
```

```
align-items: end;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">
      <div>One</div>
      <div>Two</div>
      <div>Three</div>
    </div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  display: grid;
  width: 200px;
  grid-template-columns: 1fr 1fr;
  grid-auto-rows: 80px;
  grid-gap: 10px;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}
```

Syntax

```
/* Basic keywords */
align-items: normal;
align-items: stretch;

/* Positional alignment */
/* align-items does not take left and right values */
align-items: center;
align-items: start;
align-items: end;
align-items: flex-start;
align-items: flex-end;
align-items: self-start;
align-items: self-end;
align-items: anchor-center;

/* Baseline alignment */
align-items: baseline;
align-items: first baseline;
align-items: last baseline;

/* Overflow alignment (for positional alignment only) */
align-items: safe center;
align-items: unsafe center;

/* Global values */
align-items: inherit;
align-items: initial;
align-items: revert;
align-items: revert-layer;
align-items: unset;
```

Values

This property is specified as one or two of the following keyword values:

`normal`

The effect of this keyword is dependent of the layout mode we are in:

- In absolutely-positioned layouts, the keyword behaves like `start` on *replaced* absolutely-positioned boxes, and as `stretch` on *all other* absolutely-positioned boxes.
- In static position of absolutely-positioned layouts, the keyword behaves as `stretch`.
- For flex items, the keyword behaves as `stretch`.
- For grid items, this keyword leads to a behavior similar to the one of `stretch`, except for boxes with an aspect ratio or an intrinsic size where it behaves like `start`.
- The property doesn't apply to block-level boxes, and to table cells.

`center`

The flex items' margin boxes are centered within the line on the cross-axis. If the cross-size of an item is larger than the flex container, it will overflow equally in both directions.

`start`

The items are packed flush to each other toward the start edge of the alignment container in the appropriate axis.

`end`

The items are packed flush to each other toward the end edge of the alignment container in the appropriate axis.

`self-start`

The items are packed flush to the edge of the alignment container's start side of the item, in the appropriate axis.

`self-end`

The items are packed flush to the edge of the alignment container's end side of the item, in the appropriate axis.

`baseline`, `first baseline`, `last baseline`

All flex items are aligned such that their flex container baselines align. The item with the largest distance between its cross-start margin edge and its baseline is flushed with the cross-start edge of the line.

`stretch`

If the item's cross-size is `auto`, the used size is set to the length necessary to be as close to filling the container as possible, respecting the item's width and height limits. If the item is not auto-sized, this value falls back to `flex-start`, and to `self-start` or `self-end` if the container's `align-content` is `first baseline` (or `baseline`) or `last baseline`.

`anchor-center`

In the case of anchor-positioned elements, aligns the items to the center of the associated anchor element in the block direction. See Centering on the anchor using `anchor-center`.

`safe`

Used alongside an alignment keyword. If the chosen keyword means that the item overflows the alignment container causing data loss, the item is instead aligned as if the alignment mode were `start`.

`unsafe`

Used alongside an alignment keyword. Regardless of the relative sizes of the item and alignment container and whether overflow which causes data loss might happen, the given alignment value is honored.

There are also two values that were defined for flexbox, as they are base on flex model axes concepts, that work in grid layouts as well:

`flex-start`

Used in flex layout only, aligns the flex items flush against the flex container's main-start or cross-start side. When used outside of a flex formatting context, this value behaves as `start`.

`flex-end`

Used in flex layout only, aligns the flex items flush against the flex container's main-end or cross-end side. When used outside of a flex formatting context, this value behaves as `end`.

Formal definition

Initial value	`normal`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
align-items =
  normal                                |
  stretch                               |
  <baseline-position>                   |
  <overflow-position>? <self-position>

<baseline-position> =
  [ first | last ]?  &&
  baseline

<overflow-position> =
  unsafe  |
  safe

<self-position> =
  center      |
  start       |
  end         |
  self-start  |
  self-end    |
  flex-start  |
  flex-end
```

This syntax reflects the latest standard as per CSS Box Alignment Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

In this example we have a container with six children. A `<select>` dropdown menu enables toggling the `display` of the container between `grid` and `flex`. A second menu enables changing the value of the container's `align-items` property.

CSS

We style the container and items in a manner that ensures we have two lines or rows of items. We defined `.flex` and `.grid` classes, which will be applied to the container with JavaScript. They set the `display` value of the container, and change its background and border colors providing an additional indicator that the layout has changed. The six flex items each have a different background color, with the 4th item being two lines long and the 6th item having an enlarged font.

```
.flex,
.grid {
  height: 200px;
```

```
  width: 500px;
  align-items: initial; /* Change the value in the live sample */
  border: solid 5px transparent;
  gap: 3px;
}

.flex {
  display: flex;
  flex-wrap: wrap;
  background-color: #8c8c9f;
  border-color: magenta;
}

.grid {
  display: grid;
  grid-template-columns: repeat(auto-fill, 100px);
  background-color: #9f8c8c;
  border-color: slateblue;
}

#item1 {
  background-color: #8cffa0;
  min-height: 30px;
}

#item2 {
  background-color: #a0c8ff;
  min-height: 50px;
}

#item3 {
  background-color: #ffa08c;
  min-height: 40px;
}

#item4 {
  background-color: #ffff8c;
  min-height: 60px;
}

#item5 {
  background-color: #ff8cff;
  min-height: 70px;
}

#item6 {
  background-color: #8cffff;
  min-height: 50px;
  font-size: 30px;
}
```

```
select {
  font-size: 16px;
}

.row {
  margin-top: 10px;
}

div > div {
  box-sizing: border-box;
  border: 2px solid white;
  width: 100px;
  display: flex;
  align-items: center;
  justify-content: center;
}
```

HTML

We include a container `<div>` with six nested `<div>` children. The HTML for the form and the JavaScript that changes the container's class have been hidden for the sake of brevity.

```
<div id="container" class="flex">
  <div id="item1">1</div>
  <div id="item2">2</div>
  <div id="item3">3</div>
  <div id="item4">4<br />line 2</div>
  <div id="item5">5</div>
  <div id="item6">6</div>
</div>
```

```
<div class="row">
  <label for="display">display: </label>
  <select id="display">
    <option value="flex">flex</option>
    <option value="grid">grid</option>
  </select>
</div>

<div class="row">
  <label for="values">align-items: </label>
  <select id="values">
    <option value="normal">normal</option>
    <option value="flex-start">flex-start</option>
    <option value="flex-end">flex-end</option>
    <option value="center" selected>center</option>
    <option value="baseline">baseline</option>
    <option value="stretch">stretch</option>

    <option value="start">start</option>
    <option value="end">end</option>
    <option value="self-start">self-start</option>
```

```
    <option value="self-end">self-end</option>

    <option value="first baseline">first baseline</option>
    <option value="last baseline">last baseline</option>

    <option value="safe center">safe center</option>
    <option value="unsafe center">unsafe center</option>
    <option value="safe right">safe right</option>
    <option value="unsafe right">unsafe right</option>
    <option value="safe end">safe end</option>
    <option value="unsafe end">unsafe end</option>
    <option value="safe self-end">safe self-end</option>
    <option value="unsafe self-end">unsafe self-end</option>
    <option value="safe flex-end">safe flex-end</option>
    <option value="unsafe flex-end">unsafe flex-end</option>
  </select>
</div>
```

```
const values = document.getElementById("values");
const display = document.getElementById("display");
const container = document.getElementById("container");

values.addEventListener("change", (evt) => {
  container.style.alignItems = evt.target.value;
});

display.addEventListener("change", (evt) => {
  container.className = evt.target.value;
});
```

Result

align-self CSS property

The **`align-self`** CSS property overrides a grid or flex item's `align-items` value. In grid, it aligns the item inside the grid area. In flexbox, it aligns the item on the cross axis.

The property doesn't apply to block-level boxes, or to table cells. If a flexbox item's cross-axis margin is `auto`, then `align-self` is ignored.

Try it

```
align-self: stretch;
```

```
align-self: center;
```

```
align-self: start;
```

```
align-self: end;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">One</div>
    <div>Two</div>
    <div>Three</div>
  </div>
</section>
```

```
.example-container {
  border: 1px solid #c5c5c5;
  display: grid;
  width: 200px;
  grid-template-columns: 1fr 1fr;
  grid-auto-rows: 80px;
  grid-gap: 10px;
}

.example-container > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}
```

Syntax

```
/* Keyword values */
align-self: auto;
align-self: normal;

/* Positional alignment */
/* align-self does not take left and right values */
align-self: center; /* Put the item around the center */
align-self: start; /* Put the item at the start */
align-self: end; /* Put the item at the end */
align-self: self-start; /* Align the item flush at the start */
align-self: self-end; /* Align the item flush at the end */
align-self: flex-start; /* Put the flex item at the start */
```

```
align-self: flex-end; /* Put the flex item at the end */
align-self: anchor-center;

/* Baseline alignment */
align-self: baseline;
align-self: first baseline;
align-self: last baseline;
align-self: stretch; /* Stretch 'auto'-sized items to fit the container */

/* Overflow alignment */
align-self: safe center;
align-self: unsafe center;

/* Global values */
align-self: inherit;
align-self: initial;
align-self: revert;
align-self: revert-layer;
align-self: unset;
```

Values

This property is specified as one or two of the following keyword values:

`auto`

Computes to the parent's `align-items` value.

`normal`

The effect of this keyword is dependent of the layout mode we are in:

- In absolutely-positioned layouts, the keyword behaves like `start` on *replaced* absolutely-positioned boxes, and as `stretch` on *all other* absolutely-positioned boxes.
- In static position of absolutely-positioned layouts, the keyword behaves as `stretch`.
- For flex items, the keyword behaves as `stretch`.
- For grid items, this keyword leads to a behavior similar to the one of `stretch`, except for boxes with an aspect ratio or an intrinsic size where it behaves like `start`.
- The property doesn't apply to block-level boxes, and to table cells.

`self-start`

Aligns the items to be flush with the edge of the alignment container corresponding to the item's start side in the cross axis.

`self-end`

Aligns the items to be flush with the edge of the alignment container corresponding to the item's end side in the cross axis.

`flex-start`

The cross-start margin edge of the flex item is flushed with the cross-start edge of the line.

`flex-end`

The cross-end margin edge of the flex item is flushed with the cross-end edge of the line.

`center`

The flex item's margin box is centered within the line on the cross-axis. If the cross-size of the item is larger than the flex container, it will overflow equally in both directions.

`baseline`, `first baseline`, `last baseline`

Specifies participation in first- or last-baseline alignment: aligns the alignment baseline of the box's first or last baseline set with the corresponding baseline in the shared first or last baseline set of all the boxes in its baseline-sharing group. The fallback alignment for `first baseline` is `start`, the one for `last baseline` is `end`.

`stretch`

If the item's cross-size is `auto`, the used size is set to the length necessary to be as close to filling the container as possible, respecting the item's width and height limits. If the item is not auto-sized, this value falls back to `flex-start`, and to `self-start` or `self-end` if the container's `align-content` is `first baseline` (or `baseline`) or `last baseline`.

`anchor-center`

In the case of anchor-positioned elements, aligns the item to the center of the associated anchor element in the block direction. See Centering on the anchor using `anchor-center`.

`safe`

If the size of the item overflows the alignment container, the item is instead aligned as if the alignment mode were `start`.

`unsafe`

Regardless of the relative sizes of the item and alignment container, the given alignment value is honored.

Formal definition

Initial value	`auto`
Applies to	flex items, grid items, and absolutely-positioned boxes
Inherited	no
Computed value	`auto` computes to itself on absolutely-positioned elements, and to the computed value of `align-items` on the parent (minus any legacy keywords) on all other boxes, or `start` if the box has no parent. Its behavior depends on the layout model, as described for `justify-self`. Otherwise the specified value.
Animation type	discrete

Formal syntax

```
align-self =
  auto                                          |
  <overflow-position>? [ normal | <self-position> ]  |
  stretch                                       |
  <baseline-position>                           |
  anchor-center

<overflow-position> =
```

```
  unsafe  |
  safe

<self-position> =
  center      |
  start       |
  end         |
  self-start  |
  self-end    |
  flex-start  |
  flex-end

<baseline-position> =
  [ first | last ]?  &&
  baseline
```

This syntax reflects the latest standard as per CSS Box Alignment Module Level 3, CSS Specification. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<section>
  <div>Item #1</div>
  <div>Item #2</div>
  <div>Item #3</div>
</section>
```

CSS

```
section {
  display: flex;
  align-items: center;
  height: 120px;
  background: beige;
}

div {
  height: 60px;
  background: cyan;
  margin: 5px;
}

div:nth-child(3) {
  align-self: flex-end;
  background: pink;
}
```

alignment-baseline CSS property

The **`alignment-baseline`** CSS property specifies the specific baseline used to align the box's text and inline-level contents. **Baseline alignment** is the relationship among the baselines of multiple alignment subjects within an alignment context. When performing baseline alignment, the `alignment-baseline` property value specifies which baseline of the box is aligned to the corresponding baseline of its alignment context.

> **Note:** The `alignment-baseline` property only has an effect on inline-level boxes, flex items, grid items, table cells, and the `<text>`, `<textPath>`, and `<tspan>` SVG elements. If present, it overrides the shape's `alignment-baseline` attribute.

In an inline formatting context, inline-level box fragments and glyphs share an alignment context established by their parent inline box fragment along its inline axis. In SVG text layout, these values instead specify the baseline that is aligned to the SVG current text position.

Syntax

```
/* Initial value */
alignment-baseline: baseline;

/* Keyword values */
alignment-baseline: alphabetic;
alignment-baseline: central;
alignment-baseline: ideographic;
alignment-baseline: mathematical;
alignment-baseline: middle;
alignment-baseline: text-bottom;
alignment-baseline: text-top;

/* Mapped values */
alignment-baseline: text-before-edge; /* text-top */
alignment-baseline: text-after-edge; /* text-bottom */

/* Deprecated values  */
alignment-baseline: auto;
alignment-baseline: before-edge;
alignment-baseline: after-edge;
alignment-baseline: hanging;

/* Global values */
alignment-baseline: inherit;
alignment-baseline: initial;
```

```
alignment-baseline: revert;
alignment-baseline: revert-layer;
alignment-baseline: unset;
```

Values

This property is specified as one of the following keyword values:

`baseline`

Use the `dominant-baseline` value of the parent.

`alphabetic`

Used in writing Latin, Cyrillic, Greek, and many other scripts; matches the box's alphabetic baseline to that of its parent, corresponding to the bottom of most, but not all characters.

`central`

Matches the box's central baseline to the central baseline of its parent, corresponding to the ideographic central baseline, halfway between the ideographic-under and ideographic-over baselines.

`ideographic`

Matches the box's ideographic character face under-side baseline to that of its parent, with the derived baseline-table constructed using the ideographic baseline-table in the font.

`mathematical`

Matches the box's mathematical baseline to that of its parent, corresponding to the center baseline around which mathematical characters are designed.

`middle`

Aligns the vertical midpoint of the box with the baseline of the parent box plus half the x-height of the parent. Uses the x-middle baselines; except under `text-orientation: upright;` (where the alphabetic and x-height baselines are essentially meaningless), in which case it uses the `central` baseline instead.

`text-bottom`

Matches the bottom of the box to the top of the parent's content area, using the line-under edge of an inline's content box.

`text-top`

Matches the top of the box to the top of the parent's content area; the line-over edge of an inline's content box.

> **Note:** In SVG2, the `auto`, `before-edge`, and `after-edge` were deprecated and `text-before-edge` is an alias for `text-top`, and `text-after-edge` is an alias for `text-bottom`. These keywords should not be used as part of the `vertical-align` shorthand property. Browsers support `auto` as a synonym for `baseline` and `hanging`, wherein the alignment-point of the object being aligned is aligned with the "hanging" baseline of the parent text content element, but neither is part of the specification.

Formal definition

Initial value	`baseline`
Applies to	inline-level boxes, flex items, grid items, table cells, and SVG text content elements
Inherited	no
Computed value	the specified keyword
Animation type	discrete

Formal syntax

```
alignment-baseline =
  baseline           |
  <baseline-metric>

<baseline-metric> =
  text-bottom   |
  alphabetic    |
  ideographic   |
  middle        |
  central       |
  mathematical  |
  hanging       |
  text-top
```

This syntax reflects the latest standard as per CSS Inline Layout Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Example

```
<svg viewBox="0 0 450 160" width="700" height="200">
  <text x="50" y="20">alphabetic</text>
  <text x="50" y="60">central</text>
  <text x="50" y="100">hanging</text>
  <text x="50" y="140">ideographic</text>
  <text x="250" y="20">mathematical</text>
  <text x="250" y="60">middle</text>
  <text x="250" y="100">text-bottom</text>
  <text x="250" y="140">text-top</text>
  <path
    d="M   0,20 l 400,0
       m -400,40 l 400,0
       m -400,40 l 400,0
       m -400,40 l 400,0"
    stroke="grey" />
  <text x="0" y="20" fill="red">baseline</text>
  <text x="0" y="60" fill="red">baseline</text>
  <text x="0" y="100" fill="red">baseline</text>
  <text x="0" y="140" fill="red">baseline</text>
</svg>
```

```
text {
  font-size: 20px;
  alignment-baseline: baseline;
}
```

```
text:nth-of-type(1) {
  alignment-baseline: alphabetic;
}
text:nth-of-type(2) {
  alignment-baseline: central;
}
text:nth-of-type(3) {
  alignment-baseline: hanging;
}
text:nth-of-type(4) {
  alignment-baseline: ideographic;
}
text:nth-of-type(5) {
  alignment-baseline: mathematical;
}
text:nth-of-type(6) {
  alignment-baseline: middle;
}
text:nth-of-type(7) {
  alignment-baseline: text-bottom;
}
text:nth-of-type(8) {
  alignment-baseline: text-top;
}
```

all CSS property

The **`all`** CSS shorthand property resets all of an element's properties except `unicode-bidi`, `direction`, and CSS Custom Properties. It can set properties to their initial or inherited values, or to the values specified in another cascade layer or stylesheet origin.

Try it

```
/* no all property */
```

```
all: initial;
```

```
all: inherit;
```

```
all: unset;
```

```
all: revert;
```

```
<section id="default-example">
  <div class="example-container-bg">
    <div class="example-container">
      <p id="example-element">
        This paragraph has a font size of 1.5rem and a color of gold. It also
        has 1rem of vertical margin set by the user-agent. The parent of the
        paragraph is a &lt;div&gt; with a dashed blue border.
      </p>
    </div>
  </div>
</section>
```

```
#example-element {
  color: gold;
  padding: 10px;
  font-size: 1.5rem;
  text-align: left;
  width: 100%;
}

.example-container {
  border: 2px dashed #2d5ae1;
}

.example-container-bg {
  background-color: #77767b;
  padding: 20px;
}
```

Constituent properties

This property is a shorthand for all CSS properties except for `unicode-bidi`, `direction`, and custom properties.

Syntax

```
/* Global values */
all: initial;
all: inherit;
all: unset;
all: revert;
all: revert-layer;
```

Values

The `all` property is specified as one of the CSS global keyword values. Note that none of these values affect the `unicode-bidi` and `direction` properties.

`initial`

Specifies that all the element's properties should be changed to their initial values.

`inherit`

Specifies that all the element's properties should be changed to their inherited values.

`unset`

Specifies that all the element's properties should be changed to their inherited values if they inherit by default, or to their initial values if not.

`revert`

Specifies behavior that depends on the stylesheet origin to which the declaration belongs:

- If the rule belongs to the author origin, the `revert` value rolls back the cascade to the user level, so that the specified values are calculated as if no author-level rules were specified for the element. For purposes of `revert`, the author origin includes the Override and Animation origins.
- If the rule belongs to the user origin, the `revert` value rolls back the cascade to the user-agent level, so that the specified values are calculated as if no author-level or user-level rules were specified for the element.
- If the rule belongs to the user-agent origin, the `revert` value acts like `unset`.

`revert-layer`

Specifies that all the element's properties should roll back the cascade to a previous cascade layer, if one exists. If no other cascade layer exists, the element's properties will roll back to the matching rule, if one exists, in the current layer or to a previous style origin.

Formal definition

Initial value	There is no practical initial value for it.
Applies to	all elements
Inherited	no
Computed value	as the specified value applies to each property this is a shorthand for.
Animation type	as each of the properties of the shorthand (all properties but `unicode-bidi` and `direction`)

Formal syntax

```
all =
  initial      |
  inherit      |
  unset        |
  revert       |
  revert-layer |
  revert-rule
```

This syntax reflects the latest standard as per CSS Cascading and Inheritance Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

In this example, the CSS file contains styling for the `<blockquote>` element in addition to some styling for the parent `<body>` element. Various outputs in the Results subsection demonstrate how the styling of the `<blockquote>` element is affected when different values are applied to the `all` property inside the `blockquote` rule.

HTML

```
<blockquote id="quote">
  Lorem ipsum dolor sit amet, consectetur adipiscing elit.
</blockquote>
Phasellus eget velit sagittis.
```

CSS

```
body {
  font-size: small;
  background-color: #f0f0f0;
  color: blue;
  margin: 0;
  padding: 0;
}

blockquote {
  background-color: skyblue;
  color: red;
}
```

Results

A. No `all` property

```
<blockquote id="quote">
  Lorem ipsum dolor sit amet, consectetur adipiscing elit.
</blockquote>
Phasellus eget velit sagittis.
```

```
body {
  font-size: small;
  background-color: #f0f0f0;
  color: blue;
}
blockquote {
  background-color: skyblue;
  color: red;
}
```

This is the scenario in which no `all` property is set inside the `blockquote` rule. The `<blockquote>` element uses the browser's default styling which gives it a margin, together with a specific background and text color as specified in the stylesheet. It also behaves as a *block* element: the text that follows it is beneath it.

B. `all: initial`

```
<blockquote id="quote">
  Lorem ipsum dolor sit amet, consectetur adipiscing elit.
```

```
</blockquote>
Phasellus eget velit sagittis.
```

```
body {
  font-size: small;
  background-color: #f0f0f0;
  color: blue;
}
blockquote {
  background-color: skyblue;
  color: red;
  all: initial;
}
```

With the `all` property set to `initial` in the `blockquote` rule, the `<blockquote>` element doesn't use the browser default styling anymore: it is an *inline* element now (initial value), its `background-color` is `transparent` (initial value), its `font-size` is `medium`, and its `color` is `black` (initial value).

C. `all: inherit`

```
<blockquote id="quote">
  Lorem ipsum dolor sit amet, consectetur adipiscing elit.
</blockquote>
Phasellus eget velit sagittis.
```

```
body {
  font-size: small;
  background-color: #f0f0f0;
  color: blue;
}
blockquote {
  background-color: skyblue;
  color: red;
  all: inherit;
}
```

In this case, the `<blockquote>` element doesn't use the browser default styling. Instead, it inherits style values from its parent `<body>` element: it is a *block* element now (inherited value), its `background-color` is `#F0F0F0` (inherited value), its `font-size` is `small` (inherited value), and its `color` is `blue` (inherited value).

D. `all: unset`

```
<blockquote id="quote">
  Lorem ipsum dolor sit amet, consectetur adipiscing elit.
</blockquote>
Phasellus eget velit sagittis.
```

```
body {
  font-size: small;
  background-color: #f0f0f0;
  color: blue;
}
blockquote {
  background-color: skyblue;
  color: red;
  all: unset;
}
```

When the `unset` value is applied to the `all` property in the `blockquote` rule, the `<blockquote>` element doesn't use the browser default styling. Because `background-color` is a non-inherited property and `font-size` and `color` are inherited properties, the `<blockquote>` element is an *inline* element now (initial value), its `background-color` is `transparent` (initial value), but its `font-size` is still `small` (inherited value), and its `color` is `blue` (inherited value).

E. `all: revert`

```
<blockquote id="quote">
  Lorem ipsum dolor sit amet, consectetur adipiscing elit.
</blockquote>
Phasellus eget velit sagittis.
```

```
body {
  font-size: small;
  background-color: #f0f0f0;
  color: blue;
}
blockquote {
  background-color: skyblue;
  color: red;
  all: revert;
}
```

When the `all` property is set to `revert` in the `blockquote` rule, the `blockquote` rule is considered to be non-existent and the styling property values are inherited from the ones applied to the parent element `<body>`. So the `<blockquote>` element gets styled as a *block* element, with `background-color` `#F0F0F0`, `font-size` `small`, and `color` `blue` - all values inherited from the `body` rule.

F. `all: revert-layer`

```
<blockquote id="quote">
  Lorem ipsum dolor sit amet, consectetur adipiscing elit.
</blockquote>
Phasellus eget velit sagittis.
```

```
body {
  font-size: small;
  background-color: #f0f0f0;
  color: blue;
}
blockquote {
  background-color: skyblue;
  color: red;
  all: revert-layer;
}
```

There are no cascade layers defined in the CSS file, so the `<blockquote>` element inherits its style from the matching `body` rule. The `<blockquote>` element here is styled as a *block* element, with `background-color` `#F0F0F0`, `font-size` `small`, and `color` `blue` - all values inherited from the `body` rule. This scenario is an example of the case when `all` set to `revert-layer` behaves the same as when `all` is set to `revert`.

CSS global keyword values: `initial`, `inherit`, `unset`, `revert`, `revert-layer`

anchor-name CSS property

The **`anchor-name`** CSS property enables defining an element as an **anchor element** by giving it one or more identifying **anchor names**. Each name can then be set as the value of a positioned element's `position-anchor` property to associate it with the anchor.

Syntax

```
/* Single values */
anchor-name: none;
anchor-name: --name;

/* Multiple values */
anchor-name: --name, --another-name;

/* Global values */
anchor-name: inherit;
anchor-name: initial;
anchor-name: revert;
anchor-name: revert-layer;
anchor-name: unset;
```

Values

This property is specified as a single value from the following list:

`none`

> The default value. Setting `anchor-name: none` on an element means that it is not defined as an anchor element. If the element was previously defined as an anchor and associated with a positioned element, setting `anchor-name: none` disassociates the two.

`<dashed-ident>`

> One or more comma-separated arbitrary custom identifiers defining the name or names of the anchor, which can then be referenced in a `position-anchor` property.

Description

To position an element relative to an anchor element, the positioned element requires three features: an association, a position, and a location. The `anchor-name` and `position-anchor` properties provide an explicit association.

The anchor element accepts one or more `<dashed-ident>` anchor names set on it via the `anchor-name` property. When one of those names is then set as the value of the `position-anchor` property of an element that has its `position` set to `absolute` or `fixed`, the two elements are associated. The two elements become tethered by setting a location on the associated element relative to the anchor, making it an "anchor-positioned" element.

If multiple anchor elements have the same anchor name set on them, and that name is referenced by the `position-anchor` property value of a positioned element, that positioned element will be associated with the last anchor element with that anchor name in the source order.

Anchor positioning changes the containing block of anchor-positioned elements, making its `position` relative to its anchor rather than to the nearest positioned ancestor element.

To tether and place a positioned element in a specific location relative to an anchor element, an anchor positioning feature is needed, such as the `anchor()` function (set within an inset property's value) or the `position-area` property.

You cannot associate a positioned element with an anchor element if the anchor is hidden, such as with `display: none` or `visibility: hidden`, or if the anchor is part of the skipped contents of another element due to it having `content-visibility: hidden` set on it.

The `anchor-name` property is supported on all elements that generate a principal box. This means that pseudo-elements, including generated content created using `::before` and `::after`, and UI features like the `range` input thumb (`::-webkit-slider-thumb`) can be anchor elements. Pseudo elements are implicitly anchored to the same element as the pseudo-element's originating element, unless otherwise specified.

For more information on anchor features and usage, see the CSS anchor positioning module and the Using CSS anchor positioning guide.

Formal definition

Initial value	none
Applies to	All elements that generate a principal box
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
anchor-name =
  none            |
  <anchor-name>#

<anchor-name> =
  <dashed-ident>
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example tethers a positioned element to an anchor, positioning the element to the right of the anchor.

HTML

We specify two `<div>` elements; an anchor element with a class of `anchor` and a positioned element with a class of `infobox`.

We also include some filler text around the two `<div>`s to make the `<body>` taller so that it will scroll.

```
<p>
  Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod tempor
  incididunt ut labore et dolore magna aliqua. Dui nunc mattis enim ut tellus
  elementum sagittis vitae et.
</p>

<div class="anchor">⚓</div>

<div class="infobox">
  <p>This is an information box.</p>
</div>

<p>
  Nisi quis eleifend quam adipiscing vitae proin sagittis nisl rhoncus. In arcu
  cursus euismod quis viverra nibh cras pulvinar. Vulputate ut pharetra sit amet
  aliquam.
</p>

<p>
  Malesuada nunc vel risus commodo viverra maecenas accumsan lacus. Vel elit
  scelerisque mauris pellentesque pulvinar pellentesque habitant morbi
  tristique. Porta lorem mollis aliquam ut porttitor. Turpis cursus in hac
  habitasse platea dictumst quisque. Dolor sit amet consectetur adipiscing elit.
  Ornare lectus sit amet est placerat. Nulla aliquet porttitor lacus luctus
  accumsan.
</p>
```

CSS

We first declare the `anchor` `<div>` as an anchor element by setting an anchor name on it via the `anchor-name` property:

```
body {
  width: 50%;
  margin: 0 auto;
}

.anchor {
  font-size: 1.8rem;
  color: white;
  text-shadow: 1px 1px 1px black;
  background-color: hsl(240 100% 75%);
  width: fit-content;
  border-radius: 10px;
  border: 1px solid black;
  padding: 3px;
}
```

```
.anchor {
  anchor-name: --my-anchor;
}
```

We associate the second `<div>` with the anchor element by setting its anchor name as the value of the positioned element's `position-anchor` property. We then set the positioned element's:

- `position` property to `fixed`, converting it to an *anchor-positioned element* so it can be positioned relative to the anchor's position on the page.
- `left` and `top` properties to `anchor()` functions with values of `right` and `top` respectively. This positions the infobox's left edge flush to the right edge of its anchor, and its top edge relative to the top edge of its anchor.
- `margin-left` to `10px`, creating space between the anchor positioned element and its anchor.

```
.infobox {
  color: darkblue;
  background-color: azure;
  border: 1px solid #dddddd;
  padding: 10px;
  border-radius: 10px;
  font-size: 1rem;
}
```

```
.infobox {
  position-anchor: --my-anchor;
  position: fixed;
  left: anchor(right);
  top: anchor(top);
  margin-left: 10px;
}
```

Result

Scroll the page to see how the infobox is positioned relative to the anchor. As the anchor scrolls upwards, the positioned element moves along with it.

Multiple positioned elements

This example demonstrates how you can associate multiple positioned elements with one anchor.

HTML

The HTML is the same as for the previous example, except this time we have multiple positioned element `<div>`s with different `id`s to identify them.

```
<p>
  Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod tempor
  incididunt ut labore et dolore magna aliqua. Dui nunc mattis enim ut tellus
  elementum sagittis vitae et.
</p>

<div class="anchor">⚓</div>

<div class="infobox" id="infobox1">
  <p>This is an information box.</p>
</div>
```

```
<div class="infobox" id="infobox2">
  <p>This is another information box.</p>
</div>

<p>
  Nisi quis eleifend quam adipiscing vitae proin sagittis nisl rhoncus. In arcu
  cursus euismod quis viverra nibh cras pulvinar. Vulputate ut pharetra sit amet
  aliquam.
</p>

<p>
  Malesuada nunc vel risus commodo viverra maecenas accumsan lacus. Vel elit
  scelerisque mauris pellentesque pulvinar pellentesque habitant morbi
  tristique. Porta lorem mollis aliquam ut porttitor. Turpis cursus in hac
  habitasse platea dictumst quisque. Dolor sit amet consectetur adipiscing elit.
  Ornare lectus sit amet est placerat. Nulla aliquet porttitor lacus luctus
  accumsan.
</p>
```

CSS

We declare the `anchor` `<div>` as an anchor element using the `anchor-name` property, giving it an anchor name as before.

```
body {
  width: 50%;
  margin: 0 auto;
}

.anchor {
  font-size: 1.8rem;
  color: white;
  text-shadow: 1px 1px 1px black;
  background-color: hsl(240 100% 75%);
  width: fit-content;
  border-radius: 10px;
  border: 1px solid black;
  padding: 3px;
}
```

```
.anchor {
  anchor-name: --my-anchor;
}
```

Each of the two positioned elements are associated with the anchor element by setting its anchor name as the positioned element's `position-anchor` property value. Both are also given `fixed` positioning, making them **anchor positioned elements**. The positioned elements are then positioned in different places relative to the anchor using a combination of inset properties as seen above and `align-self` / `justify-self` properties with a value of `anchor-center`, centrally aligning the infobox to the center of the anchor in the inline/block directions respectively.

```
.infobox {
  color: darkblue;
  background-color: azure;
  border: 1px solid #dddddd;
  padding: 10px;
  border-radius: 10px;
  font-size: 1rem;
}
```

```
.infobox {
  position-anchor: --my-anchor;
  position: fixed;
}

#infobox1 {
  left: anchor(right);
  align-self: anchor-center;
  margin-left: 10px;
}

#infobox2 {
  bottom: anchor(top);
  justify-self: anchor-center;
  margin-bottom: 15px;
}
```

Result

Scroll the page to see how both of the infoboxes are tethered to the anchor.

Multiple anchor names

This example demonstrates how an anchor element can have more than one anchor name.

HTML

The HTML is the same as for the previous example.

```
<p>
  Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod tempor
  incididunt ut labore et dolore magna aliqua. Dui nunc mattis enim ut tellus
  elementum sagittis vitae et.
</p>

<div class="anchor">⚓</div>

<div class="infobox" id="infobox1">
  <p>This is an information box.</p>
</div>

<div class="infobox" id="infobox2">
  <p>This is another information box.</p>
</div>
```

```
<p>
  Nisi quis eleifend quam adipiscing vitae proin sagittis nisl rhoncus. In arcu
  cursus euismod quis viverra nibh cras pulvinar. Vulputate ut pharetra sit amet
  aliquam.
</p>

<p>
  Malesuada nunc vel risus commodo viverra maecenas accumsan lacus. Vel elit
  scelerisque mauris pellentesque pulvinar pellentesque habitant morbi
  tristique. Porta lorem mollis aliquam ut porttitor. Turpis cursus in hac
  habitasse platea dictumst quisque. Dolor sit amet consectetur adipiscing elit.
  Ornare lectus sit amet est placerat. Nulla aliquet porttitor lacus luctus
  accumsan.
</p>
```

CSS

The CSS is the same as the previous example too, except we include two comma-separated names in the target's `anchor-name` property value and each positioned element has a different value for `position-anchor`.

```
body {
  width: 50%;
  margin: 0 auto;
}

.anchor {
  font-size: 1.8rem;
  color: white;
  text-shadow: 1px 1px 1px black;
  background-color: hsl(240 100% 75%);
  width: fit-content;
  border-radius: 10px;
  border: 1px solid black;
  padding: 3px;
}

.infobox {
  color: darkblue;
  background-color: azure;
  border: 1px solid #dddddd;
  padding: 10px;
  border-radius: 10px;
  font-size: 1rem;
}
```

```
.anchor {
  anchor-name: --anchor1, --anchor2;
}

.infobox {
  position: fixed;
}

#infobox1 {
  position-anchor: --anchor1;
  left: anchor(right);
  align-self: anchor-center;
  margin-left: 10px;
}

#infobox2 {
  position-anchor: --anchor2;
  bottom: anchor(top);
  justify-self: anchor-center;
  margin-bottom: 15px;
}
```

Result

Scroll the page to see how both of the infoboxes are tethered to the anchor.

anchor-scope CSS property

The **`anchor-scope`** CSS property can be used to limit the scope in which a positioned element can be associated with anchor elements to a particular subtree.

Syntax

```
/* Single values */
anchor-scope: none;
anchor-scope: all;
anchor-scope: --anchor-name;

/* Multiple <dashed-ident> values */
anchor-scope: --anchor-name, --another-name;

/* Global values */
anchor-scope: inherit;
anchor-scope: initial;
anchor-scope: revert;
anchor-scope: revert-layer;
anchor-scope: unset;
```

Values

This property is specified as the keyword `none` or `all` or a comma-separated list of `<dashed-ident>` values:

`none`

No anchor scope limiting happens on an element. This is the default value.

`all`

Sets the scope so that *any* `anchor-name` values set in the subtree can only be bound to by positioned elements in the same subtree.

`<dashed-ident>#`

One or more comma-separated `<dashed-ident>`s representing anchor names. Sets the scope so that the specified `anchor-name` values, when set in the subtree, can only be bound to by positioned elements in the same subtree.

Description

When multiple anchor elements on a page are given the same `anchor-name` value and a positioned element is associated with that anchor name (by specifying the name as its `position-anchor` property value), the positioned element will be associated with the *last* anchor element in the source order with that anchor name.

This can be a problem in certain situations. For example, if a document contains multiple repeated components, each with a positioned element tethered to an anchor, all the positioned elements will be anchored to the last anchor on the page unless each component uses a different anchor name. This is likely not the desired behavior.

The `anchor-scope` property can fix this problem by limiting the visibility, or "scope", of an `anchor-name` value to a specific subtree. The result is that each positioned element can only be anchored to an element within the same subtree of the element that has the scope set on it.

- `anchor-scope: all` sets the scope so that *any* `anchor-name` values set in the subtree can only be bound to by positioned elements in the same subtree. Let's say we include multiple anchors in a document, all with `anchor-name: --my-anchor` set on them, and place them in separate containers. We will then set `anchor-scope: all` on each container. If we then include a positioned element inside one of the containers and give it `--my-anchor` as the value of its `position-anchor` property, it will be positioned relative to the anchor inside the same container.

  Furthermore, if we create another positioned element outside the containers and give it the same anchor name, or a different anchor name, it will not be anchor-positioned relative to any of the anchors, regardless of whether the anchors have those anchor names included inside their `anchor-name` values. `anchor-scope: all` limits the anchor scope for containers it is set on for *any* anchors, regardless of `anchor-name`, to only positioned elements inside the same containers.

- `anchor-scope: <dashed-ident>#` sets the scope so that the specified `anchor-name` values, when set in the subtree, can only be bound to by positioned elements in the same subtree. If we return to the same example described in the previous bullet, but change the `anchor-scope` value set on the containers to `--my-anchor`:

  - Positioned elements with `position-anchor: --my-anchor` set on them will be limited to the scope imposed by the `anchor-scope` setting. They will only be positioned relative to the anchors if they are placed inside the containers.
  - However, positioned elements with different `position-anchor` names — for example, `--another-anchor` — *can* be positioned relative to one of the anchors, whether it is placed inside or outside the containers, provided you add the `--another-anchor` anchor name to the anchor's `anchor-name` property. The `anchor-scope` property only limits the scope for the `--my-anchor` anchor name, so it will have no effect on other anchor names.

    If multiple anchors are given the `--another-anchor` anchor name, the positioned elements with that `position-anchor` value will be positioned relative to the last anchor in the source order with that name.

- `anchor-scope: none` is the default value, which specifies that no anchor scope is set. If multiple anchors exist in a document with the same `anchor-name`, and a positioned element is given this name as the value of its `position-anchor` property, it will be positioned relative to the last anchor element in the source order, regardless of where it is placed in the DOM hierarchy.

If you have, for example, three `anchor-name` values set inside a subtree (say, `--anchor1`, `--anchor2`, and `--anchor3`), setting `anchor-scope: --anchor1, --anchor2, --anchor3` on the top-level element of the subtree would be equivalent to setting `anchor-scope: all`.

Anchor scopes only affect explicit anchor associations, that is, those made between an anchor element with an `anchor-name` set on it, and a positioned element referencing the anchor element's anchor name in its `position-anchor` value. Anchor scopes do not affect implicit anchor associations.

For more information on anchor features and usage, see the CSS anchor positioning module and the Using CSS anchor positioning guide.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
anchor-scope =
  none            |
  all             |
  <anchor-name>#

<anchor-name> =
  <dashed-ident>
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates how anchor scope works at a basic level. It shows how an anchor element inside a scoped container can be limited to only having positioned elements inside the same scoped container tethered to it.

HTML

We specify a `<section>` element that we will set an anchor scope on. This contains two `<div>` elements, one to be turned into an anchor, and one to be an anchor-positioned element.

We also include a third `<div>` outside the `<section>`, which we will also turn into an anchor-positioned element.

```
<section class="scoped">
  <div class="anchor">⚓</div>
  <div class="positioned">Positioned 1</div>
</section>
```

```
<div class="positioned">Positioned 2</div>
```

CSS

We first set `anchor-scope: --my-anchor` on the `<section>`. This limits its scope so that anchor element descendants of the `<section>` with a name of `--my-anchor` can only be bound to by positioned elements that are also descendants of the `<section>`.

To test this out, we declare the `anchor` `<div>` as an anchor element by setting an `anchor-name` of `--my-anchor` on it. We then absolutely position the `.positioned` elements, tether them to the anchor by setting their `position-anchor` values to `--my-anchor`, and position them to the right of the anchor by setting their `position-area` values to `right`:

```
.scoped {
  padding: 20px;
  background: #eeeeee;
}

.anchor {
  font-size: 1.8rem;
  color: white;
  text-shadow: 1px 1px 1px black;
  background-color: blue;
  width: fit-content;
  padding: 3px;
}

.positioned {
  background: orange;
  width: fit-content;
  padding: 3px;
}
```

```
.scoped {
  anchor-scope: --my-anchor;
}

.anchor {
  anchor-name: --my-anchor;
}

.positioned {
  position: absolute;
  position-anchor: --my-anchor;
  position-area: right;
}
```

Result

The example renders like so:

Note how the first positioned element is positioned to the right of the anchor. It is in scope for positioning relative to the `--my-anchor` anchor, as it is inside the `<section>` element where the `anchor-scope: --my-anchor` is set.

However, the second positioned element is not positioned relative to the anchor. It is not a descendant of the `<section>` element, so it is outside the anchor scope.

Comparing different <code>anchor-scope</code> values

This example demonstrates the effects of the different `anchor-scope` values by allowing you to apply different `anchor-scope` values to multiple containers, all containing anchors with the same `anchor-name` value.

HTML

We specify three `<section>` elements that we will set an anchor scope on. Each `<section>` contains two `<div>` elements, one to be turned into an anchor, and one to be an anchor-positioned element.

We also include an additional `<div>` outside the `<section>` elements, which we will also turn into an anchor-positioned element. This will have different anchor positioning settings from the others.

Finally, we include a `<form>` containing three different `<input type="radio">` elements to allow different `anchor-scope` values to be set on the `<section>` elements.

```
<section class="scoped">
  <div class="anchor">⚓</div>
  <div class="positioned">Positioned 1</div>
</section>

<section class="scoped">
  <div class="anchor">⚓</div>
  <div class="positioned">Positioned 2</div>
</section>

<section class="scoped">
  <div class="anchor">⚓</div>
  <div class="positioned">Positioned 3</div>
</section>

<div class="positioned2">Positioned 4</div>

<form>
  <fieldset>
    <legend>Select an <code>anchor-scope</code> value</legend>

    <input type="radio" id="all" name="scope" value="all" checked />
    <label for="all"><code>all</code></label>
    <input type="radio" id="my-anchor" name="scope" value="--my-anchor" />
    <label for="my-anchor"><code>--my-anchor</code></label>
    <input type="radio" id="none" name="scope" value="none" />
    <label for="none"><code>none</code></label>
  </fieldset>
</form>
```

CSS

We start by specifying our anchor elements as anchors by giving them two `anchor-name` values: `--my-anchor` and `--another-anchor`.

```
body {
  display: flex;
  justify-content: center;
  gap: 50px;
  margin-top: 5px;
}

.scoped {
  padding: 20px;
  background: #eeeeee;
  border: 2px solid #dddddd;
  border-radius: 10px;
  width: 100px;
  height: 100px;
}

.anchor {
  font-size: 1.8rem;
  color: white;
  text-shadow: 1px 1px 1px black;
  background-color: blue;
  width: fit-content;
  padding: 3px;
}

.positioned,
.positioned2 {
  border: 1px solid black;
  border-radius: 3px;
  width: fit-content;
  padding: 3px 6px;
  box-shadow: 3px 3px 3px rgb(0 0 0 / 0.2);
}

form {
  position: absolute;
  bottom: 5px;
  right: 5px;
}
```

```
.anchor {
  anchor-name: --my-anchor, --another-anchor;
}
```

Next, we position our `.positioned` elements relative to an anchor element. We absolutely position them, give them a `position-anchor` value of `--my-anchor` to associate them with an anchor, and position them relative to the anchor with a `position-area` value of `right`.

The `.positioned2` element is positioned in a similar way, except that it is given the other available anchor name as its `position-anchor` value — `--another-anchor` — and it is positioned to the `bottom` of the anchor instead. We also give it a `bottom` value of `5px`, so that if the anchor positioning is not working, it will be positioned to the bottom of the `<body>`. This element is not contained inside any scoped element, therefore it will only be anchor positioned when certain `anchor-scope` values are set on the scoped elements, as explained later on.

```
.positioned {
  position: absolute;
  position-anchor: --my-anchor;
  position-area: right;
}

.positioned2 {
  position: absolute;
  bottom: 5px;
  position-anchor: --another-anchor;
  position-area: bottom;
}
```

We handle setting `anchor-scope` on the `<section>` elements when different radio buttons are pressed using JavaScript, which has been hidden for brevity.

```
const sections = document.querySelectorAll("section");
const form = document.querySelector("form");

function updateScope(val) {
  sections.forEach((section) => (section.style.anchorScope = val));
}

form.addEventListener("input", (e) => {
  updateScope(e.target.value);
});

updateScope("all");
```

Result

The example renders as follows:

Check out the initial positioning effect applied to the positioned elements with `anchor-scope: all` set on the `<section>` elements, and then try selecting the other available `anchor-scope` values to see what their effect is. You should observe the following:

- `all`: The scope for positioning elements relative to anchor elements that are descendants of the `<section>` elements is limited to positioned elements that are themselves descendants of the `<section>` elements, regardless of the `anchor-name` value used to associate them. As a result, the positioned elements inside the `<section>` elements ("Positioned 1–3") are anchor-positioned as expected, but the positioned element outside the `<section>` elements ("Positioned 4") is not anchor-positioned. It is out of scope.
- `--my-anchor`: The scope for positioning elements relative to anchor elements that are descendants of the `<section>` elements is limited to positioned elements that are themselves descendants of the `<section>` elements, only if the `--my-anchor` `anchor-name` is used to associate them. As a result, the positioned elements inside the `<section>` elements ("Positioned 1–3") are anchor-positioned as expected, and the positioned element outside the `<section>` elements ("Positioned 4") is also anchor-positioned as expected. In the former case, the positioned elements are inside the set scope, and in the latter case, the positioned element is not affected by the set scope, as it is using an anchor name outside the scope (`--another-anchor`). The "Positioned 4" element is positioned relative to the last anchor element in the source that has the matching anchor name.
- `none`: As no anchor scope is set on the `<section>` elements, all of the positioned elements are positioned relative to the last anchor element in the source order.

animation CSS property

The **animation** CSS shorthand property applies an animation between styles. It is a shorthand for animation-name, animation-duration, animation-timing-function, animation-delay, animation-iteration-count, animation-direction, animation-fill-mode, animation-play-state, and animation-timeline.

Try it

```
animation: 3s ease-in 1s infinite reverse both running slide-in;
```

```
animation: 3s linear 1s infinite running slide-in;
```

```
animation: 3s linear 1s infinite alternate slide-in;
```

```
animation: 0.5s linear 1s infinite alternate slide-in;
```

```
<section class="flex-column" id="default-example">
  <div id="example-element"></div>
</section>
```

```
#example-element {
  background-color: #1766aa;
  margin: 20px;
  border: 5px solid #333333;
  width: 150px;
  height: 150px;
  border-radius: 50%;
}

@keyframes slide-in {
  from {
    margin-left: -20%;
  }
  to {
    margin-left: 100%;
  }
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- animation-name
- animation-duration
- animation-timing-function
- animation-delay
- animation-direction
- animation-iteration-count
- animation-fill-mode
- animation-play-state
- animation-timeline

Reset-only sub-properties

This property resets the following CSS properties to their initial values:

- animation-range-end
- animation-range-start
- animation-delay-end
- animation-composition
- animation-trigger

Syntax

```
/* Duration | easing-function | delay |
iteration-count | direction | fill-mode | play-state | name */
animation: 3s ease-in 1s 2 reverse both paused slide-in;

/* Duration | easing-function | delay | name */
animation: 3s linear 1s slide-in;

/* Duration | name */
animation: 3s slide-in;

/* Multiple animations */
animation:
  3s linear slide-in,
  3s ease-out 5s slide-out;
```

Values

This property is specified as a comma-separated list of `<animation>` values, with each value being a space-separated list of the following values:

`<keyframes-name>` or `none`

The name of a `@keyframes` at-rules that specifies the animation to apply to an element. The initial value for `animation-name` is `none`.

`<animation-duration>`

Determines the length of time that an animation takes to complete one cycle. The value must be one of those available in `animation-duration`. The initial value is `0s`.

`<easing-function>`

Determines the type of transition. The value must be one of those available in `animation-timing-function`. The initial value is `ease`.

`<animation-delay>`

Determines the amount of time to wait from applying the animation to an element before beginning to perform the animation. The value must be one of those available in `animation-delay`. The initial value is `0s`.

`<single-animation-direction>`

The direction in which the animation is played. The value must be one of those available in `animation-direction`. The initial value for `animation-direction` is `normal`.

`<single-animation-iteration-count>`

The number of times the animation is played. The value must be one of those available in `animation-iteration-count`. The initial value for `animation-iteration-count` is `1`.

`<single-animation-fill-mode>`

Determines how styles should be applied to the animation's target before and after its execution. The value must be one of those available in `animation-fill-mode`. The initial value for `animation-fill-mode` is `none`.

`<single-animation-play-state>`

Determines whether the animation is playing or not. The value must be one of those available in `animation-play-state`. The initial value for `animation-play-state` is `running`.

`<single-animation-timeline>`

Determines the timeline used to control the progress of the animation. The value must be one of those available in `animation-timeline`. The initial value is `auto`.

Description

The `animation` property is specified as one or more single animations, separated by commas. Each `animation` within the comma-separated list of animations sets the `animation-name`, `animation-duration`, `animation-timing-function`, `animation-delay`, `animation-iteration-count`, `animation-direction`, `animation-fill-mode`, `animation-play-state`, and `animation-timeline`. If any of the components are not included in an `animation` declaration, the component value is set to the component's initial value.

> **Note:** The `animation` shorthand property resets the `animation-range-start`, `animation-range-end` and `animation-trigger` properties to their initial values; `normal`, `normal` and `none`, respectively. These reset-only sub-properties cannot be set in the `animation` shorthand, and including them invalidates the entire declaration. Because the `animation` declaration sets each of these properties to their initial values, they must either be declared after any `animation` shorthand declarations or with greater specificity.

animation-name

The `<animation-name>` component of each animation is the name for the animation, which may be `none`, a `<custom-ident>`, or a `<string>`. The initial value of `animation-name` is `none`, meaning if no `animation-name` value is declared in the `animation` shorthand property, no animation is applied to any of the properties.

The order of other values within an animation definition is important for distinguishing an `animation-name` value from other values. If a value in the `animation` shorthand can be parsed as a value for an animation property other than `animation-name`, then the value will be applied to that property first and not to `animation-name`. For this reason, the recommended practice is to specify a value for `animation-name` as the last value in a list of values when using the `animation` shorthand; this holds true even when you specify multiple, comma-separated animations using the `animation` shorthand.

Time values

Each animation can include zero, one, or two occurrences of the `<time>` value. The order of time values within each animation definition is important: the first value that can be parsed as a `<time>` is assigned to the `animation-duration`, and the second one is assigned to `animation-delay`.

When no `animation-duration` value is specified in the `animation` shorthand property, the duration defaults to `0s`. In this case, the animation will still occur (the `animationStart` and `animationEnd` events will be fired), but no animation will be visible to the user.

animation-timeline

If no `<animation-timeline>` is included in the `animation` shorthand, the shorthand declaration will reset any previously-declared `animation-timeline` values to `auto`, which sets the timeline to the default `documentTimeline`.

If an `<animation-timeline>` value is included, but the user-agent doesn't support `<animation-timeline>` values within the shorthand, the entire `animation` declaration is invalid and ignored. For this reason, when creating CSS scroll-driven animations, you need to declare the `animation-timeline` property after declaring any `animation` shorthand for it to take effect.

Alternatively, the `<animation-timeline>` can be set within the `animation` shorthand within a CSS `@supports` block, such as:

```
@supports (animation: view()) {
  /* CSS for browsers supporting <animation-timeline> within `animation` shorthand */
}
```

animation-fill-mode and new stacking contexts

In the case of the `animation-fill-mode` forwards value, animated properties behave as if included in a set `will-change` property value. If a new stacking context is created during the animation, the target element retains the stacking context after the animation has finished.

Accessibility

Blinking and flashing animation can be problematic for people with cognitive concerns such as Attention Deficit Hyperactivity Disorder (ADHD). Additionally, certain kinds of motion can be a trigger for vestibular disorders, epilepsy, and migraine and scotopic sensitivity.

Consider providing a mechanism for pausing or disabling animation as well as using the reduced motion `@media` query to create a complementary experience for users who have expressed a preference for reduced animated experiences.

  <percentage>
```

This syntax reflects the latest standard as per CSS Animations Level 1, CSS Animations Level 2, CSS Easing Functions Level 2, CSS Values and Units Module Level 4, Scroll-driven Animations. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

> **Note:** Animating CSS box model properties is discouraged as it leads to layout reflow and repaints. Animating any box model property is inherently CPU-intensive; consider animating the transform property instead.

Basic usage: a sunrise

In this example, we demonstrate basic usage of the `animation` shorthand by animating a yellow sun across a light blue sky. The sun rises to the center of the viewport and then falls out of sight.

HTML

We include a single `<div>` element to represent our sun.

```
<div class="sun"></div>
```

CSS

We start by creating the sun and the sky. The sky is the `:root` of the HTML document. We hide any content that is outside the viewport, which in our case will be any part of the sun below the horizon, by setting the `overflow` to hidden. We also use the `justify-content` property to center the sun in the background. We make the sun yellow, declare its `height` to be the height of the viewport (`100vh`), and set its width to equal its height by setting the `aspect-ratio` to `1`. We turn the square `<div>` into a circle using the `border-radius` property.

```
:root {
  overflow: hidden;
  background-color: lightblue;
  display: flex;
  justify-content: center;
}

.sun {
  background-color: yellow;
  border-radius: 50%;
  height: 100vh;
  aspect-ratio: 1;
  animation: 4s linear 0s infinite alternate sunrise;
}
```

Next, we define some animation `@keyframes` that will push the element on which they are applied down past the viewport and then return the element to its default position using CSS transforms:

```
@keyframes sunrise {
  from {
    transform: translateY(110vh);
  }
  to {
    transform: translateY(0);
  }
}
```

The last step is to apply the animation! We use the `animation` shorthand property to apply the `sunrise` keyframe animation to the `.sun` `<div>`. The animation is set to play for infinite iterations, with each one lasting 4 seconds; the animation direction alternates with each iteration:

```
.sun {
  animation: 4s linear 0s infinite alternate sunrise;
}
```

Results

Applying multiple animations

This example demonstrates applying multiple animations to a single element. Expanding on the previous example, with a sun that rises and falls on a light blue background, here we will gradually rotate the sun through a rainbow of colors. The timing of the sun's position and color are independent.

```
<div class="sun"></div>
```

```
:root {
  overflow: hidden;
  background-color: lightblue;
  display: flex;
  justify-content: center;
}

.sun {
  background-color: yellow;
  border-radius: 50%;
  height: 100vh;
  aspect-ratio: 1 / 1;
}

@keyframes sunrise {
  from {
    transform: translateY(110vh);
  }
  to {
    transform: translateY(0);
  }
}
```

We include the same HTML and CSS as in the previous example, and add a second set of animation `@keyframes` to apply a `filter` that rotates the hue through all possible values using the `hue-rotate()` filter function:

```
@keyframes psychedelic {
  from {
    filter: hue-rotate(0deg);
  }
  to {
    filter: hue-rotate(360deg);
  }
}
```

We then apply the two animations to our sun. Multiple animations are separated by commas, and each animation's parameters are set independently:

```
.sun {
  animation:
    4s linear 0s infinite alternate sunrise,
    24s linear 0s infinite psychedelic;
}
```

Results

Cascading multiple animations

This example demonstrates what happens when multiple animations define values for the same property. This example expands upon the basic usage example, with two animations applied that both set a `transform` value.

```
<div class="sun"></div>
```

```
:root {
  overflow: hidden;
  background-color: lightblue;
  display: flex;
  justify-content: center;
}

.sun {
  background-color: yellow;
  border-radius: 50%;
  height: 100vh;
  aspect-ratio: 1 / 1;
}
```

We use the same HTML and CSS as in the first example, including the original `sunrise` animation, and a second animation named `bounce`. The two animations declare values for the same property:

```
@keyframes sunrise {
  from {
    transform: translateY(110vh);
  }
  to {
    transform: translateY(0);
  }
}

@keyframes bounce {
  from {
    transform: translateX(-50vw);
  }
  to {
    transform: translateX(50vw);
  }
}
```

We apply both animations to the sun. When two animations apply different values to the same property, animations declared later in the cascade override previously-declared animations. In this case, the `transform` value on the `bounce` animation "wins" the cascade, and overrides the transform set by `sunrise`, so the sun will only move horizontally.

```
.sun {
  animation:
```

```
    4s linear 0s infinite alternate sunrise,
    4s linear 0s infinite alternate bounce;
}
```

Results

The sun bounces between the left- and right-hand sides of the viewport. The sun remains in the viewport even though the `sunrise` animation is defined. The `sunrise` animation's transform property is overridden by the bounce animation.

animation-composition CSS property

The **`animation-composition`** CSS property specifies the composite operation to use when multiple animations affect the same property simultaneously.

Syntax

```
/* Single animation */
animation-composition: replace;
animation-composition: add;
animation-composition: accumulate;

/* Multiple animations */
animation-composition: replace, add;
animation-composition: add, accumulate;
animation-composition: replace, add, accumulate;

/* Global values */
animation-composition: inherit;
animation-composition: initial;
animation-composition: revert;
animation-composition: revert-layer;
animation-composition: unset;
```

Values

This property is specified as one or more comma-separated keyword values:

`replace`

> The effect value overrides the underlying value of the property. This is the default value.

`add`

> The effect value builds on the underlying value of the property. This operation produces an additive effect. For animation types where the addition operation is not commutative, the order of the operands is the underlying value followed by the effect value.

`accumulate`

> The effect and underlying values are combined. For animation types where the addition operation is not commutative, the order of the operands is the underlying value followed by the effect value.

Description

Each property that is targeted by the @keyframes at-rule is associated with an effect stack. The value of the effect stack is calculated by combining the *underlying value* of a property in a CSS style rule with the *effect value* of that property in the keyframe. The `animation-composition` property helps to specify how to combine the underlying value with the effect value.

For example, in the CSS below, `blur(5px)` is the underlying value, and `blur(10px)` is the effect value. The `animation-composition` property specifies the operation to perform to produce the final effect value after compositing the effect of the underlying value and the effect value.

```
.icon:hover {
  filter: blur(5px);
  animation: 3s infinite pulse;
  animation-composition: add;
}

@keyframes pulse {
  0% {
    filter: blur(10px);
  }
  100% {
    filter: blur(20px);
  }
}
```

Consider different values for the `animation-composition` property in the above example. The final effect value in each of those cases will be calculated as explained below:

- With `replace`, `blur(10px)` will replace `blur(5px)` in the `0%` keyframe. This is the default behavior of the property.
- With `add`, the composite effect value in the `0%` keyframe will be `blur(5px) blur(10px)`.
- With `accumulate`, the composite effect value in `0%` keyframe will be `blur(15px)`.

> **Note:** A composite operation can also be specified in a keyframe. In that case, the specified composite operation is used for each property first within that keyframe and then on each property in the next keyframe.

Multiple values

When you specify multiple comma-separated values on an `animation-*` property, they will be applied to the animations in the order in which the `animation-name`s appear. If the number of animations and compositions differ, the values listed in the `animation-composition` property will cycle from the first to the last `animation-name`, looping until all the animations have an assigned `animation-composition` value. For more information, see Setting multiple animation property values.

Formal definition

Initial value	`replace`

Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
animation-composition =
  <single-animation-composition>#

<single-animation-composition> =
  replace     |
  add         |
  accumulate
```

This syntax reflects the latest standard as per CSS Animations Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Understanding the animation-composition values

The example below shows the effect of different `animation-composition` values side-by-side.

HTML

```
<div class="container">
  replace
  <div id="replace" class="target"></div>
</div>
<div class="container">
  add
  <div id="add" class="target"></div>
</div>
<div class="container">
  accumulate
  <div id="accumulate" class="target"></div>
</div>
```

CSS

```
body {
  display: flex;
  flex-wrap: wrap;
  gap: 3px;
}

.container {
  flex: 1;
  min-width: 200px;
  height: 200px;
  background: lightblue;
  display: inline-block;
  text-align: center;
}

.target {
  width: 20px;
  height: 50px;
  background: green;
  border-radius: 10px;
  margin: 20px 0;
}
```

```
@keyframes slide {
  50% {
    transform: translateY(30px);
  }
  100% {
    transform: translateX(150px);
  }
}

.target {
  transform: translateX(30px) rotate(45deg);
  animation: slide 5s linear infinite;
}
#replace {
  animation-composition: replace;
}
#add {
  animation-composition: add;
}
#accumulate {
  animation-composition: accumulate;
}
```

Result

The underlying value for the `transform` property in all cases is `translateX(30px) rotate(45deg)`. The different `animation-composition` values' effects are as follows:

- With `replace`, the `transform` property in each keyframe entirely replaces the underlying `transform` property set on the animated element. The final effect value for the `transform` property at the `50%` keyframe is `translateY(30px)` (no `rotate` or `translateX`); at the `100%` keyframe, it is `translateX(150px)` (no `rotate` or `translateY`).

  The target starts at `transform: translateX(30px) rotate(45deg)` and effectively animates to `transform: translateY(30px)`, then to `transform: translateX(150px)`.

- With `add`, the final effect value at each keyframe is the underlying `transform` value with the effect value placed immediately after it.

  Therefore, the target starts at `transform: translateX(30px) rotate(45deg)` and effectively animates first to `transform: translateX(30px) rotate(45deg) translateY(30px)` (which is `30px` "downwards" on the rotated Y-axis), and then to `transform: translateX(30px) rotate(45deg) translateX(150px)`. Since the additive operation is relative to the underlying `transform` and not the previous keyframe, there

is no `translateY(30px)` at `100%`, placing the element `150px` along the rotated X-axis from the original position.

- With `accumulate`, the final effect value is the keyframe's effect `transform` combined with the underlying original. At `50%`, `translateY(30px)` combines with the original `translateX(30px)` into a single translation (`translate(30px, 30px)`). At `100%`, the `translateX(150px)` combines with the original `translateX(30px)` to create `translateX(180px)`.

  Therefore, the target starts at `transform: translateX(30px) rotate(45deg)` and effectively animates first to `transform: translate(30px, 30px) rotate(45deg)`, and then to `transform: translateX(180px) rotate(45deg)`.

animation-delay CSS property

The **`animation-delay`** CSS property specifies the amount of time to wait from applying the animation to an element before beginning to perform the animation. The animation can start later, immediately from its beginning, or immediately and partway through the animation.

It is often convenient to use the shorthand property `animation` to set all animation properties at once.

Try it

```
animation-delay: 250ms;
```

```
animation-delay: 2s;
```

```
animation-delay: -2s;
```

```
<section class="flex-column" id="default-example">
  <div>Animation <span id="play-status"></span></div>
  <div id="example-element">Select a delay to start!</div>
</section>
```

```
#example-element {
  background-color: #1766aa;
  color: white;
  margin: auto;
  margin-left: 0;
  border: 5px solid #333333;
  width: 150px;
  height: 150px;
  border-radius: 50%;
  display: flex;
  justify-content: center;
  align-items: center;
  flex-direction: column;
}

#play-status {
  font-weight: bold;
}

.animating {
  animation-name: slide;
  animation-duration: 3s;
  animation-timing-function: ease-in;
  animation-iteration-count: 2;
  animation-direction: alternate;
}

@keyframes slide {
  from {
    background-color: orange;
    color: black;
    margin-left: 0;
  }
  to {
    background-color: orange;
    color: black;
    margin-left: 80%;
  }
}
```

```
const el = document.getElementById("example-element");
const status = document.getElementById("play-status");

function update() {
  status.textContent = "delaying";
  el.className = "";
  window.requestAnimationFrame(() => {
    window.requestAnimationFrame(() => {
      el.className = "animating";
    });
  });
}

el.addEventListener("animationstart", () => {
  status.textContent = "playing";
});

el.addEventListener("animationend", () => {
  status.textContent = "finished";
});

const observer = new MutationObserver(() => {
  update();
});
```

```
observer.observe(el, {
  attributes: true,
  attributeFilter: ["style"],
});

update();
```

Syntax

```
/* Single animation */
animation-delay: 3s;
animation-delay: 0s;
animation-delay: -1500ms;

/* Multiple animations */
animation-delay: 2.1s, 480ms;

/* Global values */
animation-delay: inherit;
animation-delay: initial;
animation-delay: revert;
animation-delay: revert-layer;
animation-delay: unset;
```

Values

This property is specified as a comma-separated list of `<time>` values:

`<time>`

> The time offset, from the moment at which the animation is applied to the element, at which the animation should begin. This may be specified in either seconds (`s`) or milliseconds (`ms`). The unit is required.
>
> A positive value indicates that the animation should begin after the specified amount of time has elapsed. A value of `0s`, which is the default, indicates that the animation should begin as soon as it's applied.
>
> A negative value causes the animation to begin immediately, but partway through its cycle. For example, if you specify `-1s` as the animation delay time, the animation will begin immediately but will start 1 second into the animation sequence. If you specify a negative value for the animation delay, but the starting value is implicit, the starting value is taken from the moment the animation is applied to the element.

> **Note:** When you specify multiple comma-separated values on an `animation-*` property, they are applied to the animations in the order in which the `animation-name`s appear. For situations where the number of animations and `animation-*` property values do not match, see Setting multiple animation property values.

> **Note:** `animation-delay` has no effect on CSS scroll-driven animations.

Formal definition

Initial value	`0s`
Applies to	all elements, `::before` and `::after` pseudo-elements
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
animation-delay =
  [ <'animation-delay-start'> <'animation-delay-end'>? ]#

<animation-delay-start> =
  <time>#

<animation-delay-end> =
  <time [0s,∞]>#
```

This syntax reflects the latest standard as per CSS Animations Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting an animation delay

This animation has a delay of 2 seconds.

HTML

```
<div class="box"></div>
```

CSS

```
.box {
  background-color: rebeccapurple;
  border-radius: 10px;
  width: 100px;
  height: 100px;
}

.box:hover {
  animation-name: rotate;
  animation-duration: 0.7s;
  animation-delay: 2s;
}

@keyframes rotate {
  0% {
    transform: rotate(0);
  }
  100% {
```

```
    transform: rotate(360deg);
  }
}
```

Result

Hover over the rectangle to start the animation.

See CSS animations for examples.

See also

- Using CSS animations
- JavaScript `AnimationEvent` API
- Other related animation properties: `animation`, `animation-composition`, `animation-direction`, `animation-duration`, `animation-fill-mode`, `animation-iteration-count`, `animation-name`, `animation-play-state`, `animation-timeline`, `animation-timing-function`

animation-direction CSS property

The **`animation-direction`** CSS property sets whether an animation should play forward, backward, or alternate back and forth between playing the sequence forward and backward.

It is often convenient to use the shorthand property `animation` to set all animation properties at once.

Try it

```
animation-direction: normal;
```

```
animation-direction: reverse;
```

```
animation-direction: alternate;
```

```
animation-direction: alternate-reverse;
```

```
<section class="flex-column" id="default-example">
  <div id="example-element"></div>
  <button id="play-pause">Play</button>
</section>
```

```
#example-element {
  animation-duration: 3s;
  animation-iteration-count: infinite;
  animation-name: slide;
  animation-play-state: paused;
  animation-timing-function: ease-in;
  background-color: #1766aa;
  border-radius: 50%;
  border: 5px solid #333333;
  color: white;
  height: 150px;
  margin: auto;
  margin-left: 0;
  width: 150px;
}

#example-element.running {
  animation-play-state: running;
}

#play-pause {
  font-size: 2rem;
}

@keyframes slide {
  from {
    background-color: orange;
    color: black;
    margin-left: 0;
  }
  to {
    background-color: orange;
    color: black;
    margin-left: 80%;
  }
}
```

```
const el = document.getElementById("example-element");
const button = document.getElementById("play-pause");

button.addEventListener("click", () => {
  if (el.classList.contains("running")) {
    el.classList.remove("running");
    button.textContent = "Play";
  } else {
    el.classList.add("running");
    button.textContent = "Pause";
  }
});
```

Syntax

```
/* Single animation */
animation-direction: normal;
animation-direction: reverse;
animation-direction: alternate;
animation-direction: alternate-reverse;

/* Multiple animations */
animation-direction: normal, reverse;
animation-direction: alternate, reverse, normal;
```

```
/* Global values */
animation-direction: inherit;
animation-direction: initial;
animation-direction: revert;
animation-direction: revert-layer;
animation-direction: unset;
```

Values

This property is specified as a comma-separated list of the following keyword values:

`normal`

The animation plays *forwards* each cycle. In other words, each time the animation cycles, the animation will reset to the beginning state and start over again. This is the default value.

`reverse`

The animation plays *backwards* each cycle. In other words, each time the animation cycles, the animation will reset to the end state and start over again. Animation steps are performed backwards, and easing functions are also reversed. For example, an `ease-in` easing function becomes `ease-out`.

`alternate`

The animation reverses direction each cycle, with the first iteration being played *forwards*. The count to determine if a cycle is even or odd starts at one.

`alternate-reverse`

The animation reverses direction each cycle, with the first iteration being played *backwards*. The count to determine if a cycle is even or odd starts at one.

> **Note:** When you specify multiple comma-separated values on an `animation-*` property, they are applied to the animations in the order in which the `animation-name`s appear. For situations where the number of animations and `animation-*` property values do not match, see Setting multiple animation property values.

> **Note:** When creating CSS scroll-driven animations, specifying an `animation-direction` works as expected, for example `reverse` causes the animation to run in reverse over the course of the timeline's progression. A value of `alternate` (combined with an `animation-iteration-count`) causes the animation to run forwards and backwards as the timeline is progressed.

Formal definition

Initial value	`normal`
Applies to	all elements, `::before` and `::after` pseudo-elements
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
animation-direction =
  <single-animation-direction>#

<single-animation-direction> =
  normal             |
  reverse            |
  alternate          |
  alternate-reverse
```

This syntax reflects the latest standard as per CSS Animations Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Reversing the animation direction

HTML

```
<div class="box"></div>
```

CSS

```
.box {
  background-color: rebeccapurple;
  border-radius: 10px;
  width: 100px;
  height: 100px;
}

.box:hover {
  animation-name: rotate;
  animation-duration: 0.7s;
  animation-direction: reverse;
}

@keyframes rotate {
  0% {
    transform: rotate(0);
  }
  100% {
    transform: rotate(360deg);
  }
}
```

Result

See CSS animations for examples.

See also

- Using CSS animations

- JavaScript `AnimationEvent` API
- Other related animation properties: `animation`, `animation-composition`, `animation-delay`, `animation-duration`, `animation-fill-mode`, `animation-iteration-count`, `animation-name`, `animation-play-state`, `animation-timeline`, `animation-timing-function`

animation-duration CSS property

The **`animation-duration`** CSS property sets the length of time that an animation takes to complete one cycle.

It is often convenient to use the shorthand property `animation` to set all animation properties at once.

Try it

```
animation-duration: 750ms;
```

```
animation-duration: 3s;
```

```
animation-duration: 0s;
```

```
<section class="flex-column" id="default-example">
  <div class="animating" id="example-element"></div>
  <button id="play-pause">Play</button>
</section>
```

```
#example-element {
  animation-direction: alternate;
  animation-iteration-count: infinite;
  animation-name: slide;
  animation-play-state: paused;
  animation-timing-function: ease-in;
  background-color: #1766aa;
  border-radius: 50%;
  border: 5px solid #333333;
  color: white;
  height: 150px;
  margin: auto;
  margin-left: 0;
  width: 150px;
}

#example-element.running {
  animation-play-state: running;
}

#play-pause {
  font-size: 2rem;
}

@keyframes slide {
  from {
    background-color: orange;
    color: black;
    margin-left: 0;
  }
  to {
    background-color: orange;
    color: black;
    margin-left: 80%;
  }
}
```

```
const el = document.getElementById("example-element");
const button = document.getElementById("play-pause");

button.addEventListener("click", () => {
  if (el.classList.contains("running")) {
    el.classList.remove("running");
    button.textContent = "Play";
  } else {
    el.classList.add("running");
    button.textContent = "Pause";
  }
});
```

Syntax

```
/* Single animation */
animation-duration: auto; /* Default */
animation-duration: 6s;
animation-duration: 120ms;

/* Multiple animations */
animation-duration: 1.64s, 15.22s;
animation-duration: 10s, 35s, 230ms;

/* Global values */
animation-duration: inherit;
animation-duration: initial;
animation-duration: revert;
animation-duration: revert-layer;
animation-duration: unset;
```

Values

This property is specified as a comma-separated list of the following values:

`auto`

For time-based animations, `auto` is equivalent to a value of `0s` (see below). For CSS scroll-driven animations, `auto` fills the entire timeline with the animation.

`<time>`

The time that an animation takes to complete one cycle. This may be specified in either seconds (`s`) or milliseconds (`ms`). The value must be positive or zero and the unit is required.

If no value is provided, the default value of `0s` is used, in which case the animation still executes (the `animationStart` and `animationEnd` events are fired). Whether or not the animation will be visible when the duration is `0s` will depend on the value of `animation-fill-mode`, as explained below:

- If `animation-fill-mode` is set to `backwards` or `both`, the first frame of the animation as defined by `animation-direction` will be displayed during `animation-delay` countdown.
- If `animation-fill-mode` is set to `forwards` or `both`, the last frame of the animation will be displayed, as defined by `animation-direction`, after the `animation-delay` expires.
- If `animation-fill-mode` is set to `none`, the animation will have no visible effect.

> **Note:** Negative values are invalid, causing the declaration to be ignored. Some early, prefixed, implementations may consider them as identical to `0s`.

> **Note:** When you specify multiple comma-separated values on an `animation-*` property, they are applied to the animations in the order in which the `animation-name`s appear. For situations where the number of animations and `animation-*` property values do not match, see Setting multiple animation property values.

> **Note:** When creating CSS scroll-driven animations, specifying an `animation-duration` value in seconds or milliseconds doesn't really make sense. In tests, it seemed to have no effect on scroll progress timeline animations, while on view progress timeline animations it seemed to push the animation to happen nearer the end of the timeline. However, Firefox requires an `animation-duration` to be set for it to successfully apply the animation. You are therefore advised to set `animation-duration` to `1ms` so that animations will work in Firefox, but the effect is not altered too much by it.

Formal definition

Initial value	`0s`
Applies to	all elements, `::before` and `::after` pseudo-elements
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
animation-duration =
  [ auto | <time [0s,∞]> ]#
```

This syntax reflects the latest standard as per CSS Animations Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting animation duration

This animation has an animation-duration of 0.7 seconds.

HTML

```
<div class="box"></div>
```

CSS

```
.box {
  background-color: rebeccapurple;
  border-radius: 10px;
  width: 100px;
  height: 100px;
}

.box:hover {
  animation-name: rotate;
  animation-duration: 0.7s;
}

@keyframes rotate {
  0% {
    transform: rotate(0);
  }
  100% {
    transform: rotate(360deg);
  }
}
```

Result

Hover over the rectangle to start the animation.

See CSS animations for more examples.

See also

- Using CSS animations
- JavaScript `AnimationEvent` API
- Other related animation properties: `animation`, `animation-composition`, `animation-delay`, `animation-direction`, `animation-fill-mode`, `animation-iteration-count`, `animation-name`, `animation-play-state`, `animation-timeline`, `animation-timing-function`

animation-fill-mode CSS property

The **`animation-fill-mode`** CSS property sets how a CSS animation applies styles to its target before and after its execution.

It is often convenient to use the shorthand property `animation` to set all animation properties at once.

Try it

```
animation-fill-mode: none;
animation-delay: 1s;
```

```
animation-fill-mode: forwards;
animation-delay: 1s;
```

```
animation-fill-mode: backwards;
animation-delay: 1s;
```

```
animation-fill-mode: both;
animation-delay: 1s;
```

```
<section class="flex-column" id="default-example">
  <div>Animation <span id="play-status"></span></div>
  <div id="example-element">Select a mode to start!</div>
</section>
```

```
#example-element {
  background-color: #1766aa;
  color: white;
  margin: auto;
  margin-left: 0;
  border: 5px solid #333333;
  width: 150px;
  height: 150px;
  border-radius: 50%;

  display: flex;
  justify-content: center;
  align-items: center;
  flex-direction: column;
}

#play-status {
  font-weight: bold;
}

.animating {
  animation: slide 1s ease-in 1;
}

@keyframes slide {
  from {
    background-color: orange;
    color: black;
    margin-left: 0;
  }
  to {
    background-color: orange;
    color: black;
    margin-left: 80%;
  }
}
```

```
const el = document.getElementById("example-element");
const status = document.getElementById("play-status");

function update() {
  status.textContent = "delaying";
  el.className = "";
  window.requestAnimationFrame(() => {
    window.requestAnimationFrame(() => {
      el.className = "animating";
    });
  });
}

el.addEventListener("animationstart", () => {
  status.textContent = "playing";
});

el.addEventListener("animationend", () => {
  status.textContent = "finished";
});

const observer = new MutationObserver(() => {
  update();
});

observer.observe(el, {
  attributes: true,
  attributeFilter: ["style"],
});

update();
```

Syntax

```
/* Single animation */
animation-fill-mode: none;
animation-fill-mode: forwards;
animation-fill-mode: backwards;
animation-fill-mode: both;

/* Multiple animations */
animation-fill-mode: none, backwards;
animation-fill-mode: both, forwards, none;

/* Global values */
animation-fill-mode: inherit;
animation-fill-mode: initial;
animation-fill-mode: revert;
```

```
animation-fill-mode: revert-layer;
animation-fill-mode: unset;
```

Values

This property is specified as a comma-separated list of the following keyword values:

`none`

The animation will not apply any styles to the target when it's not executing. The element will instead be displayed using any other CSS rules applied to it. This is the default value.

`forwards`

The target will retain the computed values set by the last keyframe encountered during execution. The last keyframe depends on the value of `animation-direction` and `animation-iteration-count`:

`animation-direction`	`animation-iteration-count`	last keyframe encountered
`normal`	even or odd	`100%` or `to`
`reverse`	even or odd	`0%` or `from`
`alternate`	even	`0%` or `from`
`alternate`	odd	`100%` or `to`
`alternate-reverse`	even	`100%` or `to`
`alternate-reverse`	odd	`0%` or `from`

Animated properties behave as if included in a set `will-change` property value. If a new stacking context was created during the animation, the target element retains the stacking context after the animation has finished.

`backwards`

The animation will apply the values defined in the first relevant keyframe as soon as it is applied to the target, and retain this during the `animation-delay` period. The first relevant keyframe depends on the value of `animation-direction`:

`animation-direction`	first relevant keyframe
`normal` or `alternate`	`0%` or `from`
`reverse` or `alternate-reverse`	`100%` or `to`

`both`

The animation will follow the rules for both forwards and backwards, thus extending the animation properties in both directions.

> **Note:** When you specify multiple comma-separated values on an `animation-*` property, they are applied to the animations in the order in which the `animation-name`s appear. For situations where the number of animations and `animation-*` property values do not match, see Setting multiple animation property values.

> **Note:** `animation-fill-mode` has the same effect when creating CSS scroll-driven animations as it does for regular time-based animations.

Formal definition

Initial value	none
Applies to	all elements, `::before` and `::after` pseudo-elements
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
animation-fill-mode =
  <single-animation-fill-mode>#

<single-animation-fill-mode> =
  none      |
  forwards  |
  backwards |
  both
```

This syntax reflects the latest standard as per CSS Animations Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting fill mode

You can see the effect of `animation-fill-mode` in the following example. It demonstrates how you can make the animation remain in its final state rather than reverting to the original state (which is the default).

HTML

```
<p>Move your mouse over the gray box!</p>
<div class="demo">
  <div class="grows-and-stays">This grows and stays big.</div>
  <div class="grows">This just grows.</div>
</div>
```

CSS

```
.demo {
  border-top: 100px solid #cccccc;
  height: 300px;
}

@keyframes grow {
  0% {
    font-size: 0;
```

```
  }
  100% {
    font-size: 40px;
  }
}

.demo:hover .grows {
  animation-name: grow;
  animation-duration: 3s;
}

.demo:hover .grows-and-stays {
  animation-name: grow;
  animation-duration: 3s;
  animation-fill-mode: forwards;
}
```

Result

See CSS animations for more examples.

See also

- JavaScript `AnimationEvent` API
- Other related animation properties: `animation`, `animation-composition`, `animation-delay`, `animation-direction`, `animation-duration`, `animation-iteration-count`, `animation-name`, `animation-play-state`, `animation-timeline`, `animation-timing-function`

animation-iteration-count CSS property

The **`animation-iteration-count`** CSS property sets the number of times an animation sequence should be played before stopping.

It is often convenient to use the shorthand property `animation` to set all animation properties at once.

Try it

```
animation-iteration-count: 0;
```

```
animation-iteration-count: 2;
```

```
animation-iteration-count: 1.5;
```

```
<section class="flex-column" id="default-example">
  <div>Animation <span id="play-status"></span></div>
  <div id="example-element">Select a count to start!</div>
</section>
```

```
#example-element {
  align-items: center;
  background-color: #1766aa;
  border-radius: 50%;
  border: 5px solid #333333;
  color: white;
  display: flex;
  flex-direction: column;
  height: 150px;
  justify-content: center;
  margin: auto;
  margin-left: 0;
  width: 150px;
}

#play-status {
  font-weight: bold;
}

.animating {
  animation-name: slide;
  animation-duration: 3s;
  animation-timing-function: ease-in;
}

@keyframes slide {
  from {
    background-color: orange;
    color: black;
    margin-left: 0;
  }
  to {
    background-color: orange;
    color: black;
    margin-left: 80%;
  }
}
```

```
const el = document.getElementById("example-element");
const status = document.getElementById("play-status");

function update() {
  status.textContent = "delaying";
  el.className = "";
  window.requestAnimationFrame(() => {
    window.requestAnimationFrame(() => {
      el.className = "animating";
    });
  });
}

el.addEventListener("animationstart", () => {
```

```
  status.textContent = "playing";
});

el.addEventListener("animationend", () => {
  status.textContent = "finished";
});

const observer = new MutationObserver(() => {
  update();
});

observer.observe(el, {
  attributes: true,
  attributeFilter: ["style"],
});

update();
```

Syntax

```
/* Keyword value */
animation-iteration-count: infinite;

/* <number> values */
animation-iteration-count: 3;
animation-iteration-count: 2.4;

/* Multiple values */
animation-iteration-count: 2, 0, infinite;

/* Global values */
animation-iteration-count: inherit;
animation-iteration-count: initial;
animation-iteration-count: revert;
animation-iteration-count: revert-layer;
animation-iteration-count: unset;
```

Values

This property is specified as one or more comma-separated values:

`infinite`

The animation will repeat forever.

`<number>`

The number of times the animation will repeat; this is `1` by default. You may specify non-integer values to play part of an animation cycle: for example, `0.5` will play half of the animation cycle. Negative values are invalid.

> **Note:** When you specify multiple comma-separated values on an `animation-*` property, they are applied to the animations in the order in which the `animation-name`s appear. For situations where the number of animations and `animation-*` property values do not match, see Setting multiple animation property values.

> **Note:** When creating CSS scroll-driven animations, specifying an `animation-iteration-count` causes the animation to repeat that number of times over the course of the timeline's progression. If an `animation-iteration-count` is not provided, the animation will only occur once. `infinite` is a valid value for scroll-driven animations, but it results in an animation that doesn't work.

Formal definition

Initial value	`1`
Applies to	all elements, `::before` and `::after` pseudo-elements
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
animation-iteration-count =
  <single-animation-iteration-count>#

<single-animation-iteration-count> =
  infinite       |
  <number [0,∞]>
```

This syntax reflects the latest standard as per CSS Animations Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting iteration count

This animation will run 10 times.

HTML

```
<div class="box"></div>
```

CSS

```
.box {
  background-color: rebeccapurple;
  border-radius: 10px;
  width: 100px;
  height: 100px;
}

.box:hover {
```

```
  animation-name: rotate;
  animation-duration: 0.7s;
  animation-iteration-count: 10;
}

@keyframes rotate {
  0% {
    transform: rotate(0);
  }
  100% {
    transform: rotate(360deg);
  }
}
```

Result

Hover over the rectangle to start the animation.

See CSS animations for examples.

See also

- Using CSS animations
- JavaScript `AnimationEvent` API
- Other related animation properties: `animation`, `animation-composition`, `animation-delay`, `animation-direction`, `animation-duration`, `animation-fill-mode`, `animation-name`, `animation-play-state`, `animation-timeline`, `animation-timing-function`

animation-name CSS property

The **`animation-name`** CSS property specifies the names of one or more `@keyframes` at-rules that describe the animation to apply to an element. Multiple `@keyframes` at-rules are specified as a comma-separated list of names. If the specified name does not match any `@keyframes` at-rule, no properties are animated.

It is often convenient to use the shorthand property `animation` to set all animation properties at once.

Try it

```
animation-name: none;
```

```
animation-name: slide;
```

```
animation-name: bounce;
```

```
<section class="flex-column" id="default-example">
  <div class="animating" id="example-element"></div>
</section>
```

```
#example-element {
  animation-direction: alternate;
  animation-duration: 1s;
  animation-iteration-count: infinite;
  animation-timing-function: ease-in;
  background-color: #1766aa;
  border-radius: 50%;
  border: 5px solid #333333;
  color: white;
  height: 150px;
  margin: auto;
  margin-left: 0;
  width: 150px;
}

@keyframes slide {
  from {
    background-color: orange;
    color: black;
    margin-left: 0;
  }
  to {
    background-color: orange;
    color: black;
    margin-left: 80%;
  }
}

@keyframes bounce {
  from {
    background-color: orange;
    color: black;
    margin-top: 0;
  }
  to {
    background-color: orange;
    color: black;
    margin-top: 40%;
  }
}
```

Syntax

```
/* No animation */
animation-name: none;

/* Single animation */
animation-name: test_05;
animation-name: -specific;
animation-name: "sliding-vertically";

/* Multiple animations */
animation-name: test1, animation4;
```

```
animation-name:
  none,
  -moz-specific,
  sliding;

/* Global values */
animation-name: inherit;
animation-name: initial;
animation-name: revert;
animation-name: revert-layer;
animation-name: unset;
```

Values

This property is specified as one or more comma-separated values:

`none`

A special keyword denoting no keyframes. It can be used to deactivate an animation without changing the ordering of the other identifiers, or to deactivate animations coming from the cascade.

`<custom-ident>`

An unquoted name identifying the animation. This identifier is composed of a combination of case-sensitive letters `a` to `z`, numbers `0` to `9`, underscores (_), and/or dashes (-). The first non-dash character must be a letter. Also, two dashes are forbidden at the beginning of the identifier. Furthermore, the identifier can't be `none`, `unset`, `initial`, or `inherit`.

`<string>`

A series of characters following the same rules as custom identifiers, as described above, except that they are surrounded by either double (") or single (') quotes. If using a quoted string for both the `animation-name` and the corresponding `@keyframes` at-rule name, `none`, global keywords, and names starting with an underscore or double dashes are valid, though not recommended.

> **Note:** When you specify multiple comma-separated values on an `animation-*` property, they are applied to the animations in the order in which the `animation-names` appear. For situations where the number of animations and `animation-*` property values do not match, see Setting multiple animation property values.

Formal definition

Initial value	none
Applies to	all elements, `::before` and `::after` pseudo-elements
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
animation-name =
  [ none | <keyframes-name> ]#

<keyframes-name> =
  <custom-ident>  |
  <string>
```

This syntax reflects the latest standard as per CSS Animations Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Naming an animation

This animation has an `animation-name` of `rotate`.

HTML

```
<div class="box"></div>
```

CSS

```
.box {
  background-color: rebeccapurple;
  border-radius: 10px;
  width: 100px;
  height: 100px;
}

.box:hover {
  animation-name: rotate;
  animation-duration: 0.7s;
}

@keyframes rotate {
  0% {
    transform: rotate(0);
  }
  100% {
    transform: rotate(360deg);
  }
}
```

Result

Hover over the rectangle to start the animation.

See CSS animations for examples.

See also

- Using CSS animations
- JavaScript `AnimationEvent` API

- Other related animation properties: `animation`, `animation-composition`, `animation-delay`, `animation-direction`, `animation-duration`, `animation-fill-mode`, `animation-iteration-count`, `animation-play-state`, `animation-timeline`, `animation-timing-function`

animation-play-state CSS property

The **`animation-play-state`** CSS property sets whether an animation is running or paused.

Resuming a paused animation will start the animation from where it left off at the time it was paused, rather than starting over from the beginning of the animation sequence.

Try it

```
animation-play-state: paused;
```

```
animation-play-state: running;
```

```
<section class="flex-column" id="default-example">
  <div class="animating" id="example-element"></div>
</section>
```

```
#example-element {
  background-color: #1766aa;
  color: white;
  margin: auto;
  margin-left: 0;
  border: 5px solid #333333;
  width: 150px;
  height: 150px;
  border-radius: 50%;
}

.animating {
  animation-name: slide;
  animation-duration: 3s;
  animation-timing-function: ease-in;
  animation-iteration-count: infinite;
  animation-direction: alternate;
}

@keyframes slide {
  from {
    background-color: orange;
    color: black;
    margin-left: 0;
  }
  to {
    background-color: orange;
    color: black;
    margin-left: 80%;
  }
}
```

Syntax

```
/* Single animation */
animation-play-state: running;
animation-play-state: paused;

/* Multiple animations */
animation-play-state: paused, running, running;

/* Global values */
animation-play-state: inherit;
animation-play-state: initial;
animation-play-state: revert;
animation-play-state: revert-layer;
animation-play-state: unset;
```

Values

This property is specified as a comma-separated list of the following keyword values:

`running`

The **animation** is currently **playing**.

`paused`

The **animation** is currently **paused**.

> **Note:** When you specify multiple comma-separated values on an `animation-*` property, they are applied to the animations in the order in which the `animation-name`s appear. For situations where the number of animations and `animation-*` property values do not match, see Setting multiple animation property values.

Formal definition

Initial value	`running`
Applies to	all elements, `::before` and `::after` pseudo-elements
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
animation-play-state =
  <single-animation-play-state>#
```

```
<single-animation-play-state> =
  running  |
  paused
```

This syntax reflects the latest standard as per CSS Animations Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Pausing an animation

This animation is paused, but runs when you hover over it.

HTML

```
<div class="box"></div>
```

CSS

```
.box {
  background-color: rebeccapurple;
  border-radius: 10px;
  width: 100px;
  height: 100px;
  animation-name: rotate;
  animation-duration: 0.7s;
  animation-iteration-count: infinite;
  animation-play-state: paused;
}

.box:hover {
  animation-play-state: running;
}

@keyframes rotate {
  0% {
    transform: rotate(0);
  }
  100% {
    transform: rotate(360deg);
  }
}
```

Result

Hover over the rectangle to play the animation.

See CSS animations for examples.

See also

- Using CSS animations
- JavaScript `AnimationEvent` API
- Other related animation properties: `animation`, `animation-composition`, `animation-delay`, `animation-direction`, `animation-duration`, `animation-fill-mode`, `animation-iteration-count`, `animation-name`, `animation-timeline`, `animation-timing-function`

animation-range CSS property

The **`animation-range`** CSS shorthand property is used to set the start and end of an animation's attachment range along its timeline, i.e., where along the timeline an animation will start and end.

Constituent properties

This property is a shorthand for the following CSS properties:

- `animation-range-start`
- `animation-range-end`

Syntax

```
/* Range start value only*/
/* Single value syntax */
animation-range: normal;
animation-range: 20%;
animation-range: 100px;
animation-range: cover;
animation-range: contain;
/* Two value syntax */
animation-range: cover 20%;
animation-range: contain 100px;

/* Range start and end values */
/* Two value syntax */
animation-range: normal 25%;
animation-range: 25% normal;
animation-range: 25% 50%;
animation-range: entry exit;
/* Three value syntax */
animation-range: cover cover 200px;
animation-range: 10% exit 90%;
animation-range: entry 10% 90%;
/* Four value syntax */
animation-range: cover 0% cover 200px;
animation-range: entry 10% exit 100%;

/* Global values */
animation-range: inherit;
animation-range: initial;
animation-range: revert;
animation-range: revert-layer;
animation-range: unset;
```

Values

The `animation-range` shorthand property is specified as one or more single animation ranges, separated by commas. Each animation range is specified as one to four space separated values composed of `<timeline-range-name>` values, `<length-percentage>` values, and/or the keyword `normal`.

`<animation-range-start>`

> The keyword `normal`, a `<length-percentage>`, a `<timeline-range-name>`, or a `<timeline-range-name> <length-percentage>` pair, representing the `animation-range-start`. If a `<timeline-range-name>` is set without a `<length-percentage>`, the `<length-percentage>` defaults to `0%`.

`<animation-range-end>`

> The keyword `normal`, a `<length-percentage>`, a `<timeline-range-name>`, or a `<timeline-range-name> <length-percentage>` pair, representing the `animation-range-end`. If a `<timeline-range-name>` is set without a `<length-percentage>`, the `<length-percentage>` defaults to `100%`.

Description

The `animation-range` shorthand property sets the `animation-range-start` and `animation-range-end` values, defining where along the animation timeline the animation will start and end. By default, the styles defined in a keyframe animation are only applied to an element while that element is being animated. When a keyframe animation is applied to an element depends on the animation timeline of that animation. By default, animations are only applied between the timeline's range start and range end. To apply the animation outside of this range, set the `animation-fill-mode` to `backwards`, `forwards`, or `both`. These three `animation-fill-mode` values apply the first keyframe styles until range start, the last keyframe styles after the animation ends, or both before and after, respectively.

The scroll port area known as the view progress visibility range is the area inside which the subject element of a named view progress timeline animation is deemed to be visible. By default, this is the full range of the scrollport, but it can be adjusted using the `view-timeline-inset` property.

If two values are specified as components of the `<animation-range>` property, they will be interpreted in the order `<animation-range-start>` then `<animation-range-end>`. The value of each component is either the keyword `normal`, a `<length-percentage>`, or a `<timeline-range-name>` optionally followed by a `<length-percentage>`. These values are space-separated. Normal is equal to `0%` for start and `100%` for end. Setting `normal` with a `<length-percentage>` for either the start or end range is invalid.

Defining range start and defaulting range end

When you define only the `<animation-range-start>`, either by setting a single `<length-percentage>`, a single `<timeline-range-name>`, or the keyword `normal`, or by specifying a single `<timeline-range-name>` followed by a single `<length-percentage>`, the computed value of the `<animation-range-end>` follows specific rules:

If the value is a single `<length-percentage>` or the keyword `normal`, this value defines the `<animation-range-start>` and the `<animation-range-end>` is implicitly set to `normal`. For example:

- `animation-range: 20%;` is the equivalent to `animation-range-start: 20%; animation-range-end: normal;`
- `animation-range: normal;` is the equivalent to `animation-range-start: normal; animation-range-end: normal;`

If the value is a single `<timeline-range-name>` (without a `<length-percentage>` following it), that timeline range name is applied to both the `<animation-range-start>` and `<animation-range-end>` components, and the ranges of `0%` and `100%`, respectively, are implied. For example:

- `animation-range: contain;` is equivalent to `animation-range-start: contain 0%; animation-range-end: contain 100%;`
- `animation-range: cover;` is equivalent to `animation-range-start: cover 0%; animation-range-end: cover 100%;`

If the value is a single `<timeline-range-name>` with a single `<length-percentage>` following it, in that order, the pair defines the `<animation-range-start>`, and the defined `<timeline-range-name>` is applied to the `<animation-range-end>` at `100%`. For example:

- `animation-range: cover 20%;` is equivalent to `animation-range-start: cover 20%; animation-range-end: cover 100%;`
- `animation-range: contain 100px;` is equivalent to `animation-range-start: contain 100px; animation-range-end: contain 100%;`

Explicitly defining both range start and range end with two values

If two or more values are included in your `animation-range` declaration and the values are anything other than a single `<timeline-range-name>` followed by a `<length-percentage>`, both `<animation-range-start>` and `<animation-range-end>` are explicitly set.

If you include two values and the first value is the keyword `normal` or a `<length-percentage>`, that value defines the `<animation-range-start>`, and the second value defines the `<animation-range-end>`. For example:

- `animation-range: normal 25%;` is equivalent to `animation-range-start: normal; animation-range-end: 25%;`
- `animation-range: 25% 50%;` is equivalent to `animation-range-start: 25%; animation-range-end: 50%;`
- `animation-range: 25% contain;` is equivalent to `animation-range-start: 25%; animation-range-end: contain 100%;`
- `animation-range: 25% normal;` is equivalent to `animation-range-start: 25%; animation-range-end: normal;`

Multiple animations

When specifying ranges for multiple animations, the `animation-range` shorthand property is specified as one or more single animation ranges, separated by commas. Each animation-range is applied to the animations in the order in which the `animation-name`s appear. For situations where the number of animations and the `animation-range` property values do not match, if there are more `animation-range` values than animations, the extra ranges are ignored. If there are more animations than ranges, the list of `animation-range` values are repeated until there is a corresponding range for each animation. For example, if we set `animation-range: 25% 75%, normal;`, the animation range of all the odd numbered animations `25% 75%` and all the even animations will be `0% 100%`.

Formal definition

Initial value	as each of the properties of the shorthand: • `animation-range-start`: `normal` • `animation-range-end`: `normal`
Applies to	all elements
Inherited	no
Percentages	Relative to the specified named timeline range if specified, otherwise relative to the entire timeline
Computed value	as each of the properties of the shorthand: • `animation-range-start`: A list where each item may be 'normal', a length percentage, or a timeline range name and a length percentage • `animation-range-end`: A list where each item may be 'normal', a length percentage, or a timeline range name and a length percentage
Animation type	as each of the properties of the shorthand: • `animation-range-start`: Not animatable • `animation-range-end`: Not animatable

Formal syntax

```
animation-range =
  [ <'animation-range-start'> <'animation-range-end'>? ]#
```

```
<animation-range-start> =
  [ normal | <length-percentage> | <timeline-range-name> <length-percentage>? ]#

<animation-range-end> =
  [ normal | <length-percentage> | <timeline-range-name> <length-percentage>? ]#

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4, Scroll-driven Animations. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage of the <code>animation-range</code> property

In this example, we reduce the duration of the view progress scroll animation by using the `animation-range` property to offset the start and end of the animation, and demonstrate the effect of the `animation-fill-mode` property on shortened animation timelines.

HTML

In the middle of a wall of text, we include an element that we will animate. We include a lot of text to ensure that our content overflows its container, but this is hidden for the sake of brevity. We also include a checkbox to toggle the `animation-fill-mode` property on and off, to demonstrate its effect on shortened animation timelines. This is also hidden.

```
<div class="content">
  <h1>Content</h1>

  <p>
    Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod
    tempor incididunt ut labore et dolore magna aliqua. Risus quis varius quam
    quisque id. Et ligula ullamcorper malesuada proin libero nunc consequat
    interdum varius. Elit ullamcorper dignissim cras tincidunt lobortis feugiat
    vivamus at augue.
  </p>

  <p>
    Dolor sed viverra ipsum nunc aliquet. Sed sed risus pretium quam vulputate
    dignissim. Tortor aliquam nulla facilisi cras. A erat nam at lectus urna
    duis convallis convallis. Nibh ipsum consequat nisl vel pretium lectus.
    Sagittis aliquam malesuada bibendum arcu vitae elementum. Malesuada bibendum
    arcu vitae elementum curabitur vitae nunc sed velit.
  </p>
```

```
<div class="animatedElement"></div>
```

```
  <p>
    Adipiscing enim eu turpis egestas pretium aenean pharetra magna ac. Arcu
    cursus vitae congue mauris rhoncus aenean vel. Sit amet cursus sit amet
    dictum. Augue neque gravida in fermentum et. Gravida rutrum quisque non
    tellus orci ac auctor augue mauris. Risus quis varius quam quisque id diam
    vel quam elementum. Nibh praesent tristique magna sit amet purus gravida
    quis. Duis ultricies lacus sed turpis tincidunt id aliquet. In egestas erat
    imperdiet sed euismod nisi. Eget egestas purus viverra accumsan in nisl nisi
    scelerisque. Netus et malesuada fames ac.
  </p>
  <label>
    <input type="checkbox" /> Add <code>animation-fill-mode: both;</code>
  </label>
</div>
```

CSS

We define an animation that animates an element's opacity, scale, and background color, causing it to fade in, scale up, and change color as the animation progresses. We apply this animation to the `animatedElement` with the `animation` shorthand.

A view progress timeline is created by setting the `view()` function as the value of the `animation-timeline` property on our `animatedElement`. The result is that the element animates as it moves upwards through the document as it is scrolled. We declare `animation-timeline` property after the shorthand, as the shorthand resets this property.

Lastly, an `animation-range` declaration is set to make the animation begin later than expected and finish earlier.

```
.animatedElement {
  background-color: deeppink;
  animation: appear 1ms linear;
  animation-timeline: view();
  animation-range: entry 10% exit -25%;
}

@keyframes appear {
  from {
    background-color: rebeccapurple;
    opacity: 0;
    transform: scaleX(0);
  }

  to {
    background-color: darkturquoise;
    opacity: 0.75;
    transform: scaleX(0.75);
  }
}
```

We also include conditional styling: when the checkbox is checked, the `animation-fill-mode` property gets applied to the animated element:

```
:has(:checked) .animatedElement {
  animation-fill-mode: both;
}
```

The other styles are hidden for the sake of brevity.

```
.animatedElement {
  width: 300px;
  height: 200px;
  margin: 0 auto;
  background-color: deeppink;
}

:has(:checked) .animatedElement {
  animation-fill-mode: both;
}

.content {
  width: 75%;
  max-width: 800px;
  margin: 0 auto;
}

p,
h1 {
  font-family: "Helvetica", "Arial", sans-serif;
}

h1 {
  font-size: 3rem;
}

p {
  font-size: 1.5rem;
  line-height: 1.5;
}
@supports not (animation-range: normal) {
  body::before {
    content: "Your browser does not support the 'animation-range' property.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

Result

Scroll to see the element being animated.

Note how the `from`, or `0%`, keyframe property values are not applied to the animated element until the top block border edge is `10%` past the container's bottom edge; it is full size, fully opaque, and magenta. At that point, the animation is applied and it is styled with the values defined by the `0%` keyframe selector. When the `animation-range-end` is reached, 25% from the top of the scrollport, it jumps back to its original styling.

Generally, you will want to set `animation-fill-mode: both` when creating scroll-driven animations. The jump to the default state occurs because we did not set the `animation-fill-mode` property on the element, which can be used to apply an animation's styles to an element before and after the animation's execution. We initially omitted the property in this example to better enable visualizing the effects of `animation-range`.

Check the checkbox to apply the `animation-fill-mode` property to the animated element in then re-scroll: the animation styles should now be continuously applied.

animation-range-end CSS property

The **`animation-range-end`** CSS property sets the point on the timeline where an animation should end.

Syntax

```
/* Keyword or length percentage value */
animation-range-end: normal;
animation-range-end: 80%;
animation-range-end: 700px;

/* Named timeline range value */
animation-range-end: cover;
animation-range-end: contain;
animation-range-end: cover 80%;
animation-range-end: contain 700px;

/* Multiple values */
animation-range-end:
  cover 80%,
  contain 700px;

/* Global values */
animation-range-end: inherit;
animation-range-end: initial;
animation-range-end: revert;
animation-range-end: revert-layer;
animation-range-end: unset;
```

Values

This property is specified as a comma-separated list of values. Each value can be one of the following:

`normal`

Represents the end of the timeline. This is the default value.

`<length-percentage>`

Specifies a length or percentage value measured from the beginning of the timeline.

`<timeline-range-name>`

Specifies a named timeline range within the overall timeline. The range ends at `100%`.

`<timeline-range-name> <length-percentage>`

Specifies a length or percentage value measured from the beginning of the specified named timeline range.

Description

The `animation-range-end` property specifies the end of the animation's attachment range. Changing the end of the attachment range can potentially shift the end of the animation, that is, the point where keyframes mapped to `100%` progress land when the iteration count is `1`, and can also reduce the effective duration of the animation.

The property value can be `normal`, a `<length-percentage>`, or a `<timeline-range-name>` with an optional `<length-percentage>`. If the `<timeline-range-name>` value does not include a `<length-percentage>`, the percentage defaults to `100%`.

When specifying multiple comma-separated values, they apply to the animations in the order in which the `animation-name` values appear. See Setting multiple animation property values.

The `animation-range-end` property is included in the `animation` shorthand as a reset-only value. This means that using the `animation` shorthand resets any previously declared `animation-range-end` value to `normal`; the shorthand cannot be used to set a new `animation-range-end` value. When creating CSS scroll-driven animations, you should declare `animation-range-end` *after* declaring any `animation` shorthand to avoid resetting the value to `normal`.

The `animation-range-end` property, along with the `animation-range-start` property, can also be set by using the `animation-range` shorthand.

Formal definition

Initial value	`normal`
Applies to	all elements
Inherited	no
Percentages	Relative to the specified named timeline range if specified, otherwise relative to the entire timeline
Computed value	A list where each item may be 'normal', a length percentage, or a timeline range name and a length percentage
Animation type	Not animatable

Formal syntax

```
animation-range-end =
  [ normal | <length-percentage> | <timeline-range-name> <length-percentage>? ]#

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4, Scroll-driven Animations. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Creating a view progress timeline with a range end

In this example, the `animation-range-end` is applied to an element animated via a view progress timeline. This makes the animation reach its last keyframe well before the element reaches the end of it's containing viewport.

HTML

```
<div class="content">
  <h1>Content</h1>

  <p>
    Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod
    tempor incididunt ut labore et dolore magna aliqua. Risus quis varius quam
    quisque id. Et ligula ullamcorper malesuada proin libero nunc consequat
    interdum varius. Elit ullamcorper dignissim cras tincidunt lobortis feugiat
    vivamus at augue.
  </p>

  <p>
    Dolor sed viverra ipsum nunc aliquet. Sed sed risus pretium quam vulputate
    dignissim. Tortor aliquam nulla facilisi cras. A erat nam at lectus urna
    duis convallis convallis. Nibh ipsum consequat nisl vel pretium lectus.
    Sagittis aliquam malesuada bibendum arcu vitae elementum. Malesuada bibendum
    arcu vitae elementum curabitur vitae nunc sed velit.
  </p>
</div>
```

In the middle of a long block of text, we've included an element that we'll animate. We've added a lot of text to ensure that the content overflows its container; the extra text is hidden here for brevity.

```
<div class="animatedElement">
```

```
<p>
  Adipiscing enim eu turpis egestas pretium aenean pharetra magna ac. Arcu
  cursus vitae congue mauris rhoncus aenean vel. Sit amet cursus sit amet
  dictum. Augue neque gravida in fermentum et. Gravida rutrum quisque non tellus
  orci ac auctor augue mauris. Risus quis varius quam quisque id diam vel quam
  elementum. Nibh praesent tristique magna sit amet purus gravida quis. Duis
  ultricies lacus sed turpis tincidunt id aliquet. In egestas erat imperdiet sed
  euismod nisi. Eget egestas purus viverra accumsan in nisl nisi scelerisque.
  Netus et malesuada fames ac.
</p>
<p>
```

We've also included a checkbox that will toggle the `animation-fill-mode` property, so you can see how this property affects animations with shortened timelines.

```
<label>
  <input type="checkbox" /> Add <code>animation-fill-mode: forwards;</code>
</label>
```

```
  </p>
</div>
```

CSS

We've defined a view progress timeline by setting a `view()` function as the value of the `animation-timeline` property. This is declared **after** the `animation` shorthand to avoid resetting the longhand property value.

We've also set `animation-range-end` to make the animation end earlier than expected.

```
.animatedElement {
  background-color: deeppink;
  animation: appear 1ms linear;
  animation-timeline: view();
  animation-range-end: exit 25%;
}

@keyframes appear {
  from {
    background-color: rebeccapurple;
    opacity: 0;
    transform: scaleX(0);
  }

  to {
    background-color: darkturquoise;
    opacity: 0.75;
    transform: scaleX(0.75);
  }
}
```

When the checkbox is checked, the `animation-fill-mode` property gets applied to the animated element:

```
:has(:checked) .animatedElement {
  animation-fill-mode: forwards;
}
```

The other styles applied in this example has been hidden here for brevity.

```
.animatedElement {
  width: 300px;
  height: 200px;
  margin: 0 auto;
  background-color: deeppink;
}

:has(:checked) .animatedElement {
  animation-fill-mode: both;
}

.content {
  width: 75%;
  max-width: 800px;
  margin: 0 auto;
}

p,
h1 {
  font-family: "Helvetica", "Arial", sans-serif;
}

h1 {
  font-size: 3rem;
}

p {
  font-size: 1.5rem;
  line-height: 1.5;
}
@supports not (animation-range-end: normal) {
  body::before {
    content: "Your browser does not support the 'animation-range-end' property.";
    color: black;
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

Result

Scroll to see the element animate. Then toggle the checkbox at the end of the block of text and scroll again. Notice how the element finishes animating when it is 75% of the way through the viewport, and how it returns to its default state at that point when the `animation-fill-mode` property is not applied.

- CSS scroll-driven animations module
- View progress timeline: Ranges and animation progress visualizer

animation-range-start CSS property

The **`animation-range-start`** CSS property sets the point on the timeline where an animation should start.

Syntax

```
/* Keyword or length percentage value */
animation-range-start: normal;
animation-range-start: 20%;
animation-range-start: 100px;

/* Named timeline range value */
animation-range-start: cover;
animation-range-start: contain;
animation-range-start: cover 20%;
animation-range-start: contain 100px;

/* Multiple values */
animation-range-start:
  cover 20%,
  contain 100px;

/* Global values */
animation-range-start: inherit;
animation-range-start: initial;
animation-range-start: revert;
animation-range-start: revert-layer;
animation-range-start: unset;
```

Values

This property is specified as a comma-separated list of values. Each value can be one of the following:

`normal`

Represents the start of the timeline. This is the default value.

`<length-percentage>`

Specifies a length or percentage value measured from the beginning of the timeline.

`<timeline-range-name>`

Specifies a named timeline range within the overall timeline. The range starts at `0%`.

`<timeline-range-name> <length-percentage>`

Specifies a length or percentage value measured from the beginning of the specified named timeline range.

Description

Allowed values for the `animation-range-start` property are `normal`, a `<length-percentage>`, a `<timeline-range-name>`, or a `<timeline-range-name>` followed by a `<length-percentage>`. If the `<timeline-range-name>` value does not include a `<length-percentage>`, the percentage defaults to `0%`.

See `animation-range` for a detailed description of the available values.

When specifying multiple comma-separated values, they apply to the animations in the order in which the `animation-name` values appear. See Setting multiple animation property values.

The `animation-range-start` is included in the `animation` shorthand as a reset-only value. This means that using the `animation` shorthand resets any previously declared `animation-range-start` value of equal or lower specificity to `normal`; the shorthand cannot be used to set a new `animation-range-start` value. When creating CSS scroll-driven animations, you should declare `animation-range-start` *after* declaring any `animation` shorthand to avoid resetting the value to `normal`.

The `animation-range-start`, along with the `animation-range-end` property, can also be set using the `animation-range` shorthand.

Formal definition

Initial value	`normal`
Applies to	all elements
Inherited	no
Percentages	Relative to the specified named timeline range if specified, otherwise relative to the entire timeline
Computed value	A list where each item may be 'normal', a length percentage, or a timeline range name and a length percentage
Animation type	Not animatable

Formal syntax

```
animation-range-start =
  [ normal | <length-percentage> | <timeline-range-name> <length-percentage>? ]#

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4, Scroll-driven Animations. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Creating a scroll progress timeline with range start

In this example, the `animation-range-start` is applied to an element animated via a scroll progress timeline. This makes the animation start well before the element enters the scrollport.

HTML

```
<div class="content">
  <h1>Content</h1>

  <p>
    Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod
    tempor incididunt ut labore et dolore magna aliqua. Risus quis varius quam
    quisque id. Et ligula ullamcorper malesuada proin libero nunc consequat
    interdum varius. Elit ullamcorper dignissim cras tincidunt lobortis feugiat
    vivamus at augue.
  </p>

  <p>
    Dolor sed viverra ipsum nunc aliquet. Sed sed risus pretium quam vulputate
    dignissim. Tortor aliquam nulla facilisi cras. A erat nam at lectus urna
    duis convallis convallis. Nibh ipsum consequat nisl vel pretium lectus.
    Sagittis aliquam malesuada bibendum arcu vitae elementum. Malesuada bibendum
    arcu vitae elementum curabitur vitae nunc sed velit.
  </p>
```

In the middle of a long block of text, we've included an element that we'll animate. We've added a lot of text to ensure that the content overflows its container; the extra text is hidden here for brevity.

```
<div class="animatedElement"></div>
```

```
<p>
  Adipiscing enim eu turpis egestas pretium aenean pharetra magna ac. Arcu
  cursus vitae congue mauris rhoncus aenean vel. Sit amet cursus sit amet
  dictum. Augue neque gravida in fermentum et. Gravida rutrum quisque non
  tellus orci ac auctor augue mauris. Risus quis varius quam quisque id diam
  vel quam elementum. Nibh praesent tristique magna sit amet purus gravida
  quis. Duis ultricies lacus sed turpis tincidunt id aliquet. In egestas erat
  imperdiet sed euismod nisi. Eget egestas purus viverra accumsan in nisl nisi
  scelerisque. Netus et malesuada fames ac.
</p>
</div>
```

CSS

A scroll progress timeline is defined using setting a `scroll()` function as the value of the `animation-timeline` property. This is declared **after** the `animation` shorthand to avoid resetting the longhand property value.

We've also set `animation-range-start` to make the animation start earlier than expected.

```
.animatedElement {
  background-color: deeppink;

  animation: appear 1ms linear;

  animation-timeline: scroll();
  animation-range-start: -25%;
}

@keyframes appear {
  from {
    background-color: rebeccapurple;
    opacity: 0;
    transform: scaleX(0);
  }

  to {
    background-color: darkturquoise;
    opacity: 0.75;
    transform: scaleX(0.75);
  }
}
```

Other styles applied in this example have been hidden here for brevity.

```
.animatedElement {
  height: 200px;
  margin: 0 auto;
  background-color: deeppink;
}

.content {
  width: 75%;
  max-width: 800px;
  margin: 0 auto;
}

p,
h1 {
  font-family: "Helvetica", "Arial", sans-serif;
}

h1 {
  font-size: 3rem;
}

p {
  font-size: 1.5rem;
  line-height: 1.5;
}

@supports not (animation-range-start: normal) {
  body::before {
    content: "Your browser does not support the 'animation-range-start' property.";
    color: black;
    background-color: wheat;
```

```
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

Result

Scroll to see the element animate. Notice how the element is already scaled and semi-opaque as it enters the viewport. This is because the element started animating well before it entered the viewport.

animation-timeline CSS property

The **`animation-timeline`** CSS property specifies the timeline used to control the progress of a CSS animation.

Syntax

```
/* Keyword values */
animation-timeline: none;
animation-timeline: auto;

/* Named timeline */
animation-timeline: --timeline_name;

/* Anonymous scroll progress timeline */
animation-timeline: scroll();
animation-timeline: scroll(x root);

/* Anonymous view progress timeline */
animation-timeline: view();
animation-timeline: view(inline);
animation-timeline: view(x 200px auto);

/* Multiple values */
animation-timeline: --progress-bar-timeline, --carousel-timeline;
animation-timeline: auto, view(20% 80%), none, scroll(inline nearest);

/* Global values */
animation-timeline: inherit;
animation-timeline: initial;
animation-timeline: revert;
animation-timeline: revert-layer;
animation-timeline: unset;
```

Values

The `animation-timeline` property is specified as one or more comma-separated values, each of which can be one of the following:

`none`

The animation is not associated with a timeline, and no animation occurs.

`auto`

The animation's timeline is the document's default `DocumentTimeline`. This is the default value.

`scroll()`

Defines the root element, nearest scroller, or self as an anonymous scroll progress timeline, and optionally the scroll direction of the scroller.

`view()`

Defines the nearest ancestor scroll container as an anonymous view progress timeline, optionally overriding the default `baseline` axis direction and the `auto` start and ending insets.

`<dashed-ident>`

The name of a scroll-driven or view-progress timeline, as defined by the scroll container's `scroll-timeline-name` or `view-timeline-name` property (or the `scroll-timeline` or `view-timeline` shorthand property).

Description

The default timeline for a CSS keyframe animation is the time-based `DocumentTimeline`. The `animation-timeline` property can be used to set a named or anonymous scroll progress or view progress timeline. Alternatively, it can be used to explicitly set the default time-based document timeline to control the progress of an element's animation or to have no timeline at all, in which case the element does not animate.

The following types of timelines can be set via `animation-timeline`:

`DocumentTimeline`

The default document timeline, which is progressed through by the passing of time since the document was first loaded in the browser. This is the timeline traditionally associated with CSS animations and is selected with a value of `auto`, or by not specifying an `animation-timeline` value at all, as this is the default value.

Scroll progress timeline

The animation is progressed through by scrolling a scrollable element, or *scroller*, horizontally or vertically. The element that provides the scroll progress timeline can be specified in two ways:

Named scroll progress timeline

The scroller is explicitly named by setting the `scroll-timeline-name` property (or the `scroll-timeline` shorthand property) to a `<dashed-ident>`; that `<dashed-ident>` name is then set as the value of the `animation-timeline` property.

Anonymous scroll progress timeline

The `animation-timeline` property of the element to animate is set to the `scroll()` function. The function's two optional parameters define the scroller providing the scroll progress timeline and the scroll axis to be used.

View progress timeline

A keyframe animation is progressed through based on the change in visibility of an element inside a scroller; this element is known as the *subject*. By default, the timeline is at `0%` when the element first becomes visible at one edge of the scroller, and is at `100%` when its end edge exits the scroller's opposite edge. A view progress timeline can be specified in two ways:

Named view progress timeline

The subject is explicitly named by setting the `view-timeline-name` property (or the `view-timeline` shorthand property) to a `<dashed-ident>`. When you set the `animation-timeline` property of the element to animate to that `<dashed-ident>`, the subject's visibility controls the progression of the element's animation. Note that the element to animate does not have to be the same as the subject.

Anonymous view progress timeline

The `animation-timeline` property of the element to animate is set to a `view()` function, causing it to be animated based on its visibility within the scrollport of its nearest parent scroller.

No timeline

All animation timelines can be removed by selecting a value of `none`. When `animation-timeline: none` is set, no animation will occur as there is no timeline to follow.

The `animation-timeline` property is included in the `animation` shorthand as a reset-only value. This means that including `animation` resets a previously-declared `animation-timeline` value to `auto`. As this component of the shorthand is reset-only, a specific value cannot be set via `animation`. When creating CSS scroll-driven animations, you need to declare `animation-timeline` after declaring any `animation` shorthand for it to take effect.

If you specify multiple comma-separated values, each `animation-timeline` value is applied to a single animation in the order in which the `animation-name` values appear. If the number of values in the `animation-timeline` declaration is greater than the number of `animation-name` values, the excess timeline values are ignored. If there are fewer `animation-timeline` values than `animation-name` values, the `animation-timeline` values are repeated, in order, until every `animation-name` has an associated timeline.

If two or more timelines share the same `<dashed-ident>` name and the same specificity, the one last declared within the cascade will be used. If no timeline is found that matches a name included within the `animation-timeline`, the `animation-name` associated with that value is not associated with a timeline.

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	no
Computed value	a list, each item either a case-sensitive CSS identifier or the keywords `none`, `auto`
Animation type	Not animatable

Formal syntax

```
animation-timeline =
  <single-animation-timeline>#

<single-animation-timeline> =
  auto            |
  none            |
  <dashed-ident>  |
  <scroll()>      |
  <view()>

<scroll()> =
  scroll( [ <scroller> || <axis> ]? )

<view()> =
  view( [ <axis> || <'view-timeline-inset'> ]? )

<scroller> =
  root     |
  nearest  |
  self

<axis> =
  block   |
  inline  |
  x       |
  y

<view-timeline-inset> =
  [ [ auto | <length-percentage> ]{1,2} ]#

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Animations Level 2, CSS Values and Units Module Level 4, Scroll-driven Animations. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates basic usage of the `animation-timeline` property, along with the `none`, `auto`, and default (`auto`) values.

HTML

We have an `<article>` with three `<section>` children. Each `<section>` has a unique `id` and a `<div>` child.

```
<article>
  <section id="none">
    <div></div>
  </section>
  <section id="auto">
    <div></div>
  </section>
  <section id="default">
    <div></div>
```

```
  </section>
</article>
```

CSS

We use flexible box layout to set the three sections side-by-side. We use generated content to display the `id`. We style all elements the same, applying the `rotate` `@keyframes` animation that rotates the element by 1 full turn. Using the `animation` shorthand, we declare infinite, 2-second, linearly progressing iterations of the `rotate` animation, alternating the direction of each animation.

```
article {
  display: flex;
  gap: 10px;
  text-align: center;
}
section {
  background-color: beige;
  padding: 20px;
}
section::after {
  content: attr(id);
  display: block;
}
div {
  height: 100px;
  width: 100px;
  background-color: magenta;
  animation: rotate 2s infinite alternate linear;
}
@keyframes rotate {
  to {
    rotate: 1turn;
  }
}
```

The only difference is the `animation-timeline` declaration (or lack thereof in the case of `default`) for each `<div>`.

```
#none div {
  animation-timeline: none;
}
#auto div {
  animation-timeline: auto;
}
```

```
@layer no-support {
  @supports not (animation-timeline: none) {
    body::before {
      content: "Your browser doesn't support the `animation-timeline` property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

Because the `animation-timeline` property is included in the `animation` shorthand as a reset-only value, the `animation-timeline` must come after the `animation` shorthand, or be applied with greater specificity than the `animation` shorthand, to be applied.

Results

Note that declaring a value of `auto` has the same effect as allowing the `animation-timeline` to default to that value, and that `none` removes all timelines from the element, so no animation in the `none` case.

Setting a named scroll progress timeline

In this example, the animation timeline is set to a horizontal scroll progress timeline.

HTML

Our container includes three stretcher elements which will be wide enough to ensure our container is a scroll container. The middle one contains a shape that we will animate.

```
<div id="container">
  <div class="stretcher"></div>
  <div class="stretcher">
    <div id="shape"></div>
  </div>
  <div class="stretcher"></div>
</div>
```

CSS

We define the container as a flex container, setting a `width` on the container that is half the width of it's combined flex children. Adding an `overflow-x` value of `scroll` sets it to have a horizontal scrollbar.

Our scroll progress timeline, defined using the `scroll-timeline-name` and `scroll-timeline-axis` properties, is named `--square-timeline`. This timeline is applied to our `#shape` element using `animation-timeline: --square-timeline`.

```
#container {
  display: flex;
  width: 300px;
  border: 1px solid;

  overflow-x: scroll;
  scroll-timeline-axis: inline;
  scroll-timeline-name: --square-timeline;
}

.stretcher {
  flex: 0 0 200px;
}
```

The CSS below defines a square that rotates in alternate directions according to the timeline provided by the `animation-timeline` property, which is set to the `--square-timeline` timeline named above. The animation is set two occur twice, in alternating directions, as it passes through the viewport. We added notched corners to make the animation effect more apparent.

```
#shape {
  background-color: deeppink;
  width: 100px;
  height: 100px;
  border-radius: 25px;
  corner-shape: notch;

  animation: rotateAnimation 1ms linear 2 alternate;
  animation-timeline: --square-timeline;
}

@keyframes rotateAnimation {
  from {
    transform: rotate(0deg);
  }
  to {
    transform: rotate(360deg);
  }
}
```

```
@layer no-support {
  @supports not (animation-timeline: --square-timeline) {
    body::before {
      content: "Your browser doesn't support named animation timelines.";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

Result

Scroll to see the element being animated.

Setting an anonymous scroll progress timeline

This example expands on the previous one, applying an anonymous scroll progress timeline using the `scroll()` function.

CSS

We include all the CSS from the previous example, only setting the `animation-timeline` property to override the previous example's value. The timeline is provided by the `scroll(inline nearest)` value, which selects the scrollbar in the inline direction of the nearest ancestor element that has scrollbars. This is the vertical scrollbar of the `#container` element, as the `.stretcher` elements don't have overflowing content and therefore aren't scroll containers.

```
#shape {
  animation-timeline: scroll(inline nearest);
}
```

```
@layer no-support {
  @supports not (animation-timeline: scroll()) {
    body::before {
      content: "Your browser doesn't support the scroll() function.";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

Result

Scroll to see the square element being animated.

Setting a named view progress timeline

In this example, we demonstrate how to create and apply a named view progress timeline. Two elements will be animated, with different elements serving as the scroller.

HTML

```
<main class="scroller">
  <div class="container">
    <h1>Directions</h1>
    <h2>Lincoln Memorial to Martin Luther King, Jr. Memorial</h2>
    <ol>
      <li>Head south on Lincoln Memorial Circle</li>
      <li>Turn right toward Independence Ave</li>
      <li>Turn left onto Independence Ave</li>
      <li>Turn right onto West Basin Dr</li>
      <li>Look up when you reach 64 Independence Ave!</li>
    </ol>
    <section>
```

Our HTML includes a lot of text in a container within a scroller, which we've hidden for brevity. In the middle of the wall of text, we include two `<div>` elements that we will animate based on the visibility of the element itself in the first case and based on the visibility of its parent in the second case:

```
<div class="animated-element self">SELF</div>
<div class="animated-element parent">PARENT</div>
```

```
</section>
<h2>Martin Luther King, Jr. Memorial to Lincoln Memorial</h2>
<ol>
  <li>Head north toward Independence Ave SW</li
  ><li>Turn left onto Independence Ave</li
```

```
  ><li>Turn right toward the Korean War Veterans Memorial</li
  ><li>Take a photo of the memorial as you walk past it.</li
  ><li>Head north on Lincoln Memorial Circle</li
  ><li>Look up. You can't miss it!</li>
</ol>
  </div>
</main>
```

CSS

We create a keyframe animation that changes the opacity and scale of the element, and apply it to both animated elements:

```
@keyframes animation-effect {
  0% {
    opacity: 0;
    scale: 0;
  }
  100% {
    opacity: 1;
    scale: 1;
  }
}

.animated-element {
  animation: animation-effect 1ms linear;
}
```

The `self` element is explicitly named as the scroller for itself by setting the `view-timeline-name` property to a `<dashed-ident>` and also setting that `<dashed-ident>` name as the value of the `animation-timeline` property. In the `parent` case, we set the `container` as the scroller for the animated element:

```
.self {
  view-timeline-name: --self-scroller-element;
  animation-timeline: --self-scroller-element;
}
.container {
  view-timeline-name: --parent-scroller-element;
}
.parent {
  animation-timeline: --parent-scroller-element;
}
```

Additional CSS declarations were hidden for brevity.

```
@layer setup {
  section {
    display: flex;
    gap: 10px;
  }
  main {
    width: 400px;
    padding: 1em;
    height: 300px;
    overflow: scroll;
    border: 1px solid;
    background-color: beige;
    font-family: sans-serif;
  }

  li {
    margin-bottom: 0.75lh;
  }

  .animated-element {
    height: 200px;
    width: calc(100% - 2em);
    margin: auto;
    background-color: forestgreen;
    background-image:
      repeating-linear-gradient(37deg, transparent 0 52px, beige 52px 57px),
      repeating-linear-gradient(94deg, transparent 0 52px, beige 52px 57px);
    border: 1px solid;
    font-size: 3em;
    place-content: center;
  }
}
```

Result

Scroll the container to see both elements animate.

Note how the visibility of the `self` element controls its own animation. In this case, the element is at the `0%` keyframe when the top edge enters the viewport, or visible part of the scrollport, and only reaches the `100%` keyframe when the bottom edge exits the viewport.

The `parent` element only becomes visible when that parent is visible, meaning that when it comes into view, it is already about `25%` of the way through the animation. It is only about `75%` through its animation when it exits the top of the viewport.

scroll() CSS function

The **`scroll()`** CSS function can be used with the `animation-timeline` property to create an anonymous scroll progress timeline, defining the scroller and axis of the timeline.

Syntax

```
/* No arguments */
animation-timeline: scroll();

/* <scroller> argument only */
animation-timeline: scroll(nearest);
animation-timeline: scroll(root);
animation-timeline: scroll(self);

/*`<axis>` argument only */
animation-timeline: scroll(block);
animation-timeline: scroll(inline);
animation-timeline: scroll(y);
animation-timeline: scroll(x);

/* <scroller> and <axis> */
animation-timeline: scroll(block nearest);
animation-timeline: scroll(inline root);
animation-timeline: scroll(x self);
```

Parameters

`<scroller>`

The scroller element that will provide the scroll progress timeline. Valid values include:

`nearest`

The nearest ancestor of the current element that has scrollbars on either axis. This is the default value.

`root`

The root element of the document.

`self`

The current element itself.

`<axis>`

An `<axis>` keyword value describing the direction, or axis, of the scrollport that controls the scroll-driven animation. The default value is `block`.

Description

The `scroll()` CSS function can be used as a single value within the comma-separated `animation-timeline` property to specify a scroll progress timeline for a `@keyframes` animation. It defines the scrollable element (*scroller*) and scrollbar axis that will provide the animation timeline.

By default, `scroll()` references the `block` axis of the `nearest` ancestor scroll container. The scroller and axis values can be specified in any order.

The following five declarations are equivalent:

```
animation-timeline: scroll();
animation-timeline: scroll(block);
animation-timeline: scroll(nearest);
animation-timeline: scroll(block nearest);
animation-timeline: scroll(nearest block);
```

The scroll progress timeline is progressed through by scrolling the scroller horizontally or vertically, depending on the `<axis>` and writing mode. If the indicated axis does not contain a scrollbar, then the animation timeline will be inactive.

Formal syntax

```
<scroll()> =
  scroll( [ <scroller> || <axis> ]? )

<scroller> =
  root     |
  nearest  |
  self

<axis> =
  block   |
  inline  |
  x       |
  y
```

This syntax reflects the latest standard as per Scroll-driven Animations. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting an anonymous scroll progress timeline

In this example, the `#square` element is animated using an anonymous scroll progress timeline, which is applied to the element to be animated using the `scroll()` function. The timeline in this particular example is provided by the nearest parent element that has (any) scrollbar, from the scrollbar in the block direction.

HTML

The HTML for the example is shown below.

```
<div id="container">
  <div id="square"></div>
  <div id="stretcher"></div>
</div>
```

CSS

The CSS below defines a square that rotates in alternate directions according to the timeline provided by the `animation-timeline` property. In this case, the timeline is provided by `scroll(block nearest)`, which means that it will select the scrollbar in the block direction of the nearest ancestor element that has scrollbars; in this case the vertical scrollbar of the "container" element.

> **Note:** `block` and `nearest` are actually the default parameter values, so we could have used just `scroll()`.

```
#square {
  background-color: deeppink;
  width: 100px;
  height: 100px;
  margin-top: 100px;
  position: absolute;
  bottom: 0;

  animation-name: rotateAnimation;
  animation-duration: 1ms; /* Firefox requires this to apply the animation */
  animation-direction: alternate;
  animation-timeline: scroll(block nearest);
}

@keyframes rotateAnimation {
  from {
    transform: rotate(0deg);
  }
  to {
    transform: rotate(360deg);
  }
}
```

The CSS for the container sets its height to 300px and we also set the container to create a vertical scrollbar if it overflows. The "stretcher" CSS sets the block height to 600px, which forces the container element to overflow. These two together ensure that the container has a vertical scrollbar, which allows it to be used as the source of the anonymous scroll progress timeline.

```
#container {
  height: 300px;
  overflow-y: scroll;
  position: relative;
}

#stretcher {
  height: 600px;
}
```

```
@layer no-support {
  @supports not (animation-timeline: scroll()) {
    body::before {
      content: "Your browser doesn't support the CSS `scroll()` function.";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

Result

Scroll to see the square element being animated.

view() CSS function

The **`view()`** CSS function is used with the `animation-timeline` property to create an anonymous view progress timeline based on when an element comes into view inside its nearest scroll container. You can adjust the tracking axis and the optional insets to control when the element is considered "in view".

Syntax

```
/* No parameters */
animation-timeline: view();

/* Axis parameter */
animation-timeline: view(block);
animation-timeline: view(x);

/* Inset parameter */
animation-timeline: view(auto);
animation-timeline: view(20%);
animation-timeline: view(200px);
animation-timeline: view(20% 40%);
animation-timeline: view(20% 200px);
animation-timeline: view(100px 200px);
animation-timeline: view(auto 200px);

/* Axis and inset parameters */
animation-timeline: view(block auto);
animation-timeline: view(inline 20%);
animation-timeline: view(x 200px auto);
```

Parameters

`<axis>`

Specifies the scroll direction used by the view progress timeline. The value can be one of the `<axis>` keywords: `block`, `inline`, `x`, or `y`. The default value is `block`.

`<view-timeline-inset>`

Specifies the inset area that defines when an element is considered "in view". The value can be the keyword `auto` or up to two `<length-percentage>` values.

Description

A view progress timeline progresses based on changes in the visibility of a subject element inside its nearest scroll container. The `view()` function is used with the `animation-timeline` property to create such a view progress timeline.

The function's parameters can specify the scrollbar axis along which timeline progress is tracked and insets that adjust the position of the box in which the subject is considered visible.

- **Axis**: By default, `view()` uses the block axis. You can change this by providing an explicit `<axis>` value. If the chosen axis does not contain a scrollbar, then the animation timeline will be inactive (zero progress).
- **Inset**: By default, the timeline is at `0%` (the `from` keyframe in the `@keyframes` animation) when the subject is first visible at one edge of the scroller, and at `100%` (the `to` keyframe) when the subject's outer border edge reaches the opposite edge of the scroller. You can control these points with the `<view-timeline-inset>` parameters. The animation lasts as long as the element is in the inset-adjusted view. The inset is used to determine whether the element is in view, which in turn determines the length of the animation timeline. The inset consists of up to two values, each of which can be either `auto` or a `<length-percentage>`.
  - The first value defines the start, an inward offset from the scrollport's beginning.
  - The second value, if present, specifies the end, an inward offset from the scrollport's end. If the value is greater than `0`, it specifies an inset (positive). A negative value defines an outset adjustment to the scrollport.

The axis and inset components can be specified in any order. Within the inset component, the first value defines the start inset, and the second value defines the end inset.

Formal syntax

```
<view()> =
  view( [ <axis> || <'view-timeline-inset'> ]? )

<axis> =
  block   |
  inline  |
  x       |
  y

<view-timeline-inset> =
  [ [ auto | <length-percentage> ]{1,2} ]#

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4, Scroll-driven Animations. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Creating an anonymous view progress timeline using <code>view()</code>

In this example, we create an anonymous view progress timeline for the element with the `subject` and `animation` classes using `animation-timeline: view()`. The result is that as you scroll the document, this element animates as it moves upward through the document.

HTML

In the middle of the text, we include the following (note that the HTML includes a lot of content that we've hidden for brevity):

```
<div class="subject-container">
  <div class="subject animation"></div>
</div>
```

```
<div class="content">
  <h1>Content</h1>
  <p>
    Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod
    tempor incididunt ut labore et dolore magna aliqua. Risus quis varius quam
    quisque id. Et ligula ullamcorper malesuada proin libero nunc consequat
    interdum varius. Elit ullamcorper dignissim cras tincidunt lobortis feugiat
    vivamus at augue.
  </p>

  <p>
    Dolor sed viverra ipsum nunc aliquet. Sed sed risus pretium quam vulputate
    dignissim. Tortor aliquam nulla facilisi cras. A erat nam at lectus urna
    duis convallis convallis. Nibh ipsum consequat nisl vel pretium lectus.
    Sagittis aliquam malesuada bibendum arcu vitae elementum. Malesuada bibendum
    arcu vitae elementum curabitur vitae nunc sed velit.
  </p>

  <div class="subject-container">
    <div class="subject animation"></div>
  </div>

  <p>
    Adipiscing enim eu turpis egestas pretium aenean pharetra magna ac. Arcu
    cursus vitae congue mauris rhoncus aenean vel. Sit amet cursus sit amet
    dictum. Augue neque gravida in fermentum et. Gravida rutrum quisque non
    tellus orci ac auctor augue mauris. Risus quis varius quam quisque id diam
    vel quam elementum. Nibh praesent tristique magna sit amet purus gravida
    quis. Duis ultricies lacus sed turpis tincidunt id aliquet. In egestas erat
    imperdiet sed euismod nisi. Eget egestas purus viverra accumsan in nisl nisi
    scelerisque. Netus et malesuada fames ac.
  </p>
</div>
```

We also include two overlays to enable visualizing the animation range:

```
<div class="overlay top">inset start 50%</div>
<div class="overlay bottom">inset end 10%</div>
```

CSS

The styles for the `subject` and `subject-container` include:

```
.subject {
  width: 300px;
  height: 200px;
  background-color: deeppink;
}
.subject-container {
  border: 2px dashed black;
  width: 300px;
  margin: 0 auto;
}
```

The `subject-container` class shows the bounds of the animation. We define `top` and `bottom` overlays to mark the inset-adjusted scrollport.

```
.overlay {
  position: fixed;
}

.top {
  top: 0;
  height: 50%;
}

.bottom {
  bottom: 0;
  height: 10%;
}
```

The `<div>` element with the `subject` class is also given a class of `animation`. The `grow` animation causes the `subject` element to grow or shrink. The `animation-timeline: view(block 50% 10%)` rule sets the element to be animated as it progresses through the view progress timeline created by its nearest scroll container (in this case, the document's root element).

While scrolling down, note how the inset values `50% 10%` cause the animation to start when the element is 10% from the bottom of the scrollport and to finish when it is 50% from the top. As the animation progresses along the timeline, the `subject` grows. When scrolling up the animation proceeds in the reverse direction, starting at 50% from the top, moving backward through the keyframes, and ending at 10% from the bottom. So, as the animation runs backward, the `subject` shrinks.

An important point to remember is that the animation lasts only as long as the `subject` element is within view, which is defined here by `50% 10%` inset values.

```
.animation {
  animation-timeline: view(block 50% 10%);
  animation-name: grow;
  animation-timing-function: linear;
}

@keyframes grow {
  from {
    transform: scaleX(0);
  }

  to {
    transform: scaleX(1);
  }
}
```

```
.content {
  width: 75%;
  max-width: 800px;
  margin: 0 auto;
}

p {
  font-size: 1.5rem;
  line-height: 1.8;
}

.overlay {
  width: 100%;
  background-color: #f5deb3aa;
  display: flex;
  font-size: 1.2rem;
  font-weight: bold;
  color: red;
  justify-content: flex-end;
}
.top {
  align-items: end;
}

@layer no-support {
  @supports not (animation-timeline: view()) {
    body::after {
      content: "Your browser doesn't support the CSS `view()` function.";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;

      position: absolute;
      inset: 0;
      bottom: auto;
    }
  }
}
```

The rest of the CSS is hidden for brevity.

Result

Scroll to see the element with the `subject` class animate as it enters and leaves the adjusted inset view.

animation-timing-function CSS property

The **`animation-timing-function`** CSS property sets how an animation progresses through the duration of each cycle.

It is often convenient to use the shorthand property `animation` to set all animation properties at once.

Try it

```
animation-timing-function: linear;
```

```
animation-timing-function: ease-in-out;
```

```
animation-timing-function: steps(5, end);
```

```
animation-timing-function: cubic-bezier(0.1, -0.6, 0.2, 0);
```

```
<section class="flex-column" id="default-example">
  <div class="animating" id="example-element"></div>
  <button id="play-pause">Play</button>
</section>
```

```
#example-element {
  animation-duration: 3s;
  animation-iteration-count: infinite;
  animation-name: slide;
  animation-play-state: paused;
  background-color: #1766aa;
  border-radius: 50%;
  border: 5px solid #333333;
  color: white;
  height: 150px;
  margin: auto;
  margin-left: 0;
  width: 150px;
}

#example-element.running {
  animation-play-state: running;
}

#play-pause {
  font-size: 2rem;
}

@keyframes slide {
  from {
    background-color: orange;
    color: black;
    margin-left: 0;
  }
  to {
    background-color: orange;
    color: black;
    margin-left: 80%;
  }
}
```

```
const el = document.getElementById("example-element");
const button = document.getElementById("play-pause");

button.addEventListener("click", () => {
  if (el.classList.contains("running")) {
    el.classList.remove("running");
    button.textContent = "Play";
  } else {
    el.classList.add("running");
    button.textContent = "Pause";
  }
});
```

Syntax

```
/* Keyword values */
animation-timing-function: ease;
animation-timing-function: ease-in;
animation-timing-function: ease-out;
animation-timing-function: ease-in-out;
animation-timing-function: linear;
animation-timing-function: step-start;
animation-timing-function: step-end;

/* cubic-bezier() function values */
```

```
animation-timing-function: cubic-bezier(0.42, 0, 1, 1); /* ease-in */
animation-timing-function: cubic-bezier(0, 0, 0.58, 1); /* ease-out */
animation-timing-function: cubic-bezier(0.42, 0, 0.58, 1); /* ease-in-out */

/* linear() function values */
animation-timing-function: linear(0, 0.25, 1);
animation-timing-function: linear(0 0%, 0.25 50%, 1 100%);
animation-timing-function: linear(0, 0.25 50% 75%, 1);
animation-timing-function: linear(0, 0.25 50%, 0.25 75%, 1);

/* steps() function values */
animation-timing-function: steps(4, jump-start);
animation-timing-function: steps(10, jump-end);
animation-timing-function: steps(20, jump-none);
animation-timing-function: steps(5, jump-both);
animation-timing-function: steps(6, start);
animation-timing-function: steps(8, end);

/* Multiple animations */
animation-timing-function: ease, step-start, cubic-bezier(0.1, 0.7, 1, 0.1);

/* Global values */
animation-timing-function: inherit;
animation-timing-function: initial;
animation-timing-function: revert;
animation-timing-function: revert-layer;
animation-timing-function: unset;
```

Values

`<easing-function>`

The easing function that corresponds to a given animation, as determined by `animation-name`.

The non-step keyword values (`ease`, `linear`, `ease-in-out`, etc.) each represent cubic Bézier curves with fixed four-point values, while the `cubic-bezier()` function value allows non-predefined values to be specified. The `steps()` easing function divides the input time into a specified number of equal-length intervals. Its parameters include a number of steps and a step position.

`linear`

Equal to `cubic-bezier(0.0, 0.0, 1.0, 1.0)`, animates at an even speed.

`ease`

Equal to `cubic-bezier(0.25, 0.1, 0.25, 1.0)`, the default value, increases in velocity towards the middle of the animation, slowing back down at the end.

`ease-in`

Equal to `cubic-bezier(0.42, 0, 1.0, 1.0)`, starts off slowly, with the speed of the transition of the animating property increasing until complete.

`ease-out`

Equal to `cubic-bezier(0, 0, 0.58, 1.0)`, starts quickly, slowing down the animation continues.

`ease-in-out`

Equal to `cubic-bezier(0.42, 0, 0.58, 1.0)`, with the animating properties slowly transitioning, speeding up, and then slowing down again.

`cubic-bezier(<number [0,1]> , <number> , <number [0,1]> , <number>)`

An author defined cubic-bezier curve, where the first and third values must be in the range of 0 to 1.

`linear(<number> <percentage>{1,2}, …)`

The function interpolates linearly between the provided easing stop points. A stop point is a pair of an output progress and an input percentage. The input percentage is optional and is inferred if not specified. If an input percentage is not provided then the first and last stop points are set to `0%` and `100%` respectively, and the stop points in the middle receive percentage values derived by linearly interpolating between the closest previous and next points that have a percentage value.

`steps(<integer>, <step-position>)`

Displays an animation iteration along *n* stops along the transition, displaying each stop for equal lengths of time. For example, if *n* is 5, there are 5 steps. Whether the animation holds temporarily at 0%, 20%, 40%, 60% and 80%, on the 20%, 40%, 60%, 80% and 100%, or makes 5 stops between the 0% and 100% along the animation, or makes 5 stops including the 0% and 100% marks (on the 0%, 25%, 50%, 75%, and 100%) depends on which of the following step position is used:

`jump-start`

Denotes a left-continuous function, so that the first jump happens when the animation begins.

`jump-end`

Denotes a right-continuous function, so that the last jump happens when the animation ends. This is the default.

`jump-none`

There is no jump on either end, effectively removing a step during the interpolation iteration. Instead, it holds at both the 0% mark and the 100% mark, each for 1/n of the duration.

`jump-both`

Includes pauses at both the 0% and 100% marks, effectively adding a step during the animation iteration.

`start`

Same as `jump-start`.

`end`

Same as `jump-end`.

`step-start`

Equal to `steps(1, jump-start)`

`step-end`

Equal to `steps(1, jump-end)`

> **Note:** When you specify multiple comma-separated values on an `animation-*` property, they are applied to the animations in the order in which the `animation-name`s appear. For situations where the number of animations and `animation-*` property values do not match, see Setting multiple animation property values.

> **Note:** `animation-timing-function` has the same effect when creating CSS scroll-driven animations as it does for regular time-based animations.

Description

Easing functions may be specified on individual keyframes in a `@keyframes` rule. If no **`animation-timing-function`** is specified on a keyframe, the corresponding value of **`animation-timing-function`** from the element to which the animation is applied is used for that keyframe.

Within a keyframe, `animation-timing-function` is an at-rule-specific descriptor, not the property of the same name. The timing is not being animated. Rather, a keyframe's easing function is applied on a property-by-property basis from the keyframe on which it is specified until the next keyframe specifying that property, or until the end of the animation if there is no subsequent keyframe specifying that property. As a result, an **`animation-timing-function`** specified on the **`100%`** or **`to`** keyframe will never be used.

Formal definition

Initial value	ease
Applies to	all elements, `::before` and `::after` pseudo-elements
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
animation-timing-function =
  <easing-function>#

<easing-function> =
  <linear-easing-function>        |
  <cubic-bezier-easing-function>  |
  <step-easing-function>

<linear-easing-function> =
  linear      |
  <linear()>

<cubic-bezier-easing-function> =
  ease              |
  ease-in           |
  ease-out          |
  ease-in-out       |
  <cubic-bezier()>

<step-easing-function> =
  step-start  |
  step-end    |
  <steps()>

<linear()> =
  linear( [ <number> && <percentage>{0,2} ]# )

<cubic-bezier()> =
  cubic-bezier( [ <number [0,1]> , <number> ]#{2} )

<steps()> =
  steps( <integer> , <step-position>? )

<integer> =
  <number-token>

<step-position> =
  jump-start  |
  jump-end    |
  jump-none   |
  jump-both   |
  start       |
  end
```

This syntax reflects the latest standard as per CSS Animations Level 1, CSS Easing Functions Level 2, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

All the examples in this section animate the `width` and `background-color` properties of several `<div>` elements with different `animation-timing-function` values. The width is being animated from `0` to `100%`, and the background color is being animated from lime to magenta.

Linear function examples

The example demonstrates the effects of various `linear()` easing function values.

```
<div class="parent">
  <div class="linear">'linear' value</div>
  <div class="linear-fn1">linear(0, 0.5 50%, 1)</div>
  <div class="linear-fn2">linear(0, 0.25 75%, 1)</div>
  <div class="linear-fn3">linear(0, 0.75 25%, 1)</div>
  <div class="linear-fn4">linear(0, 0.5 25% 75%, 1)</div>
  <div class="linear-fn5">linear(0, 0.25 45%, 0.75 55%, 0.5 70%, 1)</div>
  <div class="linear-fn6">linear(0, 1.2 50%, 0.75 80%, 1)</div>
  <div class="linear-fn7">linear(0, 0.5 75%, 1 120%)</div>
</div>
<div class="x-axis"><span>25%</span><span>50%</span><span>75%</span></div>
<button>Play animation</button>
```

```
const btn = document.querySelector("button");
const divs = document.querySelectorAll(".parent > div[class]");

btn.addEventListener("click", () => {
  btn.setAttribute("disabled", "true");
  for (const div of divs) {
    div.classList.remove("animate");
    void div.offsetWidth;
    div.classList.add("animate");
  }
  setTimeout(() => {
    btn.removeAttribute("disabled");
  }, 11000);
});
```

```
.x-axis {
  display: flex;
  justify-content: space-evenly;
  width: 80vw;
  margin-left: 4px;
}

.parent {
  background: linear-gradient(
    to right,
    white 24.8%,
    grey 24.8%,
    grey 25.2%,
    white 25.2%,
    white 49.8%,
    grey 49.8%,
    grey 50.2%,
    white 50.2%,
    white 74.8%,
    grey 74.8%,
    grey 75.2%,
    white 75.2%
  );
  width: 80vw;
  font-family: monospace;
  font-weight: bold;
  border: 2px solid grey;
}

.animate {
  animation-name: changeme;
}

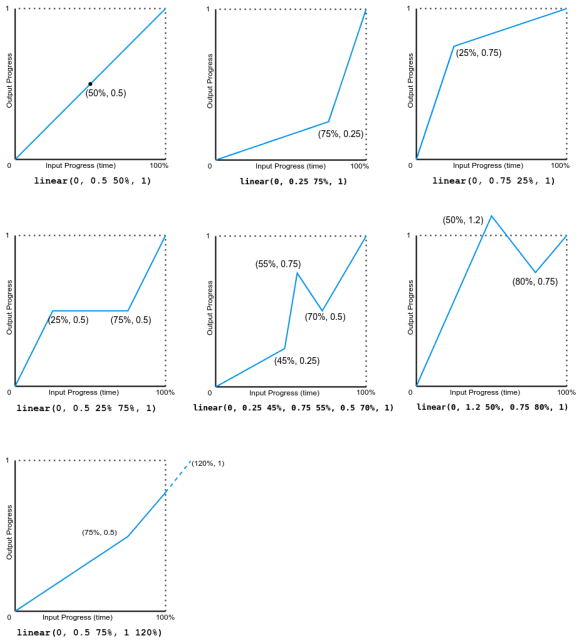
.parent > div[class] {
  animation-fill-mode: forwards;
  animation-duration: 10s;

  width: 0;
  margin-bottom: 4px;
  padding: 5px 0;
  box-sizing: border-box;
  text-wrap: nowrap;
  background-color: lime;
}

@keyframes changeme {
  0% {
    width: 0em;
  }
  100% {
    width: 100%;
    background-color: orange;
  }
}

.linear {
  animation-timing-function: linear;
}
.linear-fn1 {
  animation-timing-function: linear(0, 0.5 50%, 1);
}
.linear-fn2 {
  animation-timing-function: linear(0, 0.25 75%, 1);
}
.linear-fn3 {
  animation-timing-function: linear(0, 0.75 25%, 1);
}
.linear-fn4 {
  animation-timing-function: linear(0, 0.5 25% 75%, 1);
}
.linear-fn5 {
  animation-timing-function: linear(0, 0.25 45%, 0.75 55%, 0.5 70%, 1);
}
.linear-fn6 {
  animation-timing-function: linear(0, 1.2 50%, 0.75 80%, 1);
}
.linear-fn7 {
  animation-timing-function: linear(0, 0.5 75%, 1 120%);
}
```

The following image shows graphs of all the `linear()` function values used in this example. Input progress (time) is plotted on the x-axis and output progress is plotted on the y-axis. As per the syntax, the input progress ranges from 0 to 100%, and the output ranges from 0 to 1.



Note that the output can go forward or backward.

Cubic-Bézier examples

The example demonstrates the effects of various bézier curve easing functions.

```
<div class="parent">
  <div class="linear">linear</div>
  <div class="ease">ease</div>
  <div class="ease-in">ease-in</div>
  <div class="ease-out">ease-out</div>
  <div class="ease-in-out">ease-in-out</div>
  <div class="cb">cubic-bezier(.5, -0.5, 1, 1.5)</div>
</div>
<div class="x-axis"><span>50%</span></div>
<button>Play animation</button>
```

```
const btn = document.querySelector("button");
const divs = document.querySelectorAll(".parent > div[class]");

btn.addEventListener("click", () => {
  btn.setAttribute("disabled", "true");
  for (const div of divs) {
    div.classList.remove("animate");
    void div.offsetWidth;
    div.classList.add("animate");
  }
  setTimeout(() => {
    btn.removeAttribute("disabled");
  }, 11000);
});
```

```
.x-axis {
  display: flex;
  justify-content: space-evenly;
  width: 80vw;
  margin-left: 4px;
}

.parent {
  background: linear-gradient(
    to right,
    white 49.8%,
    grey 49.8%,
    grey 50.2%,
    white 50.2%
  );
  width: 80vw;
  font-family: monospace;
  font-weight: bold;
  border: 2px solid grey;
}

.animate {
  animation-name: changeme;
}

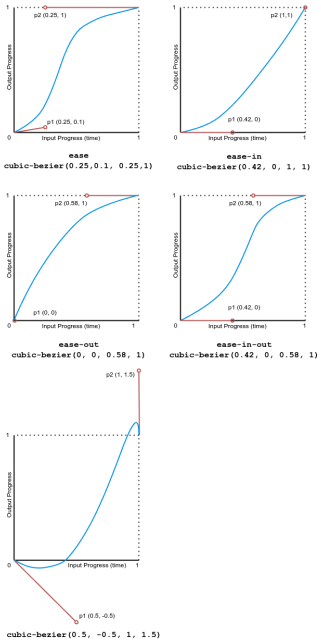
.parent > div[class] {
  animation-fill-mode: forwards;
  animation-duration: 10s;

  width: 0;
  margin-bottom: 4px;
  padding: 5px 0;
  box-sizing: border-box;
  text-wrap: nowrap;
  background-color: lime;
}
```

```
@keyframes changeme {
  0% {
    width: 0em;
  }
  100% {
    width: 100%;
    background-color: orange;
  }
}

.linear {
  animation-timing-function: linear;
}
.ease {
  animation-timing-function: ease;
}
.ease-in {
  animation-timing-function: ease-in;
}
.ease-out {
  animation-timing-function: ease-out;
}
.ease-in-out {
  animation-timing-function: ease-in-out;
}
.cb {
  animation-timing-function: cubic-bezier(0.5, -0.5, 1, 1.5);
}
```

The following image shows graphs of all the cubic bézier function values used in this example. The input progress (time) ranges from 0 to 1 and the output progress ranges from 0 to 1.



Step examples

This example demonstrates the effects of several step easing function values.

```
<div class="parent">
  <div class="linear">linear</div>
  <div class="start">steps(4, start)</div>
  <div class="jump-start">steps(4, jump-start)</div>
  <div class="end">steps(4, end)</div>
  <div class="jump-end">steps(4, jump-end)</div>
  <div class="jump-both">steps(4, jump-both)</div>
  <div class="jump-none">steps(4, jump-none)</div>
  <div class="step-start">step-start</div>
  <div class="step-end">step-end</div>
</div>
<div class="x-axis"><span>25%</span><span>50%</span><span>75%</span></div>
<button>Play animation</button>
```

```
const btn = document.querySelector("button");
const divs = document.querySelectorAll(".parent > div[class]");

btn.addEventListener("click", () => {
  btn.setAttribute("disabled", "true");
  for (const div of divs) {
    div.classList.remove("animate");
    void div.offsetWidth;
    div.classList.add("animate");
  }
  setTimeout(() => {
    btn.removeAttribute("disabled");
  }, 11000);
});
```

```
.x-axis {
  display: flex;
  justify-content: space-evenly;
```

```
  width: 80vw;
  margin-left: 4px;
}

.parent {
  background: linear-gradient(
    to right,
    white 24.8%,
    grey 24.8%,
    grey 25.2%,
    white 25.2%,
    white 49.8%,
    grey 49.8%,
    grey 50.2%,
    white 50.2%,
    white 74.8%,
    grey 74.8%,
    grey 75.2%,
    white 75.2%
  );
  width: 80vw;
  font-family: monospace;
  font-weight: bold;
  border: 2px solid grey;
}

.animate {
  animation-name: changeme;
}

.parent > div[class] {
  animation-fill-mode: forwards;
  animation-duration: 10s;

  width: 0;
  margin-bottom: 4px;
  padding: 5px 0;
  box-sizing: border-box;
  text-wrap: nowrap;
  background-color: lime;
}

@keyframes changeme {
  0% {
    width: 0em;
  }
  100% {
    width: 100%;
    background-color: orange;
  }
}
```

```
.linear {
  animation-timing-function: linear;
}

.start {
  animation-timing-function: steps(4, start);
}
.jump-start {
  animation-timing-function: steps(4, jump-start);
}
.end {
  animation-timing-function: steps(4, end);
}
.jump-end {
  animation-timing-function: steps(4, jump-end);
}
.jump-both {
  animation-timing-function: steps(4, jump-both);
}
.jump-none {
  animation-timing-function: steps(4, jump-none);
}
.step-start {
  animation-timing-function: step-start;
}
.step-end {
  animation-timing-function: step-end;
}
```

The following image shows graphs of all the `step()` function values used in this example. The input progress (time) and output progress range from 0 to 1.

animation-trigger CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`animation-trigger`** CSS property specifies whether CSS animations declared on an element are triggered animations (or not) and, if so, what their triggers are and how they should behave when the trigger becomes active or inactive. This is used to create scroll-triggered animations.

Syntax

```
/* Keywords */
animation-trigger: none;

/* One trigger */
animation-trigger: --my-trigger play;
animation-trigger: --my-other-trigger play-once;
animation-trigger: --my-trigger play-forwards play-backwards;
animation-trigger: --my-other-trigger play reset;

/* Multiple values */
animation-trigger:
  none,
  -forwards play-backwards,
  --my-other-trigger play reset;

/* Global values */
animation-trigger: inherit;
animation-trigger: initial;
animation-trigger: revert;
animation-trigger: revert-layer;
animation-trigger: unset;
```

Values

Specified as a comma-separated list of values. Each value is either the keyword `none` or a `<dashed-ident>` followed by one or two `<animation-action>` values.

`none`

The associated animation is not a triggered animation.

`<dashed-ident>`

A custom identifier defining the name of the trigger that will trigger the animation.

`<animation-action>`

An `<animation-action>`: The keywords `none`, `play`, `play-forwards`, `play-backwards`, `play-once`, `pause`, `replay`, or `reset`.

Description

The `animation-trigger` property specifies which trigger will control an animated element's animations. A value other than `none` turns the animation into a scroll-triggered animation.

Defining a trigger

The trigger is identified via a `<dashed-ident>` value, which is defined in the tracked element's `timeline-trigger-name` property.

For example:

```
.animated {
  animation: rotate 3s infinite linear both;
  animation-trigger: --my-trigger play;
}
```

In this case, the animation will play when an element with a `timeline-trigger-name` of `--my-trigger` enters the activation range defined on the trigger.

Here we create a trigger by setting the `timeline-trigger-name` using the `timeline-trigger` shorthand property. The `.trigger` can be any element, including the `.animated` element.

```
.trigger {
  timeline-trigger: --my-trigger view();
}
```

If an element has an animation *and* an `animation-trigger` set on it, but no scrolling element exists with the same `<dashed-ident>` set as its `timeline-trigger-name` value, the animation will not have a trigger and therefore will never play.

Defining the triggered animation actions

The `animation-trigger` value must include one or two `<animation-action>` keywords after the `<dashed-ident>` to specify the animation behavior when the trigger is activated and deactivated. If two `<animation-action>`s are specified, the first is the activation action and the second is the deactivation action. If only one `<animation-action>` is set, this is the activation action, and nothing happens on deactivation.

For example:

```
.animated {
  animation: rotate 3s infinite linear both;
  animation-trigger: --my-trigger play-forwards play-backwards;
}
```

When the trigger is activated, the animation will `play-forwards`. When the trigger is deactivated, the animation will `play-backwards`.

There are eight `<animation-action>` values, each providing different animation behaviors.

Setting `play-forwards play-backwards` is a common pattern, often used to "animate in" an element when its trigger becomes active, for example by scrolling it into view, and then "animate out" the element again when the trigger becomes inactive, for example by scrolling it out of view.

The `play-once` action is generally used on its own or as part of `play-once pause`; setting `play-once` as the activation action causes the animation to play only once when it scrolls into view. Adding `pause` on deactivation pauses the animation when the trigger scrolls out of its active range; if the trigger is re-activated, the animation will restart from where it was paused.

See the `<animation-action>` data type for examples and more about each keyword value.

Triggering one animation via multiple triggers

If you want to define triggers on multiple elements that all trigger the same animation on an element, you need to specify the animation multiple times on that animated element, giving each `animation` instance a different trigger.

For example:

```
.animated {
  animation:
    spinOnce 2s 1 ease-out,
    spinOnce 2s 1 ease-out;
  animation-trigger:
    --t1 play-forwards play-backwards,
    --t2 play-forwards play-backwards;
}

.trigger1 {
  timeline-trigger: --t1 view();
}

.trigger2 {
  timeline-trigger: --t2 view();
}
```

See Multiple triggers for the same animation for a working example.

Reset by the <code>animation</code> shorthand

The `animation-trigger` property is a reset-only sub-property of the `animation` shorthand property. This means trigger names and animation actions can not be included in the `animation` shorthand, but setting the `animation` shorthand resets `animation-trigger` to its initial value of `none`. For this reason, you should always set `animation-trigger` after a corresponding `animation` property in a declaration list or declare the `animation-trigger` in a declaration block with selectors with stronger `specificity`.

Multiple <code>animation-trigger</code> values

Setting multiple `animation-trigger` values works in the same way as setting multiple values for the `animation` shorthand property and the other animation longhand properties:

- If multiple `animation-name` values are set, but only a single `animation-trigger` value is set, the `animation-trigger` will apply to all the animations.
- If two or more comma-separated `animation-trigger` values are set, they will cycle between the animations until all of them have an `animation-trigger` value set. See an example of declaring multiple scroll-triggered animations.

Given the following CSS:

```
.animated {
  animation:
    fade-in linear 1s forwards,
    rotate infinite 5s both,
    shrink ease-in 3s forwards,
    color-change steps(5) 5s forwards;

  animation-trigger:
    --t1 play pause,
    --t2 forwards backwards;
}
.trigger1 {
  timeline-trigger: --t1 view();
}
.trigger2 {
```

```
  timeline-trigger: --t2 view();
}
```

With `animation-trigger: --t1 play pause, --t2 forwards backwards` set on the animated element, `--t1` triggers the `fade-in` and `shrink` animations while `--t2` triggers the `rotate` and `color-change` animations.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
animation-trigger =
  [ none | [ <dashed-ident> <animation-action>+ ]+ ]#
```

This syntax reflects the latest standard as per Animation Triggers. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates how to create a scroll-triggered animation that plays when activated and pauses when deactivated.

HTML

The markup contains two `<div>` elements, one to animate and one to create a trigger, plus some basic text content to make the page scrollable. The text is hidden for brevity.

```
<div class="animated">I am animated</div>

...

<div class="trigger">I create the trigger</div>

...
```

```
<div class="animated">I am animated</div>

<p>
  Fusce dictum ex quis ipsum consectetur placerat. Cras sed lectus ex. Quisque
  purus dolor, vulputate ac mi eget, commodo varius odio. Suspendisse faucibus
  ipsum vel libero finibus, in placerat nibh congue. Sed iaculis, metus et
  euismod posuere, mi diam vestibulum felis, ac vulputate eros ipsum id justo.
  Etiam a tincidunt purus. Maecenas semper sed enim at blandit. Aenean ut
  sagittis lorem, eget gravida purus. Phasellus eleifend, lectus nec pulvinar

```

CSS

The `.animated` element's `position` is set to `fixed`, positioning it near the top-left of the scrollport to allow us to see the animation play and pause.

```
body {
  width: 80%;
  margin: 0 auto;
  font-family: "Helvetica", "Arial";
  font-size: 1.3rem;
}

div {
  height: 100px;
  border: 5px solid black;
}

.animated {
  width: 100px;
  background: orange;
}

.trigger {
  background: wheat;
}
```

```
.animated {
  position: fixed;
  top: 25px;
  left: 25px;
}
```

Next, we define the `@keyframes` for the `rotate` animation:

```
@keyframes rotate {
  from {
    rotate: 0deg;
  }

  to {
    rotate: 360deg;
  }
}
```

Using the `animation` shorthand, the `rotate` animation is applied to the `.animated` element. Without an associated trigger, the animation would start when the page loads. The `animation-trigger` property makes it a triggered animation. The value references a `timeline-trigger-name` of `--t` and specifies two `<animation-action>` values — `play` and `pause` — which specify that the animation will play on activation and pause on deactivation.

```
.animated {
  animation: rotate 3s infinite linear both;
  animation-trigger: --t play pause;
}
```

We set a `timeline-trigger-name` of `--t` on the `.trigger` element. As this value is the identifier referenced in the `.animated` declaration block's `animation-trigger` property value, this associates the two together, creating the animated element's trigger. We also include a `timeline-trigger-source` value of `view()`, which sets the timeline trigger as a view progress timeline and both the active and activation ranges as the full `cover` timeline. We could have declared both together as `timeline-trigger: view() --t`.

```
.trigger {
  timeline-trigger-name: --t;
  timeline-trigger-source: view();
}
```

Result

Try scrolling the content up and down. When any part of the `.trigger` element appears in the scrollport, the animation plays; when it has completely left the scrollport at either edge, the animation pauses.

Making the animated element create the trigger

In this example, we demonstrate how an animated element can also create its own trigger.

HTML

This time, the markup contains only a single `<div>` element, plus basic text content to cause the page to scroll. We have hidden the content markup for brevity.

```
<div>I create my own trigger</div>
```

```
<p>
  Fusce dictum ex quis ipsum consectetur placerat. Cras sed lectus ex. Quisque
  purus dolor, vulputate ac mi eget, commodo varius odio. Suspendisse faucibus

  luctus quis. Maecenas scelerisque scelerisque elit eu consequat. Etiam ac
  tristique tellus, sed tincidunt velit.
</p>
```

CSS

We create an `@keyframes` block that inverts the background and foreground colors:

```
body {
  width: 80%;
  margin: 0 auto;
  font-family: "Helvetica", "Arial";
  font-size: 1.3rem;
}

div {
  height: 100px;
  background: orange;
  border: 5px solid black;
}
```

```
@keyframes invert-colors {
  from {
    background: orange;
    color: black;
  }

  to {
    background: black;
    color: orange;
  }
}
```

We set the `animation` on the `<div>` element, inverting the colors smoothly over 600ms. We also set an `animation-trigger` value that references a `timeline-trigger-name` of `--t` and include two `<animation-action>` values — `play-forwards` and `play-backwards` — which specify that the animation will play forwards on activation and play in reverse on deactivation.

We also specify a `timeline-trigger` value of `--t view() contain` on the `<div>`, so it creates the trigger for its own animation. The `timeline-trigger` shorthand includes three longhand property values:

- A `timeline-trigger-name` value: A `<dashed-ident>` identifier referenced in the `animation-trigger` property.
- A `timeline-trigger-source` value: The `view()` value sets the timeline trigger to a view progress timeline tracking the element inside its nearest scrolling ancestor element.
- A `timeline-trigger-activation-range` value: The `<timeline-range-name>` value of `contain` sets the trigger to activate when the `<div>` is fully inside the scrollport. Because we didn't set a value for the `timeline-trigger-active-range` component, the active range is the same as the activation range, so it deactivates when it starts to exit the scrollport.

```
div {
  animation: invert-colors 0.6s ease-in both;
  animation-trigger: --t play-forwards play-backwards;
  timeline-trigger: --t view() contain;
}
```

Result

Try scrolling the content up. When the `<div>` is fully in the scrollport, its animation plays. When any part leaves the scrollport at either edge, the animation plays backward.

Multiple triggers for the same animation

This example shows how to assign multiple triggers to control the same animation. This example is similar to the basic usage example, but with multiple triggers triggering the same keyframe animation.

HTML

We include three `<div>` elements as triggers. The text content is hidden for brevity.

```
<div class="animated">I am animated</div>

...

<div class="trigger1">I create a trigger</div>

...
```

```
<div class="trigger2">I create another trigger</div>

...

<div class="trigger3">I create yet another trigger</div>

...
```

```
<div class="animated">I am animated</div>

<p>
  Fusce dictum ex quis ipsum consectetur placerat. Cras sed lectus ex. Quisque
  purus dolor, vulputate ac mi eget, commodo varius odio. Suspendisse faucibus
  ipsum vel libero finibus, in placerat nibh congue. Sed iaculis, metus et

  iaculis sodales sed eget diam. Quisque sodales nunc sapien, vitae lacinia ex
  luctus quis. Maecenas scelerisque scelerisque elit eu consequat. Etiam ac
  tristique tellus, sed tincidunt velit.
</p>

<div class="trigger3">I create yet another trigger</div>

<p>
  Fusce dictum ex quis ipsum consectetur placerat. Cras sed lectus ex. Quisque
  purus dolor, vulputate ac mi eget, commodo varius odio. Suspendisse faucibus
  ipsum vel libero finibus, in placerat nibh congue. Sed iaculis, metus et
  euismod posuere, mi diam vestibulum felis, ac vulputate eros ipsum id justo.
  Etiam a tincidunt purus. Maecenas semper sed enim at blandit. Aenean ut
  sagittis lorem, eget gravida purus. Phasellus eleifend, lectus nec pulvinar
  facilisis, dui dolor feugiat odio, iaculis tempor felis est non tortor. In
  suscipit lorem efficitur molestie tempus. Integer sit amet neque et risus
  iaculis sodales sed eget diam. Quisque sodales nunc sapien, vitae lacinia ex
  luctus quis. Maecenas scelerisque scelerisque elit eu consequat. Etiam ac
  tristique tellus, sed tincidunt velit.
</p>
```

CSS

```
body {
  width: 80%;
  margin: 0 auto;
  font-family: "Helvetica", "Arial";
  font-size: 1.3rem;
}

div {
  height: 100px;
  border: 5px solid black;
}

.animated {
  width: 100px;
  background: orange;
}

.trigger1,
.trigger2,
.trigger3 {
  background: palegoldenrod;
}
```

The `animation` shorthand property value is a comma-separated list of animations, applying the same `animation-name` — `rotate` — three times. The `animation-trigger` value is a comma-separated list with three animation triggers, one for each animation instance.

```
.animated {
  animation:
    rotate 3s infinite linear both,
    rotate 3s infinite linear forwards,
    rotate 3s infinite linear forwards;
  animation-trigger:
    --t1 play-forwards play-backwards,
    --t2 play-forwards play-backwards,
    --t3 play-forwards play-backwards;
}
```

We define a timeline trigger with a different name on each trigger `<div>` element. These names correspond to the names referenced in the `.animated` element's `animation-trigger` property.

```
.trigger1 {
  timeline-trigger: --t1 view();
}

.trigger2 {
  timeline-trigger: --t2 view();
}

.trigger3 {
  timeline-trigger: --t3 view();
}
```

```
@supports not (animation-trigger: --t play-forwards play-backwards) {
  body::before {
    content: "Your browser does not support the animation-trigger property.";
    background-color: wheat;
    text-align: center;
    padding: 1rem 0;

    z-index: 1;
    position: fixed;
    inset: 40% 0 auto;
  }
}
```

Result

Try scrolling the content up and down, and note how the animation activates and then deactivates when each trigger element scrolls into and out of view.

appearance CSS property

The **`appearance`** CSS property specifies the rendered appearance of replaced UI widget elements such as form controls. Most commonly, such elements are given native, platform-specific styling based on the operating system's theme, or a primitive appearance with styles that can be overridden using CSS.

Try it

```
appearance: auto;
```

```
appearance: none;
```

```
appearance: textfield;
```

```
<section id="default-example">
  <div class="background" id="example-element">
    <input type="search" value="search" aria-label="unlabeled search" />
    <input type="checkbox" aria-label="unlabeled checkbox" />
    <input type="radio" aria-label="unlabeled radio button" />
    <button>Button</button>
  </div>
</section>
```

```
input,
button {
  appearance: inherit;
}
```

Syntax

```
/* CSS Basic User Interface Module Level 4 values */
appearance: none;
appearance: auto;
appearance: menulist-button;
appearance: textfield;
appearance: base-select;

/* Global values */
appearance: inherit;
appearance: initial;
appearance: revert;
appearance: revert-layer;
appearance: unset;

/* <compat-auto> values have the same effect as 'auto' */
```

```
appearance: button;
appearance: checkbox;
```

Values

The `appearance` property can be applied to all elements and pseudo-elements, but the effect of the specified value, if any, depends on the element to which it is applied.

`none`

Gives the widget a *primitive* appearance, making it stylable via CSS, while maintaining the widget's native functionality. This value does not affect non-widgets.

`auto`

Sets interactive widgets to render with their *OS-native* appearance. Behaves as `none` on elements with no OS-native styling.

`base-select`

Relevant only to the `<select>` element and `::picker(select)` pseudo-element, allowing them to be fully styled.

`<compat-special>`

Has an effect similar to `auto` on certain elements.

`textfield`

Causes the appearance of certain `<input>` types to match the appearance of the `text` type.

`menulist-button`

When set on the `<select>` element, the drop-down picker's style matches that of its default state.

`<compat-auto>`

Included for backwards compatibility; possible values include `button`, `checkbox`, `listbox`, `menulist`, `meter`, `progress-bar`, `push-button`, `radio`, `searchfield`, `slider-horizontal`, `square-button`, and `textarea`. The values all behave as `auto`: use `auto` instead.

> **Note:** The specification also defines a `base` value. This is not yet supported by any browser.

Non-standard values

Some non-standard values are also supported in some browsers:

`slider-vertical`

Makes the slider vertical when applied to `<input type="range">` elements. To create a vertical slider you should instead set the `writing-mode` to `vertical-lr` and the `direction` to `rtl`.

`-apple-pay-button`

Displays the Apple Pay logo when set on a `<button>`, `<a>`, or `<input>` element of type `button` or `reset`.

Description

The `appearance` property enables displaying elements in their OS-native style based on the operating system's theme, as well as the removal of any platform-native styling with the `none` value. Setting `appearance: none`, or otherwise changing the appearance of UI widgets, does not change the element's functionality.

While most elements in a document can be fully styled by CSS, UI controls (*widgets*) are typically rendered by the browser using the operating system's native UI styles. This *native* appearance differs between operating systems and browsers. In this default state, widgets have limited, if any, features that can be styled with CSS. Which elements have this native UI appearance is defined in HTML.

The `appearance` property provides some control over the appearance of HTML widgets that, by default, look like native operating system controls. Most notably, the `none` value suppresses some of a widget's native appearance. This results in a *primitive* look that can be styled via CSS while still maintaining functionality and supporting native user interactions.

Some widgets disappear completely when set to `appearance: none`. The hidden controls are still interactive, however. For example, clicking on a `<label>` associated with an `appearance: none` checkbox will toggle the checkbox's checked state.

Because `none` can cause a widget to be hidden, the `base` value is being added to provide widgets with a base appearance. When supported, the `base` value will ensure widgets maintain their native appearance while enabling CSS to be used to change a widget's styles that are not changeable by default. Unlike `none`, which can make radio buttons and checkboxes disappear, `base` gives the widget a primitive appearance with default native styles that are usable and interoperable, as well as enabling a good degree of customization via CSS. While this `base` value is not yet supported, the many `<compat-auto>` values provide similar functionality but are type-specific and not global.

Customizable select elements

The `base-select` value, which is relevant only to the `<select>` element and `::picker(select)` pseudo-element, enables styling `<select>` elements and the select picker (which contains the `<option>` elements). The picker is rendered in the top layer, similar to a popover. When `base-select` is set, the picker can be positioned relative to the select (or other elements) using CSS anchor positioning features. In addition, the `base-select` value causes the `<select>` not to render outside the browser pane or to trigger built-in mobile operating system components. It is also no longer sized based on the width of the widest `<option>`.

See Customizable select elements for more information.

Prefixed non-standard values

Before standardization, the prefixed **`-moz-appearance`** and **`-webkit-appearance`** properties allowed elements to be shown as widgets such as buttons or checkboxes. The following non-standard values may be encountered in legacy style sheets, most commonly as values of shadow DOM component prefixed pseudo-elements.

Authors are encouraged to use only standard keywords.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
appearance =
  none              |
  auto              |
```

```
  base              |
  base-select       |
  <compat-auto>     |
  <compat-special>

<compat-auto> =
  searchfield   |
  textarea      |
  checkbox      |
  radio         |
  menulist      |
  listbox       |
  meter         |
  progress-bar  |
  button

<compat-special> =
  textfield        |
  menulist-button
```

This syntax reflects the latest standard as per CSS Basic User Interface Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

This example demonstrates basic usage of the `appearance` property, altering the appearance of an `<input>` element in some browsers.

HTML

We include two `number` form controls along with their labels.

```
<p>
  <label>Enter a number: <input type="number" min="0" max="10" /></label>
</p>
<p>
  <label
    >Enter a number: <input type="number" min="0" max="10" class="text"
  /></label>
</p>
```

CSS

We set the element with the class of `text` to look like a text field.

```
.text {
  appearance: textfield;
}
```

Results

Depending on the browser, the spinner may be visually removed when the control is set to look like a text field. The `appearance` property has no effect on the functionality: for example, while there may no longer be a spinner to click on, the up and down cursor keys will still increment and decrement the value.

Appearance set to <code>none</code>

The following example shows how to remove the default styling from a checkbox, a radio button, and a `<select>` element, and apply custom styling.

HTML

We include pairs of checkboxes, radio buttons, and `<select>` elements, along with their associated labels:

```
<label><input type="checkbox" /> Default unchecked </label>
<label><input type="checkbox" checked /> Default checked </label>

<hr />

<label><input type="radio" name="radio" /> Default unchecked </label>
<label><input type="radio" name="radio" checked /> Default checked </label>

<hr />

<label
  >Unstyled select
  <select>
    <option>Option 1</option>
    <option>Option 2</option>
  </select>
</label>

<label
  >Styled select
  <select class="none">
    <option>Option 1</option>
    <option>Option 2</option>
  </select>
</label>
```

CSS

```
label {
  display: block;
  margin: 0.5em 0;
}
```

We apply styles to both `<input>` elements of type `checkbox`; these styles create a red square if the element is stylable. We set `appearance: none` on the `:checked` UI state for all inputs (`checkbox` and `radio`), as well as to elements with the `.none` class. This removes all the style of the radio button and checkbox, other than the margins, and allows any set styles to be applied. There are no alternative styles provided for the radio buttons or `<select>` elements for when `none` is set.

```
[type="checkbox"] {
  width: 1em;
```

```
  height: 1em;
  display: inline-block;
  background: red;
}
input:checked,
.none {
  appearance: none;
}
```

Result

Setting `appearance: none` enables UI elements to be styled, but it also runs the risk of hiding the widget. The unchecked checkbox, with its `appearance` defaulting to `auto`, looks like a checkbox. Setting `appearance: none` in the `:checked` state enables it to be styled.

Like the unchecked checkbox, the unchecked radio button looks like the native UI widget, because it is. When in the checked state, with `appearance: none` applied, the radio button disappears; its functionality is retained, and only its margins affect page rendering.

Setting the appearance of a select

We can use the `appearance` property to opt-in to custom select functionality, enabling styling the `<select>` element and its picker, which represents the part of the form control that pops out of the page.

HTML

We include three `<select>` elements, with the same multiple `<option>` children. As with every `<select>`, we also include associated `<label>` elements. The third option has more text to demonstrate the effect of `base-select` on the width of the `<select>`:

```
<label for="ice-cream1"
  >Default flavor:
  <select id="ice-cream1">
    <option>Asparagus</option>
    <option>Dulce de leche</option>
    <option>Pistachio, rum raisin, and coffee</option>
  </select>
</label>
<label for="ice-cream2"
  >Base select flavor:
  <select id="ice-cream2" class="baseSelect">
    <option>Asparagus</option>
    <option>Dulce de leche</option>
    <option>Pistachio, rum raisin, and coffee</option>
  </select>
</label>
<label for="ice-cream3"
  >Menulist button flavor:
  <select id="ice-cream3" class="menulistButton">
    <option>Asparagus</option>
    <option>Dulce de leche</option>
    <option>Pistachio, rum raisin, and coffee</option>
  </select>
</label>
```

CSS

We select the pickers of all the `<select>` elements using the `::picker()` pseudo-element with the `select` parameter. We set the `appearance` value of all the pickers and one `<select>` element to `base-select`. We set the last `<select>` to `menulist-button`. The first `<select>` defaults to the `auto` state:

```
.baseSelect,
::picker(select) {
  appearance: base-select;
}
.menulistButton {
  appearance: menulist-button;
}
```

```
label {
  display: block;
}
```

We set values for the `<select>` and pickers' `background-color` and `border` properties to demonstrate the effects of the `appearance` values:

```
select {
  border: 1px solid red;
  background-color: orange;
}

::picker(select) {
  background-color: yellow;
  border: none;
}
```

Results

While the `background-color` and `border` styles are defined on all the `<select>` elements and their pickers, the `::picker(select)` styles only affect the picker where both the select and the picker have the `appearance` property set to `base-select`. The first and third selects look the same because `menulist-button` is a compatibility keyword.

Notice that, by default, the inline-size of the `<select>` is generally the inline-size of the `<option>` with the most text, and that the drop-down picker appears over the top of the rendered page when opened, making it not constrained by the surrounding page and therefore fully visible. These statements are no longer true when `base-select` is set.

aspect-ratio CSS property

The **`aspect-ratio`** CSS property allows you to define the desired width-to-height ratio of an element's box.

Try it

```
aspect-ratio: auto;
```

```
aspect-ratio: 1 / 1;
```

```
aspect-ratio: 16 / 9;
```

```
aspect-ratio: 0.5;
```

```
<section id="default-example">
  <img
    class="transition-all"
    height="640"
    id="example-element"
    src="/shared-assets/images/examples/plumeria.jpg"
    width="466" />
</section>
```

```
#example-element {
  height: 100%;
  width: auto;
}
```

Syntax

```
aspect-ratio: 1 / 1;
aspect-ratio: 1;

/* fallback to 'auto' for replaced elements */
aspect-ratio: auto 3/4;
aspect-ratio: 9/6 auto;

/* Global values */
aspect-ratio: inherit;
aspect-ratio: initial;
aspect-ratio: revert;
aspect-ratio: revert-layer;
aspect-ratio: unset;
```

Values

This property is specified as one or both of the keyword `auto` or a `<ratio>`.

`auto`

> Replaced elements with an intrinsic aspect ratio use *that* aspect ratio, otherwise the box has no preferred aspect ratio. Size calculations involving intrinsic aspect ratio always work with the content box dimensions.

`<ratio>`

> The box's preferred aspect ratio is the specified ratio of `width` / `height`. If `height` and the preceding slash character are omitted, `height` defaults to `1`. Size calculations involving preferred aspect ratio work with the dimensions of the box specified by `box-sizing`.

`auto && <ratio>`

> When both `auto` and a `<ratio>` are specified together, `auto` is used if the element is a replaced element with a natural aspect ratio, like an `<img>` element. Otherwise, the specified ratio of `width` / `height` is used as the preferred aspect ratio.

Description

The `aspect-ratio` property defines a desired width-to-height ratio of an element's box. This means that even if the parent container or viewport size changes, the browser will adjust the element's dimensions to maintain the specified width-to-height ratio. The specified aspect ratio is used in the calculation of auto sizes and some other layout functions.

At least one of the box's sizes needs to be automatic in order for `aspect-ratio` to have any effect. If neither the width nor height is an automatic size, then the provided aspect ratio has no effect on the box's preferred sizes.

This property is specified as one or both of the keyword auto or a `<ratio>`. If both are given, and the element is a replaced element, such as `<img>`, then the given ratio is used until the content is loaded. After the content is loaded, the `auto` value is applied, so the intrinsic aspect ratio of the loaded content is used.

If the element is not a replaced element, then the given `ratio` is used.

Formal definition

Initial value	`auto`
Applies to	all elements except inline boxes and internal ruby or table boxes
Inherited	no
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
aspect-ratio =
  auto     ||
  <ratio>

<ratio> =
  <number [0,∞]> [ / <number [0,∞]> ]?
```

This syntax reflects the latest standard as per CSS Box Sizing Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Exploring aspect-ratio effects with fixed width

In this example, the width of the `<div>` elements has been set to `100px` and height to `auto`. Since the width value is fixed here, the `aspect-ratio` property affects only the height of the `<div>` elements to maintain the specified width-to-height ratio.

```
<div>1/1</div>
<div>0.5</div>
<div>1</div>
<div>1/0.5</div>
<div>16/9</div>
```

```
div {
  display: inline-flex;
  background-color: lime;
  justify-content: center;
}
```

```
div {
  width: 100px;
  height: auto;
}
div:nth-child(1) {
  aspect-ratio: 1/1;
}
div:nth-child(2) {
  aspect-ratio: 0.5;
}
div:nth-child(3) {
  aspect-ratio: 1;
}
div:nth-child(4) {
  aspect-ratio: 1/0.5;
}
div:nth-child(5) {
  aspect-ratio: 16/9;
}
```

Fallback to natural aspect ratio

In this example we are using two `<img>` elements. The first element does not have its `src` attribute set to an image file.

```
<img src="" /> <img src="plumeria.jpg" />
```

The following code sets `3/2` as the preferred aspect ratio and `auto` as a fallback.

```
img {
  display: inline;
  width: 200px;
  border: 2px dashed red;
  background-color: lime;
  vertical-align: top;

  aspect-ratio: 3/2 auto;
}
```

Note how the first image without replaced content keeps the `3/2` aspect ratio, while the second image after the content is loaded uses the image's natural aspect ratio.

backdrop-filter CSS property

The **`backdrop-filter`** CSS property lets you apply graphical effects such as blurring or color shifting to the area behind an element. Because it applies to everything *behind* the element, to see the effect the element or its background needs to be transparent or partially transparent.

Try it

```
backdrop-filter: blur(10px);
```

```
backdrop-filter: invert(80%);
```

```
backdrop-filter: sepia(90%);
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div id="example-element">Example</div>
  </div>
</section>
```

```
.example-container {
  background-image: url("/shared-assets/images/examples/balloon.jpg");
  background-size: cover;
  width: 200px;
  height: 200px;
  display: flex;
  align-items: center;
  justify-content: center;
  color: black;
}

#example-element {
```

```
  font-weight: bold;
  flex: 1;
  text-align: center;
  padding: 20px 10px;
  background-color: rgb(255 255 255 / 0.2);
}
```

Syntax

```
/* Keyword value */
backdrop-filter: none;

/* URL to SVG filter */
backdrop-filter: url("common-filters.svg#filter");

/* <filter-function> values */
backdrop-filter: blur(2px);
backdrop-filter: brightness(60%);
backdrop-filter: contrast(40%);
backdrop-filter: drop-shadow(4px 4px 10px blue);
backdrop-filter: grayscale(30%);
backdrop-filter: hue-rotate(120deg);
backdrop-filter: invert(70%);
backdrop-filter: opacity(20%);
backdrop-filter: sepia(90%);
backdrop-filter: saturate(80%);

/* Multiple filters */
backdrop-filter: url("filters.svg#filter") blur(4px) saturate(150%);

/* Global values */
backdrop-filter: inherit;
backdrop-filter: initial;
backdrop-filter: revert;
backdrop-filter: revert-layer;
backdrop-filter: unset;
```

Values

`none`

No filter is applied to the backdrop.

`<filter-value-list>`

A space-separated list of `<filter-function>`s or an SVG filter that will be applied to the backdrop. CSS `<filter-function>`s include `blur()`, `brightness()`, `contrast()`, `drop-shadow()`, `grayscale()`, `hue-rotate()`, `invert()`, `opacity()`, `saturate()`, and `sepia()`.

Description

The `backdrop-filter` property applies filter effects to the pixels painted *behind* an element, up to the nearest ancestor that is a **backdrop root**. Content above the backdrop root is not affected.

Backdrop root

A backdrop root is an element that establishes a boundary for `backdrop-filter` effects. The following elements are backdrop roots:

- The root element (`<html>`)
- An element with a `filter` value other than `none`
- An element with an `opacity` value less than `1`
- An element with a `mask`, `mask-image`, `mask-border`, or `clip-path` value other than `none`
- An element with a `backdrop-filter` value other than `none`
- An element with a `mix-blend-mode` value other than `normal`
- An element with `will-change` set to any of the above properties

This means that if a parent element has `opacity: 0.9`, it becomes a backdrop root and any child's `backdrop-filter` will only blur the content between that parent and the child - not the content behind the parent. This is a common source of confusion when `backdrop-filter` appears to have no visible effect despite being correctly applied.

The following example demonstrates how backdrop roots affect `backdrop-filter`. The first container has `will-change: opacity`, making it a backdrop root - notice that the blur circle only affects the text and square inside the container, not the checkered background behind it. The second container is not a backdrop root, so its blur circle affects everything behind it, including the page background.

```
<div class="parent backdrop-root">
  <div class="text">Text</div>
  <div class="square"></div>
  <div class="overlay"></div>
</div>
<div class="parent">
  <div class="text">Text</div>
  <div class="square"></div>
  <div class="overlay"></div>
</div>
```

```
body {
  display: flex;
  column-gap: 16px;
  padding: 16px;
  background-image: conic-gradient(
    gray 90deg,
    silver 90deg 180deg,
    gray 180deg 270deg,
    silver 270deg
  );
  background-size: 32px 32px;
}

.parent {
  position: relative;
  width: 256px;
  height: 256px;
}
```

```
.backdrop-root {
  outline: 2px solid crimson;
  will-change: opacity;
}

.square {
  position: absolute;
  top: 35px;
  left: 40%;
  width: 25%;
  height: 25%;
  border: 10px solid white;
}

.text {
  position: absolute;
  left: 40%;
  color: white;
  font-size: 32px;
  font-weight: 500;
  text-align: center;
  line-height: 256px;
  filter: blur(1px);
}

.overlay {
  position: absolute;
  top: 25%;
  left: 50%;
  width: 50%;
  height: 50%;
  outline: 3px solid gainsboro;
  border-radius: 9999px;
  backdrop-filter: blur(10px);
}
```

Formal definition

Initial value	none
Applies to	all elements; In SVG, it applies to container elements excluding the `<defs>` element and all graphics elements
Inherited	no
Computed value	as specified
Animation type	a filter function list

Formal syntax

```
backdrop-filter =
  none                |
  <filter-value-list>

<filter-value-list> =
  [ <filter-function> | <url> ]+

<filter-function> =
  <blur()>         |
  <brightness()>   |
  <contrast()>     |
  <drop-shadow()>  |
  <grayscale()>    |
  <hue-rotate()>   |
  <invert()>       |
  <opacity()>      |
  <sepia()>        |
  <saturate()>

<blur()> =
  blur( <length>? )

<brightness()> =
  brightness( [ <number> | <percentage> ]? )

<contrast()> =
  contrast( [ <number> | <percentage> ]? )

<drop-shadow()> =
  drop-shadow( [ <color>? && <length>{2,3} ] )

<grayscale()> =
  grayscale( [ <number> | <percentage> ]? )

<hue-rotate()> =
  hue-rotate( [ <angle> | <zero> ]? )

<invert()> =
  invert( [ <number> | <percentage> ]? )

<opacity()> =
  opacity( [ <number> | <percentage> ]? )

<sepia()> =
  sepia( [ <number> | <percentage> ]? )

<saturate()> =
  saturate( [ <number> | <percentage> ]? )
```

This syntax reflects the latest standard as per Filter Effects Module Level 1, Filter Effects Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

CSS

```
.box {
  background-color: rgb(255 255 255 / 30%);
  backdrop-filter: blur(10px);
}

body {
  background-image: url("anemones.jpg");
}
```

```
html,
body {
  height: 100%;
  width: 100%;
}

.container {
  background-size: cover;
  align-items: center;
  display: flex;
  justify-content: center;
  height: 100%;
  width: 100%;
}
.box {
  border-radius: 5px;
  font-family: sans-serif;
  text-align: center;
  max-width: 50%;
  max-height: 50%;
  padding: 20px 40px;
}
```

HTML

```
<div class="container">
  <div class="box">
    <p>backdrop-filter: blur(10px)</p>
  </div>
</div>
```

backface-visibility CSS property

The **`backface-visibility`** CSS property sets whether the back face of an element is visible when turned towards the user.

An element's back face is a mirror image of its front face. Though invisible in 2D, the back face can become visible when a transformation causes the element to be rotated in 3D space. (This property has no effect on 2D transforms, which have no perspective.)

Try it

```
backface-visibility: visible;
```

```
backface-visibility: hidden;
```

```
<section class="default-example" id="default-example">
  <div id="example-element">
    <div class="face front">1</div>
    <div class="face back">2</div>
    <div class="face right">3</div>
    <div class="face bottom">6</div>
  </div>
</section>
```

```
#default-example {
  background: linear-gradient(skyblue, khaki);
}

#example-element {
  width: 100px;
  height: 100px;
  perspective: 550px;
  perspective-origin: 220% 220%;
  transform-style: preserve-3d;
}

.face {
  display: flex;
  align-items: center;
  justify-content: center;
  width: 100%;
  height: 100%;
  position: absolute;
  backface-visibility: inherit;
  background: rgb(0 0 0 / 0.4);
  font-size: 60px;
  color: white;
```

```
}

.front {
  transform: translateZ(50px);
}

.back {
  background: rgb(230 0 0);
  color: white;
  transform: rotateY(180deg) translateZ(50px);
}

.right {
  background: rgb(0 0 0 / 0.6);
  transform: rotateY(90deg) translateZ(50px);
}

.bottom {
  background: rgb(0 0 0 / 0.6);
  transform: rotateX(-90deg) translateZ(50px);
}
```

Syntax

```
/* Keyword values */
backface-visibility: visible;
backface-visibility: hidden;

/* Global values */
backface-visibility: inherit;
backface-visibility: initial;
backface-visibility: revert;
backface-visibility: revert-layer;
backface-visibility: unset;
```

Values

This property is specified as one of the following keywords:

`visible`

The back face is visible when turned towards the user.

`hidden`

The back face is hidden, effectively making the element invisible when turned away from the user.

Formal definition

Initial value	`visible`
Applies to	transformable elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
backface-visibility =
  visible  |
  hidden
```

This syntax reflects the latest standard as per CSS Transforms Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Cube with transparent and opaque faces

This example shows a cube with transparent faces, and one with opaque faces.

HTML

```
<table>
  <thead>
    <tr>
      <th><code>backface-visibility: visible;</code></th>
      <th><code>backface-visibility: hidden;</code></th>
    </tr>
  </thead>
  <tbody>
    <tr>
      <td>
        <div class="container">
          <div class="cube show-bf">
            <div class="face front">1</div>
            <div class="face back">2</div>
            <div class="face right">3</div>
            <div class="face left">4</div>
            <div class="face top">5</div>
            <div class="face bottom">6</div>
          </div>
        </div>
        <p>
          Since all faces are partially transparent, the back faces (2, 4, 5)
          are visible through the front faces (1, 3, 6).
        </p>
      </td>
      <td>
        <div class="container">
          <div class="cube hide-bf">
            <div class="face front">1</div>
```

```
            <div class="face back">2</div>
            <div class="face right">3</div>
            <div class="face left">4</div>
            <div class="face top">5</div>
            <div class="face bottom">6</div>
          </div>
        </div>
        <p>The three back faces (2, 4, 5) are hidden.</p>
      </td>
    </tr>
  </tbody>
</table>
```

CSS

```
/* Classes that will show or hide the
   three back faces of the "cube" */
.show-bf div {
  backface-visibility: visible;
}

.hide-bf div {
  backface-visibility: hidden;
}

/* Define the container div, the cube div, and a generic face */
.container {
  width: 150px;
  height: 150px;
  margin: 75px 0 0 75px;
  border: none;
}

.cube {
  width: 100%;
  height: 100%;
  perspective: 550px;
  perspective-origin: 150% 150%;
  transform-style: preserve-3d;
}

.face {
  display: block;
  position: absolute;
  width: 100px;
  height: 100px;
  border: none;
  line-height: 100px;
  font-family: sans-serif;
  font-size: 60px;
  color: white;
  text-align: center;
}

/* Define each face based on direction */
.front {
  background: rgb(0 0 0 / 30%);
  transform: translateZ(50px);
}

.back {
  background: lime;
  color: black;
  transform: rotateY(180deg) translateZ(50px);
}

.right {
  background: rgb(196 0 0 / 70%);
  transform: rotateY(90deg) translateZ(50px);
}

.left {
  background: rgb(0 0 196 / 70%);
  transform: rotateY(-90deg) translateZ(50px);
}

.top {
  background: rgb(196 196 0 / 70%);
  transform: rotateX(90deg) translateZ(50px);
}

.bottom {
  background: rgb(196 0 196 / 70%);
  transform: rotateX(-90deg) translateZ(50px);
}

/* Make the table a little nicer */
th,
p,
td {
  background-color: #eeeeee;
  margin: 0px;
  padding: 6px;
  font-family: sans-serif;
  text-align: left;
}
```

- Using CSS transforms

background CSS property

The **background** CSS shorthand property sets all background style properties at once, such as color, image, origin, size, and repeat method.

Try it

```
background: green;
```

```
background: content-box radial-gradient(crimson, skyblue);
```

```
background: no-repeat url("/shared-assets/images/examples/lizard.png");
```

```
background: left 5% / 15% 60% repeat-x
  url("/shared-assets/images/examples/star.png");
```

```
background:
  center / contain no-repeat
    url("/shared-assets/images/examples/firefox-logo.svg"),
  #eeeeee 35% url("/shared-assets/images/examples/lizard.png");
```

```
<section id="default-example">
  <div id="example-element"></div>
</section>
```

```
#example-element {
  min-width: 100%;
  min-height: 100%;
  padding: 10%;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- background-attachment
- background-clip
- background-color
- background-image
- background-origin
- background-position
- background-repeat
- background-size

Reset-only sub-properties

This property resets the following CSS properties to their initial values:

- background-blend-mode

Syntax

```
/* Using a <background-color> */
background: green;

/* Using a <bg-image> and <repeat-style> */
background: url("test.jpg") repeat-y;

/* Using a <visual-box> and <'background-color'> */
background: border-box red;

/* A single image, centered and scaled */
background: no-repeat center/80% url("../img/image.png");

/* Global values */
background: inherit;
background: initial;
background: revert;
background: revert-layer;
background: unset;
```

Values

`<attachment>`

See background-attachment. Default: scroll.

`<visual-box>`

See background-clip and background-origin. Default: border-box and padding-box respectively.

`<'background-color'>`

See background-color. Default: transparent.

`<bg-image>`

See background-image. Default: none.

`<bg-position>`

See background-position. Default: 0% 0%.

`<repeat-style>`

See background-repeat. Default: repeat.

`<bg-size>`

See background-size. Default: auto.

Description

The background shorthand property enables you to declare all CSS background properties in a single declaration. The background lies underneath the content of an element. When you have multiple, comma-separated background values, each is a background layer that is painted on top of the previous layers.

The background property is specified as one or more background layers, separated by commas. Each layer may include zero, one, or two <visual-box> components and zero or one <attachment>, <bg-image>, <bg-position>, <bg-size>, and <repeat-style> components. If two <bg-position>, <bg-size>, or <repeat-style> components are specified, the first value is the horizontal value and the second value is the vertical value. If only a single value is set, that value is applied to both dimensions.

The <'background-color'> component may only be included in the last background layer specified.

Component properties not set in the background shorthand property value declaration are set to their default values.

Component property order

Because some of the component properties share value types, the order of those component properties within the shorthand is important.

The <bg-size> value may only be included immediately after <bg-position>, separated with the / character. For example: 10px 10px / 80% 80% means the background image is 80% as tall and as wide as the element, and will be positioned 10px from the top and 10px from the left of the element's top-left corner. Within the <bg-position>, if both values are lengths, or one is a length and the other is center, the first value refers to the horizontal position and the second value refers to the vertical position.

Each background layer can include zero, one, or two <visual-box> values. If only one value is included, it sets both background-origin and background-clip. If two values are present, the first occurrence specifies the background-origin and the second specifies the background-clip value. If no <visual-box> values are present, the background-origin defaults to padding-box and the background-clip defaults to border-box.

While there is no order requirement for the other background properties, the following order is recommended for consistency and legibility; remember that none of the values are required:

<bg-image> <bg-position> / <bg-size> <repeat-style> <attachment> <bg-clip> <bg-origin> <'background-color'>

The following background explicitly sets all the default values in this order:

```
background: none 0% 0% / auto auto repeat scroll border-box padding-box
  transparent;
```

The following three lines of CSS are equivalent to the above, even if the order differs:

```
background: none;
background: transparent;
background: repeat scroll 0% 0% / auto padding-box border-box none transparent;
```

Image painting order

If multiple comma-separated backgrounds are included, they create multiple background layers on top of one another. The first background in the list creates the top layer. If the top layer contains no transparent areas, this is the only layer that will be visible.

The last layer is the bottom layer. The background color is always included in this layer.

Body background applied to the entire document

If the document <html> :root element's computed background-image value is none and its background-color is transparent, the browser will transfer the background styles set on the <body> element onto the :root and treat the <body> as if background: initial were set. In other words, the <html> element gets all the background styles set on the <body> element, and the <body> element's background properties are set to their initial values.

Because of this behavior, the specification authors recommend setting your document's background styles in your body style block rather than your html style block. However, it's important to note that using containment disables this behavior. When the contain property is set to anything other than none on either the <html> or <body> element, the background property and any longhand components do not propagate from the <body> element to the root <html> element.

Formal definition

Initial value	as each of the properties of the shorthand: • background-image: none • background-position: 0% 0% • background-size: auto auto • background-repeat: repeat • background-origin: padding-box • background-clip: border-box • background-attachment: scroll • background-color: transparent
Applies to	all elements. It also applies to ::first-letter and ::first-line.
Inherited	no
Percentages	as each of the properties of the shorthand: • background-position: refer to the size of the background positioning area minus size of background image; size refers to the width for horizontal offsets and to the height for vertical offsets • background-size: relative to the background positioning area

Computed value	as each of the properties of the shorthand:
	• background-image: as specified, but with <url> values made absolute
	• background-position: as each of the properties of the shorthand:
	  ◦ background-position-x: A list, each item consisting of: an offset given as a combination of an absolute length and a percentage, plus an origin keyword
	  ◦ background-position-y: A list, each item consisting of: an offset given as a combination of an absolute length and a percentage, plus an origin keyword
	• background-size: as specified, but with relative lengths converted into absolute lengths
	• background-repeat: a list, each item consisting of two keywords, one per dimension
	• background-origin: as specified
	• background-clip: as specified
	• background-attachment: as specified
	• background-color: computed color

Animation type	as each of the properties of the shorthand:

	• background-color: a color • background-image: discrete • background-clip: a repeatable list • background-position: a repeatable list • background-size: a repeatable list • background-repeat: discrete • background-attachment: discrete

Formal syntax

```
background =
  <bg-layer>#? , <final-bg-layer>

<bg-layer> =
  <bg-image>                    ||
  <bg-position> [ / <bg-size> ]?  ||
  <repeat-style>                ||
  <attachment>                  ||
  <visual-box>                  ||
  <bg-clip>

<final-bg-layer> =
  <bg-image>                    ||
  <bg-position> [ / <bg-size> ]?  ||
  <repeat-style>                ||
  <attachment>                  ||
  <visual-box>                  ||
  <bg-clip>                     ||
  <'background-color'>

<bg-image> =

  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Backgrounds Module Level 4, CSS Box Model Module Level 4, CSS Images Module Level 4, CSS Images Module Level 5, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Accessibility

Browsers do not provide any special information on background images to assistive technology. This is important primarily for screen readers, as a screen reader will not announce its presence and therefore convey nothing to its users. If the image contains information critical to understanding the page's overall purpose, it is better to describe it semantically in the document.

- Understanding Success Criterion 1.1.1 | W3C Understanding WCAG 2.0

Examples

Setting backgrounds with color keywords and images

HTML

```
<p class="top-banner">
  Starry sky<br />
  Twinkle twinkle<br />
  Starry sky
</p>
<p class="warning">Here is a paragraph</p>
```

CSS

```
.warning {
  background: pink;
}

.top-banner {
  background: url("star-solid.gif") #9999ff repeat-y fixed;
}
```

Result

background-attachment CSS property

The **background-attachment** CSS property sets whether a background image's position is fixed within the viewport, or scrolls with its containing block.

Try it

```
background-attachment: scroll;
```

```
background-attachment: fixed;
```

```
background-attachment: local;
```

```
background-attachment: fixed, scroll;
```

```
background-attachment: scroll, fixed;
```

```
<section id="default-example">
  <div id="example-element">
    <p>
      From there to here<br />
      from here to there,<br />
      Funny things<br />
      Are everywhere.
    </p>
    <p>--Dr. Seuss</p>
  </div>
</section>
```

```
body {
  overflow: scroll;
}

#default-example {
  height: 600px;
}

#example-element {
  max-width: 20rem;
  height: 100%;
  background:
    url("/shared-assets/images/examples/lizard.png") right 3rem top 1rem / 15rem
      no-repeat,
    url("/shared-assets/images/examples/moon.jpg") center / 10rem;
  font-size: 1.2rem;
  font-weight: bolder;
  overflow: auto;
  padding: 20px;
  color: red;
  text-shadow:
    0 0 0.5rem black,
    0 0 0.5rem black;
}
```

Syntax

```
/* Keyword values */
background-attachment: scroll;
background-attachment: fixed;
background-attachment: local;

/* Global values */
background-attachment: inherit;
background-attachment: initial;
background-attachment: revert;
background-attachment: revert-layer;
background-attachment: unset;
```

Values

This property is specified as one or more comma-separated keyword values:

`fixed`

The background is fixed relative to the viewport. Even if an element has a scrolling mechanism, the background doesn't move with the element. If set, the `background-origin` property is ignored.

`local`

The background is fixed relative to the element's contents. If the element has a scrolling mechanism, the background scrolls with the element's contents, and the background painting area and background positioning area are relative to the scrollable area of the element rather than to the border framing them.

`scroll`

The background is fixed relative to the element itself and does not scroll with its contents. (It is effectively attached to the element's border.)

Formal definition

Initial value	`scroll`
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
background-attachment =
  <attachment>#

<attachment> =
  scroll  |
  fixed   |
  local
```

This syntax reflects the latest standard as per CSS Backgrounds Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

HTML

We include an unordered list (`<ul>`) with some list items (`<li>`).

```
<ul>
  <li>One fish</li>
  <li>Two fish</li>
  <li>Red fish</li>
  <li>Blue fish</li>
  <li>Black fish</li>
  <li>Blue fish</li>
  <li>Old fish</li>
  <li>New fish.</li>
  <li>This one has a little star.</li>
  <li>This one has a little car.</li>
  <li>Say! What a lot</li>
  <li>Of fish there are.</li>
</ul>
```

CSS

We define a `background-image` and set the `background-attachment` to `fixed`. We also include a `height`, `width`, and `overflow` to ensure the element scrolls.

```
ul {
  background-image: url("star-solid.gif");
  background-attachment: fixed;

  width: 300px;
  height: 70px;
  overflow: scroll;
}
```

Result

Note how the background remains fixed relative to the list's viewport when you scroll the overflowing text into view.

Multiple background images

This property supports multiple background images. You can specify a different `<attachment>` for each background, separated by commas. Each image is matched with the corresponding `<attachment>` type, from first specified to last.

HTML

We include all of Dr. Seuss's poem.

```
<div>
  <ul>
    <li>One fish</li>
    <li>Two fish</li>
    <li>Red fish</li>
    <li>Blue fish</li>
    <li>Black fish</li>
    <li>Blue fish</li>
    <li>Old fish</li>
    <li>New fish.</li>
    <li>This one has a little star.</li>
    <li>This one has a little car.</li>
    <li>Say! What a lot</li>
    <li>Of fish there are.</li>
    <li>Yes. Some are red. And some are blue.</li>
    <li>Some are old. And some are new.</li>
    <li>Some are sad.</li>
    <li>And some are glad.</li>
    <li>And some are very, very bad.</li>
    <li>Why are they</li>
    <li>Sad and glad and bad?</li>
    <li>I do not know.</li>
    <li>Go ask your dad.</li>
    <li>Some are thin.</li>
    <li>And some are fat.</li>
    <li>The fat one has</li>
    <li>A yellow hat.</li>
    <li>From there to here, from here to there,</li>
    <li>Funny things</li>
    <li>Are everywhere.</li>
  </ul>
  <p>--Dr. Seuss</p>
</div>
```

CSS

We include a `height`, `width`, and `overflow` on the parent `<div>` to ensure the contents scroll.

We define two comma-separated background images on the list, and set the `background-attachment` to `fixed, scroll`, meaning the first background image will be `fixed` and the second will `scroll`. We set the `background-repeat` to make both background images repeat vertically, separating them with the `background-position` property.

```
div {
  width: 300px;
  height: 200px;
  overflow: scroll;
}
ul {
  background-image: url("star-solid.gif"), url("star-transparent.gif");
  background-attachment: fixed, scroll;
  background-repeat: repeat-y;
  background-position:
    0 0,
    100px 0;
}
```

Result

Note how the first background image is fixed to the viewport while the second background image is fixed relative to the list.

- CSS backgrounds and borders module

background-blend-mode CSS property

The **`background-blend-mode`** CSS property sets how an element's background images should blend with each other and with the element's background color.

Blending modes should be defined in the same order as the `background-image` property. If the blending modes' and background images' list lengths are not equal, it will be repeated and/or truncated until lengths match.

Try it

```
background-blend-mode: normal;
```

```
background-blend-mode: multiply;
```

```
background-blend-mode: hard-light;
```

```
background-blend-mode: difference;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element"></div>
  </div>
</section>
```

```
#example-element {
  background-color: green;
  background-image: url("/shared-assets/images/examples/balloon.jpg");
  width: 250px;
  height: 305px;
}
```

Syntax

```
/* One value */
background-blend-mode: normal;

/* Two values, one per background */
background-blend-mode: darken, luminosity;

/* Global values */
background-blend-mode: inherit;
background-blend-mode: initial;
background-blend-mode: revert;
background-blend-mode: revert-layer;
background-blend-mode: unset;
```

Values

`<blend-mode>`

The blending mode to be applied. There can be several values, separated by commas.

Formal definition

Initial value	`normal`
Applies to	All elements. In SVG, it applies to container elements, graphics elements, and graphics referencing elements.. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
background-blend-mode =
  <'mix-blend-mode'>#

<mix-blend-mode> =
  <blend-mode>  |
  plus-lighter

<blend-mode> =
  normal       |
  darken       |
  multiply     |
  color-burn   |
  lighten      |
  screen       |
  color-dodge  |
  overlay      |
  soft-light   |
  hard-light   |
  difference   |
  exclusion    |
  hue          |
```

```
  saturation   |
  color        |
  luminosity
```

This syntax reflects the latest standard as per Compositing and Blending Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

```
.item {
  width: 300px;
  height: 300px;
  background: url("image1.png"), url("image2.png");
  background-blend-mode: screen;
}
```

Try out different blend modes

```
<div id="div"></div>
<select id="select">
  <option>normal</option>
  <option>multiply</option>
  <option selected>screen</option>
  <option>overlay</option>
  <option>darken</option>
  <option>lighten</option>
  <option>color-dodge</option>
  <option>color-burn</option>
  <option>hard-light</option>
  <option>soft-light</option>
  <option>difference</option>
  <option>exclusion</option>
  <option>hue</option>
  <option>saturation</option>
  <option>color</option>
  <option>luminosity</option>
</select>
```

```
#div {
  width: 300px;
  height: 300px;
  background: url("br.png"), url("tr.png");
  background-blend-mode: screen;
}
```

```
document.getElementById("select").onchange = (event) => {
  document.getElementById("div").style.backgroundBlendMode =
    document.getElementById("select").selectedOptions[0].innerHTML;
};
console.log(document.getElementById("div"));
```

See also

- `<blend-mode>`
- `mix-blend-mode`

background-clip CSS property

The **`background-clip`** CSS property sets whether an element's background extends underneath its border box, padding box, or content box.

Try it

```
background-clip: border-box;
```

```
background-clip: padding-box;
```

```
background-clip: content-box;
```

```
background-clip: text;
color: transparent;
text-shadow: none;
```

```
<section id="default-example">
  <div id="example-element">This is the content of the element.</div>
</section>
```

```
#example-element {
  background-image: url("/shared-assets/images/examples/leopard.jpg");
  color: white;
  text-shadow: 2px 2px black;
  padding: 20px;
  border: 10px dashed #333333;
  font-size: 2em;
  font-weight: bold;
}
```

Syntax

```
/* Keyword values */
background-clip: border-box;
background-clip: padding-box;
background-clip: content-box;
background-clip: text;
background-clip: border-area;

/* Global values */
background-clip: inherit;
```

```
background-clip: initial;
background-clip: revert;
background-clip: revert-layer;
background-clip: unset;
```

Values

`border-box`

The background extends to the outside edge of the border (but underneath the border in z-ordering).

`padding-box`

The background extends to the outside edge of the padding. No background is drawn beneath the border.

`content-box`

The background is painted within (clipped to) the content box.

`text`

The background is painted within (clipped to) the foreground text.

`border-area`

The background is painted within (clipped to) the area painted by the border, taking `border-width` and `border-style` into account but ignoring any transparency introduced by `border-color`.

Description

The background is always drawn behind the border, so `background-clip: border-box` has a visual effect only when the border is partially opaque or has transparent or partially opaque regions. Also, the `background-clip: text` property has little to no visual effect if the text is fully or partially opaque.

> **Note:** Because the root element has a different background painting area, the `background-clip` property has no effect when specified on it. See "The backgrounds of special elements."

> **Note:** For documents whose root element is an HTML element: if the computed value of `background-image` on the root element is `none` and its `background-color` is `transparent`, user agents must instead propagate the computed values of the `background` properties from that element's first HTML `<body>` child element. The used values of that `<body>` element's `background` properties are their initial values, and the propagated values are treated as if they were specified on the root element. It is recommended that authors of HTML documents specify the canvas background for the `<body>` element rather than the HTML element.

Accessibility

When using `background-clip: text`, check that the contrast ratio between the background color and the color of the text placed over it is high enough that people experiencing low vision conditions will be able to read the content of the page.

If the background image does not load, this could also lead to the text becoming unreadable. Add a fallback `background-color` to prevent this from happening, and test without the image.

Consider using feature queries with `@supports` to test for support of `background-clip: text` and provide an accessible alternative where it is not supported.

Formal definition

Initial value	`border-box`
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Computed value	as specified
Animation type	a repeatable list

Formal syntax

```
background-clip =
  <bg-clip>#

<bg-clip> =
  <visual-box>             |
  [ border-area || text ]

<visual-box> =
  content-box  |
  padding-box  |
  border-box
```

This syntax reflects the latest standard as per CSS Backgrounds Module Level 4, CSS Box Model Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<p class="border-box">The background extends behind the border.</p>
<p class="padding-box">
  The background extends to the inside edge of the border.
</p>
<p class="content-box">
  The background extends only to the edge of the content box.
</p>
<p class="text">The background is clipped to the foreground text.</p>
<p class="border-area">
  The background is clipped to the area painted by the border.
</p>
```

CSS

```
p {
  border: 0.8em darkviolet;
  border-style: dotted double;
  margin: 1em 0;
```

```
  padding: 1.4em;
  background: linear-gradient(60deg, red, yellow, red, yellow, red);
  font: 900 1.2em sans-serif;
  text-decoration: underline;
}

.border-box {
  background-clip: border-box;
}
.padding-box {
  background-clip: padding-box;
}
.content-box {
  background-clip: content-box;
}

.text {
  background-clip: text;
  color: rgb(0 0 0 / 20%);
}

.border-area {
  background-clip: border-area;
  border-color: transparent;
}
```

Result

- The `clip-path` property creates a clipping region that defines what part of an *entire element* should be displayed.
- Background properties: `background`, `background-color`, `background-image`, `background-origin`
- Introduction to the CSS box model

background-color CSS property

The **`background-color`** CSS property sets the background color of an element.

Try it

```
background-color: brown;
```

```
background-color: #74992e;
```

```
background-color: rgb(255 255 128);
```

```
background-color: rgb(255 255 128 / 0.5);
```

```
background-color: hsl(50 33% 25%);
```

```
background-color: hsl(50 33% 25% / 0.75);
```

```
<section id="default-example">
  <div class="transition-all" id="example-element"></div>
</section>
```

```
#example-element {
  min-width: 100%;
  min-height: 100%;
  padding: 10%;
}
```

Syntax

```
/* Keyword values */
background-color: red;
background-color: indigo;

/* Hexadecimal value */
background-color: #bbff00; /* Fully opaque */
background-color: #bf0; /* Fully opaque shorthand */
background-color: #11ffee00; /* Fully transparent */
background-color: #1fe0; /* Fully transparent shorthand */
background-color: #11ffeeff; /* Fully opaque */
background-color: #1fef; /* Fully opaque shorthand */

/* RGB value */
background-color: rgb(255 255 128); /* Fully opaque */
background-color: rgb(117 190 218 / 50%); /* 50% transparent */

/* HSL value */
background-color: hsl(50 33% 25%); /* Fully opaque */
background-color: hsl(50 33% 25% / 75%); /* 75% opaque, i.e. 25% transparent */

/* Special keyword values */
background-color: currentColor;
background-color: transparent;

/* Global values */
background-color: inherit;
background-color: initial;
background-color: revert;
background-color: revert-layer;
background-color: unset;
```

Values

This property is specified as one `<color>` value:

`<color>`

The uniform color of the background. It is rendered behind any `background-image` that is specified, although the color will still be visible through any transparency in the image.

Description

The `background-color` property sets the background color of an element box. The color is drawn behind any background images. By default, the background color is painted within the border-box, meaning it's painted behind the border, ending at the outer edge of the border-box.

Clipping of the `background-color` paint area is controlled via the `background-clip` property. If multiple background images are set, the background color's clipping is determined by the value of the `background-clip` associated with the bottom-most background image.

Accessibility

It is important to ensure that the contrast ratio between the background color and the color of the text placed over it is high enough that people experiencing low vision conditions will be able to read the content of the page. A high contrast ratio also improves content accessibility for glossy-screened mobile device users when in a bright environment, such as sunlight.

Color contrast ratio is determined by comparing the luminance of the text and background color values. In order to meet current Web Content Accessibility Guidelines (WCAG), a ratio of 4.5:1 is required for text content and 3:1 for larger text such as headings. Large text is defined as 18.66px and bold or larger, or 24px or larger.

- Understanding color contrast
- WebAIM: Color Contrast Checker
- Understanding Success Criterion 1.4.3 | W3C Understanding WCAG 2.0

Formal definition

Initial value	`transparent`
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Computed value	computed color
Animation type	a color

Formal syntax

```
background-color =
  <color>
```

This syntax reflects the latest standard as per CSS Backgrounds Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

This example demonstrates applying `background-color` to HTML `<p>` elements using different CSS `<color>` values.

HTML

```
<p class="example-one">Lorem ipsum dolor sit amet, consectetuer</p>

<p class="example-two">Lorem ipsum dolor sit amet, consectetuer</p>

<p class="example-three">Lorem ipsum dolor sit amet, consectetuer</p>
```

CSS

Each paragraph is set to a different background color, including explicitly setting the default `transparent`, an `rgb()` color function, and a `<hex-color>`. We also set the `color` property to ensure enough contrast between the text and its background.

```
.example-one {
  background-color: transparent;
}

.example-two {
  background-color: rgb(153 102 153);
  color: rgb(255 255 204);
}

.example-three {
  background-color: #777799;
  color: white;
}
```

Result

Colorized tables

This example demonstrates the use of `background-color` on HTML `<table>` elements, including `<tr>` rows and `<td>` cells. It also demonstrates how background colors are painted behind any borders.

HTML

```
<table>
  <tbody>
    <tr id="r1">
      <td id="c11">11</td>
      <td id="c12">12</td>
      <td id="c13">13</td>
    </tr>
    <tr id="r2">
      <td id="c21">21</td>
      <td id="c22">22</td>
      <td id="c23">23</td>
    </tr>
    <tr id="r3">
      <td id="c31">31</td>
      <td id="c32">32</td>
      <td id="c33">33</td>
```

```
    </tr>
  </tbody>
</table>
```

CSS

We use CSS to set different `<named-color>` values. We also set a large dashed border on the table and every cell to demonstrate how the `background-color` is painted to the outer edge of the border-box.

```
table {
  border-collapse: collapse;
  border: dashed black 5px;
  width: 250px;
  height: 150px;
}
td {
  border: dashed 5px black;
}
#r1 {
  background-color: lightblue;
}
#c12 {
  background-color: cyan;
}
#r2 {
  background-color: grey;
}
#r3 {
  background-color: olive;
}
```

background-image CSS property

The **`background-image`** CSS property sets one or more background images on an element.

Try it

```
background-image: url("/shared-assets/images/examples/lizard.png");
```

```
background-image:
  url("/shared-assets/images/examples/lizard.png"),
  url("/shared-assets/images/examples/star.png");
```

```
background-image:
  url("/shared-assets/images/examples/star.png"),
  url("/shared-assets/images/examples/lizard.png");
```

```
background-image:
  linear-gradient(rgb(0 0 255 / 0.5), rgb(255 255 0 / 0.5)),
  url("/shared-assets/images/examples/lizard.png");
```

```
<section id="default-example">
  <div id="example-element"></div>
</section>
```

```
#example-element {
  min-width: 100%;
  min-height: 100%;
  padding: 10%;
}
```

Syntax

```
/* single image */
background-image: linear-gradient(black, white);
background-image: url("cat-front.png");

/* multiple images */
background-image:
  radial-gradient(circle, transparent 45%, black 48%),
  radial-gradient(ellipse farthest-corner, #fc1c14 20%, #cf15cf 80%);

/* Global values */
background-image: inherit;
background-image: initial;
background-image: revert;
background-image: revert-layer;
background-image: unset;
```

Values

This property is specified as the keyword `none` or as a comma-separated list of `<image>` values.

`none`

Is a keyword denoting the absence of images.

`<image>`

Is an `<image>` denoting the image to display.

Description

The `background-image` property sets background images on an element.

You can define multiple backgrounds on an element by specifying a list of comma-separated image. The background images are drawn on stacking context layers on top of each other. The first layer specified is drawn as if it is closest to the user.

The borders of the element are then drawn on top of them, and the `background-color` is drawn beneath them. How the images are drawn relative to the box and its borders is defined by the `background-clip` and `background-origin` CSS properties.

If a specified image cannot be drawn (for example, when the file denoted by the specified URI cannot be loaded), browsers handle it as they would a `none` value.

> **Note:** Even if the images are opaque and the color won't be displayed in normal circumstances, web developers should always specify a `background-color`. If the images cannot be loaded—for instance, when the network is down—the background color will be used as a fallback.

Accessibility

Browsers do not provide any special information on background images to assistive technology. This is important primarily for screen readers, as a screen reader will not announce its presence and therefore convey nothing to its users. If the image contains information critical to understanding the page's overall purpose, it is better to describe it semantically in the document.

- MDN Understanding WCAG, Guideline 1.1 explanations
- Understanding Success Criterion 1.1.1 | W3C Understanding WCAG 2.0

Additionally, it is important to ensure that the contrast ratio between the background image and the foreground text is high enough that people with low vision can read the page content.

Color contrast ratio is determined by comparing the luminance of the text and background color values. To meet Web Content Accessibility Guidelines (WCAG), a ratio of 4.5:1 is required for body text content and 3:1 for larger text such as headings. Large text is defined as 24px or larger, or bolded 18.66px or larger.

Formal definition

Initial value	none
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Computed value	as specified, but with `<url>` values made absolute
Animation type	discrete

Formal syntax

```
background-image =
  <bg-image>#

<bg-image> =
  <image>  |
  none

<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
  <gradient>

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-set()> =
  image-set( <image-set-option># )

<cross-fade()> =
  cross-fade( <cf-image># )

<element()> =
  element( <id-selector> )

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Backgrounds Module Level 4, CSS Images Module Level 4, CSS Images Module Level 5, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Layering background images

Note that the star image is partially transparent and is layered over the cat image.

HTML

```
<div>
  <p class="cats-and-stars">This paragraph is full of cats<br />and stars.</p>
  <p>This paragraph is not.</p>
  <p class="cats-and-stars">Here are more cats for you.<br />Look at them!</p>
  <p>And no more.</p>
</div>
```

CSS

```
p {
  font-weight: bold;
  font-size: 1.5em;
  color: white;
  text-shadow: 0.07em 0.07em 0.05em black;
  background-image: none;
  background-color: transparent;
}

div {
  background-image: url("mdn_logo_only_color.png");
}

.cats-and-stars {
  background-image: url("star-transparent.gif"), url("cat-front.png");
  background-color: transparent;
}
```

background-origin CSS property

The **`background-origin`** CSS property sets the background's origin: from the border start, inside the border, or inside the padding.

Note that `background-origin` is ignored when `background-attachment` is `fixed`.

Try it

```
background-origin: border-box;
background-repeat: no-repeat;
```

```
background-origin: padding-box;
background-repeat: no-repeat;
```

```
background-origin: content-box;
background-repeat: no-repeat;
```

```
<section id="default-example">
  <div id="example-element">This is the content of the element.</div>
</section>
```

```
#example-element {
  background-image: url("/shared-assets/images/examples/leopard.jpg");
  color: #d73611;
  text-shadow: 2px 2px black;
  padding: 20px;
  border: 10px dashed #333333;
  font-size: 2em;
```

```
  font-weight: bold;
}
```

Syntax

```
/* Keyword values */
background-origin: border-box;
background-origin: padding-box;
background-origin: content-box;

/* Global values */
background-origin: inherit;
background-origin: initial;
background-origin: revert;
background-origin: revert-layer;
background-origin: unset;
```

Values

This property is specified as one of the following keyword values:

`border-box`

The background is positioned relative to the border box.

`padding-box`

The background is positioned relative to the padding box. Default value.

`content-box`

The background is positioned relative to the content box.

Formal definition

Initial value	`padding-box`
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Computed value	as specified
Animation type	a repeatable list

Formal syntax

```
background-origin =
  <visual-box>#

<visual-box> =
  content-box  |
  padding-box  |
  border-box
```

This syntax reflects the latest standard as per CSS Backgrounds Module Level 4, CSS Box Model Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting background origins

```
.example {
  border: 10px double;
  padding: 10px;
  background: url("image.jpg");
  background-position: center left;
  background-origin: content-box;
}
```

```
#example2 {
  border: 4px solid black;
  padding: 10px;
  background: url("image.gif");
  background-repeat: no-repeat;
  background-origin: border-box;
}
```

```
div {
  background-image:
    url("logo.jpg"), url("main-back.png"); /* Applies two images to the background */
  background-position:
    top right,
    0px 0px;
  background-origin: content-box, padding-box;
}
```

Using two gradients

In this example the box has a thick dotted border. The first gradient uses the `padding-box` as the `background-origin` and therefore the background sits inside the border. The second uses the `content-box` and so only displays behind the content.

```
.box {
  margin: 10px 0;
  color: white;
  background:
    linear-gradient(
      90deg,
      rgb(131 58 180 / 100%) 0%,
      rgb(253 29 29 / 60%) 60%,
      rgb(252 176 69 / 100%) 100%
    ),
```

```
    radial-gradient(circle, white 0%, black 28%);
  border: 20px dashed black;
  padding: 20px;
  width: 400px;
  background-origin: padding-box, content-box;
  background-repeat: no-repeat;
}
```

```
<div class="box">Hello!</div>
```

See also

- background-clip

background-position CSS property

The **background-position** CSS property sets the initial position for each background image.

Try it

```
background-position: top;
```

```
background-position: left;
```

```
background-position: center;
```

```
background-position: 25% 75%;
```

```
background-position: bottom 50px right 100px;
```

```
background-position: right 35% bottom 45%;
```

```
<section class="display-block" id="default-example">
  <div class="transition-all" id="example-element"></div>
</section>
```

```
#example-element {
  background-color: navajowhite;
  background-image: url("/shared-assets/images/examples/star.png");
  background-repeat: no-repeat;
  height: 100%;
}
```

Syntax

```
/* Keyword values */
background-position: top;
background-position: bottom;
background-position: left;
background-position: right;
background-position: center;

/* <percentage> values */
background-position: 25% 75%;

/* <length> values */
background-position: 0 0;
background-position: 1cm 2cm;
background-position: 10ch 8em;

/* Multiple images */
background-position:
  0 0,
  center;

/* Edge offsets values */
background-position: bottom 10px right 20px;
background-position: right 3em bottom 10px;
background-position: bottom 10px right;
background-position: top right 10px;

/* Global values */
background-position: inherit;
background-position: initial;
background-position: revert;
background-position: revert-layer;
background-position: unset;
```

Values

This property is specified as one or more comma-separated `<position>` values:

`<position>`

A `<position>`. A two-dimensional coordinate, made up of one to two offsets, and optionally one to two offset sides, used to set a location relative to the edges of an element's box.

Description

The `background-position` property sets the initial position for each background image. The position is relative to the position layer set by `background-origin`.

The value is specified as a list of comma-separated image positions, with each image position defined using one to four values. If two non-keyword values are used, the first value represents the horizontal position and the second represents the vertical position. If only one value is specified, the second value is assumed to be `center`. If three or four values are used, the length-percentage values are offsets for the preceding keyword value(s).

1-value syntax

The value may be:

- The keyword value `center`, which centers the image.
- One of the keyword values `top`, `left`, `bottom`, or `right`. This specifies an edge against which to place the item. The other dimension is then set to 50%, so the item is placed in the middle of the edge specified.
- A `<length>` or `<percentage>`. This specifies the X coordinate relative to the left edge, with the Y coordinate set to 50%.

2-value syntax

One value defines X and the other defines Y. Each value may be:

- One of the keyword values `top`, `left`, `bottom`, or `right`. If `left` or `right` is given, then this defines X and the other given value defines Y. If `top` or `bottom` is given, then this defines Y and the other value defines X.
- A `<length>` or `<percentage>`. If the other value is `left` or `right`, then this value defines Y, relative to the top edge. If the other value is `top` or `bottom`, then this value defines X, relative to the left edge. If both values are `<length>` or `<percentage>` values, then the first defines X and the second Y.
- Note that: If one value is `top` or `bottom`, then the other value may not be `top` or `bottom`. If one value is `left` or `right`, then the other value may not be `left` or `right`. This means, e.g., that `top top` and `left right` are not valid.
- Order: When pairing keywords, placement is not important as the browser can reorder it; the values `top left` and `left top` will yield the same result. When pairing `<length>` or `<percentage>` with a keyword, the placement is important: the value defining X should come first followed by Y, so for example the value `right 20px` is valid while `20px right` is invalid. The values `left 20%` and `20% bottom` are valid as X and Y values are clearly defined and the placement is correct.
- The default value is `left top` or `0% 0%`.

3-value syntax

Two values are keyword values, and the third is the offset for the preceding value:

- The first value is one of the keyword values `top`, `left`, `bottom`, `right`, or `center`. If `left` or `right` are given here, then this defines X. If `top` or `bottom` are given, then this defines Y and the other keyword value defines X.
- The `<length>` or `<percentage>` value, if it is the second value, is the offset for the first value. If it is the third value, it is the offset for the second value.
- The single length or percentage value is an offset for the keyword value that precedes it. The combination of one keyword with two `<length>` or `<percentage>` values is not valid.

4-value syntax

The first and third values are keyword values defining X and Y. The second and fourth values are offsets for the preceding X and Y keyword values:

- The first and third values are equal to one of the keyword values `top`, `left`, `bottom`, or `right`. If `left` or `right` is given for the first value, then this defines X and the other value defines Y. If `top` or `bottom` is given for the first value, then this defines Y and the other keyword value defines X.
- The second and fourth values are `<length>` or `<percentage>` values. The second value is the offset for the first keyword. The fourth value is the offset for the second keyword.

Regarding Percentages

The percentage offset of the given background image's position is relative to the container. A value of 0% means that the left (or top) edge of the background image is aligned with the corresponding left (or top) edge of the container, or the 0% mark of the image will be on the 0% mark of the container. A value of 100% means that the *right* (or *bottom*) edge of the background image is aligned with the *right* (or *bottom*) edge of the container, or the 100% mark of the image will be on the 100% mark of the container. Thus a value of 50% horizontally or vertically centers the background image as the 50% of the image will be at the 50% mark of the container. Similarly, `background-position: 25% 75%` means the spot on the image that is 25% from the left and 75% from the top will be placed at the spot of the container that is 25% from the container's left and 75% from the container's top.

Essentially what happens is the background image dimension is *subtracted* from the corresponding container dimension, and then a percentage of the resulting value is used as the direct offset from the left (or top) edge.

```
(container width - image width) * (position x%) = (x offset value)
(container height - image height) * (position y%) = (y offset value)
```

Using the X axis for an example, let's say we have an image that is 300px wide and we are using it in a container that is 100px wide, with `background-size` set to auto:

```
100px - 300px = -200px (container & image difference)
```

So that with position percentages of -25%, 0%, 50%, 100%, 125%, we get these image-to-container edge offset values:

```
-200px * -25% = 50px
-200px * 0% = 0px
-200px * 50% = -100px
-200px * 100% = -200px
-200px * 125% = -250px
```

So with these resultant values for our example, the **left edge** of the **image** is offset from the **left edge** of the **container** by:

- + 50px (putting the left image edge in the center of the 100-pixel-wide container)
- 0px (left image edge coincident with the left container edge)
- -100px (left image edge 100px to the left of the container, in this example that means the middle 100px image area is centered in the container)
- -200px (left image edge 200px to the left of the container, in this example that means the right image edge is coincident with the right container edge)
- -250px (left image edge 250px to the left of the container, in this example that puts the right edge of the 300px-wide image in the center of the container)

It's worth mentioning that if your `background-size` is equal to the container size for a given axis, then a *percentage* position for that axis will have no effect because the "container-image difference" will be zero. You will need to offset using absolute values.

Formal definition

Initial value	`0% 0%`
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Percentages	refer to the size of the background positioning area minus size of background image; size refers to the width for horizontal offsets and to the height for vertical offsets
Computed value	as each of the properties of the shorthand: • `background-position-x`: A list, each item consisting of: an offset given as a combination of an absolute length and a percentage, plus an origin keyword • `background-position-y`: A list, each item consisting of: an offset given as a combination of an absolute length and a percentage, plus an origin keyword
Animation type	a repeatable list

Formal syntax

```
background-position =
  <bg-position>#

<bg-position> =
  <position>        |
```

```
  <position-three>

  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Backgrounds Module Level 4, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Positioning background images

Each of these three examples uses the `background` property to create a yellow, rectangular element containing a star image. In each example, the star is in a different position. The third example illustrates how to specify positions for two different background images within one element.

HTML

```
<div class="example-one">Example One</div>
<div class="example-two">Example Two</div>
<div class="example-three">Example Three</div>
```

CSS

```
/* Shared among all <div>s */
div {
  background-color: #ffee99;
  background-repeat: no-repeat;
  width: 300px;
  height: 80px;
  margin-bottom: 12px;
}

/* These examples use the `background` shorthand property */
.example-one {
  background: url("star-transparent.gif") #ffee99 2.5cm bottom no-repeat;
}
.example-two {
  background: url("star-transparent.gif") #ffee99 left 4em bottom 1em no-repeat;
}

/* Multiple background images: Each image is matched with the
   corresponding position, from first specified to last. */
.example-three {
  background-image: url("star-transparent.gif"), url("cat-front.png");
  background-position:
    0px 0px,
    right 3em bottom 2em;
}
```

background-position-x CSS property

The **`background-position-x`** CSS property sets the initial horizontal position for each background image. The position is relative to the position layer set by `background-origin`.

The value of this property is overridden by any declaration of the `background` or `background-position` shorthand properties applied to the element after it.

Try it

```
background-position-x: left;
```

```
background-position-x: center;
```

```
background-position-x: 25%;
```

```
background-position-x: 2rem;
```

```
background-position-x: right 32px;
```

```
<section class="display-block" id="default-example">
  <div class="transition-all" id="example-element"></div>
</section>
```

```
#example-element {
  background-color: navajowhite;
  background-image: url("/shared-assets/images/examples/star.png");
  background-repeat: no-repeat;
  height: 100%;
}
```

Syntax

```
/* Keyword values */
background-position-x: left;
background-position-x: center;
background-position-x: right;

/* <percentage> values */
background-position-x: 25%;

/* <length> values */
background-position-x: 0px;
background-position-x: 1cm;
background-position-x: 8em;

/* Side-relative values */
background-position-x: right 3px;
background-position-x: left 25%;

/* Multiple values */
background-position-x: 0px, center;

/* Global values */
background-position-x: inherit;
background-position-x: initial;
background-position-x: revert;
background-position-x: revert-layer;
background-position-x: unset;
```

Values

This property is specified as one or more comma-separated values:

`left`

Aligns the left edge of the background image with the left edge of the background position layer.

`center`

Aligns the center of the background image with the center of the background position layer.

`right`

Aligns the right edge of the background image with the right edge of the background position layer.

`<length>`

The offset of the given background image's left vertical edge from the background position layer's left vertical edge. (Some browsers allow assigning the right edge for offset).

`<percentage>`

The offset of the given background image's horizontal position relative to the container. A value of 0% means that the left edge of the background image is aligned with the left edge of the container, and a value of 100% means that the *right* edge of the background image is aligned with the *right* edge of the container, thus a value of 50% horizontally centers the background image.

Formal definition

Initial value	`0%`
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Percentages	refer to width of background positioning area minus width of background image
Computed value	A list, each item consisting of: an offset given as a combination of an absolute length and a percentage, plus an origin keyword
Animation type	a repeatable list

Formal syntax

```
background-position-x =
  [ center | [ [ left | right | x-start | x-end ]? <length-percentage>? ]! ]#

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Backgrounds Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

The following example shows a background image implementation, with background-position-x and background-position-y used to define the image's horizontal and vertical positions separately.

HTML

```
<div></div>
```

CSS

```
div {
  width: 300px;
  height: 300px;
  background-color: skyblue;
  background-image: url("https://mdn.dev/archives/media/attachments/2020/07/29/17350/3b4892b7e820122ac6dd7678891d4507/firefox.png");
  background-repeat: no-repeat;
  background-position-x: center;
  background-position-y: bottom;
}
```

Result

Side-relative values

The following example shows support for side-relative offset syntax, which allows the developer to offset the background from any edge.

HTML

```
<div></div>
```

CSS

```
div {
  width: 300px;
  height: 300px;
  background-color: seagreen;
  background-image: url("https://mdn.dev/archives/media/attachments/2020/07/29/17350/3b4892b7e820122ac6dd7678891d4507/firefox.png");
  background-repeat: no-repeat;
  background-position-x: right 20px;
  background-position-y: bottom 10px;
}
```

Result

background-position-y CSS property

The **`background-position-y`** CSS property sets the initial vertical position for each background image. The position is relative to the position layer set by `background-origin`.

The value of this property is overridden by any declaration of the `background` or `background-position` shorthand properties applied to the element after it.

Try it

```
background-position-y: top;
```

```
background-position-y: center;
```

```
background-position-y: 25%;
```

```
background-position-y: 2rem;
```

```
background-position-y: bottom 32px;
```

```
<section class="display-block" id="default-example">
  <div class="transition-all" id="example-element"></div>
</section>
```

```
#example-element {
  background-color: navajowhite;
  background-image: url("/shared-assets/images/examples/star.png");
  background-repeat: no-repeat;
  height: 100%;
}
```

Syntax

```
/* Keyword values */
background-position-y: top;
background-position-y: center;
background-position-y: bottom;

/* <percentage> values */
background-position-y: 25%;

/* <length> values */
background-position-y: 0px;
background-position-y: 1cm;
background-position-y: 8em;
```

```
/* Side-relative values */
background-position-y: bottom 3px;
background-position-y: bottom 10%;

/* Multiple values */
background-position-y: 0px, center;

/* Global values */
background-position-y: inherit;
background-position-y: initial;
background-position-y: revert;
background-position-y: revert-layer;
background-position-y: unset;
```

Values

This property is specified as one or more comma-separated values:

`top`

Aligns the top edge of the background image with the top edge of the background position layer.

`center`

Aligns the vertical center of the background image with the vertical center of the background position layer.

`bottom`

Aligns the bottom edge of the background image with the bottom edge of the background position layer.

`<length>`

The offset of the given background image's horizontal edge from the corresponding background position layer's top horizontal edge. (Some browsers allow assigning the bottom edge for offset).

`<percentage>`

The offset of the given background image's vertical position relative to the container. A value of 0% means that the top edge of the background image is aligned with the top edge of the container, and a value of 100% means that the *bottom* edge of the background image is aligned with the *bottom* edge of the container, thus a value of 50% vertically centers the background image.

Formal definition

Initial value	`0%`
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Percentages	refer to height of background positioning area minus height of background image
Computed value	A list, each item consisting of: an offset given as a combination of an absolute length and a percentage, plus an origin keyword
Animation type	a repeatable list

Formal syntax

```
background-position-y =
  [ center | [ [ top | bottom | y-start | y-end ]? <length-percentage>? ]! ]#

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Backgrounds Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

The following example shows a background image implementation, with background-position-x and background-position-y used to define the image's horizontal and vertical positions separately.

HTML

```
<div></div>
```

CSS

```
div {
  width: 300px;
  height: 300px;
  background-color: skyblue;
  background-image: url("https://mdn.dev/archives/media/attachments/2020/07/29/17350/3b4892b7e820122ac6dd7678891d4507/firefox.png");
  background-repeat: no-repeat;

background-repeat CSS property

The **background-repeat** CSS shorthand property sets how background images are repeated. A background image can be repeated along the horizontal and vertical axes, or not repeated at all.

Try it

```
background-repeat: repeat-x;
```

```
background-repeat: repeat;
```

```
background-repeat: space;
```

```
background-repeat: round;
```

```
background-repeat: no-repeat;
```

```
background-repeat: space repeat;
```

```
<section id="default-example">
  <div id="example-element"></div>
</section>
```

```
#example-element {
  background: #cccccc url("/shared-assets/images/examples/moon.jpg") center /
    120px;
  min-width: 100%;
  min-height: 100%;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- background-repeat-x
- background-repeat-y

Syntax

```
/* Keyword values */
background-repeat: repeat;
background-repeat: repeat-x;
background-repeat: repeat-y;
background-repeat: space;
background-repeat: round;
background-repeat: no-repeat;

/* Two-value syntax: horizontal | vertical */
background-repeat: repeat space;
background-repeat: repeat repeat;
background-repeat: round space;
background-repeat: no-repeat round;

/* Global values */
background-repeat: inherit;
background-repeat: initial;
background-repeat: revert;
background-repeat: revert-layer;
background-repeat: unset;
```

Description

The property accepts a comma-separated list of two <repeat-style> keyterms, or one keyterm as a shorthand for the two values. When two values are provided, the first value defines the horizontal repetition behavior and the second value defines the vertical behavior. Property values can be used to repeat only horizontally, vertically, or not at all.

The default value is repeat repeat. With this value, the background image maintains its intrinsic aspect ratio, repeating both horizontally and vertically to cover the entire background paint area, with edge images being clipped to the size of the element. Which edges clipped depends on the value of the corresponding background-position value. How many times they are repeated and how much the images on the edges are clipped depends on the size of the background painting area and the corresponding background-size value.

The repeating images can be evenly spaced apart, ensuring the repeated image maintains its aspect ratio without being clipped. With the space value, if the background paint area has a different aspect ratio than the image or does not otherwise have a size that is a multiple of the background size in either direction, there will be areas not covered by the background image.

Alternatively, the repeated background image can be stretched to cover the entire area without clipping. With round, the repeated image is stretched to fill all the available space until there is room to add an additional repeated image if the aspect ratio of the background image is not the same as the paint area's aspect ratio. For example, given a background image that is 100px x 100px and a background paint area of 1099px x 750px, the image will be repeated 10 times in the horizontal direction and 7 times vertically, for a total of 70 repetitions, with each image stretched in both directions to be 109.9px x 105px, altering the image's aspect ratio and potentially distorting it. If the width of the paint area increases by 1px, becoming 1100px wide, an 11th image will fit horizontally for a total of 77 image repetitions, with each image being painted at 100px wide and 105px tall, stretched only in the vertical direction.

Values

The property accepts a comma-separated list of two <repeat-style> keyterms or one keyterm as a shorthand for the two values. The first value is the horizontal repetition. The second value is the vertical behavior. If only a single value is set to a value other than repeat-x or repeat-y, that value is applied the both vertices. The values include:

`repeat`

The default value. The image is repeated as many times as needed to cover the entire background image painting area, with the edge image being clipped if the dimension of the painting area is not a multiple of the dimension of your background image.

`no-repeat`

The image is not repeated (and hence the background image painting area will not necessarily be entirely covered). The position of the non-repeated background image is defined by the `background-position` CSS property.

`space`

The image is repeated as much as possible without clipping. The first and last images are pinned to either side of the element, and whitespace is distributed evenly between the images. The `background-position` property is ignored unless only one image can be displayed without clipping. The only case where clipping happens using `space` is when there isn't enough room to display one image.

`round`

As the allowed space increases in size, the repeated images will stretch (leaving no gaps) until there is room for another one to be added. This is the only `<repeat-style>` value that can lead to the distortion of the background image's aspect ratio, which will occur if the aspect ratio of the background image differs from the aspect ratio of the background paint area.

`repeat-x`

Shorthand for `repeat no-repeat`, the background image repeats horizontally only, with the edge image being clipped if the width of the paint area is not a multiple of the background image's width.

`repeat-y`

Shorthand for `no-repeat repeat`, the background image repeats vertically only, with the edge image being clipped if the height of the paint area is not a multiple of the background image's height.

When one `<repeat-style>` keyterm is provided, the value is shorthand for the following two-value syntax:

Single value	Two-value equivalent
`repeat-x`	`repeat no-repeat`
`repeat-y`	`no-repeat repeat`
`repeat`	`repeat repeat`
`space`	`space space`
`round`	`round round`
`no-repeat`	`no-repeat no-repeat`

Formal definition

Initial value	`repeat`
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Computed value	a list, each item consisting of two keywords, one per dimension
Animation type	discrete

Formal syntax

```
background-repeat =
  <repeat-style>#

<repeat-style> =
  repeat-x           |
  repeat-y           |
  repeat-block       |
  repeat-inline      |
  <repetition>{1,2}

<repetition> =
  repeat     |
  space      |
  round      |
  no-repeat
```

This syntax reflects the latest standard as per CSS Backgrounds Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting background-repeat

HTML

```
<ol>
  <li>
    no-repeat
    <div class="one"></div>
  </li>
  <li>
    repeat
    <div class="two"></div>
  </li>
  <li>
    repeat-x
    <div class="three"></div>
  </li>
  <li>
    repeat-y
    <div class="four"></div>
  </li>
  <li>
    space
    <div class="five"></div>
  </li>
  <li>
    round
```

```
    <div class="six"></div>
  </li>
  <li>
    repeat-x, repeat-y (multiple images)
    <div class="seven"></div>
  </li>
</ol>
```

CSS

```
/* Shared for all DIVS in example */
ol,
li {
  margin: 0;
  padding: 0;
}
li {
  margin-bottom: 12px;
}
div {
  background-image: url("star-solid.gif");
  width: 160px;
  height: 70px;
}

/* Background repeats */
.one {
  background-repeat: no-repeat;
}
.two {
  background-repeat: repeat;
}
.three {
  background-repeat: repeat-x;
}
.four {
  background-repeat: repeat-y;
}
.five {
  background-repeat: space;
}
.six {
  background-repeat: round;
}

/* Multiple images */
.seven {
  background-image:
    url("star-solid.gif"), url("/shared-assets/images/examples/favicon32.png");
  background-repeat: repeat-x, repeat-y;
  height: 144px;
}
```

Result

In this example, each list item is matched with a different value of `background-repeat`.

background-repeat-x CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`background-repeat-x`** CSS property sets how background images are repeated, or not, along the horizontal axis.

The `background-repeat-x` and `background-repeat-y` properties can also be set using the `background-repeat` or `background` shorthand properties.

Try it

```
background-repeat-x: repeat;
```

```
background-repeat-x: space;
```

```
background-repeat-x: round;
```

```
background-repeat-x: no-repeat;
```

```
<section id="default-example">
  <div id="example-element"></div>
</section>
```

```
#example-element {
  background: #cccccc url("/shared-assets/images/examples/moon.jpg") no-repeat
    center / 120px;
  min-width: 100%;
  min-height: 100%;
}
```

Syntax

```
/* Keyword values */
background-repeat-x: repeat;
background-repeat-x: space;
background-repeat-x: round;
background-repeat-x: no-repeat;

/* Global values */
background-repeat-x: inherit;
background-repeat-x: initial;
background-repeat-x: revert;
background-repeat-x: revert-layer;
background-repeat-x: unset;
```

The `background-repeat-x` property is specified as one or more values, separated by commas.

Values

`repeat`

> The default value. The image is repeated as many times as needed to cover the entire width of the background image painting area. The edge image is clipped if multiple images do not fit exactly into the background width.

`no-repeat`

> The image is not repeated. The position of the non-repeated background image is defined by the `background-position` CSS property.

`space`

> The image is repeated as much as possible without clipping. The first and last images are pinned to the left and right of the element, and the whitespace is evenly distributed between them. The `background-position-x` property is ignored unless one or more images can be displayed without clipping. If the image is wider than the element, it is clipped, as there isn't enough room to display it.

`round`

> The image is repeated horizontally. As the available space increases in size, the repeated images will stretch (leaving no gaps) until there is room for another one to be added. If multiple images don't fit the background exactly, they are rescaled to fit.

Description

The `background-repeat-x` property accepts a comma-separated list of `<repetition>` keyterms, which define how the background image(s) should repeat horizontally, or not repeat at all.

The default value is `repeat`. With this value, the background image repeats horizontally, covering the entire width of the background paint area, with edge images being clipped to the size of the element. Whether the left, right, or both edges are clipped depends on the value of the corresponding `background-position` value. How many times images are repeated and how much the images on the edges are clipped depends on the size of the background painting area and width value of the corresponding `background-size` property.

The repeating images can be evenly spaced apart, ensuring the repeated images aren't clipped in the horizontal direction. With the `space` value, if the width of the background paint area is not a multiple of the width of the image or does not otherwise have a size that is a multiple of the background size in the width direction, there will be areas not covered by the background image.

Alternatively, the repeated background image can be stretched to cover the entire width of the background area without clipping. With `round`, the repeated image is stretched to fill all the available space until there is room to add an additional repeated image.

For example, given a background image that is `100px` x `100px` and a background paint area that is `1099px` wide, the image will be resized to `109.9px wide` and repeated 10 times in the horizontal direction. This will alter the image's aspect ratio and distort it. If the width of the paint area increases by `1px` to `1100px`, an 11th image will fit horizontally, with each image being painted at `100px` wide, and no longer distorted horizontally.

Formal definition

Value not found in DB!

Formal syntax

```
background-repeat-x =
  <repetition>#

<repetition> =
  repeat     |
  space      |
  round      |
  no-repeat
```

This syntax reflects the latest standard as per CSS Backgrounds Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting background-repeat-x

HTML

```
<ol>
  <li>
    no-repeat
    <div class="one"></div>
  </li>
  <li>
    repeat
    <div class="two"></div>
  </li>
  <li>
    space
    <div class="three"></div>
  </li>
  <li>
    round
    <div class="four"></div>
  </li>
</ol>
```

CSS

```
ol,
li {
```

```
  margin: 0;
  padding: 0;
}
li {
  margin-bottom: 12px;
}
div {
  background-image: url("star-solid.gif");
  width: 160px;
  height: 70px;
}

/* Background repeats */
.one {
  background-repeat-x: no-repeat;
}
.two {
  background-repeat-x: repeat;
}
.three {
  background-repeat-x: space;
}
.four {
  background-repeat-x: round;
}
```

```
@layer no-support {
  @supports not (background-repeat-x: repeat) {
    body::before {
      content: "Your browser doesn't support the `background-repeat-x` property.";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

Result

In this example, each list item is matched with a different value of `background-repeat-x`.

See also

- `background-repeat-y` and the `background-repeat` shorthand.
- `background` shorthand components: `background-attachment`, `background-clip`, `background-color`, `background-image`, `background-origin`, `background-position` (`background-position-x` and `background-position-y`), and `background-size`

- CSS backgrounds and borders module
- Understanding aspect ratios

background-repeat-y CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`background-repeat-y`** CSS property sets how background images are repeated, or not, along the vertical axis.

The `background-repeat-x` and `background-repeat-y` properties can also be set using the `background-repeat` or `background` shorthand properties.

Try it

```
background-repeat-y: repeat;
```

```
background-repeat-y: space;
```

```
background-repeat-y: round;
```

```
background-repeat-y: no-repeat;
```

```
<section id="default-example">
  <div id="example-element"></div>
</section>
```

```
#example-element {
  background: #cccccc url("/shared-assets/images/examples/moon.jpg") center /
    120px;
  min-width: 100%;
  min-height: 100%;
}
```

Syntax

```
/* Keyword values */
background-repeat-y: repeat;
background-repeat-y: space;
background-repeat-y: round;
background-repeat-y: no-repeat;

/* Global values */
background-repeat-y: inherit;
background-repeat-y: initial;
background-repeat-y: revert;
background-repeat-y: revert-layer;
background-repeat-y: unset;
```

The `background-repeat-y` property is specified as one or more values, separated by commas.

Values

`repeat`

> The default value. The image is repeated as many times as needed to cover the entire height of the background image painting area. The edge image is clipped if multiple images do not fit exactly into the background height.

`no-repeat`

> The image is not repeated. The position of the non-repeated background image is defined by the `background-position` CSS property.

`space`

> The image is repeated as much as possible without clipping. The first and last images are pinned to the top and bottom of the element, and the whitespace is distributed evenly between the images. The `background-position-y` property is ignored unless one or more images can be displayed without clipping. If the image is taller than the element, it is clipped, as there isn't enough room to display it.

`round`

> The image is repeated vertically. As the available space increases in size, the repeated images will stretch (leaving no gaps) until there is room for another one to be added. If multiple images don't fit the background exactly, they are rescaled to fit.

Description

The `background-repeat-y` property accepts a comma-separated list of `<repetition>` keyterms, which define how background image(s) should repeat vertically, or not repeat at all.

The default value is `repeat`. With this value, the background image repeats vertically, covering the entire height of the background paint area, with edge images being clipped to the size of the element. Whether the top, bottom, or both edges are clipped depends on the value of the corresponding `background-position` value. How many times images are repeated and how much the images on the edges are clipped depends on the size of the background painting area and height value of the corresponding `background-size` property.

The repeating images can be evenly spaced apart, ensuring the repeated images aren't clipped in the vertical direction. With the `space` value, if the height of the background paint area is not a multiple of the image's height or does not otherwise have a size that is a multiple of the background size in along the y-axis, there will be areas not covered by the background image.

Alternatively, the repeated background image can be stretched to cover the entire height of the background area without clipping. With `round`, if the height of the background paint area is not a multiple of the height of the background image, the repeated image is stretched to fill all the available space until there is room to add an additional repeated image.

For example, given a background image that is 100px x 100px and a background paint area that is 1099px tall, the image will be repeated 10 times in the vertical direction with each image stretched to be 109.9px tall, possibly altering the image's aspect ratio and distorting it. If the height of the paint area increases by 1px, becoming 1100px tall, an 11th image will fit vertically, with each image will be painted at 100px tall, no longer being stretched in the vertical direction.

Formal definition

Value not found in DB!

Formal syntax

```
background-repeat-y =
  <repetition>#

<repetition> =
  repeat     |
  space      |
  round      |
  no-repeat
```

This syntax reflects the latest standard as per CSS Backgrounds Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting background-repeat-y

HTML

```
<ol>
  <li>
    no-repeat
    <div class="one"></div>
  </li>
  <li>
    repeat
    <div class="two"></div>
  </li>
  <li>
    space
    <div class="three"></div>
  </li>
  <li>
    round
    <div class="four"></div>
  </li>
</ol>
```

CSS

```
ol,
li {
  margin: 0;
  padding: 0;
}
li {
  margin-bottom: 12px;
}
div {
  background-image: url("star-solid.gif");
  width: 160px;
  height: 70px;
}

/* Background repeats */
.one {
  background-repeat-y: no-repeat;
}
```

```
.two {
  background-repeat-y: repeat;
}
.three {
  background-repeat-y: space;
}
.four {
  background-repeat-y: round;
}
```

```
@layer no-support {
  @supports not (background-repeat-y: repeat) {
    body::before {
      content: "Your browser doesn't support the `background-repeat-y` property.";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

Result

In this example, each list item is matched with a different value of `background-repeat-y`.

- CSS backgrounds and borders module
- Understanding aspect ratios

background-size CSS property

The **`background-size`** CSS property sets the size of the element's background image. The image can be left to its natural size, stretched, or constrained to fit the available space.

Spaces not covered by a background image are filled with the `background-color` property, and the background color will be visible behind background images that have transparency/translucency.

Try it

```
background-size: contain;
```

```
background-size: contain;
background-repeat: no-repeat;
```

```
background-size: cover;
```

```
background-size: 30%;
```

```
background-size: 200px 100px;
```

```
<section id="default-example">
  <div class="transition-all" id="example-element"></div>
</section>
```

```
#example-element {
  background-image: url("/shared-assets/images/examples/hand.jpg");
  min-width: 100%;
  min-height: 100%;
}
```

Syntax

```
/* Keyword values */
background-size: cover;
background-size: contain;

/* One-value syntax */
/* the width of the image (height becomes 'auto') */
background-size: 50%;
background-size: 3.2em;
background-size: 12px;
background-size: auto;

/* Two-value syntax */
/* first value: width of the image, second value: height */
background-size: 50% auto;
background-size: 3em 25%;
background-size: auto 6px;
background-size: auto auto;

/* Multiple backgrounds */
background-size: auto, auto; /* Not to be confused with `auto auto` */
background-size: 50%, 25%, 25%;
background-size: 6px, auto, contain;

/* Global values */
background-size: inherit;
background-size: initial;
background-size: revert;
background-size: revert-layer;
background-size: unset;
```

The `background-size` property is specified in one of the following ways:

- Using the keyword values `contain` or `cover`.
- Using a width value only, in which case the height defaults to `auto`.
- Using both a width and a height value, in which case the first sets the width and the second sets the height. Each value can be a `<length>`, a `<percentage>`, or `auto`.

To specify the size of multiple background images, separate the value for each one with a comma.

Values

`contain`

Scales the image as large as possible within its container without cropping or stretching the image. If the container is larger than the image, this will result in image tiling, unless the `background-repeat` property is set to `no-repeat`.

`cover`

Scales the image (while preserving its ratio) to the smallest possible size to fill the container (that is: both its height and width completely *cover* the container), leaving no empty space. If the proportions of the background differ from the element, the image is cropped either vertically or horizontally.

`auto`

Scales the background image in the corresponding direction such that its intrinsic proportions are maintained.

`<length>`

Stretches the image in the corresponding dimension to the specified length. Negative values are not allowed.

`<percentage>`

Stretches the image in the corresponding dimension to the specified percentage of the *background positioning area*. The background positioning area is determined by the value of `background-origin` (by default, the padding box). However, if the background's `background-attachment` value is `fixed`, the positioning area is instead the entire viewport. Negative values are not allowed.

Intrinsic dimensions and proportions

The computation of values depends on the image's intrinsic dimensions (width and height) and intrinsic proportions (width-to-height ratio). These attributes are as follows:

- A bitmap image (such as JPG) always has intrinsic dimensions and proportions.
- A vector image (such as SVG) does not necessarily have intrinsic dimensions. If it has both horizontal and vertical intrinsic dimensions, it also has intrinsic proportions. If it has no dimensions or only one dimension, it may or may not have proportions.
- CSS `<gradient>`s have no intrinsic dimensions or intrinsic proportions.
- Background images created with the `element()` function use the intrinsic dimensions and proportions of the generating element.

> **Note:** In Gecko, background images created using the `element()` function are currently treated as images with the dimensions of the element, or of the background positioning area if the element is SVG, with the corresponding intrinsic proportion. This is non-standard behavior.

Based on the intrinsic dimensions and proportions, the rendered size of the background image is computed as follows:

- **If both components of `background-size` are specified and are not `auto`:** The background image is rendered at the specified size.
- **If the `background-size` is `contain` or `cover`:** While preserving its intrinsic proportions, the image is rendered at the largest size contained within, or covering, the background positioning area. If the image has no intrinsic proportions, then it's rendered at the size of the background positioning area.
- **If the `background-size` is `auto` or `auto auto`:**
  - If the image has both horizontal and vertical intrinsic dimensions, it's rendered at that size.
  - If the image has no intrinsic dimensions and has no intrinsic proportions, it's rendered at the size of the background positioning area.
  - If the image has no intrinsic dimensions but has intrinsic proportions, it's rendered as if `contain` had been specified instead.
  - If the image has only one intrinsic dimension and has intrinsic proportions, it's rendered at the size corresponding to that one dimension. The other dimension is computed using the specified dimension and the intrinsic proportions.
  - If the image has only one intrinsic dimension but has no intrinsic proportions, it's rendered using the specified dimension and the other dimension of the background positioning area.

  > **Note:** SVG images have a `preserveAspectRatio` attribute that defaults to the equivalent of `contain`; an explicit `background-size` causes `preserveAspectRatio` to be ignored.

- **If the `background-size` has one `auto` component and one non-`auto` component:**
  - If the image has intrinsic proportions, it's stretched to the specified dimension. The unspecified dimension is computed using the specified dimension and the intrinsic proportions.
  - If the image has no intrinsic proportions, it's stretched to the specified dimension. The unspecified dimension is computed using the image's corresponding intrinsic dimension, if there is one. If there is no such intrinsic dimension, it becomes the corresponding dimension of the background positioning area.

> **Note:** Background sizing for vector images that lack intrinsic dimensions or proportions is not yet fully implemented in all browsers. Be careful about relying on the behavior described above, and test in multiple browsers to be sure the results are acceptable.

Formal definition

Initial value	`auto auto`
Applies to	all elements. It also applies to `::first-letter` and `::first-line`.
Inherited	no
Percentages	relative to the background positioning area
Computed value	as specified, but with relative lengths converted into absolute lengths
Animation type	a repeatable list

Formal syntax

```
background-size =
  <bg-size>#

<bg-size> =
  [ <length-percentage [0,∞]> | auto ]{1,2}  |
  cover                                      |
  contain

<length-percentage> =
```

```
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Backgrounds Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Tiling a large image

Let's consider a large image, a 2982x2808 Firefox logo image. We want to tile four copies of this image into a 300x300-pixel element. To do this, we can use a fixed `background-size` value of 150 pixels.

HTML

```
<div class="tiledBackground"></div>
```

CSS

```
.tiledBackground {
  background-image: url("https://www.mozilla.org/media/img/logos/firefox/logo-quantum.9c5e96634f92.png");
  background-size: 150px;
  width: 300px;
  height: 300px;
  border: 2px solid;
  color: pink;
}
```

Result

See Resizing background images for more examples.

See also

- Resizing background images

- `object-fit`

baseline-shift CSS property

The **`baseline-shift`** CSS property repositions the dominant-baseline of a text element relative to the dominant-baseline of its parent text content element. The shifted element might be a sub- or superscript. If the property is present, the value overrides the element's `baseline-shift` attribute.

> **Note:** The `baseline-shift` property only applies to `<textPath>` and `<tspan>` elements nested in an `<svg>`. It doesn't apply to other SVG, HTML, or pseudo-elements.

Syntax

```
/* <length-percentage> values */
baseline-shift: -0.5px;
baseline-shift: 4%;

/* keyword values */
baseline-shift: sub;
baseline-shift: super;

/* Global values */
baseline-shift: inherit;
baseline-shift: initial;
baseline-shift: revert;
baseline-shift: revert-layer;
baseline-shift: unset;
```

Values

`sub`

: The dominant-baseline is shifted to the default position for subscripts.

`super`

: The dominant-baseline is shifted to the default position for superscripts.

`<length-percentage>`

: Raises (if positive) or lowers (if negative) the dominant-baseline of the text content element by the specified length or percentage, with the percentage being relative to the dominant-baseline of the parent text content element's `line-height`.

Formal definition

Initial value	`0`
Applies to	inline-level boxes and SVG text content elements
Inherited	no
Percentages	refer to the used value of `line-height`
Computed value	the specified keyword or a computed value
Animation type	by computed value type

Formal syntax

```
baseline-shift =
  <length-percentage>  |
  sub                  |
  super                |
  top                  |
  center               |
  bottom
```

```
<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Inline Layout Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using keyword values

This example demonstrates the basic usage of the `sub` and `super` keyword values of the `baseline-shift` property, as well as how the `baseline-shift` CSS property takes precedence over the `baseline-shift` SVG attribute.

HTML

We define an SVG with two SVG `<text>` elements, each containing a `<tspan>` element with the SVG `baseline-shift` attribute set on it.

```
<p>Original SVG</p>
```

```
<svg viewBox="0 0 500 120" xmlns="http://www.w3.org/2000/svg">
  <text x="10" y="50">
    Ceci
    <tspan baseline-shift="super">n'est pas</tspan>
    une pipe super!
  </text>
  <text x="10" y="90">
    Ceci
    <tspan baseline-shift="sub">n'est pas</tspan>
    une pipe sub!
  </text>
</svg>
```

```
<p><code>baseline-shift: sub;</code></p>
<svg viewBox="0 0 500 120" xmlns="http://www.w3.org/2000/svg">
  <text x="10" y="50">
    Ceci
    <tspan baseline-shift="super">n'est pas</tspan>
    une pipe super!
  </text>
  <text x="10" y="90">
    Ceci
    <tspan baseline-shift="sub">n'est pas</tspan>
    une pipe sub!
  </text>
</svg>
<p><code>baseline-shift: super;</code></p>
<svg viewBox="0 0 500 120" xmlns="http://www.w3.org/2000/svg">
  <text x="10" y="50">
    Ceci
    <tspan baseline-shift="super">n'est pas</tspan>
    une pipe super!
  </text>
  <text x="10" y="90">
    Ceci
    <tspan baseline-shift="sub">n'est pas</tspan>
    une pipe sub!
  </text>
</svg>
```

The SVG is repeated three times; we've only shown one copy for the sake of brevity.

CSS

We make the text in all three SVG images large and cursive, adding some color to differentiate the content within the `<tspan>` elements.

We set the `baseline-shift` property value to `sub` on the second SVG's `<tspan>` element and `super` on the third SVG's `<tspan>` element. The first SVG has no additional CSS applied to it.

```
text {
  font-family: cursive;
  font-size: 2rem;
}
[baseline-shift="sub"] {
  fill: deeppink;
}
[baseline-shift="super"] {
  fill: rebeccapurple;
}

svg:nth-of-type(2) tspan {
  baseline-shift: sub;
}
svg:nth-of-type(3) tspan {
  baseline-shift: super;
}
```

```
svg {
  border: 1px solid;
  width: 15em;
  margin-bottom: 10px;
}
@supports not (baseline-shift: sub) {
  body::before {
    content: "Your browser doesn't support the `baseline-shift` property.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

Results

The SVG `baseline-shift` attribute values are used in the first SVG. In the second and third SVGs, the CSS `baseline-shift` values override the attribute values.

See also

- SVG `baseline-shift` attribute
- Presentation properties: `baseline-shift`, `clip-rule`, `color-interpolation-filters`, `fill-opacity`, `fill-rule`, `fill`, `marker-end`, `marker-mid`, `marker-start`, `shape-rendering`, `stop-color`, `stop-opacity`, `stroke`, `stroke-dasharray`, `stroke-dashoffset`, `stroke-linecap`, `stroke-linejoin`, `stroke-miterlimit`, `stroke-opacity`, `stroke-width`, `text-anchor`, and `vector-effect`

baseline-source CSS property

The **`baseline-source`** CSS property defines which baseline to use when inline-level boxes have multiple possible baselines, such as multi-line inline blocks or inline flex containers. The values allow for choosing between aligning to the box's first baseline, last baseline, or letting the browser decide automatically based on the box type.

Syntax

```
/* Keyword values */
baseline-source: auto;
baseline-source: first;
baseline-source: last;

/* Global values */
baseline-source: inherit;
baseline-source: initial;
baseline-source: revert;
baseline-source: revert-layer;
baseline-source: unset;
```

Values

`auto`

Specifies `last baseline` alignment for inline-block, `first baseline` alignment for everything else.

`first`

Specifies `first baseline` alignment.

`last`

Specifies `last baseline` alignment.

Formal definition

Initial value	`auto`
Applies to	inline-level boxes
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
baseline-source =
  auto   |
  first  |
  last
```

This syntax reflects the latest standard as per CSS Inline Layout Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Baseline selection in inline flex containers

This example demonstrates using the `baseline-source` property to control the baseline alignment of inline flex containers.

HTML

Our HTML includes several `<span>` elements, which are generic inline containers for phrasing content. Three of the `<span>` elements contain nested `<span>` children.

```
<span>Baseline ___</span>

<span class="box first">
  <span>First</span>
  <span>A</span>
  <span>B</span>
  <span>C</span>
</span>

<span class="box auto">
  <span>Auto</span>
  <span>A</span>
  <span>B</span>
  <span>C</span>
</span>

<span class="box last">
  <span>A</span>
  <span>B</span>
  <span>C</span>
  <span>Last</span>
</span>
```

CSS

```
body {
  font-family: sans-serif;
}
```

```
.box {
  border: 2px solid #888888;
  width: 50px;
}

span {
  padding: 0.4rem;
}
```

We define all the boxes to be inline flex containers. We set the `.first` box to use the first baseline, the `.auto` box uses the default baseline (which is `first` for inline flex containers), and the `.last` box uses the last baseline.

```
.box {
  display: inline-flex;
  flex-direction: column;
}

.first {
  baseline-source: first;
}

.auto {
  baseline-source: auto;
}

.last {
  baseline-source: last;
}
```

Result

See also

- `vertical-align` property
- CSS box alignment overview

block-size CSS property

The **`block-size`** CSS property defines the size of an element's block along the block axis. If the `writing-mode` is horizontal, it corresponds to the `height`; if the writing mode is vertical, it corresponds to the `width`. A related property is `inline-size`, which defines the other dimension of the element.

Try it

```
block-size: 150px;
writing-mode: horizontal-tb;
```

```
block-size: 150px;
writing-mode: vertical-rl;
```

```
block-size: auto;
writing-mode: horizontal-tb;
```

```
block-size: auto;
writing-mode: vertical-lr;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box where you can change the block-size.
  </div>
</section>
```

```
#example-element {
  display: flex;
  flex-direction: column;
  background-color: #5b6dcd;
  justify-content: center;
  color: white;
}
```

Syntax

```
/* <length> values */
block-size: 300px;
block-size: 25em;
block-size: anchor-size(height);
block-size: calc(anchor-size(--my-anchor block) * 0.75);

/* <percentage> values */
block-size: 75%;

/* Keyword values */
block-size: max-content;
block-size: min-content;
block-size: fit-content;
block-size: fit-content(20em);
block-size: auto;

/* Global values */
block-size: inherit;
block-size: initial;
block-size: revert;
block-size: revert-layer;
block-size: unset;
```

Values

The `block-size` property takes the same values as the `width` and `height` properties.

Formal definition

Initial value	`auto`
Applies to	same as `width` and `height`
Inherited	no
Percentages	block-size of containing block
Computed value	same as `width` and `height`
Animation type	a length, percentage or calc();

Formal syntax

```
block-size =
  auto             |
  <box-size>       |
  <anchor-size()>

<box-size> =
  <length-percentage [0,∞]>                |
  stretch                                  |
  contain                                  |
  min-content                              |
  max-content                              |
  fit-content                              |
  stretch( <length-percentage [0,∞]> )     |
  fit-content( <length-percentage [0,∞]> ) |
  <calc-size()>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<length-percentage> =
  <length>      |
  <percentage>

<calc-size()> =
  calc-size( <calc-size-basis> , <calc-sum> )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width        |
  height       |
  block        |
  inline       |
  self-block   |
  self-inline

<calc-size-basis> =
  <size-keyword>  |
  <calc-sum>      |
  <calc-size()>   |
  any

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Sizing Module Level 3, CSS Box Sizing Module Level 4, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Block size with vertical text

HTML

```
<p class="exampleText">Example text</p>
```

CSS

```
.exampleText {
  writing-mode: vertical-rl;
  background-color: yellow;
  block-size: 200px;
}
```

Result

See also

- The mapped physical properties: `width` and `height`
- `writing-mode`

border CSS property

The **`border`** CSS shorthand property sets an element's border. It sets the values of `border-width`, `border-style`, and `border-color`.

Try it

```
border: solid;
```

```
border: dashed red;
```

```
border: 1rem solid;
```

```
border: thick double #32a1ce;
```

```
border: 4mm ridge rgb(211 220 50 / 0.6);
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: darkmagenta;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `border-width`
- `border-style`
- `border-color`

Reset-only sub-properties

This property resets the following CSS properties to their initial values:

- `border-image-outset`
- `border-image-repeat`
- `border-image-slice`
- `border-image-source`
- `border-image-width`

Syntax

```
/* style */
border: solid;

/* width | style */
border: 2px dotted;

/* style | color */
border: outset #ff3333;

/* width | style | color */
border: medium dashed green;

/* Global values */
border: inherit;
border: initial;
border: revert;
border: revert-layer;
border: unset;
```

Values

This property is specified as a space-separated list of one to three of the following values:

`<line-width>`

Sets the thickness of the border. Defaults to `medium` if absent. See `border-width`.

`<line-style>`

Sets the style of the border. Defaults to `none` if absent. See `border-style`.

`<color>`

Sets the color of the border. Defaults to `currentColor` if absent. See `border-color`.

Description

The `border` shorthand property sets the width, style, and color of all four sides of an element's border. It is specified using one, two, or all three of the component property values, in any order.

Any omitted sub-values are set to their initial value. For a border to be displayed, the `<line-style>` component must be set because the style defaults to `none`.

Importantly, `border` cannot be used to specify a custom value for `border-image`, but instead sets it to its initial value, i.e., `none`.

The `border` shorthand is especially useful when you want all four borders to be the same. To make them different from each other, however, you can use the longhand `border-width`, `border-style`, and `border-color` properties, which accept different values for each side. Alternatively, you can target one border at a time with the physical (e.g., `border-top`) and logical (e.g., `border-block-start`) border properties.

Borders vs. outlines

Borders and outlines are very similar. However, outlines differ from borders in the following ways:

- Outlines never take up space, as they are drawn outside of an element's content.
- According to the spec, outlines don't have to be rectangular, although they usually are.

Formal definition

Initial value	as each of the properties of the shorthand:
	• `border-width`: as each of the properties of the shorthand:
	  ◦ `border-top-width`: `medium`
	  ◦ `border-right-width`: `medium`
	  ◦ `border-bottom-width`: `medium`
	  ◦ `border-left-width`: `medium`
	• `border-style`: as each of the properties of the shorthand:
	  ◦ `border-top-style`: `none`
	  ◦ `border-right-style`: `none`
	  ◦ `border-bottom-style`: `none`
	  ◦ `border-left-style`: `none`
	• `border-color`: as each of the properties of the shorthand:
	  ◦ `border-top-color`: `currentcolor`
	  ◦ `border-right-color`: `currentcolor`
	  ◦ `border-bottom-color`: `currentcolor`
	  ◦ `border-left-color`: `currentcolor`

Applies to	all elements. It also applies to `::first-letter`.
Inherited	no

Computed value	as each of the properties of the shorthand:
	• `border-width`: as each of the properties of the shorthand:
	  ◦ `border-top-width`: the absolute `<length>`, snapped as a line width
	  ◦ `border-right-width`: the absolute `<length>`, snapped as a line width
	  ◦ `border-bottom-width`: the absolute `<length>`, snapped as a line width
	  ◦ `border-left-width`: the absolute `<length>`, snapped as a line width
	• `border-style`: as each of the properties of the shorthand:
	  ◦ `border-top-style`: as specified
	  ◦ `border-right-style`: as specified
	  ◦ `border-bottom-style`: as specified
	  ◦ `border-left-style`: as specified
	• `border-color`: as each of the properties of the shorthand:
	  ◦ `border-top-color`: computed color
	  ◦ `border-right-color`: computed color
	  ◦ `border-bottom-color`: computed color
	  ◦ `border-left-color`: computed color

Animation type	as each of the properties of the shorthand:
	• `border-width`: as each of the properties of the shorthand:
	  ◦ `border-top-width`: a length
	  ◦ `border-right-width`: a length
	  ◦ `border-bottom-width`: a length
	  ◦ `border-left-width`: a length
	• `border-style`: discrete
	• `border-color`: as each of the properties of the shorthand:
	  ◦ `border-top-color`: a color
	  ◦ `border-right-color`: a color
	  ◦ `border-bottom-color`: a color
	  ◦ `border-left-color`: a color

Formal syntax

```
border =
  <line-width> ||
  <line-style> ||
  <color>

<line-width> =
  <length [0,∞]> |
  hairline       |
  thin           |
  medium         |
  thick

<line-style> =
  none   |
  hidden |
  dotted |
  dashed |
  solid  |
  double |
  groove |
  ridge  |
  inset  |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting a pink outset border

HTML

```
<div>I have a border, an outline, and a box shadow! Amazing, isn't it?</div>
```

CSS

```
div {
  border: 0.5rem outset pink;
  outline: 0.5rem solid khaki;
  box-shadow: 0 0 0 2rem skyblue;
  border-radius: 12px;
  font: bold 1rem sans-serif;
  margin: 2rem;
  padding: 1rem;
  outline-offset: 0.5rem;
}
```

border-block CSS property

The **`border-block`** CSS shorthand property sets the individual logical block border property values in a single place in the style sheet.

Try it

```
border-block: solid;
writing-mode: horizontal-tb;
```

```
border-block: dashed red;
writing-mode: vertical-rl;
```

```
border-block: 1rem solid;
writing-mode: horizontal-tb;
direction: rtl;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: darkmagenta;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `border-block-color`
- `border-block-style`
- `border-block-width`

Syntax

```
border-block: 1px;
border-block: 2px dotted;
border-block: medium dashed blue;

/* Global values */
border-block: inherit;
border-block: initial;
border-block: revert;
border-block: revert-layer;
border-block: unset;
```

Values

The `border-block` is specified with one or more of the following, in any order:

`<line-width>`

The width of the border. See `border-width`.

`<line-style>`

The line style of the border. See `border-style`.

`<color>`

The color of the border.

Description

`border-block` can be used to set the values for one or more of `border-block-width`, `border-block-style`, and `border-block-color` setting both the start and end in the block dimension at once. The physical borders to which it maps depends on the element's writing mode, directionality, and text orientation. It corresponds to the `border-top` and `border-bottom` or `border-right`, and `border-left` properties depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

The borders in the other dimension can be set with `border-inline`, which sets `border-inline-start`, and `border-inline-end`.

Formal definition

Initial value	as each of the properties of the shorthand:
	• `border-block-width`: as each of the properties of the shorthand:
	  ◦ `border-block-start-width`: `medium`
	  ◦ `border-block-end-width`: `medium`
	• `border-block-style`: as each of the properties of the shorthand:
	  ◦ `border-block-start-style`: `none`
	  ◦ `border-block-end-style`: `none`
	• `border-block-color`: as each of the properties of the shorthand:
	  ◦ `border-block-start-color`: `currentcolor`
	  ◦ `border-block-end-color`: `currentcolor`

Applies to	all elements
Inherited	no

Computed value	as each of the properties of the shorthand:
	• `border-block-width`: as each of the properties of the shorthand:
	  ◦ `border-block-start-width`: the absolute `<length>`, snapped as a line width
	  ◦ `border-block-end-width`: the absolute `<length>`, snapped as a line width
	• `border-block-style`: as each of the properties of the shorthand:
	  ◦ `border-block-start-style`: as specified
	  ◦ `border-block-end-style`: as specified
	• `border-block-color`: as each of the properties of the shorthand:
	  ◦ `border-block-start-color`: computed color
	  ◦ `border-block-end-color`: computed color

Animation type	as each of the properties of the shorthand:
	• `border-block-width`: as each of the properties of the shorthand:
	  ◦ `border-block-start-width`: by computed value type
	  ◦ `border-block-end-width`: by computed value type
	• `border-block-style`: discrete
	• `border-block-color`: as each of the properties of the shorthand:
	  ◦ `border-block-start-color`: by computed value type
	  ◦ `border-block-end-color`: by computed value type

Formal syntax

```
border-block =
  <'border-block-start'>

<border-block-start> =
  <line-width>  ||
  <line-style>  ||
  <color>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick

<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Border with vertical text

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}
```

```
.exampleText {
  writing-mode: vertical-rl;
  border-block: 5px dashed blue;
}
```

border-block-color CSS property

The **`border-block-color`** CSS property defines the color of the logical block borders of an element, which maps to a physical border color depending on the element's writing mode, directionality, and text orientation. It corresponds to the `border-top-color` and `border-bottom-color`, or `border-right-color` and `border-left-color` property depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

The border color in the other dimension can be set with `border-inline-color` which sets `border-inline-start-color`, and `border-inline-end-color`.

Try it

```
border-block-color: red;
writing-mode: horizontal-tb;
```

```
border-block-color: #32a1ce;
writing-mode: vertical-rl;
```

```
border-block-color: rgb(170 50 220 / 0.6);
writing-mode: horizontal-tb;
direction: rtl;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: black;
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
border-block-color: yellow;
border-block-color: #f5f6f7;

/* Global values */
border-block-color: inherit;
border-block-color: initial;
border-block-color: revert;
border-block-color: revert-layer;
border-block-color: unset;
```

Values

This property is specified as one `<color>` value:

`<color>`

> The color of the border.

Formal definition

Initial value	as each of the properties of the shorthand: • `border-block-start-color`: `currentcolor` • `border-block-end-color`: `currentcolor`
Applies to	all elements
Inherited	no
Computed value	as each of the properties of the shorthand: • `border-block-start-color`: computed color • `border-block-end-color`: computed color
Animation type	as each of the properties of the shorthand: • `border-block-start-color`: by computed value type • `border-block-end-color`: by computed value type

Formal syntax

```
border-block-color =
  <'border-top-color'>{1,2}

<border-top-color> =
```

```
  <color>     |
  <image-1D>

<image-1D> =
  <stripes()>

<stripes()> =
  stripes( <color-stripe># )

<color-stripe> =
  <color>                          &&
  [ <length-percentage> | <flex> ]?

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Images Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Border with vertical text

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  border: 10px solid blue;
  border-block-color: red;
}
```

Results

- `writing-mode`, `direction`, `text-orientation`

border-block-end CSS property

The **`border-block-end`** CSS shorthand property sets the individual logical block-end border property values in a single place in the style sheet.

Try it

```
border-block-end: solid;
writing-mode: horizontal-tb;
```

```
border-block-end: dashed red;
writing-mode: vertical-rl;
```

```
border-block-end: 1rem solid;
writing-mode: horizontal-tb;
```

```
border-block-end: thick double #32a1ce;
writing-mode: vertical-lr;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: darkmagenta;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `border-block-end-color`
- `border-block-end-style`
- `border-block-end-width`

Syntax

```
border-block-end: 1px;
border-block-end: 2px dotted;
border-block-end: medium dashed blue;
```

```
/* Global values */
border-block-end: inherit;
border-block-end: initial;
border-block-end: revert;
border-block-end: revert-layer;
border-block-end: unset;
```

`border-block-end` can be used to set the values for one or more of `border-block-end-width`, `border-block-end-style`, and `border-block-end-color`. The physical border to which it maps depends on the element's writing mode, directionality, and text orientation. It corresponds to the `border-top`, `border-right`, `border-bottom`, or `border-left` property depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

Related properties are `border-block-start`, `border-inline-start`, and `border-inline-end`, which define the other borders of the element.

Values

The `border-block-end` is specified with one or more of the following, in any order:

`<line-width>`

The width of the border. See `border-width`.

`<line-style>`

The line style of the border. See `border-style`.

`<color>`

The color of the border.

Formal definition

Initial value	as each of the properties of the shorthand: • `border-block-end-width`: `medium` • `border-block-end-style`: `none` • `border-block-end-color`: `currentcolor`
Applies to	all elements
Inherited	no
Computed value	as each of the properties of the shorthand: • `border-block-end-width`: the absolute `<length>`, snapped as a line width • `border-block-end-style`: as specified • `border-block-end-color`: computed color
Animation type	as each of the properties of the shorthand: • `border-block-end-width`: by computed value type • `border-block-end-style`: discrete • `border-block-end-color`: by computed value type

Formal syntax

```
border-block-end =
  <line-width>  ||
  <line-style>  ||
  <color>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick

<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Border with vertical text

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-rl;
```

```
  border-block-end: 5px dashed blue;
}
```

  color: black;
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
border-block-end-color: yellow;
border-block-end-color: #f5f6f7;

/* Global values */
border-block-end-color: inherit;
border-block-end-color: initial;
border-block-end-color: revert;
border-block-end-color: revert-layer;
border-block-end-color: unset;
```

Related properties are `border-block-start-color`, `border-inline-start-color`, and `border-inline-end-color`, which define the other border colors of the element.

Values

`<color>`

The color of the border.

Formal definition

Initial value	`currentcolor`
Applies to	all elements
Inherited	no
Computed value	computed color
Animation type	by computed value type

Formal syntax

```
border-block-end-color =
  <color>     |
  <image-1D>

<image-1D> =
  <stripes()>

<stripes()> =
  stripes( <color-stripe># )

<color-stripe> =
  <color>                          &&
  [ <length-percentage> | <flex> ]?

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Images Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Border color with vertical text

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  border: 10px solid blue;
  border-block-end-color: red;
}
```

  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: black;
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
/* Keyword values */
border-block-end-style: dashed;
border-block-end-style: dotted;
border-block-end-style: groove;

/* Global values */
border-block-end-style: inherit;
border-block-end-style: initial;
border-block-end-style: revert;
border-block-end-style: revert-layer;
border-block-end-style: unset;
```

Related properties are `border-block-start-style`, `border-inline-start-style`, and `border-inline-end-style`, which define the other border styles of the element.

Values

`<line-style>`

The line style of the border. See `border-style`.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified

Animation type	discrete

Formal syntax

```
border-block-end-style =
  <line-style>

<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Dashed border with vertical text

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  border: 5px solid blue;
  border-block-end-style: dashed;
}
```

```
#example-element {
  background-color: palegreen;
  color: black;
  border: 0 solid crimson;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
/* <'line-width'> values */
border-block-end-width: 5px;
border-block-end-width: thick;

/* Global values */
border-block-end-width: inherit;
border-block-end-width: initial;
border-block-end-width: revert;
```

```
border-block-end-width: revert-layer;
border-block-end-width: unset;
```

Related properties are `border-block-start-width`, `border-inline-start-width`, and `border-inline-end-width`, which define the other border widths of the element.

Values

`<line-width>`

Defines the width of the border, either as an explicit non-negative `<length>` or the keywords: `thin`, `medium`, or `thick`. The default is `medium`.

Formal definition

Initial value	`medium`
Applies to	all elements
Inherited	no
Computed value	the absolute `<length>`, snapped as a line width
Animation type	by computed value type

Formal syntax

```
border-block-end-width =
  <line-width>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Border width with vertical text

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  border: 1px solid blue;
  border-block-end-width: 5px;
}
```

- `writing-mode`, `direction`, `text-orientation`

border-block-start CSS property

The **`border-block-start`** CSS shorthand property sets the individual logical block-start border property values in a single place in the style sheet.

Try it

```
border-block-start: solid;
writing-mode: horizontal-tb;
```

```
border-block-start: dashed red;
writing-mode: vertical-rl;
```

```
border-block-start: 1rem solid;
writing-mode: horizontal-tb;
```

```
border-block-start: thick double #32a1ce;
writing-mode: vertical-lr;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: darkmagenta;
  padding: 0.75em;
  width: 80%;
  height: 100px;
```

```
  unicode-bidi: bidi-override;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `border-block-start-color`
- `border-block-start-style`
- `border-block-start-width`

Syntax

```
border-block-start: 1px;
border-block-start: 2px dotted;
border-block-start: medium dashed blue;

/* Global values */
border-block-start: inherit;
border-block-start: initial;
border-block-start: revert;
border-block-start: revert-layer;
border-block-start: unset;
```

`border-block-start` can be used to set the values for one or more of `border-block-start-width`, `border-block-start-style`, and `border-block-start-color`. The physical border to which it maps depends on the element's writing mode, directionality, and text orientation. It corresponds to the `border-top`, `border-right`, `border-bottom`, or `border-left` property depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

Related properties are `border-block-end`, `border-inline-start`, and `border-inline-end`, which define the other borders of the element.

Values

The `border-block-start` is specified with one or more of the following, in any order:

`<line-width>`

The width of the border. See `border-width`.

`<line-style>`

The line style of the border. See `border-style`.

`<color>`

The color of the border.

Formal definition

Initial value	as each of the properties of the shorthand: • `border-block-start-width`: `medium` • `border-block-start-style`: `none` • `border-block-start-color`: `currentcolor`
Applies to	all elements
Inherited	no
Computed value	as each of the properties of the shorthand: • `border-block-start-width`: the absolute `<length>`, snapped as a line width • `border-block-start-style`: as specified • `border-block-start-color`: computed color
Animation type	as each of the properties of the shorthand: • `border-block-start-width`: by computed value type • `border-block-start-style`: discrete • `border-block-start-color`: by computed value type

Formal syntax

```
border-block-start =
  <line-width>  ||
  <line-style>  ||
  <color>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick

<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Border with vertical text

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-rl;
  border-block-start: 5px dashed blue;
}
```

See also

border-block-start-color CSS property

The **`border-block-start-color`** CSS property defines the color of the logical block-start border of an element, which maps to a physical border color depending on the element's writing mode, directionality, and text orientation. It corresponds to the `border-top-color`, `border-right-color`, `border-bottom-color`, or `border-left-color` property depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

Try it

```
border-block-start-color: red;
writing-mode: horizontal-tb;
```

```
border-block-start-color: #32a1ce;
writing-mode: vertical-rl;
```

```
border-block-start-color: rgb(170 50 220 / 0.6);
writing-mode: horizontal-tb;
```

```
border-block-start-color: hsl(60 90% 50% / 0.8);
writing-mode: vertical-lr;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: black;
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
border-block-start-color: blue;
border-block-start-color: #4c5d21;

/* Global values */
border-block-start-color: inherit;
border-block-start-color: initial;
border-block-start-color: revert;
border-block-start-color: revert-layer;
border-block-start-color: unset;
```

Related properties are `border-block-end-color`, `border-inline-start-color`, and `border-inline-end-color`, which define the other border colors of the element.

Values

`<color>`

The color of the border.

Formal definition

Initial value	`currentcolor`
Applies to	all elements
Inherited	no
Computed value	computed color
Animation type	by computed value type

Formal syntax

```
border-block-start-color =
  <color>     |
  <image-1D>

<image-1D> =
  <stripes()>

<stripes()> =
  stripes( <color-stripe># )

<color-stripe> =
  <color>                          &&
  [ <length-percentage> | <flex> ]?

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Images Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Border color with vertical text

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  border: 10px solid blue;
  border-block-start-color: red;
}
```

border-block-start-style CSS property

The **`border-block-start-style`** CSS property defines the style of the logical block start border of an element, which maps to a physical border style depending on the element's writing mode, directionality, and text orientation. It corresponds to the `border-top-style`, `border-right-style`, `border-bottom-style`, or `border-left-style` property depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

Try it

```
border-block-start-style: dotted;
writing-mode: horizontal-tb;
```

```
border-block-start-style: dotted;
writing-mode: vertical-rl;
```

```
border-block-start-style: groove;
writing-mode: horizontal-tb;
```

```
border-block-start-style: dashed;
writing-mode: vertical-lr;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: black;
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
/* Keyword values */
border-block-start-style: dashed;
border-block-start-style: dotted;
border-block-start-style: groove;

/* Global values */
```

```
border-block-start-style: inherit;
border-block-start-style: initial;
border-block-start-style: revert;
border-block-start-style: revert-layer;
border-block-start-style: unset;
```

Related properties are `border-block-end-style`, `border-inline-start-style`, and `border-inline-end-style`, which define the other border styles of the element.

Values

`<line-style>`

The line style of the border. See `border-style`.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
border-block-start-style =
  <line-style>

<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Dashed border with vertical text

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  border: 5px solid blue;
  border-block-start-style: dashed;
}
```

  background-color: palegreen;
  color: black;
  border: 0 solid crimson;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
/* <'line-width'> values */
border-block-start-width: 5px;
border-block-start-width: thick;

/* Global values */
border-block-start-width: inherit;
border-block-start-width: initial;
border-block-start-width: revert;
border-block-start-width: revert-layer;
border-block-start-width: unset;
```

Related properties are `border-block-end-width`, `border-inline-start-width`, and `border-inline-end-width`, which define the other border widths of the element.

Values

`<line-width>`

Defines the width of the border, either as an explicit non-negative `<length>` or the keywords: `thin`, `medium`, or `thick`. The default is `medium`.

Formal definition

Initial value	`medium`
Applies to	all elements
Inherited	no
Computed value	the absolute `<length>`, snapped as a line width
Animation type	by computed value type

Formal syntax

```
border-block-start-width =
  <line-width>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Border width with vertical text

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  border: 1px solid blue;
  border-block-start-width: 5px;
}
```

  background-color: #eeeeee;
  color: black;
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
/* Keyword values */
border-block-style: dashed;
border-block-style: dotted;
border-block-style: groove;

/* Global values */
border-block-style: inherit;
border-block-style: initial;
border-block-style: revert;
border-block-style: revert-layer;
border-block-style: unset;
```

Values

`<line-style>`

The line style of the border. See `border-style`.

Formal definition

Initial value	as each of the properties of the shorthand: • `border-block-start-style`: none • `border-block-end-style`: none
Applies to	all elements
Inherited	no
Computed value	as each of the properties of the shorthand: • `border-block-start-style`: as specified • `border-block-end-style`: as specified
Animation type	discrete

Formal syntax

```
border-block-style =
  <'border-top-style'>{1,2}

<border-top-style> =
  <line-style>

<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

```
border-block-width: thick;
writing-mode: horizontal-tb;
```

```
border-block-width: thick;
writing-mode: vertical-rl;
```

```
border-block-width: 4px;
writing-mode: horizontal-tb;
direction: rtl;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: palegreen;
  color: black;
  border: 0 solid crimson;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
/* <'line-width'> values */
border-block-width: 5px;
border-block-width: thick;

/* Global values */
border-block-width: inherit;
border-block-width: initial;
border-block-width: revert;
border-block-width: revert-layer;
border-block-width: unset;
```

Values

`<line-width>`

Defines the width of the border, either as an explicit non-negative `<length>` or the keywords: `thin`, `medium`, or `thick`. The default is `medium`.

Formal definition

Initial value	as each of the properties of the shorthand: • `border-block-start-width`: `medium` • `border-block-end-width`: `medium`
Applies to	all elements
Inherited	no
Computed value	as each of the properties of the shorthand: • `border-block-start-width`: the absolute `<length>`, snapped as a line width • `border-block-end-width`: the absolute `<length>`, snapped as a line width
Animation type	as each of the properties of the shorthand: • `border-block-start-width`: by computed value type • `border-block-end-width`: by computed value type

Formal syntax

```
border-block-width =
  <'border-top-width'>{1,2}

<border-top-width> =
  <line-width>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Border width with vertical text

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  border: 1px solid blue;
  border-block-width: 5px;
}
```

Results

border-bottom CSS property

The **`border-bottom`** CSS shorthand property sets an element's bottom border. It sets the values of `border-bottom-width`, `border-bottom-style` and `border-bottom-color`.

Try it

```
border-bottom: solid;
```

```
border-bottom: dashed red;
```

```
border-bottom: 1rem solid;
```

```
border-bottom: thick double #32a1ce;
```

```
border-bottom: 4mm ridge rgb(211 220 50 / 0.6);
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: darkmagenta;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `border-bottom-color`
- `border-bottom-style`
- `border-bottom-width`

Syntax

```
border-bottom: 1px;
border-bottom: 2px dotted;
border-bottom: medium dashed blue;

/* Global values */
border-bottom: inherit;
border-bottom: initial;
border-bottom: revert;
```

```
border-bottom: revert-layer;
border-bottom: unset;
```

The three values of the shorthand property can be specified in any order, and one or two of them may be omitted.

Values

`<br-width>`

See `border-bottom-width`.

`<br-style>`

See `border-bottom-style`.

`<color>`

See `border-bottom-color`.

Description

As with all shorthand properties, `border-bottom` always sets the values of all of the properties that it can set, even if they are not specified. It sets those that are not specified to their default values. Consider the following code:

```
border-bottom-style: dotted;
border-bottom: thick green;
```

It is actually the same as this one:

```
border-bottom-style: dotted;
border-bottom: none thick green;
```

The value of `border-bottom-style` given before `border-bottom` is ignored. Since the default value of `border-bottom-style` is `none`, not specifying the `border-style` part results in no border.

Formal definition

Initial value	as each of the properties of the shorthand: • `border-bottom-width`: `medium` • `border-bottom-style`: `none` • `border-bottom-color`: `currentcolor`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	as each of the properties of the shorthand: • `border-bottom-width`: the absolute `<length>`, snapped as a line width • `border-bottom-style`: as specified • `border-bottom-color`: computed color
Animation type	as each of the properties of the shorthand: • `border-bottom-width`: a length • `border-bottom-style`: discrete • `border-bottom-color`: a color

Formal syntax

```
border-bottom =
  <line-width>  ||
  <line-style>  ||
  <color>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick

<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Applying a bottom border

HTML

```
<div>This box has a border on the bottom side.</div>
```

CSS

```
div {
  border-bottom: 4px dashed blue;
  background-color: gold;
  height: 100px;
```

```
  width: 100px;
  font-weight: bold;
  text-align: center;
}
```

- `border`
- `border-block`
- `outline`

border-bottom-color CSS property

The **`border-bottom-color`** CSS property sets the color of an element's bottom border. It can also be set with the shorthand CSS properties `border-color` or `border-bottom`.

Try it

```
border-bottom-color: red;
```

```
border-bottom-color: #32a1ce;
```

```
border-bottom-color: rgb(170 50 220 / 0.6);
```

```
border-bottom-color: hsl(60 90% 50% / 0.8);
```

```
border-bottom-color: transparent;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: black;
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}
```

Syntax

```
/* <color> values */
border-bottom-color: red;
border-bottom-color: #ffbb00;
border-bottom-color: rgb(255 0 0);
border-bottom-color: hsl(100deg 50% 25% / 75%);
border-bottom-color: currentColor;
border-bottom-color: transparent;

/* Global values */
border-bottom-color: inherit;
border-bottom-color: initial;
border-bottom-color: revert;
border-bottom-color: revert-layer;
border-bottom-color: unset;
```

Values

This property is specified as one value:

`<color>`

The color of the bottom border.

Formal definition

Initial value	`currentcolor`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	computed color
Animation type	a color

Formal syntax

```
border-bottom-color =
  <color>     |
  <image-1D>

<image-1D> =
  <stripes()>

<stripes()> =
  stripes( <color-stripe># )

<color-stripe> =
  <color>                          &&
  [ <length-percentage> | <flex> ]?

<length-percentage> =
```

```
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Images Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

A div with a border

HTML

```
<div class="my-box">
  <p>
    This is a box with a border around it. Note which side of the box is
    <span class="red-text">red</span>.
  </p>
</div>
```

CSS

```
.my-box {
  border: solid 0.3em gold;
  border-bottom-color: red;
  width: auto;
}

.red-text {
  color: red;
}
```

Result

See also

- The color-related CSS properties for the other borders: `border-right-color`, `border-top-color`, and `border-left-color`.
- The other border-related CSS properties applying to the same border: `border-bottom-style` and `border-bottom-width`.
- The default `currentColor` color value.

border-bottom-left-radius CSS property

The **`border-bottom-left-radius`** CSS property rounds the bottom-left corner of an element by specifying the radius (or the radius of the semi-major and semi-minor axes) of the ellipse defining the curvature of the corner.

Try it

```
border-bottom-left-radius: 80px 80px;
```

```
border-bottom-left-radius: 250px 100px;
```

```
border-bottom-left-radius: 50%;
```

```
border-bottom-left-radius: 50%;
border: black 10px double;
background-clip: content-box;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a bottom left rounded corner.
  </div>
</section>
```

```
#example-element {
  width: 80%;
  height: 80%;
  display: flex;
  justify-content: center;
  flex-direction: column;
  background-color: #5b6dcd;
  color: white;
  padding: 10px;
}
```

Syntax

```
/* the corner is a circle */
/* border-bottom-left-radius: radius */
border-bottom-left-radius: 3px;

/* Percentage values */

/* circle if box is a square or ellipse if box is a rectangle */
border-bottom-left-radius: 20%;

/* same as above: 20% of horizontal(width) and vertical(height) */
border-bottom-left-radius: 20% 20%;

/* 20% of horizontal(width) and 10% of vertical(height) */
border-bottom-left-radius: 20% 10%;

/* the corner is an ellipse */
/* border-bottom-left-radius: horizontal vertical */
border-bottom-left-radius: 0.5em 1em;

/* Global values */
border-bottom-left-radius: inherit;
border-bottom-left-radius: initial;
```

```
border-bottom-left-radius: revert;
border-bottom-left-radius: revert-layer;
border-bottom-left-radius: unset;
```

With one value:

- the value is a `<length>` or a `<percentage>` denoting the radius of the circle to use for the border in that corner.

With two values:

- the first value is a `<length>` or a `<percentage>` denoting the horizontal semi-major axis of the ellipse to use for the border in that corner.
- the second value is a `<length>` or a `<percentage>` denoting the vertical semi-major axis of the ellipse to use for the border in that corner.

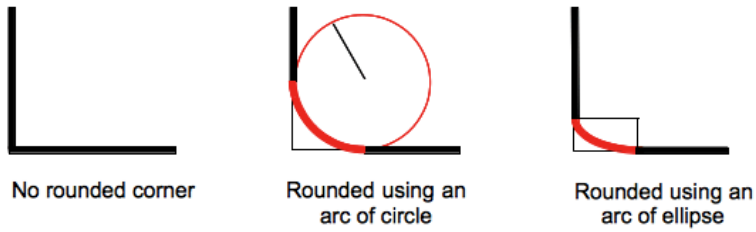
Values

`<length-percentage>`

Denotes the size of the circle radius or the semi-major and semi-minor axes of the ellipse. As absolute length it can be expressed in any unit allowed by the CSS `<length>` data type. Percentages for the horizontal axis refer to the width of the box, percentages for the vertical axis refer to the height of the box. Negative values are invalid.

Description

The rounding can be a circle or an ellipse, or if one of the values is `0` no rounding is done and the corner is square.



A background, being an image or a color, is clipped at the border, even a rounded one; the exact location of the clipping is defined by the value of the `background-clip` property.

> **Note:** If the value of this property is not set in a `border-radius` shorthand property that is applied to the element after the `border-bottom-left-radius` CSS property, the value of this property is then reset to its initial value by the shorthand property.

Formal definition

Initial value	`0`
Applies to	all elements; but User Agents are not required to apply to `table` and `inline-table` elements when `border-collapse` is `collapse`. The behavior on internal table elements is undefined for the moment.. It also applies to `::first-letter`.
Inherited	no
Percentages	refer to the corresponding dimension of the border box
Computed value	two absolute `<length>`s or `<percentage>`s
Animation type	a length, percentage or calc();

Formal syntax

```
border-bottom-left-radius =
  <border-radius>

<border-radius> =
  <slash-separated-border-radius-syntax>  |
  <legacy-border-radius-syntax>

<slash-separated-border-radius-syntax> =
  <length-percentage [0,∞]> [ / <length-percentage [0,∞]> ]?

<legacy-border-radius-syntax> =
  <length-percentage [0,∞]>{1,2}

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Arc of a circle

A single `<length>` value produces an arc of a circle.

```
<div></div>
```

```
div {
  border-bottom-left-radius: 40px;
  background-color: lightgreen;
  border: solid 1px black;
  width: 100px;
  height: 100px;
}
```

Arc of an ellipse

Two different `<length>` values produce an arc of an ellipse.

```
<div></div>
```

```
div {
  border-bottom-left-radius: 40px 20px;
  background-color: lightgreen;
  border: solid 1px black;
  width: 100px;
  height: 100px;
}
```

Square element with percentage radius

A square element with a single `<percentage>` value produces an arc of a circle.

```
<div></div>
```

```
div {
  border-bottom-left-radius: 40%;
  background-color: lightgreen;
  border: solid 1px black;
  width: 100px;
  height: 100px;
}
```

Non-square element with percentage radius

A non-square element with a single `<percentage>` value produces an arc of an ellipse.

```
<div></div>
```

```
div {
  border-bottom-left-radius: 40%;
  background-color: lightgreen;
  border: solid 1px black;
  width: 200px;
  height: 100px;
}
```

See also

- `border-radius` shorthand property
- `border-top-right-radius`, `border-bottom-right-radius`, and `border-top-left-radius`

border-bottom-right-radius CSS property

The **`border-bottom-right-radius`** CSS property rounds the bottom-right corner of an element by specifying the radius (or the radius of the semi-major and semi-minor axes) of the ellipse defining the curvature of the corner.

Try it

```
border-bottom-right-radius: 80px 80px;
```

```
border-bottom-right-radius: 250px 100px;
```

```
border-bottom-right-radius: 50%;
```

```
border-bottom-right-radius: 50%;
border: black 10px double;
background-clip: content-box;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a bottom right rounded corner.
  </div>
</section>
```

```
#example-element {
  width: 80%;
  height: 80%;
  display: flex;
  justify-content: center;
  flex-direction: column;
  background-color: #5b6dcd;
  color: white;
  padding: 10px;
}
```

Syntax

```
/* The corner is a circle */
/* border-bottom-right-radius: radius */
border-bottom-right-radius: 3px;

/* Percentage values */
border-bottom-right-radius: 20%; /* corner of a circle if box is a square or else corner of a rectangle */
border-bottom-right-radius: 20% 20%; /* same as above */ /* 20% of horizontal(width) and vertical(height) */
border-bottom-right-radius: 20% 10%; /* 20% of horizontal(width) and 10% of vertical(height) */

/*The corner is an ellipse */
/* border-bottom-right-radius: horizontal vertical */
border-bottom-right-radius: 0.5em 1em;

/* Global values */
border-bottom-right-radius: inherit;
border-bottom-right-radius: initial;
border-bottom-right-radius: revert;
```

```
border-bottom-right-radius: revert-layer;
border-bottom-right-radius: unset;
```

With one value:

- the value is a `<length>` or a `<percentage>` denoting the radius of the circle to use for the border in that corner.

With two values:

- the first value is a `<length>` or a `<percentage>` denoting the horizontal semi-major axis of the ellipse to use for the border in that corner.
- the second value is a `<length>` or a `<percentage>` denoting the vertical semi-major axis of the ellipse to use for the border in that corner.

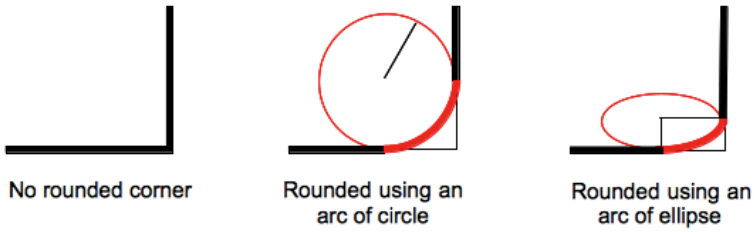
Values

`<length-percentage>`

> Denotes the size of the circle radius or the semi-major and semi-minor axes of the ellipse. As absolute length it can be expressed in any unit allowed by the CSS `<length>` data type. Percentages for the horizontal axis refer to the width of the box, percentages for the vertical axis refer to the height of the box. Negative values are invalid.

Description

The rounding can be a circle or an ellipse, or if one of the values is `0` no rounding is done and the corner is square.



A background, being an image or a color, is clipped at the border, even a rounded one; the exact location of the clipping is defined by the value of the `background-clip` property.

> **Note:** If the value of this property is not set in a `border-radius` shorthand property that is applied to the element after the `border-bottom-right-radius` CSS property, the value of this property is then reset to its initial value by the shorthand property.

Formal definition

Initial value	`0`
Applies to	all elements; but User Agents are not required to apply to `table` and `inline-table` elements when `border-collapse` is `collapse`. The behavior on internal table elements is undefined for the moment.. It also applies to `::first-letter`.
Inherited	no
Percentages	refer to the corresponding dimension of the border box
Computed value	two absolute `<length>`s or `<percentage>`s
Animation type	a length, percentage or calc();

Formal syntax

```
border-bottom-right-radius =
  <border-radius>

<border-radius> =
  <slash-separated-border-radius-syntax>  |
  <legacy-border-radius-syntax>

<slash-separated-border-radius-syntax> =
  <length-percentage [0,∞]> [ / <length-percentage [0,∞]> ]?

<legacy-border-radius-syntax> =
  <length-percentage [0,∞]>{1,2}

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Arc of a circle

A single `<length>` value produces an arc of a circle.

```
<div></div>
```

```
div {
  border-bottom-right-radius: 40px;
  background-color: lightgreen;
  border: solid 1px black;
  width: 100px;
  height: 100px;
}
```

Arc of an ellipse

Two different `<length>` values produce an arc of an ellipse.

```
<div></div>
```

```
div {
  border-bottom-right-radius: 40px 20px;
  background-color: lightgreen;
  border: solid 1px black;
  width: 100px;
  height: 100px;
}
```

Square element with percentage radius

A square element with a single `<percentage>` value produces an arc of a circle.

```
<div></div>
```

```
div {
  border-bottom-right-radius: 40%;
  background-color: lightgreen;
  border: solid 1px black;
  width: 100px;
  height: 100px;
}
```

Non-square element with percentage radius

A non-square element with a single `<percentage>` value produces an arc of an ellipse.

```
<div></div>
```

```
div {
  border-bottom-right-radius: 40%;
  background-color: lightgreen;
  border: solid 1px black;
  width: 200px;
  height: 100px;
}
```

- `border-radius` shorthand property
- `border-top-right-radius`, `border-bottom-left-radius`, and `border-top-left-radius`

border-bottom-style CSS property

The **`border-bottom-style`** CSS property sets the line style of an element's bottom `border`.

> **Note:** The specification doesn't define how borders of different styles connect in the corners.

Try it

```
border-bottom-style: none;
```

```
border-bottom-style: dotted;
```

```
border-bottom-style: dashed;
```

```
border-bottom-style: solid;
```

```
border-bottom-style: groove;
```

```
border-bottom-style: inset;
```

```
<section id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: black;
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}

body {
  background-color: white;
}
```

Syntax

```
/* Keyword values */
border-bottom-style: none;
border-bottom-style: hidden;
border-bottom-style: dotted;
border-bottom-style: dashed;
border-bottom-style: solid;
border-bottom-style: double;
border-bottom-style: groove;
border-bottom-style: ridge;
```

```
border-bottom-style: inset;
border-bottom-style: outset;

/* Global values */
border-bottom-style: inherit;
border-bottom-style: initial;
border-bottom-style: revert;
border-bottom-style: revert-layer;
border-bottom-style: unset;
```

The `border-bottom-style` property is specified as a single `<line-style>` keyword value.

Formal definition

Initial value	none
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
border-bottom-style =
  <line-style>

<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Demonstrating all border styles

HTML

```
<table>
  <tbody>
    <tr>
      <td class="b1">none</td>
      <td class="b2">hidden</td>
      <td class="b3">dotted</td>
      <td class="b4">dashed</td>
    </tr>
    <tr>
      <td class="b5">solid</td>
      <td class="b6">double</td>
      <td class="b7">groove</td>
      <td class="b8">ridge</td>
    </tr>
    <tr>
      <td class="b9">inset</td>
      <td class="b10">outset</td>
    </tr>
  </tbody>
</table>
```

CSS

```
/* Define look of the table */
table {
  border-width: 3px;
  background-color: #52e385;
}
tr,
td {
  padding: 3px;
}

/* border-bottom-style example classes */
.b1 {
  border-bottom-style: none;
}
.b2 {
  border-bottom-style: hidden;
}
.b3 {
  border-bottom-style: dotted;
}
.b4 {
  border-bottom-style: dashed;
}
.b5 {
  border-bottom-style: solid;
}
.b6 {
  border-bottom-style: double;
}
.b7 {
  border-bottom-style: groove;
}
```

```
.b8 {
  border-bottom-style: ridge;
}
.b9 {
  border-bottom-style: inset;
}
.b10 {
  border-bottom-style: outset;
}
```

Result

See also

- The other style-related border properties: `border-left-style`, `border-right-style`, `border-top-style`, and `border-style`.
- The other bottom-border-related properties: `border-bottom`, `border-bottom-color`, and `border-bottom-width`.

border-bottom-width CSS property

The **`border-bottom-width`** CSS property sets the width of the bottom border of an element.

Try it

```
border-bottom-width: thick;
```

```
border-bottom-width: 2em;
```

```
border-bottom-width: 4px;
```

```
border-bottom-width: 2ex;
```

```
border-bottom-width: 0;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: palegreen;
  color: black;
  border: 0 solid crimson;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}
```

Syntax

```
/* Keyword values */
border-bottom-width: thin;
border-bottom-width: medium;
border-bottom-width: thick;

/* <length> values */
border-bottom-width: 10em;
border-bottom-width: 3vmax;
border-bottom-width: 6px;

/* Global keywords */
border-bottom-width: inherit;
border-bottom-width: initial;
border-bottom-width: revert;
border-bottom-width: revert-layer;
border-bottom-width: unset;
```

Values

`<line-width>`

Defines the width of the border, either as an explicit non-negative `<length>` or the keywords: `thin`, `medium`, or `thick`. The default is `medium`.

Formal definition

Initial value	`medium`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	the absolute `<length>`, snapped as a line width
Animation type	a length

Formal syntax

```
border-bottom-width =
  <line-width>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Comparing bottom border widths

HTML

```
<div>Element 1</div>
<div>Element 2</div>
```

CSS

```
div {
  border: 1px solid red;
  margin: 1em 0;
}

div:nth-child(1) {
  border-bottom-width: thick;
}
div:nth-child(2) {
  border-bottom-width: 2em;
}
```

Result

See also

- The other border-width-related CSS properties: `border-left-width`, `border-right-width`, `border-top-width`, and `border-width`.
- The other border-bottom-related CSS properties: `border`, `border-bottom`, `border-bottom-style`, and `border-bottom-color`.

border-collapse CSS property

The **`border-collapse`** CSS property sets whether cells inside a `<table>` have shared or separate borders.

When cells are collapsed, the `border-style` value of `inset` behaves like `ridge`, and `outset` behaves like `groove`.

When cells are separated, the distance between cells is defined by the `border-spacing` property.

Try it

```
border-collapse: collapse;
```

```
border-collapse: separate;
```

```
<section class="default-example" id="default-example">
  <table class="transition-all" id="example-element">
    <tbody>
      <tr>
        <td>Cell 1.1</td>
        <td>Cell 1.2</td>
      </tr>
      <tr>
        <td>Cell 2.1</td>
        <td>Cell 2.2</td>
      </tr>
      <tr>
        <td>Cell 3.1</td>
        <td>Cell 3.2</td>
      </tr>
    </tbody>
  </table>
</section>
```

```
table {
  width: 15rem;
  table-layout: fixed;
}

td {
  border: 5px solid;
  border-color: crimson dodgerblue orange limegreen;
  padding: 0.75rem;
}
```

Syntax

```
/* Keyword values */
border-collapse: collapse;
border-collapse: separate;

/* Global values */
border-collapse: inherit;
border-collapse: initial;
border-collapse: revert;
border-collapse: revert-layer;
border-collapse: unset;
```

Values

This property is specified as one of the following keyword values:

`collapse`

Adjacent cells have shared borders (the collapsed-border table rendering model).

`separate`

Adjacent cells have distinct borders (the separated-border table rendering model).

Formal definition

Initial value	`separate`
Applies to	`table` and `inline-table` elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
border-collapse =
  separate  |
  collapse
```

This syntax reflects the latest standard as per CSS Table Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

A colorful table of browser engines

HTML

```
<table class="separate">
  <caption>
    <code>border-collapse: separate</code>
  </caption>
  <tbody>
    <tr>
      <th>Browser</th>
      <th>Layout Engine</th>
    </tr>
    <tr>
      <td class="fx">Firefox</td>
      <td class="gk">Gecko</td>
    </tr>
    <tr>
      <td class="ed">Edge</td>
      <td class="tr">EdgeHTML</td>
    </tr>
    <tr>
      <td class="sa">Safari</td>
      <td class="wk">WebKit</td>
    </tr>
    <tr>
      <td class="ch">Chrome</td>
      <td class="bk">Blink</td>
    </tr>
    <tr>
      <td class="op">Opera</td>
      <td class="bk">Blink</td>
    </tr>
  </tbody>
</table>
<table class="collapse">
  <caption>
    <code>border-collapse: collapse</code>
  </caption>
  <tbody>
    <tr>
      <th>Browser</th>
      <th>Layout Engine</th>
    </tr>
    <tr>
      <td class="fx">Firefox</td>
      <td class="gk">Gecko</td>
    </tr>
    <tr>
      <td class="ed">Edge</td>
      <td class="tr">EdgeHTML</td>
    </tr>
    <tr>
      <td class="sa">Safari</td>
      <td class="wk">WebKit</td>
    </tr>
    <tr>
      <td class="ch">Chrome</td>
      <td class="bk">Blink</td>
    </tr>
    <tr>
      <td class="op">Opera</td>
      <td class="bk">Blink</td>
    </tr>
  </tbody>
</table>
```

CSS

```
.collapse {
  border-collapse: collapse;
}

.separate {
  border-collapse: separate;
}

table {
  display: inline-table;
  margin: 1em;
  border: dashed 5px;
}
```

```
table th,
table td {
  border: solid 3px;
}

.fx {
  border-color: orange blue;
}
.gk {
  border-color: black red;
}
.ed {
  border-color: blue gold;
}
.tr {
  border-color: aqua;
}
.sa {
  border-color: silver blue;
}
.wk {
  border-color: gold blue;
}
.ch {
  border-color: red yellow green blue;
}
.bk {
  border-color: navy blue teal aqua;
}
.op {
  border-color: red;
}
```

border-color CSS property

The **`border-color`** CSS shorthand property sets the color of an element's border.

Try it

```
border-color: red;
```

```
border-color: red #32a1ce;
```

```
border-color: red rgb(170 50 220 / 0.6) green;
```

```
border-color: red yellow green hsl(60 90% 50% / 0.8);
```

```
border-color: red yellow green transparent;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: black;
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `border-bottom-color`
- `border-left-color`
- `border-right-color`
- `border-top-color`

Syntax

```
/* <color> values */
border-color: red;

/* top and bottom | left and right */
border-color: red #f015ca;

/* top | left and right | bottom */
border-color: red rgb(240 30 50 / 70%) green;

/* top | right | bottom | left */
border-color: red yellow green blue;

/* Global values */
border-color: inherit;
```

```
border-color: initial;
border-color: revert;
border-color: revert-layer;
border-color: unset;
```

The `border-color` property may be specified using one, two, three, or four values.

- When **one** value is specified, it applies the same color to **all four sides**.
- When **two** values are specified, the first color applies to the **top and bottom**, the second to the **left and right**.
- When **three** values are specified, the first color applies to the **top**, the second to the **left and right**, the third to the **bottom**.
- When **four** values are specified, the colors apply to the **top**, **right**, **bottom**, and **left** in that order (clockwise).

Values

`<color>`

Defines the color of the border.

Description

Each side can be set individually using `border-top-color`, `border-right-color`, `border-bottom-color`, and `border-left-color`; or using the writing mode-aware `border-block-start-color`, `border-block-end-color`, `border-inline-start-color`, and `border-inline-end-color`.

You can find out more information about border colors in Applying colors to HTML elements.

Formal definition

Initial value	as each of the properties of the shorthand: • `border-top-color`: `currentcolor` • `border-right-color`: `currentcolor` • `border-bottom-color`: `currentcolor` • `border-left-color`: `currentcolor`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	as each of the properties of the shorthand: • `border-top-color`: computed color • `border-right-color`: computed color • `border-bottom-color`: computed color • `border-left-color`: computed color
Animation type	as each of the properties of the shorthand: • `border-top-color`: a color • `border-right-color`: a color • `border-bottom-color`: a color • `border-left-color`: a color

Formal syntax

```
border-color =
  [ <color> | <image-1D> ]{1,4}

<image-1D> =
  <stripes()>

<stripes()> =
  stripes( <color-stripe># )

<color-stripe> =
  <color>                          &&
  [ <length-percentage> | <flex> ]?

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Images Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Complete border-color usage

HTML

```
<div id="justone">
  <p><code>border-color: red;</code> is equivalent to</p>
  <ul>
    <li><code>border-top-color: red;</code></li>
    <li><code>border-right-color: red;</code></li>
    <li><code>border-bottom-color: red;</code></li>
    <li><code>border-left-color: red;</code></li>
  </ul>
</div>
<div id="horzvert">
  <p><code>border-color: gold red;</code> is equivalent to</p>
  <ul>
    <li><code>border-top-color: gold;</code></li>
    <li><code>border-right-color: red;</code></li>
    <li><code>border-bottom-color: gold;</code></li>
    <li><code>border-left-color: red;</code></li>
  </ul>
</div>
<div id="topvertbott">
  <p><code>border-color: red cyan gold;</code> is equivalent to</p>
```

```
  <ul>
    <li><code>border-top-color: red;</code></li>
    <li><code>border-right-color: cyan;</code></li>
    <li><code>border-bottom-color: gold;</code></li>
    <li><code>border-left-color: cyan;</code></li>
  </ul>
</div>
<div id="trbl">
  <p><code>border-color: red cyan black gold;</code> is equivalent to</p>
  <ul>
    <li><code>border-top-color: red;</code></li>
    <li><code>border-right-color: cyan;</code></li>
    <li><code>border-bottom-color: black;</code></li>
    <li><code>border-left-color: gold;</code></li>
  </ul>
</div>
```

CSS

```
#justone {
  border-color: red;
}

#horzvert {
  border-color: gold red;
}

#topvertbott {
  border-color: red cyan gold;
}

#trbl {
  border-color: red cyan black gold;
}

/* Set width and style for all divs */
div {
  border: solid 0.3em;
  width: auto;
  margin: 0.5em;
  padding: 0.5em;
}

ul {
  margin: 0;
  list-style: none;
}
```

- Applying color to HTML elements using CSS

border-end-end-radius CSS property

The **`border-end-end-radius`** CSS property defines a logical border radius on an element, which maps to a physical border radius that depends on the element's `writing-mode`, `direction`, and `text-orientation`. This is useful when building styles to work regardless of the text orientation and writing mode.

This property affects the corner between the block-end and the inline-end sides of the element. For instance, in a `horizontal-tb` writing mode with `ltr` direction, it corresponds to the `border-bottom-right-radius` property.

Try it

```
border-end-end-radius: 80px 80px;
```

```
border-end-end-radius: 250px 100px;
direction: rtl;
```

```
border-end-end-radius: 50%;
writing-mode: vertical-lr;
```

```
border-end-end-radius: 50%;
writing-mode: vertical-rl;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a bottom right rounded corner.
  </div>
</section>
```

```
#example-element {
  width: 80%;
  height: 80%;
  display: flex;
  justify-content: center;
  flex-direction: column;
  background-color: #5b6dcd;
  color: white;
  padding: 10px;
}
```

Syntax

```
/* <length> values */
/* With one value the corner will be a circle */
border-end-end-radius: 10px;
border-end-end-radius: 1em;

/* With two values the corner will be an ellipse */
border-end-end-radius: 1em 2em;

/* Global values */
border-end-end-radius: inherit;
border-end-end-radius: initial;
border-end-end-radius: revert;
border-end-end-radius: revert-layer;
border-end-end-radius: unset;
```

Values

`<length-percentage>`

Denotes the size of the circle radius or the semi-major and semi-minor axes of the ellipse. As absolute length it can be expressed in any unit allowed by the CSS `<length>` data type. Percentages for the horizontal axis refer to the width of the box, percentages for the vertical axis refer to the height of the box. Negative values are invalid.

Formal definition

Initial value	`0`
Applies to	all elements; but User Agents are not required to apply to `table` and `inline-table` elements when `border-collapse` is `collapse`. The behavior on internal table elements is undefined for the moment.. It also applies to `::first-letter`.
Inherited	no
Percentages	refer to the corresponding dimension of the border box
Computed value	two absolute `<length>`s or `<percentage>`s
Animation type	a length, percentage or calc();

Formal syntax

```
border-end-end-radius =
  <border-radius>

<border-radius> =
  <slash-separated-border-radius-syntax>  |
  <legacy-border-radius-syntax>

<slash-separated-border-radius-syntax> =
  <length-percentage [0,∞]> [ / <length-percentage [0,∞]> ]?

<legacy-border-radius-syntax> =
  <length-percentage [0,∞]>{1,2}

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Border radius with vertical text

HTML

```
<div>
  <p class="exampleText">Example</p>
</div>
```

CSS

```
div {
  background-color: rebeccapurple;
  width: 120px;
  height: 120px;
  border-end-end-radius: 10px;
}

.exampleText {
  writing-mode: vertical-rl;
  padding: 10px;
  background-color: white;
  border-end-end-radius: 10px;
}
```

border-end-start-radius CSS property

The **`border-end-start-radius`** CSS property defines a logical border radius on an element, which maps to a physical border radius depending on the element's `writing-mode`, `direction`, and `text-orientation`. This is useful when building styles to work regardless of the text orientation and writing mode.

This property affects the corner between the block-end and the inline-start sides of the element. For instance, in a `horizontal-tb` writing mode with `ltr` direction, it corresponds to the `border-bottom-left-radius` property.

Try it

```
border-end-start-radius: 80px 80px;
```

```
border-end-start-radius: 250px 100px;
direction: rtl;
```

```
border-end-start-radius: 50%;
writing-mode: vertical-lr;
```

```
border-end-start-radius: 50%;
writing-mode: vertical-rl;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a bottom left rounded corner.
  </div>
</section>
```

```
#example-element {
  width: 80%;
  height: 80%;
  display: flex;
  justify-content: center;
  flex-direction: column;
  background-color: #5b6dcd;
  color: white;
  padding: 10px;
}
```

Syntax

```
/* <length> values */
/* With one value the corner will be a circle */
border-end-start-radius: 10px;
border-end-start-radius: 1em;

/* With two values the corner will be an ellipse */
border-end-start-radius: 1em 2em;

/* Global values */
border-end-start-radius: inherit;
border-end-start-radius: initial;
border-end-start-radius: revert;
border-end-start-radius: revert-layer;
border-end-start-radius: unset;
```

Values

`<length-percentage>`

> Denotes the size of the circle radius or the semi-major and semi-minor axes of the ellipse. As absolute length it can be expressed in any unit allowed by the CSS `<length>` data type. Percentages for the horizontal axis refer to the width of the box, percentages for the vertical axis refer to the height of the box. Negative values are invalid.

Formal definition

Initial value	`0`
Applies to	all elements; but User Agents are not required to apply to `table` and `inline-table` elements when `border-collapse` is `collapse`. The behavior on internal table elements is undefined for the moment.. It also applies to `::first-letter`.
Inherited	no
Percentages	refer to the corresponding dimension of the border box
Computed value	two absolute `<length>`s or `<percentage>`s
Animation type	a length, percentage or calc();

Formal syntax

```
border-end-start-radius =
  <border-radius>

<border-radius> =
  <slash-separated-border-radius-syntax>  |
  <legacy-border-radius-syntax>

<slash-separated-border-radius-syntax> =
  <length-percentage [0,∞]> [ / <length-percentage [0,∞]> ]?

<legacy-border-radius-syntax> =
  <length-percentage [0,∞]>{1,2}

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Border radius with vertical text

HTML

```
<div>
  <p class="exampleText">Example</p>
</div>
```

CSS

```
div {
  background-color: rebeccapurple;
  width: 120px;
  height: 120px;
  border-end-start-radius: 10px;

border-image CSS property

The **`border-image`** CSS shorthand property draws an image around a given element. It replaces the element's regular border.

> **Note:** You should specify a separate `border-style` in case the border image fails to load. Although the specification doesn't strictly require it, some browsers don't render the border image if `border-style` is `none` or `border-width` is `0`.

Try it

```
border-image: url("/shared-assets/images/examples/border-diamonds.png") 30;
```

```
border-image: url("/shared-assets/images/examples/border-diamonds.png") 30 /
  19px round;
```

```
border-image: url("/shared-assets/images/examples/border-diamonds.png") 30
  fill / 30px / 30px space;
```

```
border-image: linear-gradient(#f6b73c, #4d9f0c) 30;
```

```
border-image: repeating-linear-gradient(30deg, #4d9f0c, #9198e5, #4d9f0c 20px)
  60;
```

```
<section id="default-example">
  <div id="example-element">This is a box with a border around it.</div>
</section>
```

```
#example-element {
  width: 80%;
  height: 80%;
  display: flex;
  align-items: center;
  justify-content: center;
  padding: 50px;
  background: #fff3d4;
  color: black;
  border: 30px solid;
  border-image: url("/shared-assets/images/examples/border-diamonds.png") 30
    round;
  font-size: 1.2em;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `border-image-outset`
- `border-image-repeat`
- `border-image-slice`
- `border-image-source`
- `border-image-width`

This shorthand property is reset, with all the longhand properties set to their initial values, by the CSS `border` shorthand property.

Syntax

```
/* source | slice */
border-image: linear-gradient(red, blue) 27;

/* source | slice | repeat */
border-image: url("/images/border.png") 27 space;
```

```
/* source | slice | width */
border-image: linear-gradient(red, blue) 27 / 35px;

/* source | slice | width | outset | repeat */
border-image: url("/images/border.png") 27 23 / 50px 30px / 1rem round space;

/* Global values */
border-image: inherit;
border-image: initial;
border-image: revert;
border-image: revert-layer;
border-image: unset;
```

The `border-image` property may be specified with anywhere from one to five of the values listed below.

> **Note:** If the computed value of `border-image-source` is `none`, or if the image cannot be displayed, the `border-style` will be displayed instead.

Values

`<'border-image-source'>`

The source image. See `border-image-source`.

`<'border-image-slice'>`

The dimensions for slicing the source image into regions. Up to four values may be specified. See `border-image-slice`.

`<'border-image-width'>`

The width of the border image. Up to four values may be specified. See `border-image-width`.

`<'border-image-outset'>`

The distance of the border image from the element's outside edge. Up to four values may be specified. See `border-image-outset`.

`<'border-image-repeat'>`

Defines how the edge regions of the source image are adjusted to fit the dimensions of the border image. Up to two values may be specified. See `border-image-repeat`.

Accessibility

Assistive technology cannot parse border images. If the image contains information critical to understanding the page's overall purpose, it is better to describe it semantically in the document.

- MDN Understanding WCAG, Guideline 1.1 explanations
- Understanding Success Criterion 1.1.1 | Understanding WCAG 2.0

Formal definition

Initial value	as each of the properties of the shorthand: • `border-image-source`: `none` • `border-image-slice`: `100%` • `border-image-width`: `1` • `border-image-outset`: `0` • `border-image-repeat`: `stretch`
Applies to	all elements, except internal table elements when `border-collapse` is `collapse`. It also applies to `::first-letter`.
Inherited	no
Percentages	as each of the properties of the shorthand: • `border-image-slice`: refer to the size of the border image • `border-image-width`: refer to the width or height of the border image area
Computed value	as each of the properties of the shorthand: • `border-image-source`: `none` or the image with its URI made absolute • `border-image-slice`: one to four percentage(s) (as specified) or absolute length(s), plus the keyword `fill` if specified • `border-image-width`: as specified, but with relative lengths converted into absolute lengths • `border-image-outset`: as specified, but with relative lengths converted into absolute lengths • `border-image-repeat`: as specified
Animation type	as each of the properties of the shorthand: • `border-image-source`: discrete • `border-image-slice`: by computed value type • `border-image-width`: by computed value type • `border-image-outset`: by computed value type • `border-image-repeat`: discrete

Formal syntax

```
border-image =
  <'border-image-source'>                           ||
  <'border-image-slice'> [ / <'border-image-width'> | / <'border-image-width'>? / <'border-image-outset'> ]?  ||
  <'border-image-repeat'>

<border-image-source> =
  none     |
  <image>

<border-image-slice> =
  [ <number [0,∞]> | <percentage [0,∞]> ]{1,4}  &&
  fill?

<border-image-width> =
```

```
  [ <length-percentage [0,∞]> | <number [0,∞]> | auto ]{1,4}

<border-image-outset> =
  [ <length [0,∞]> | <number [0,∞]> ]{1,4}

<border-image-repeat> =
  [ stretch | repeat | round | space ]{1,2}

<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
  <gradient>

<length-percentage> =
  <length>      |
  <percentage>

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-set()> =
  image-set( <image-set-option># )

<cross-fade()> =
  cross-fade( <cf-image># )

<element()> =
  element( <id-selector> )

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Images Module Level 4, CSS Images Module Level 5, CSS Values and Units Module Level 4, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Bitmap

In this example, we will apply a diamond pattern to an element's borders. The source for the border image is a ".png" file of 81 by 81 pixels, with three diamonds going vertically and horizontally:

HTML

```
<div id="bitmap">
  This element is surrounded by a bitmap-based border image!
</div>
```

CSS

To match the size of a single diamond, we will use a value of 81 divided by 3, or 27, for slicing the image into corner and edge regions. To center the border image on the edge of the element's background, we will make the outset values equal to half of the width values. Finally, a repeat value of `round` will make the border slices fit evenly, i.e., without clipping or gaps.

```
#bitmap {
  width: 200px;
  background-color: #ffffaa;
  border: 36px solid orange;
  margin: 30px;
  padding: 10px;

  border-image: url("border.png") 27 / 36px 28px 18px 8px / 18px 14px 9px 4px
    round;
}
```

Result

Gradient

HTML

```
<div id="gradient">
  This element is surrounded by a gradient-based border image!
</div>
```

CSS

```
#gradient {
  width: 200px;
  border: 30px solid;
  border-image: repeating-linear-gradient(45deg, #ff3333, #33bbff, #ff3333 30px)
    60;
```

```
  padding: 20px;
}
```

Result

Rounded borders

`border-radius` has no effect on the border image. This is because `border-image-outset` is able to place the image outside the border box, so it doesn't make sense for the border image to be clipped by the border area. To create rounded borders when using a border image, you should create the image itself with rounded corners, or, in the case of a gradient, draw it as the background instead. Below, we show one approach to do this, which is to use two `background-image`s: one that extends the border box, and another for the padding box.

HTML

```
<div id="rounded">
  This element is surrounded by a border image with rounded corners!
</div>
```

CSS

```
#rounded {
  width: 200px;
  /* Use transparent so the background image is visible */
  border: 10px solid transparent;
  padding: 20px;
  border-radius: 20px;
  background-image:
    linear-gradient(white, white), linear-gradient(to right, cyan, lime);
  background-origin: border-box;
  background-clip: padding-box, border-box;
}
```

Result

> **Note:** There is a new `background-clip: border-area` value being proposed to address this use case.

border-image-outset CSS property

The **`border-image-outset`** CSS property sets the distance by which an element's border image is set out from its border box.

The parts of the border image that are rendered outside the element's border box with `border-image-outset` do not trigger overflow scrollbars and don't capture mouse events.

Try it

```
border-image-outset: 0;
```

```
border-image-outset: 15px;
```

```
border-image-outset: 30px;
```

```
border-image-outset: 40px;
```

```
<section id="default-example">
  <div id="example-element">This is a box with a border around it.</div>
</section>
```

```
#example-element {
  width: 80%;
  height: 80%;
  display: flex;
  align-items: center;
  justify-content: center;
  padding: 50px;
  background: #fff3d4;
  color: black;
  border: 30px solid;
  border-image: url("/shared-assets/images/examples/border-diamonds.png") 30
    round;
  font-size: 1.2em;
}
```

Syntax

```
/* <length> value */
border-image-outset: 1rem;

/* <number> value */
border-image-outset: 1.5;

/* top and bottom | left and right */
border-image-outset: 1 1.2;

/* top | left and right | bottom */
border-image-outset: 30px 2 45px;

/* top | right | bottom | left */
border-image-outset: 7px 12px 14px 5px;
```

```
/* Global values */
border-image-outset: inherit;
border-image-outset: initial;
border-image-outset: revert;
border-image-outset: revert-layer;
border-image-outset: unset;
```

The `border-image-outset` property may be specified as one, two, three, or four values. Each value is a `<length>` or `<number>`. Negative values are invalid and will cause the `border-image-outset` declaration to be ignored.

1. If **one** value is specified, it applies to **all four sides**.
2. If **two** values are specified, the first applies to the **top and bottom** and the second to the **left and right**.
3. If **three** values are specified, the first applies to the **top**, the second to the **left and right**, and the third to the **bottom**.
4. If **four** values are specified, they apply to the **top**, **right**, **bottom**, and **left** in that order (clockwise).

Values

`<length>`

> The size of the `border-image` outset as a dimension — a number with a unit.

`<number>`

> The size of the `border-image` outset as a multiple of the element's corresponding `border-width`s. For example, if an element has `border-width: 1em 2px 0 1.5rem`, and `border-image-outset: 2`, the final `border-image-outset` would be calculated as `2em 4px 0 3rem`.

Formal definition

Initial value	`0`
Applies to	all elements, except internal table elements when `border-collapse` is `collapse`. It also applies to `::first-letter`.
Inherited	no
Computed value	as specified, but with relative lengths converted into absolute lengths
Animation type	by computed value type

Formal syntax

```
border-image-outset =
  [ <length [0,∞]> | <number [0,∞]> ]{1,4}
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Outsetting a border image

HTML

```
<div id="outset">This element has an outset border image!</div>
```

CSS

```
#outset {
  width: 10rem;
  background: #cceeff;
  border: 1.4rem solid;
  border-image: radial-gradient(#ffff22, #5555ff) 40;
  border-image-outset: 1.5; /* 1.5 × 1.4rem = 2.1rem */
  margin: 2.1rem;
}
```

border-image-repeat CSS property

The **`border-image-repeat`** CSS property defines how the images for the sides and the middle part of the border image are scaled and tiled. The middle region can be displayed by using the keyword "fill" in the `border-image-slice` property.

Try it

```
border-image-repeat: stretch;
```

```
border-image-repeat: repeat;
```

```
border-image-repeat: round;
```

```
border-image-repeat: space;
```

```
border-image-repeat: round stretch;
```

```
<section id="default-example">
  <div id="example-element">This is a box with a border around it.</div>
</section>
```

```
#example-element {
  width: 80%;
  height: 80%;
  display: flex;
```

```
  align-items: center;
  justify-content: center;
  padding: 50px;
  background: #fff3d4;
  color: black;
  border: 30px solid;
  border-image: url("/shared-assets/images/examples/border-diamonds.png") 30
    round;
  font-size: 1.2em;
}
```

Syntax

```
/* Keyword values */
border-image-repeat: stretch;
border-image-repeat: repeat;
border-image-repeat: round;
border-image-repeat: space;

/* top and bottom | left and right */
border-image-repeat: round stretch;

/* Global values */
border-image-repeat: inherit;
border-image-repeat: initial;
border-image-repeat: revert;
border-image-repeat: revert-layer;
border-image-repeat: unset;
```

The `border-image-repeat` property may be specified using one or two values chosen from the list of values below.

- When **one** value is specified, it applies the same behavior on **all four sides**.
- When **two** values are specified, the first applies to the **top, middle, and bottom**, the second to the **left and right**.

Values

`stretch`

The source image's edge regions are stretched to fill the gap between each border.

`repeat`

The source image's edge regions are tiled (repeated) to fill the gap between each border. Tiles may be clipped to achieve the proper fit.

`round`

The source image's edge regions are tiled (repeated) to fill the gap between each border. Tiles may be stretched to achieve the proper fit.

`space`

The source image's edge regions are tiled (repeated) to fill the gap between each border. Extra space will be distributed in between tiles to achieve the proper fit.

Formal definition

Initial value	`stretch`
Applies to	all elements, except internal table elements when `border-collapse` is `collapse`. It also applies to `::first-letter`.
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
border-image-repeat =
  [ stretch | repeat | round | space ]{1,2}
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Repeating border images

CSS

```
#bordered {
  width: 12rem;
  margin-bottom: 1rem;
  padding: 1rem;
  border: 40px solid;
  border-image: url("border.png") 27;
  border-image-repeat: stretch; /* Can be changed in the live sample */
}
```

```
<div id="bordered">You can try out various border repetition rules on me!</div>

<select id="repetition">
  <option value="stretch">stretch</option>
  <option value="repeat">repeat</option>
  <option value="round">round</option>
  <option value="space">space</option>
  <option value="stretch repeat">stretch repeat</option>
  <option value="space round">space round</option>
</select>
```

```
const repetition = document.getElementById("repetition");
repetition.addEventListener("change", (evt) => {
  document.getElementById("bordered").style.borderImageRepeat =
    evt.target.value;
});
```

border-image-slice CSS property

The **`border-image-slice`** CSS property divides the image specified by `border-image-source` into regions. These regions form the components of an element's border image.

Try it

```
border-image-slice: 30;
```

```
border-image-slice: 30 fill;
```

```
border-image-slice: 44;
```

```
border-image: url("/shared-assets/images/examples/border-florid.svg") round;
border-image-slice: calc(50 / 184 * 100%) calc(80 / 284 * 100%) fill;
border-image-width: 30px 48px;
```

```
<section id="default-example">
  <div id="example-element">This is a box with a border around it.</div>
</section>
```

```
#example-element {
  width: 80%;
  height: 80%;
  display: flex;
  align-items: center;
  justify-content: center;
  padding: 50px;
  background: #fff3d4;
  color: black;
  border: 30px solid;
  border-image: url("/shared-assets/images/examples/border-diamonds.png") 30
    round;
  font-size: 1.2em;
}
```

Syntax

```
/* All sides */
border-image-slice: 30%;

/* top and bottom | left and right */
border-image-slice: 10% 30%;

/* top | left and right | bottom */
border-image-slice: 30 30% 45;

/* top | right | bottom | left */
border-image-slice: 7 12 14 5;

/* Using the `fill` keyword */
border-image-slice: 10% fill;
border-image-slice: fill 10%;

/* Global values */
border-image-slice: inherit;
border-image-slice: initial;
border-image-slice: revert;
border-image-slice: revert-layer;
border-image-slice: unset;
```

The `border-image-slice` property may be specified using one to four `<number-percentage>` values to represent the position of each image slice. Negative values are invalid; values greater than their corresponding dimension are clamped to `100%`.

- When **one** position is specified, it creates all four slices at the same distance from their respective sides.
- When **two** positions are specified, the first value creates slices measured from the **top and bottom**, the second creates slices measured from the **left and right**.
- When **three** positions are specified, the first value creates a slice measured from the **top**, the second creates slices measured from the **left and right**, the third creates a slice measured from the **bottom**.
- When **four** positions are specified, they create slices measured from the **top**, **right**, **bottom**, and **left** in that order (clockwise).

The optional `fill` value, if used, can be placed anywhere in the declaration.

Values

`<number>`

Represents an edge offset in *pixels* for raster images and *coordinates* for vector images. For vector images, the number is relative to the element's size, not the size of the source image, so percentages are generally preferable in these cases.

`<percentage>`

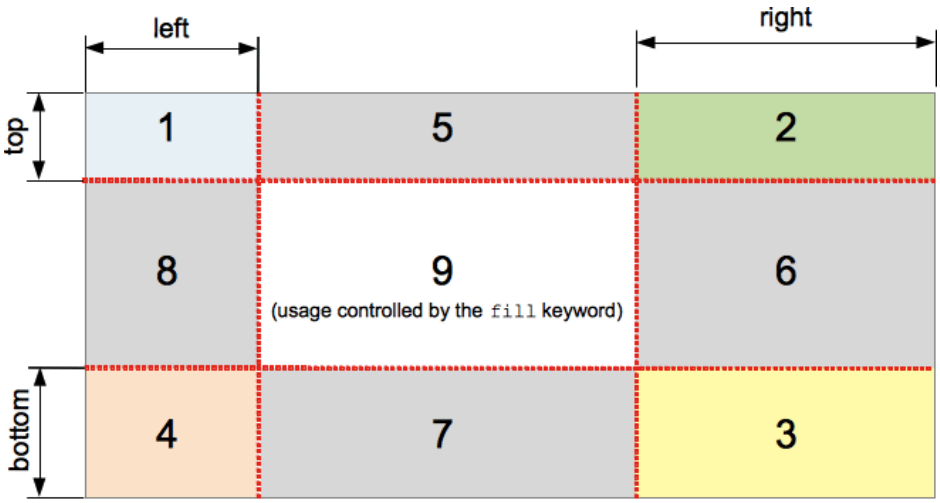
Represents an edge offset as a percentage of the source image's size: the width of the image for horizontal offsets, the height for vertical offsets.

`fill`

Preserves the middle image region and displays it like a background image, but stacked above the actual `background`. Its width and height are sized to match the top and left image regions, respectively.

Description

The slicing process creates nine regions in total: four corners, four edges, and a middle region. Four slice lines, set a given distance from their respective sides, control the size of the regions.



The above diagram illustrates the location of each region.

- Zones 1-4 are corner regions. Each one is used a single time to form the corners of the final border image.
- Zones 5-8 are edge regions. These are repeated, scaled, or otherwise modified in the final border image to match the dimensions of the element.
- Zone 9 is the middle region. It is discarded by default, but is used like a background image if the keyword `fill` is set.

The `border-image-repeat`, `border-image-width`, and `border-image-outset` properties determine how these regions are used to form the final border image.

Formal definition

Initial value	`100%`
Applies to	all elements, except internal table elements when `border-collapse` is `collapse`. It also applies to `::first-letter`.
Inherited	no
Percentages	refer to the size of the border image
Computed value	one to four percentage(s) (as specified) or absolute length(s), plus the keyword `fill` if specified
Animation type	by computed value type

Formal syntax

```
border-image-slice =
  [ <number [0,∞]> | <percentage [0,∞]> ]{1,4}  &&
  fill?
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Adjustable border width and slice

The following example shows a `<div>` with a border image set on it. The source image for the borders is as follows:

The diamonds in the source image are 30px across, so setting 30 pixels as the value for both `border-width` and `border-image-slice` will get you complete and fairly crisp diamonds in your border:

```
border-width: 30px;
border-image-slice: 30;
```

These are the default values we have used in this example. However, we have also provided two sliders to allow you to dynamically change the values of the above two properties, allowing you to appreciate the effect they have:

`border-image-slice` Changes the size of the image slice sampled for use in each border and border corner (and the content area, if the `fill` keyword is used) — varying this away from 30 causes the border to look somewhat irregular, but can have some interesting effects.

`border-width`: Changes the width of the border. The sampled image size is scaled to fit inside the border, which means that if the width is bigger than the slice, the image can start to look somewhat pixelated (unless of course you use an SVG image).

HTML

```
<div class="wrapper">
  <div></div>
</div>

<ul>
  <li>
    <label for="width">slide to adjust <code>border-width</code></label>
    <input type="range" min="10" max="45" id="width" />
    <output id="width-output">30px</output>
  </li>
  <li>
    <label for="slice">slide to adjust <code>border-image-slice</code></label>
    <input type="range" min="10" max="45" id="slice" />
    <output id="slice-output">30</output>
  </li>
</ul>
```

CSS

```
.wrapper {
  width: 400px;
  height: 300px;
}

div > div {
  width: 300px;
  height: 200px;
  border-width: 30px;
  border-style: solid;
  border-image: url("/shared-assets/images/examples/border-diamonds.png");
  border-image-slice: 30;
  border-image-repeat: round;
}

li {
  display: flex;
  place-content: center;
}
```

JavaScript

```
const widthSlider = document.getElementById("width");
const sliceSlider = document.getElementById("slice");
const widthOutput = document.getElementById("width-output");
const sliceOutput = document.getElementById("slice-output");
const divElem = document.querySelector("div > div");

widthSlider.addEventListener("input", () => {
  const newValue = `${widthSlider.value}px`;
  divElem.style.borderWidth = newValue;
  widthOutput.textContent = newValue;
});

sliceSlider.addEventListener("input", () => {
  const newValue = sliceSlider.value;
  divElem.style.borderImageSlice = newValue;
  sliceOutput.textContent = newValue;
});
```

border-image-source CSS property

The **`border-image-source`** CSS property sets the source image used to create an element's border image.

The `border-image-slice` property is used to divide the source image into regions, which are then dynamically applied to the final border image.

Try it

```
border-image-source: url("/shared-assets/images/examples/border-diamonds.png");
```

```
border-image-source: url("/shared-assets/images/examples/border-stars.png");
```

```
border-image-source: repeating-linear-gradient(
  45deg,
  transparent,
  #4d9f0c 20px
);
```

```
border-image-source: none;
```

```
<section id="default-example">
  <div id="example-element">This is a box with a border around it.</div>
</section>
```

```
#example-element {
  width: 80%;
  height: 80%;
  display: flex;
  align-items: center;
  justify-content: center;
  padding: 50px;
  background: #fff3d4;
  color: black;
  border: 30px solid;
  border-image: url("/shared-assets/images/examples/border-diamonds.png") 30
    round;
  font-size: 1.2em;
}
```

Syntax

```
/* Keyword value */
border-image-source: none;

/* <image> values */
border-image-source: url("image.jpg");
border-image-source: linear-gradient(to top, red, yellow);

/* Global values */
border-image-source: inherit;
```

```
border-image-source: initial;
border-image-source: revert;
border-image-source: revert-layer;
border-image-source: unset;
```

Values

`none`

No border image is used. The appearance defined by `border-style` is displayed instead.

`<image>`

Image reference to use for the border.

Formal definition

Initial value	none
Applies to	all elements, except internal table elements when `border-collapse` is `collapse`. It also applies to `::first-letter`.
Inherited	no
Computed value	none or the image with its URI made absolute
Animation type	discrete

Formal syntax

```
border-image-source =
  none     |
  <image>

<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
  <gradient>

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-set()> =
  image-set( <image-set-option># )

<cross-fade()> =
  cross-fade( <cf-image># )

<element()> =
  element( <id-selector> )

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Images Module Level 4, CSS Images Module Level 5, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

```
.box {
  border-image-source: url("image.png");
}
```

border-image-width CSS property

The **`border-image-width`** CSS property sets the width of an element's border image.

If this property's value is greater than the element's `border-width`, the border image will extend beyond the padding (and/or content) edge.

Try it

```
border-image-width: 30px;
```

```
border-image-width: 15px 40px;
```

```
border-image-width: 2.6rem;
```

```
border-image-width: 20% 8%;
```

```
<section id="default-example">
  <div id="example-element">This is a box with a border around it.</div>
</section>
```

```
#example-element {
  width: 80%;
  height: 80%;
  display: flex;
  align-items: center;
  justify-content: center;
  padding: 50px;
  background: #fff3d4;
  color: black;
  border: 30px solid;
  border-image: url("/shared-assets/images/examples/border-diamonds.png") 30
    round;
  font-size: 1.2em;
}
```

Syntax

```
/* Keyword value */
border-image-width: auto;

/* <length> value */
border-image-width: 1rem;

/* <percentage> value */
border-image-width: 25%;

/* <number> value */
border-image-width: 3;

/* top and bottom | left and right */
border-image-width: 2em 3em;

/* top | left and right | bottom */
border-image-width: 5% 15% 10%;

/* top | right | bottom | left */
border-image-width: 5% 2em 10% auto;

/* Global values */
border-image-width: inherit;
border-image-width: initial;
border-image-width: revert;
border-image-width: revert-layer;
border-image-width: unset;
```

The `border-image-width` property may be specified using one, two, three, or four values chosen from the list of values below.

- When **one** value is specified, it applies the same width to **all four sides**.
- When **two** values are specified, the first width applies to the **top and bottom**, the second to the **left and right**.
- When **three** values are specified, the first width applies to the **top**, the second to the **left and right**, the third to the **bottom**.
- When **four** values are specified, the widths apply to the **top**, **right**, **bottom**, and **left** in that order (clockwise).

Values

`<length-percentage>`

The width of the border, specified as a `<length>` or a `<percentage>`. Percentages are relative to the *width* of the border image area for horizontal offsets and the *height* of the border image area for vertical offsets. Must not be negative.

`<number>`

The width of the border, specified as a multiple of the corresponding `border-width`. Must not be negative.

`auto`

The width of the border is made equal to the intrinsic width or height (whichever is applicable) of the corresponding `border-image-slice`. If the image does not have the required intrinsic dimension, the corresponding `border-width` is used instead.

Formal definition

Initial value	`1`
Applies to	all elements, except internal table elements when `border-collapse` is `collapse`. It also applies to `::first-letter`.
Inherited	no
Percentages	refer to the width or height of the border image area
Computed value	as specified, but with relative lengths converted into absolute lengths
Animation type	by computed value type

Formal syntax

```
border-image-width =
  [ <length-percentage [0,∞]> | <number [0,∞]> | auto ]{1,4}

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Tiling a border image

This example creates a border image using the following ".png" file, which is 90 by 90 pixels:

Thus, each circle in the source image is 30 by 30 pixels.

HTML

```
<p>
  Lorem ipsum dolor sit amet, consetetur sadipscing elitr, sed diam nonumy
  eirmod tempor invidunt ut labore et dolore magna aliquyam erat, sed diam
  voluptua. At vero eos et accusam et justo duo dolores et ea rebum. Stet clita
  kasd gubergren, no sea takimata sanctus est Lorem ipsum dolor sit amet.
</p>
```

CSS

```
p {
  border: 20px solid;
  border-image: url("border.png") 30 round;
  border-image-width: 16px;
  padding: 40px;
}
```

Result

border-inline CSS property

The **`border-inline`** CSS shorthand property sets the individual logical inline border property values in a single place in the style sheet.

Try it

```
border-inline: solid;
writing-mode: horizontal-tb;
```

```
border-inline: dashed red;
writing-mode: vertical-rl;
```

```
border-inline: 1rem solid;
writing-mode: horizontal-tb;
direction: rtl;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: darkmagenta;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `border-inline-color`
- `border-inline-style`
- `border-inline-width`

Syntax

```
border-inline: 1px;
border-inline: 2px dotted;
border-inline: medium dashed blue;

/* Global values */
border-inline: inherit;
border-inline: initial;
border-inline: revert;
border-inline: revert-layer;
border-inline: unset;
```

Values

The `border-inline` is specified with one or more of the following, in any order:

`<line-width>`

The width of the border. See `border-width`.

`<line-style>`

The line style of the border. See `border-style`.

`<color>`

The color of the border.

Description

The physical borders to which `border-inline` maps depends on the element's writing mode, directionality, and text orientation. It corresponds to the `border-top` and `border-bottom` or `border-right`, and `border-left` properties, depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

The borders in the other dimension can be set with `border-block`, which sets `border-block-start`, and `border-block-end`.

Formal definition

Initial value	as each of the properties of the shorthand:
	• `border-inline-width`: as each of the properties of the shorthand:
	  ◦ `border-inline-start-width`: `medium`
	  ◦ `border-inline-end-width`: `medium`
	• `border-inline-style`: as each of the properties of the shorthand:
	  ◦ `border-inline-start-style`: `none`
	  ◦ `border-inline-end-style`: `none`
	• `border-inline-color`: as each of the properties of the shorthand:
	  ◦ `border-inline-start-color`: `currentcolor`
	  ◦ `border-inline-end-color`: `currentcolor`

Applies to	all elements
Inherited	no

Computed value	as each of the properties of the shorthand:
	• `border-inline-width`: as each of the properties of the shorthand:
	  ◦ `border-inline-start-width`: the absolute `<length>`, snapped as a line width
	  ◦ `border-inline-end-width`: the absolute `<length>`, snapped as a line width
	• `border-inline-style`: as each of the properties of the shorthand:
	  ◦ `border-inline-start-style`: as specified
	  ◦ `border-inline-end-style`: as specified
	• `border-inline-color`: as each of the properties of the shorthand:
	  ◦ `border-inline-start-color`: computed color
	  ◦ `border-inline-end-color`: computed color

Animation type	as each of the properties of the shorthand:
	• `border-inline-width`: as each of the properties of the shorthand:
	  ◦ `border-inline-start-width`: by computed value type
	  ◦ `border-inline-end-width`: by computed value type
	• `border-inline-style`: discrete
	• `border-inline-color`: as each of the properties of the shorthand:
	  ◦ `border-inline-start-color`: by computed value type
	  ◦ `border-inline-end-color`: by computed value type

Formal syntax

```
border-inline =
  <'border-block-start'>

<border-block-start> =
  <line-width> ||
  <line-style> ||
  <color>

<line-width> =
  <length [0,∞]> |
  hairline       |
  thin           |
  medium         |
  thick

<line-style> =
  none   |
  hidden |
  dotted |
  dashed |
  solid  |
  double |
  groove |
  ridge  |
  inset  |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Border with vertical text

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-rl;
  border-inline: 5px dashed blue;
}
```

- This property maps to one of the physical border properties: `border-top`, `border-right`, `border-bottom`, or `border-left`.
- `writing-mode`, `direction`, `text-orientation`

border-inline-color CSS property

The **`border-inline-color`** CSS property defines the color of the logical inline borders of an element, which maps to a physical border color depending on the element's writing mode, directionality, and text orientation. It corresponds to the `border-top-color` and `border-bottom-color`, or `border-right-color` and `border-left-color` property depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

The border color in the other dimension can be set with `border-block-color` which sets `border-block-start-color`, and `border-block-end-color`.

Try it

```
border-inline-color: red;
writing-mode: horizontal-tb;
```

```
border-inline-color: #32a1ce;
writing-mode: vertical-rl;
```

```
border-inline-color: rgb(170 50 220 / 0.6);
writing-mode: horizontal-tb;
direction: rtl;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: black;
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
border-inline-color: yellow;
border-inline-color: #f5f6f7;

/* Global values */
border-inline-color: inherit;
border-inline-color: initial;
border-inline-color: revert;
border-inline-color: revert-layer;
border-inline-color: unset;
```

Values

This property is specified as one `<color>` value:

`<color>`

The color of the border.

Formal definition

Initial value	as each of the properties of the shorthand: • `border-inline-start-color`: `currentcolor` • `border-inline-end-color`: `currentcolor`
Applies to	all elements
Inherited	no
Computed value	as each of the properties of the shorthand: • `border-inline-start-color`: computed color • `border-inline-end-color`: computed color
Animation type	as each of the properties of the shorthand: • `border-inline-start-color`: by computed value type • `border-inline-end-color`: by computed value type

Formal syntax

```
border-inline-color =
  <'border-top-color'>{1,2}

<border-top-color> =
  <color>     |
  <image-1D>

<image-1D> =
  <stripes()>

<stripes()> =
  stripes( <color-stripe># )

<color-stripe> =
  <color>                          &&
  [ <length-percentage> | <flex> ]?

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Images Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Border color with vertical text

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  border: 10px solid blue;
  border-inline-color: red;
}
```

- `writing-mode`, `direction`, `text-orientation`

border-inline-end CSS property

The **`border-inline-end`** CSS shorthand property sets the individual logical inline-end border property values in a single place in the style sheet.

Try it

```
border-inline-end: solid;
writing-mode: horizontal-tb;
```

```
border-inline-end: dashed red;
writing-mode: vertical-rl;
```

```
border-inline-end: 1rem solid;
writing-mode: horizontal-tb;
direction: rtl;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: darkmagenta;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `border-inline-end-color`
- `border-inline-end-style`
- `border-inline-end-width`

Syntax

```
border-inline-end: 1px;
border-inline-end: 2px dashed;
border-inline-end: medium dashed blue;

/* Global values */
border-inline-end: inherit;
border-inline-end: initial;
border-inline-end: revert;
border-inline-end: revert-layer;
border-inline-end: unset;
```

The physical border to which `border-inline-end` maps depends on the element's writing mode, directionality, and text orientation. It corresponds to the `border-top`, `border-right`, `border-bottom`, or `border-left` property depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

Related properties are `border-block-start`, `border-block-end`, and `border-inline-start`, which define the other borders of the element.

Values

The `border-inline-end` is specified with one or more of the following, in any order:

`<line-width>`

The width of the border. See `border-width`.

`<line-style>`

The line style of the border. See `border-style`.

`<color>`

The color of the border.

Formal definition

Initial value	as each of the properties of the shorthand: • `border-inline-end-width`: `medium` • `border-inline-end-style`: `none` • `border-inline-end-color`: `currentcolor`
Applies to	all elements
Inherited	no
Computed value	as each of the properties of the shorthand: • `border-inline-end-width`: the absolute `<length>`, snapped as a line width • `border-inline-end-style`: as specified • `border-inline-end-color`: computed color
Animation type	as each of the properties of the shorthand: • `border-inline-end-width`: by computed value type • `border-inline-end-style`: discrete • `border-inline-end-color`: by computed value type

Formal syntax

```
border-inline-end =
  <line-width>  ||
  <line-style>  ||
  <color>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick

<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}
```

```
.exampleText {
  writing-mode: vertical-rl;
  border-inline-end: 5px dashed blue;
}
```

border-inline-end-color CSS property

The **`border-inline-end-color`** CSS property defines the color of the logical inline-end border of an element, which maps to a physical border color depending on the element's writing mode, directionality, and text orientation. It corresponds to the `border-top-color`, `border-right-color`, `border-bottom-color`, or `border-left-color` property depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

Try it

```
border-inline-end-color: red;
writing-mode: horizontal-tb;
```

```
border-inline-end-color: #32a1ce;
writing-mode: vertical-rl;
```

```
border-inline-end-color: rgb(170 50 220 / 0.6);
writing-mode: horizontal-tb;
direction: rtl;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: black;
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
border-inline-end-color: rebeccapurple;
border-inline-end-color: #663399;

/* Global values */
border-inline-end-color: inherit;
border-inline-end-color: initial;
border-inline-end-color: revert;
border-inline-end-color: revert-layer;
border-inline-end-color: unset;
```

Related properties are `border-block-start-color`, `border-block-end-color`, and `border-inline-start-color`, which define the other border colors of the element.

Values

`<color>`

The color of the border.

Formal definition

Initial value	`currentcolor`
Applies to	all elements
Inherited	no
Computed value	computed color
Animation type	by computed value type

Formal syntax

```
border-inline-end-color =
  <color>     |
  <image-1D>

<image-1D> =
  <stripes()>

<stripes()> =
  stripes( <color-stripe># )

<color-stripe> =
  <color>                          &&
  [ <length-percentage> | <flex> ]?

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Images Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  border: 10px solid blue;
  border-inline-end-color: red;
}
```

- This property maps to one of the physical border properties: `border-top-color`, `border-right-color`, `border-bottom-color`, or `border-left-color`.
- `writing-mode`, `direction`, `text-orientation`

border-inline-end-style CSS property

The **`border-inline-end-style`** CSS property defines the style of the logical inline end border of an element, which maps to a physical border style depending on the element's writing mode, directionality, and text orientation. It corresponds to the `border-top-style`, `border-right-style`, `border-bottom-style`, or `border-left-style` property depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

Try it

```
border-inline-end-style: dotted;
writing-mode: horizontal-tb;
```

```
border-inline-end-style: dotted;
writing-mode: vertical-rl;
```

```
border-inline-end-style: groove;
writing-mode: horizontal-tb;
direction: rtl;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: black;
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
/* Keyword values */
border-inline-end-style: dashed;
border-inline-end-style: dotted;
border-inline-end-style: groove;

/* Global values */
border-inline-end-style: inherit;
border-inline-end-style: initial;
border-inline-end-style: revert;
border-inline-end-style: revert-layer;
border-inline-end-style: unset;
```

Related properties are `border-block-start-style`, `border-block-end-style`, and `border-inline-start-style`, which define the other border styles of the element.

Values

`<line-style>`

The line style of the border. See `border-style`.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
border-inline-end-style =
  <line-style>
```

```
<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting inline-end-style

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  border: 5px solid blue;
  border-inline-end-style: dashed;
}
```

- `writing-mode`, `direction`, `text-orientation`

border-inline-end-width CSS property

The **`border-inline-end-width`** CSS property defines the width of the logical inline-end border of an element, which maps to a physical border width depending on the element's writing mode, directionality, and text orientation. It corresponds to the `border-top-width`, `border-right-width`, `border-bottom-width`, or `border-left-width` property depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

Try it

```
border-inline-end-width: thick;
writing-mode: horizontal-tb;
```

```
border-inline-end-width: thick;
writing-mode: vertical-rl;
```

```
border-inline-end-width: 4px;
writing-mode: horizontal-tb;
direction: rtl;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: palegreen;
  color: black;
  border: 0 solid crimson;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
/* <'line-width'> values */
border-inline-end-width: 2px;
border-inline-end-width: thick;

/* Global values */
border-inline-end-width: inherit;
border-inline-end-width: initial;
border-inline-end-width: revert;
border-inline-end-width: revert-layer;
border-inline-end-width: unset;
```

Related properties are `border-block-start-width`, `border-block-end-width`, and `border-inline-start-width`, which define the other border widths of the element.

Values

`<line-width>`

Defines the width of the border, either as an explicit non-negative `<length>` or the keywords: `thin`, `medium`, or `thick`. The default is `medium`.

Formal definition

Initial value	`medium`
Applies to	all elements
Inherited	no
Computed value	the absolute `<length>`, snapped as a line width
Animation type	by computed value type

Formal syntax

```
border-inline-end-width =
  <line-width>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Applying a border with vertical text

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  border: 1px solid blue;
  border-inline-end-width: 5px;
}
```

Results

- This property maps to one of the physical border properties: `border-top-width`, `border-right-width`, `border-bottom-width`, and `border-left-width`
- `writing-mode`, `direction`, `text-orientation`

border-inline-start CSS property

The **`border-inline-start`** CSS shorthand property sets the individual logical inline-start border property values in a single place in the style sheet.

Try it

```
border-inline-start: solid;
writing-mode: horizontal-tb;
```

```
border-inline-start: dashed red;
writing-mode: vertical-rl;
```

```
border-inline-start: 1rem solid;
writing-mode: horizontal-tb;
direction: rtl;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: darkmagenta;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `border-inline-start-color`
- `border-inline-start-style`
- `border-inline-start-width`

Syntax

```
border-inline-start: 1px;
border-inline-start: 2px dotted;
border-inline-start: medium dashed green;

/* Global values */
border-inline-start: inherit;
border-inline-start: initial;
border-inline-start: revert;
border-inline-start: revert-layer;
border-inline-start: unset;
```

The physical border to which `border-inline-start` maps depends on the element's writing mode, directionality, and text orientation. It corresponds to the `border-top`, `border-right`, `border-bottom`, or `border-left` property depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

Related properties are `border-block-start`, `border-block-end`, and `border-inline-end`, which define the other borders of the element.

Values

The `border-inline-start` is specified with one or more of the following, in any order:

`<line-width>`

The width of the border. See `border-width`.

`<line-style>`

The line style of the border. See `border-style`.

`<color>`

The color of the border.

Formal definition

Initial value	as each of the properties of the shorthand: • `border-inline-start-width`: `medium` • `border-inline-start-style`: `none` • `border-inline-start-color`: `currentcolor`
Applies to	all elements
Inherited	no
Computed value	as each of the properties of the shorthand: • `border-inline-start-width`: the absolute `<length>`, snapped as a line width • `border-inline-start-style`: as specified • `border-inline-start-color`: computed color
Animation type	as each of the properties of the shorthand: • `border-inline-start-width`: by computed value type • `border-inline-start-style`: discrete • `border-inline-start-color`: by computed value type

Formal syntax

```
border-inline-start =
  <line-width>  ||
  <line-style>  ||
  <color>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick

<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}
```

```
.exampleText {
  writing-mode: vertical-rl;
  border-inline-start: 5px dashed blue;
}
```

border-inline-start-color CSS property

The **`border-inline-start-color`** CSS property defines the color of the logical inline start border of an element, which maps to a physical border color depending on the element's writing mode, directionality, and text orientation. It corresponds to the `border-top-color`, `border-right-color`, `border-bottom-color`, or `border-left-color` property depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

Try it

```
border-inline-start-color: red;
writing-mode: horizontal-tb;
```

```
border-inline-start-color: #32a1ce;
writing-mode: vertical-rl;
```

```
border-inline-start-color: rgb(170 50 220 / 0.6);
writing-mode: horizontal-tb;
direction: rtl;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: black;
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
border-inline-start-color: red;
border-inline-start-color: #ee4141;

/* Global values */
border-inline-start-color: inherit;
border-inline-start-color: initial;
border-inline-start-color: revert;
border-inline-start-color: revert-layer;
border-inline-start-color: unset;
```

Related properties are `border-block-start-color`, `border-block-end-color`, and `border-inline-end-color`, which define the other border colors of the element.

Values

`<color>`

The color of the border.

Formal definition

Initial value	`currentcolor`
Applies to	all elements
Inherited	no
Computed value	computed color
Animation type	by computed value type

Formal syntax

```
border-inline-start-color =
  <color>     |
  <image-1D>

<image-1D> =
  <stripes()>

<stripes()> =
  stripes( <color-stripe># )

<color-stripe> =
  <color>                          &&
  [ <length-percentage> | <flex> ]?

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Images Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  border: 10px solid blue;
  border-inline-start-color: red;
}
```

    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: black;
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
/* Keyword values */
border-inline-start-style: dashed;
border-inline-start-style: dotted;
border-inline-start-style: groove;

/* Global values */
border-inline-start-style: inherit;
border-inline-start-style: initial;
border-inline-start-style: revert;
border-inline-start-style: revert-layer;
border-inline-start-style: unset;
```

Related properties are `border-block-start-style`, `border-block-end-style`, and `border-inline-end-style`, which define the other border styles of the element.

Values

`<line-style>`

The line style of the border. See `border-style`.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
border-inline-start-style =
  <line-style>

<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  border: 5px solid blue;
  border-inline-start-style: dashed;
}
```

See also

- CSS Logical Properties and Values
- This property maps to one of the physical border properties: `border-top-style`, `border-right-style`, `border-bottom-style`, or `border-left-style`.
- `writing-mode`, `direction`, `text-orientation`

border-inline-start-width CSS property

The **`border-inline-start-width`** CSS property defines the width of the logical inline-start border of an element, which maps to a physical border width depending on the element's writing mode, directionality, and text orientation. It corresponds to the `border-top-width`, `border-right-width`, `border-bottom-width`, or `border-left-width` property depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

Try it

```
border-inline-start-width: thick;
writing-mode: horizontal-tb;
```

```
border-inline-start-width: thick;
writing-mode: vertical-rl;
```

```
border-inline-start-width: 4px;
writing-mode: horizontal-tb;
direction: rtl;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: palegreen;
  color: black;
  border: 0 solid crimson;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
/* <'line-width'> values */
border-inline-start-width: 5px;
border-inline-start-width: thick;

/* Global values */
border-inline-start-width: inherit;
border-inline-start-width: initial;
border-inline-start-width: revert;
border-inline-start-width: revert-layer;
border-inline-start-width: unset;
```

Related properties are `border-block-start-width`, `border-block-end-width`, and `border-inline-end-width`, which define the other border widths of the element.

Values

`<line-width>`

Defines the width of the border, either as an explicit non-negative `<length>` or the keywords: `thin`, `medium`, or `thick`. The default is `medium`.

Formal definition

Initial value	`medium`
Applies to	all elements
Inherited	no
Computed value	the absolute `<length>`, snapped as a line width
Animation type	by computed value type

Formal syntax

```
border-inline-start-width =
  <line-width>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  border: 1px solid blue;
  border-inline-start-width: 5px;
}
```

See also

- CSS Logical Properties and Values
- This property maps to one of the physical border properties: `border-top-width`, `border-right-width`, `border-bottom-width`, and `border-left-width`
- `writing-mode`, `direction`, `text-orientation`

border-inline-style CSS property

The **`border-inline-style`** CSS property defines the style of the logical inline borders of an element, which maps to a physical border style depending on the element's writing mode, directionality, and text orientation. It corresponds to the `border-top-style` and `border-bottom-style`, or `border-left-style` and `border-right-style` properties depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

The border style in the other dimension can be set with `border-block-style`, which sets `border-block-start-style`, and `border-block-end-style`.

Try it

```
border-inline-style: dotted;
writing-mode: horizontal-tb;
```

```
border-inline-style: dotted;
writing-mode: vertical-rl;
```

```
border-inline-style: groove;
writing-mode: horizontal-tb;
direction: rtl;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: black;
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
/* Keyword values */
border-inline-style: dashed;
border-inline-style: dotted;
border-inline-style: groove;

/* Global values */
```

```
border-inline-style: inherit;
border-inline-style: initial;
border-inline-style: revert;
border-inline-style: revert-layer;
border-inline-style: unset;
```

Values

`<line-style>`

The line style of the border. See `border-style`.

Formal definition

Initial value	as each of the properties of the shorthand: • `border-inline-start-style`: none • `border-inline-end-style`: none
Applies to	all elements
Inherited	no
Computed value	as each of the properties of the shorthand: • `border-inline-start-style`: as specified • `border-inline-end-style`: as specified
Animation type	discrete

Formal syntax

```
border-inline-style =
  <'border-top-style'>{1,2}

<border-top-style> =
  <line-style>

<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting border-inline-style

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  border: 5px solid blue;
  border-inline-style: dashed;
}
```

See also

border-inline-width CSS property

The **`border-inline-width`** CSS property defines the width of the logical inline borders of an element, which maps to a physical border width depending on the element's writing mode, directionality, and text orientation. It corresponds to the `border-top-width` and `border-bottom-width`, or `border-left-width`, and `border-right-width` property depending on the values defined for `writing-mode`, `direction`, and `text-orientation`.

The border width in the other dimension can be set with `border-block-width`, which sets `border-block-start-width`, and `border-block-end-width`.

Try it

```
border-inline-width: thick;
writing-mode: horizontal-tb;
```

```
border-inline-width: thick;
writing-mode: vertical-rl;
```

```
border-inline-width: 4px;
writing-mode: horizontal-tb;
```

```
direction: rtl;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: palegreen;
  color: black;
  border: 0 solid crimson;
  padding: 0.75em;
  width: 80%;
  height: 100px;
  unicode-bidi: bidi-override;
}
```

Syntax

```
/* <'line-width'> values */
border-inline-width: 5px 10px;
border-inline-width: 5px;
border-inline-width: thick;

/* Global values */
border-inline-width: inherit;
border-inline-width: initial;
border-inline-width: revert;
border-inline-width: revert-layer;
border-inline-width: unset;
```

Values

`<line-width>`

Defines the width of the border, either as an explicit non-negative `<length>` or the keywords: `thin`, `medium`, or `thick`. The default is `medium`.

Formal definition

Initial value	as each of the properties of the shorthand: • `border-inline-start-width`: `medium` • `border-inline-end-width`: `medium`
Applies to	all elements
Inherited	no
Computed value	as each of the properties of the shorthand: • `border-inline-start-width`: the absolute `<length>`, snapped as a line width • `border-inline-end-width`: the absolute `<length>`, snapped as a line width
Animation type	as each of the properties of the shorthand: • `border-inline-start-width`: by computed value type • `border-inline-end-width`: by computed value type

Formal syntax

```
border-inline-width =
  <'border-top-width'>{1,2}

<border-top-width> =
  <line-width>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<div>
  <p class="exampleText">Example text</p>
</div>
```

CSS

```
div {
  background-color: yellow;
  width: 120px;
  height: 120px;
}

.exampleText {
  writing-mode: vertical-lr;
  border: 1px solid blue;
  border-inline-width: 5px 10px;
}
```

See also

- CSS Logical Properties and Values

- `writing-mode`, `direction`, `text-orientation`

border-left CSS property

The **`border-left`** CSS shorthand property sets all the properties of an element's left border.

Try it

```
border-left: solid;
```

```
border-left: dashed red;
```

```
border-left: 1rem solid;
```

```
border-left: thick double #32a1ce;
```

```
border-left: 4mm ridge rgb(211 220 50 / 0.6);
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: darkmagenta;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `border-left-color`
- `border-left-style`
- `border-left-width`

Syntax

```
border-left: 1px;
border-left: 2px dotted;
border-left: medium dashed blue;

/* Global values */
border-left: inherit;
border-left: initial;
border-left: revert;
border-left: revert-layer;
border-left: unset;
```

The three values of the shorthand property can be specified in any order, and one or two of them may be omitted.

Values

`<br-width>`

See `border-left-width`.

`<br-style>`

See `border-left-style`.

`<color>`

See `border-left-color`.

Description

As with all shorthand properties, `border-left` always sets the values of all of the properties that it can set, even if they are not specified. It sets those that are not specified to their default values. Consider the following code:

```
border-left-style: dotted;
border-left: thick green;
```

It is actually the same as this one:

```
border-left-style: dotted;
border-left: none thick green;
```

The value of `border-left-style` given before `border-left` is ignored. Since the default value of `border-left-style` is `none`, not specifying the `border-style` part results in no border.

Formal definition

Initial value	as each of the properties of the shorthand: • `border-left-width`: `medium` • `border-left-style`: `none` • `border-left-color`: `currentcolor`

Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	as each of the properties of the shorthand: • `border-left-width`: the absolute `<length>`, snapped as a line width • `border-left-style`: as specified • `border-left-color`: computed color
Animation type	as each of the properties of the shorthand: • `border-left-width`: a length • `border-left-style`: discrete • `border-left-color`: a color

Formal syntax

```
border-left =
  <line-width>  ||
  <line-style>  ||
  <color>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick

<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Applying a left border

HTML

```
<div>This box has a border on the left side.</div>
```

CSS

```
div {
  border-left: 4px dashed blue;
  background-color: gold;
  height: 100px;
  width: 100px;
  font-weight: bold;
  text-align: center;
}
```

border-left-color CSS property

The **`border-left-color`** CSS property sets the color of an element's left border. It can also be set with the shorthand CSS properties `border-color` or `border-left`.

Try it

```
border-left-color: red;
```

```
border-left-color: #32a1ce;
```

```
border-left-color: rgb(170 50 220 / 0.6);
```

```
border-left-color: hsl(60 90% 50% / 0.8);
```

```
border-left-color: transparent;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: black;
```

```
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}
```

Syntax

```
/* <color> values */
border-left-color: red;
border-left-color: #ffbb00;
border-left-color: rgb(255 0 0);
border-left-color: hsl(100deg 50% 25% / 75%);
border-left-color: currentColor;
border-left-color: transparent;

/* Global values */
border-left-color: inherit;
border-left-color: initial;
border-left-color: revert;
border-left-color: revert-layer;
border-left-color: unset;
```

Values

This property is specified as one value:

`<color>`

The color of the left border.

Formal definition

Initial value	`currentcolor`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	computed color
Animation type	a color

Formal syntax

```
border-left-color =
  <color>     |
  <image-1D>

<image-1D> =
  <stripes()>

<stripes()> =
  stripes( <color-stripe># )

<color-stripe> =
  <color>                          &&
  [ <length-percentage> | <flex> ]?

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Images Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

A div with a border

HTML

```
<div class="my-box">
  <p>
    This is a box with a border around it. Note which side of the box is
    <span class="red-text">red</span>.
  </p>
</div>
```

CSS

```
.my-box {
  border: solid 0.3em gold;
  border-left-color: red;
  width: auto;
}

.red-text {
  color: red;
}
```

Result

See also

- The border-related CSS shorthand properties: `border`, `border-left`, and `border-color`.
- The color-related CSS properties for the other borders: `border-right-color`, `border-bottom-color`, and `border-top-color`.
- The other border-related CSS properties applying to the same border: `border-left-style` and `border-left-width`.
- The default `currentColor` color value.

border-left-style CSS property

The **`border-left-style`** CSS property sets the line style of an element's left `border`.

> **Note:** The specification doesn't define how borders of different styles connect in the corners.

Try it

```
border-left-style: none;
```

```
border-left-style: dotted;
```

```
border-left-style: dashed;
```

```
border-left-style: solid;
```

```
border-left-style: groove;
```

```
border-left-style: inset;
```

```
<section id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: black;
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}

body {
  background-color: white;
}
```

Syntax

```
/* Keyword values */
border-left-style: none;
border-left-style: hidden;
border-left-style: dotted;
border-left-style: dashed;
border-left-style: solid;
border-left-style: double;
border-left-style: groove;
border-left-style: ridge;
border-left-style: inset;
border-left-style: outset;

/* Global values */
border-left-style: inherit;
border-left-style: initial;
border-left-style: revert;
border-left-style: revert-layer;
border-left-style: unset;
```

The `border-left-style` property is specified as a single `<line-style>` keyword value.

Formal definition

Initial value	none
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
border-left-style =
  <line-style>

<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting border-left-style

HTML

```
<table>
  <tbody>
    <tr>
      <td class="b1">none</td>
      <td class="b2">hidden</td>
      <td class="b3">dotted</td>
      <td class="b4">dashed</td>
    </tr>
    <tr>
      <td class="b5">solid</td>
      <td class="b6">double</td>
      <td class="b7">groove</td>
      <td class="b8">ridge</td>
    </tr>
    <tr>
      <td class="b9">inset</td>
      <td class="b10">outset</td>
    </tr>
  </tbody>
</table>
```

CSS

```
/* Define look of the table */
table {
  border-width: 2px;
  background-color: #52e385;
}
tr,
td {
  padding: 3px;
}

/* border-left-style example classes */
.b1 {
  border-left-style: none;
}
.b2 {
  border-left-style: hidden;
}
.b3 {
  border-left-style: dotted;
}
.b4 {
  border-left-style: dashed;
}
.b5 {
  border-left-style: solid;
}
.b6 {
  border-left-style: double;
}
.b7 {
  border-left-style: groove;
}
.b8 {
  border-left-style: ridge;
}
.b9 {
  border-left-style: inset;
}
.b10 {
  border-left-style: outset;
}
```

Result

See also

- The other style-related border properties: `border-bottom-style`, `border-right-style`, `border-top-style`, and `border-style`.
- The other left-border-related properties: `border-left`, `border-left-color`, and `border-left-width`.

border-left-width CSS property

The **`border-left-width`** CSS property sets the width of the left border of an element.

Try it

```
border-left-width: thick;
```

```
border-left-width: 2em;
```

```
border-left-width: 4px;
```

```
border-left-width: 2ex;
```

```
border-left-width: 0;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: palegreen;
  color: black;
  border: 0 solid crimson;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}
```

Syntax

```
/* Keyword values */
border-left-width: thin;
border-left-width: medium;
border-left-width: thick;

/* <length> values */
border-left-width: 10em;
border-left-width: 3vmax;
border-left-width: 6px;

/* Global keywords */
border-left-width: inherit;
border-left-width: initial;
border-left-width: revert;
border-left-width: revert-layer;
border-left-width: unset;
```

Values

`<line-width>`

Defines the width of the border, either as an explicit non-negative `<length>` or the keywords: `thin`, `medium`, or `thick`. The default is `medium`.

Formal definition

Initial value	`medium`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	the absolute `<length>`, snapped as a line width
Animation type	a length

Formal syntax

```
border-left-width =
  <line-width>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Comparing border widths

HTML

```
<div>Element 1</div>
<div>Element 2</div>
```

CSS

```
div {
  border: 1px solid red;
  margin: 1em 0;
}

div:nth-child(1) {
  border-left-width: thick;
}
div:nth-child(2) {
  border-left-width: 2em;
}
```

Result

See also

- The other border-width-related CSS properties: `border-top-width`, `border-right-width`, `border-bottom-width`, and `border-width`.
- The other border-left-related CSS properties: `border`, `border-left`, `border-left-style`, and `border-left-color`.

border-radius CSS property

The **`border-radius`** CSS shorthand property rounds the corners of an element's outer border edge. You can set a single radius to make circular corners, or two radii to make elliptical corners.

Try it

```
border-radius: 30px;
```

```
border-radius: 25% 10%;
```

```
border-radius: 10% 30% 50% 70%;
```

```
border-radius: 10% / 50%;
```

```
border-radius: 10px 100px / 120px;
```

```
border-radius: 50% 20% / 10% 40%;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with rounded corners.
  </div>
</section>
```

```
#example-element {
  width: 80%;
  height: 80%;
  display: flex;
  justify-content: center;
  flex-direction: column;
  background-color: #5b6dcd;
  color: white;
  padding: 10px;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `border-top-left-radius`
- `border-top-right-radius`
- `border-bottom-right-radius`
- `border-bottom-left-radius`

Syntax

```
/* The syntax of the first radius allows one to four values */
/* Radius is set for all 4 sides */
border-radius: 10px;

/* top-left-and-bottom-right | top-right-and-bottom-left */
border-radius: 10px 5%;

/* top-left | top-right-and-bottom-left | bottom-right */
border-radius: 2px 4px 2px;

/* top-left | top-right | bottom-right | bottom-left */
border-radius: 1px 0 3px 4px;

/* The syntax of the second radius allows one to four values */
/* (first radius values) / radius */
border-radius: 10px / 20px;

/* (first radius values) / top-left-and-bottom-right | top-right-and-bottom-left */
border-radius: 10px 5% / 20px 30px;

/* (first radius values) / top-left | top-right-and-bottom-left | bottom-right */
border-radius: 10px 5px 2em / 20px 25px 30%;

/* (first radius values) / top-left | top-right | bottom-right | bottom-left */
border-radius: 10px 5% / 20px 25em 30px 35em;

/* Global values */
border-radius: inherit;
border-radius: initial;
border-radius: revert;
border-radius: revert-layer;
border-radius: unset;
```

The `border-radius` property is specified as:

- one, two, three, or four `<length>` or `<percentage>` values. This is used to set a single radius for the corners.
- followed optionally by "/" and one, two, three, or four `<length>` or `<percentage>` values. This is used to set an additional radius, so you can have elliptical corners.

Values

radius		Is a `<length>` or a `<percentage>` denoting a radius to use for the border in each corner of the border. It is used only in the one-value syntax.
top-left-and-bottom-right		Is a `<length>` or a `<percentage>` denoting a radius to use for the border in the top-left and bottom-right corners of the element's box. It is used only in the two-value syntax.
top-right-and-bottom-left		Is a `<length>` or a `<percentage>` denoting a radius to use for the border in the top-right and bottom-left corners of the element's box. It is used only in the two- and three-value syntaxes.
top-left		Is a `<length>` or a `<percentage>` denoting a radius to use for the border in the top-left corner of the element's box. It is used only in the three- and four-value syntaxes.

top-right		Is a `<length>` or a `<percentage>` denoting a radius to use for the border in the top-right corner of the element's box. It is used only in the four-value syntax.
bottom-right		Is a `<length>` or a `<percentage>` denoting a radius to use for the border in the bottom-right corner of the element's box. It is used only in the three- and four-value syntaxes.
bottom-left		Is a `<length>` or a `<percentage>` denoting a radius to use for the border in the bottom-left corner of the element's box. It is used only in the four-value syntax.

`<length>`

Denotes the size of the circle radius, or the semi-major and semi-minor axes of the ellipse, using length values. Negative values are invalid.

`<percentage>`

Denotes the size of the circle radius, or the semi-major and semi-minor axes of the ellipse, using percentage values. Percentages for the horizontal axis refer to the width of the box; percentages for the vertical axis refer to the height of the box. Negative values are invalid.

For example:

```
border-radius: 1em / 5em;

/* It is equivalent to: */
border-top-left-radius: 1em 5em;
border-top-right-radius: 1em 5em;
border-bottom-right-radius: 1em 5em;
border-bottom-left-radius: 1em 5em;
```

```
border-radius: 4px 3px 6px / 2px 4px;

/* It is equivalent to: */
border-top-left-radius: 4px 2px;
border-top-right-radius: 3px 4px;
border-bottom-right-radius: 6px 2px;
border-bottom-left-radius: 3px 4px;
```

Description

The radius applies to the whole `background`, even if the element has no border; the exact position of the clipping is defined by the `background-clip` property.

The `border-radius` property does not apply to table elements when `border-collapse` is `collapse`.

> **Note:** As with any shorthand property, individual sub-properties cannot inherit, such as in `border-radius:0 0 inherit inherit`, which would partially override existing definitions. Instead, the individual longhand properties have to be used.

Formal definition

Initial value	as each of the properties of the shorthand: • `border-top-left-radius`: `0` • `border-top-right-radius`: `0` • `border-bottom-right-radius`: `0` • `border-bottom-left-radius`: `0`
Applies to	all elements; but User Agents are not required to apply to `table` and `inline-table` elements when `border-collapse` is `collapse`. The behavior on internal table elements is undefined for the moment.. It also applies to `::first-letter`.
Inherited	no
Percentages	refer to the corresponding dimension of the border box
Computed value	as each of the properties of the shorthand: • `border-top-left-radius`: two absolute `<length>`s or `<percentage>`s • `border-top-right-radius`: two absolute `<length>`s or `<percentage>`s • `border-bottom-right-radius`: two absolute `<length>`s or `<percentage>`s • `border-bottom-left-radius`: two absolute `<length>`s or `<percentage>`s
Animation type	as each of the properties of the shorthand: • `border-top-left-radius`: a length, percentage or calc(); • `border-top-right-radius`: a length, percentage or calc(); • `border-bottom-right-radius`: a length, percentage or calc(); • `border-bottom-left-radius`: a length, percentage or calc();

Formal syntax

```
border-radius =
  <length-percentage [0,∞]>{1,4} [ / <length-percentage [0,∞]>{1,4} ]?

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Comparing border styles

The following example has seven `<pre>` elements, each of which demonstrates combinations of `border` and `border-radius` styles. The styles applied to each `<pre>` element are included as the element's contents, so you can see the CSS declarations necessary to create the associated border style:

```
<pre id="example-1">
  border: solid 10px;
  border-radius: 10px 40px 40px 10px;
</pre>

<pre id="example-2">
  border: groove 1em red;
  border-radius: 2em;
</pre>

<pre id="example-3">
  background: gold;
  border: ridge gold;
  border-radius: 13em / 3em;
</pre>

<pre id="example-4">
  border: none;
  border-radius: 40px 10px;
  background: gold;
</pre>

<pre id="example-5">
  border: none;
  border-radius: 50%;
  background: burlywood;
</pre>

<pre id="example-6">
  border: dotted;
  border-width: 10px 4px;
  border-radius: 10px 40px;
</pre>

<pre id="example-7">
  border: dashed;
  border-width: 2px 4px;
  border-radius: 40px;
</pre>
```

```
pre {
  margin: 20px;
  padding: 20px;
  width: 80%;
  height: 50px;
}

pre#example-1 {
  border: solid 10px;
  border-radius: 10px 40px 40px 10px;
}

pre#example-2 {
  border: groove 1em red;
  border-radius: 2em;
}

pre#example-3 {
  background: gold;
  border: ridge gold;
  border-radius: 13em / 3em;
}

pre#example-4 {
  border: none;
  border-radius: 40px 10px;
  background: gold;
}

pre#example-5 {
  border: none;
  border-radius: 50%;
  background: burlywood;
}

pre#example-6 {
  border: dotted;
  border-width: 10px 4px;
  border-radius: 10px 40px;
}

pre#example-7 {
  border: dashed;
  border-width: 2px 4px;
  border-radius: 40px;
}
```

Using <code>corner-shape</code> with <code>border-radius</code>

When a non-`0` `border-radius` value is applied to a box corner, you can use the `corner-shape` property (or one of its longhands and shorthands) to apply custom shapes to that corner, such as a bevel, notch, or squircle. This example demonstrates `corner-shape` usage.

HTML

The markup for this example contains a single `<div>` element.

```
<div></div>
```

CSS

We give the box some basic styles, which we've hidden for brevity. We also apply a `box-shadow`, a `border-radius` of `0 20% 50px 30%`, and a `corner-shape` of `superellipse(0.5) bevel notch squircle`.

```
body {
  font-family: "Helvetica", "Arial", sans-serif;
  width: 240px;
  margin: 20px auto;
}

div {
  width: 100%;
  height: 180px;
  display: flex;
  justify-content: center;
  align-items: center;
  background-color: green;
  background-image: linear-gradient(
    to bottom,
    rgb(255 255 255 / 0),
    rgb(255 255 255 / 0.5)
  );
}
```

```
div {
  box-shadow: 1px 1px 3px gray;
  border-radius: 0 20% 50px 30%;
  corner-shape: superellipse(0.5) bevel notch squircle;
}
```

Result

The rendered result looks like this:

Note how no corner shape is applied to the top-left corner, because it has a `border-radius` of `0` set.

See also

- Border-radius-related CSS properties: `border-top-left-radius`, `border-top-right-radius`, `border-bottom-right-radius`, `border-bottom-left-radius`, `border-start-start-radius`, `border-start-end-radius`, `border-end-start-radius`, `border-end-end-radius`

border-right CSS property

The **`border-right`** CSS shorthand property sets all the properties of an element's right border.

Try it

```
border-right: solid;
```

```
border-right: dashed red;
```

```
border-right: 1rem solid;
```

```
border-right: thick double #32a1ce;
```

```
border-right: 4mm ridge rgb(211 220 50 / 0.6);
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: darkmagenta;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `border-right-color`
- `border-right-style`
- `border-right-width`

Syntax

```
border-right: 1px;
border-right: 2px dotted;
border-right: medium dashed green;

/* Global values */
border-right: inherit;
border-right: initial;
border-right: revert;
border-right: revert-layer;
border-right: unset;
```

The three values of the shorthand property can be specified in any order, and one or two of them may be omitted.

Values

`<br-width>`

See `border-right-width`.

`<br-style>`

See `border-right-style`.

`<color>`

See `border-right-color`.

Description

As with all shorthand properties, `border-right` always sets the values of all of the properties that it can set, even if they are not specified. It sets those that are not specified to their default values. Consider the following code:

```
border-right-style: dotted;
border-right: thick green;
```

It is actually the same as this one:

```
border-right-style: dotted;
border-right: none thick green;
```

The value of `border-right-style` given before `border-right` is ignored. Since the default value of `border-right-style` is `none`, not specifying the `border-style` part results in no border.

Formal definition

Initial value	as each of the properties of the shorthand: • `border-right-width`: `medium` • `border-right-style`: `none` • `border-right-color`: `currentcolor`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	as each of the properties of the shorthand: • `border-right-width`: the absolute `<length>`, snapped as a line width • `border-right-style`: as specified • `border-right-color`: computed color
Animation type	as each of the properties of the shorthand: • `border-right-width`: a length • `border-right-style`: discrete • `border-right-color`: a color

Formal syntax

```
border-right =
  <line-width> ||
  <line-style> ||
  <color>

<line-width> =
  <length [0,∞]> |
  hairline       |
  thin           |
  medium         |
  thick

<line-style> =
  none   |
  hidden |
  dotted |
  dashed |
  solid  |
  double |
  groove |
  ridge  |
  inset  |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Applying a right border

HTML

```
<div>This box has a border on the right side.</div>
```

CSS

```
div {
  border-right: 4px dashed blue;
  background-color: gold;
  height: 100px;
  width: 100px;
  font-weight: bold;
```

```
  text-align: center;
}
```

- `outline`

border-right-color CSS property

The **`border-right-color`** CSS property sets the color of an element's right border. It can also be set with the shorthand CSS properties `border-color` or `border-right`.

Try it

```
border-right-color: red;
```

```
border-right-color: #32a1ce;
```

```
border-right-color: rgb(170 50 220 / 0.6);
```

```
border-right-color: hsl(60 90% 50% / 0.8);
```

```
border-right-color: transparent;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: black;
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}
```

Syntax

```
/* <color> values */
border-right-color: red;
border-right-color: #ffbb00;
border-right-color: rgb(255 0 0);
border-right-color: hsl(100deg 50% 25% / 75%);
border-right-color: currentColor;
border-right-color: transparent;

/* Global values */
border-right-color: inherit;
border-right-color: initial;
border-right-color: revert;
border-right-color: revert-layer;
border-right-color: unset;
```

Values

This property is specified as one value:

`<color>`

The color of the right border.

Formal definition

Initial value	`currentcolor`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	computed color
Animation type	a color

Formal syntax

```
border-right-color =
  <color>     |
  <image-1D>

<image-1D> =
  <stripes()>

<stripes()> =
  stripes( <color-stripe># )

<color-stripe> =
  <color>                          &&
  [ <length-percentage> | <flex> ]?

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Images Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

A div with a border

HTML

```
<div class="my-box">
  <p>
    This is a box with a border around it. Note which side of the box is
    <span class="red-text">red</span>.
  </p>
</div>
```

CSS

```
.my-box {
  border: solid 0.3em gold;
  border-right-color: red;
  width: auto;
}

.red-text {
  color: red;
}
```

Result

See also

- The default `currentColor` color value.

border-right-style CSS property

The **`border-right-style`** CSS property sets the line style of an element's right `border`.

> **Note:** The specification doesn't define how borders of different styles connect in the corners.

Try it

```
border-right-style: none;
```

```
border-right-style: dotted;
```

```
border-right-style: dashed;
```

```
border-right-style: solid;
```

```
border-right-style: groove;
```

```
border-right-style: inset;
```

```
<section id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: black;
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}

body {
  background-color: white;
}
```

Syntax

```
/* Keyword values */
border-right-style: none;
border-right-style: hidden;
border-right-style: dotted;
border-right-style: dashed;
border-right-style: solid;
border-right-style: double;
border-right-style: groove;
border-right-style: ridge;
border-right-style: inset;
border-right-style: outset;

/* Global values */
border-right-style: inherit;
border-right-style: initial;
border-right-style: revert;
```

```
border-right-style: revert-layer;
border-right-style: unset;
```

The `border-right-style` property is specified as a single `<line-style>` keyword value.

Formal definition

Initial value	none
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
border-right-style =
  <line-style>

<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Border styles

HTML

```
<table>
  <tbody>
    <tr>
      <td class="b1">none</td>
      <td class="b2">hidden</td>
      <td class="b3">dotted</td>
      <td class="b4">dashed</td>
    </tr>
    <tr>
      <td class="b5">solid</td>
      <td class="b6">double</td>
      <td class="b7">groove</td>
      <td class="b8">ridge</td>
    </tr>
    <tr>
      <td class="b9">inset</td>
      <td class="b10">outset</td>
    </tr>
  </tbody>
</table>
```

CSS

```
/* Define look of the table */
table {
  border-width: 2px;
  background-color: #52e385;
}
tr,
td {
  padding: 3px;
}

/* border-right-style example classes */
.b1 {
  border-right-style: none;
}
.b2 {
  border-right-style: hidden;
}
.b3 {
  border-right-style: dotted;
}
.b4 {
  border-right-style: dashed;
}
.b5 {
  border-right-style: solid;
}
.b6 {
  border-right-style: double;
}
.b7 {
  border-right-style: groove;
}
.b8 {
  border-right-style: ridge;
}
.b9 {
  border-right-style: inset;
}
.b10 {
```

```
  border-right-style: outset;
}
```

Result

- The other style-related border properties: `border-bottom-style`, `border-left-style`, `border-top-style`, and `border-style`.
- The other right-border-related properties: `border-right`, `border-right-color`, and `border-right-width`.

border-right-width CSS property

The **`border-right-width`** CSS property sets the width of the right border of an element.

Try it

```
border-right-width: thick;
```

```
border-right-width: 2em;
```

```
border-right-width: 4px;
```

```
border-right-width: 2ex;
```

```
border-right-width: 0;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: palegreen;
  color: black;
  border: 0 solid crimson;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}
```

Syntax

```
/* Keyword values */
border-right-width: thin;
border-right-width: medium;
border-right-width: thick;

/* <length> values */
border-right-width: 10em;
border-right-width: 3vmax;
border-right-width: 6px;

/* Global keywords */
border-right-width: inherit;
border-right-width: initial;
border-right-width: revert;
border-right-width: revert-layer;
border-right-width: unset;
```

Values

`<line-width>`

Defines the width of the border, either as an explicit non-negative `<length>` or the keywords: `thin`, `medium`, or `thick`. The default is `medium`.

Formal definition

Initial value	`medium`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	the absolute `<length>`, snapped as a line width
Animation type	a length

Formal syntax

```
border-right-width =
  <line-width>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Comparing border widths

HTML

```
<div>Element 1</div>
```

```
<div>Element 2</div>
```

CSS

```
div {
  border: 1px solid red;
  margin: 1em 0;
}

div:nth-child(1) {
  border-right-width: thick;
}
div:nth-child(2) {
  border-right-width: 2em;
}
```

Result

border-shape CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`border-shape`** CSS property defines an element's border shape using `<basic-shape>` values.

Syntax

```
/* Keyword value */
border-shape: none;

/* Single <basic-shape> value */
border-shape: circle(50%);
border-shape: rect(10px 460px 130px 20px round 20px);
border-shape: shape(
  from 5% 0.5rem,
  arc to 80px 1pt of 10% ccw large rotate 25deg
);

/* Two <basic-shape> values */
border-shape: circle(50%) ellipse(40% 30%);
border-shape: polygon(0% 0%, 0% 100%, 100% 0%)
  polygon(10% 10%, 10% 70%, 70% 10%);

/* <basic-shape> and <geometry-box> values */
border-shape: circle(50%) border-box ellipse(40% 30%) view-box;
border-shape: rect(5px 198px 189px 0px round 20px) view-box circle(50%);
border-shape: path(
    "M 35,95 C 35,50 60,15 100,20 C 120,5 160,5 180,22 C 200,5 250,5 270,22 C 295,5 340,5 360,22 C 395,10 440,35 440,75 C 455,90 450,120 430,128 C 400,145 360,145 330,130 C 300,145 260,145
230,130 C 200,145 160,145 130,130 C 80,142 35,120 35,95 Z"
  )
  view-box;

/* Global values */
border-shape: inherit;
border-shape: initial;
border-shape: revert;
border-shape: revert-layer;
border-shape: unset;
```

The `border-shape` property may be specified using the keyword `none`, or one or two space-separated shape definitions, each consisting of a `<basic-shape>` value or a `<basic-shape>` value and a `<geometry-box>` value.

Values

`none`

Specifies that no border shape is defined. This is the initial value.

`<basic-shape>`

Defines the shape of the border using one of the `<basic-shape>` functions.

`<geometry-box>` Optional

Defines the reference box relative to which the border shape is drawn. If not included, the shape's reference geometry box defaults to:

- `half-border-box` if a single basic shape is specified, which means that any defined border is drawn on top of the shape path, with the path going down its center.
- `border-box` for the first (outer) shape and `padding-box` for the second (inner) shape if two basic shapes are specified. The border then occupies the area between the two shapes.

Description

The `border-shape` property can be applied to elements to create precisely-shaped containers such as speech bubbles, as shown here, or abstract tooltip designs, without having to use workarounds.

```
<img src="https://mdn.github.io/shared-assets/images/examples/leopard.jpg" />
<p>I am a leopard</p>
```

```
html {
  height: 100%;
}

body {
  margin: 0;
  height: inherit;
  display: flex;
```

```
  justify-content: center;
  align-items: center;
}

img {
  display: block;
  width: 300px;
  anchor-name: --leopard;
  position: relative;
  top: 45px;
}

p {
  font-family: "Helvetica", "Arial";
  font-size: 1.3rem;
  padding: 15px 0;
  margin: 0 0 -30px -110px;
  background-color: chartreuse;
  border: 7px solid rgb(50 50 50);
  box-shadow: 5px 5px 10px rgb(0 0 0 / 0.75);

  width: 250px;
  height: 100px;
  border-shape: shape(
      from 50.08% 0%,
      curve to 97.71% 25.55% with 72.95% 0%/93.9% 8.76%,
      curve to 97.71% 62.04% with 100.76% 37.96%/100.76% 49.64%,
      curve to 50.08% 83.94% with 93.9% 75.18%/72.95% 83.94%,
      curve to 23.41% 82.48% with 36.75% 83.94%/27.22% 83.21%,
      curve to 17.7% 100% with 21.51% 87.59%/19.22% 94.16%,
      curve to 11.98% 82.48% with 16.17% 94.16%/13.89% 87.59%,
      curve to 1.31% 62.04% with 13.5% 81.75%/3.98% 76.64%,
      curve to 2.45% 25.55% with -0.59% 49.64%/-0.59% 37.96%,
      curve to 50.08% 0% with 6.26% 8.76%/27.22% 0%,
      close
    )
    content-box;

  text-align: center;
  line-height: 4;

  position: absolute;
  position-anchor: --leopard;
  bottom: anchor(top);
  left: anchor(right);
}
```

Note how the applied `border-shape` plays well with the `border` and `box-shadow` defined on the element — they follow the shape of the border.

Supported shape functions

You can define an element's `border-shape` (including that of an inline or pseudo-element) using one of the `<basic-shape>` functions. These functions include:

- `inset()`, `rect()`, and `xywh()`: Provide different ways to define basic rectangle shapes.
- `circle()`: Defines circle shapes.
- `ellipse()`: Defines ellipse shapes.
- `path()`: Defines any kind of shape using SVG path string syntax. SVG path syntax has limitations — it can use only pixel values and the path has to be defined as a single string, so custom properties can't be included via `var()`. You are advised to use `shape()` instead.
- `polygon()`: Defines any kind of polygon via pairs of vertex coordinates. If your desired shape includes smooth curves, you are advised to use `shape()`.
- `shape()`: Defines any kind of shape. The syntax of `shape()` is more CSS-compatible than that of `path()` and solves its shortcomings.

You can also include an optional `<geometry-box>` keyword after each `<basic-shape>` value to specify the reference box relative to which the shapes should be drawn.

Stroke and fill modes

The `border-shape` property has the following two modes:

- If a single `<basic-shape>` is provided in the value, that shape defines the shape of the element's border, with the defined border styles drawn as a stroke around the shape, as shown in the previous example. This is known as **stroke mode**.
- If two `<basic-shape>`s are provided in the value, the first shape defines the outer boundary of the border, the second shape defines the inner boundary of the border, and any defined border color fills the area between the two boundaries. This is known as **fill mode**.

> **Note:** Avoid defining a shape for the inner boundary that's larger than the outer boundary. If you do this, the border area does not render properly; you might end up with no border fill rendered or one shape rendered behind the other.

Effect on layout and rendering

The `border-shape` property creates a purely visual effect — the element's layout is still computed using the underlying rectangular box definition, and the content flow is not affected.

The element's content and background are clipped by the `border-shape` property (the inner shape in fill mode). When the specified `border-shape` is the same size or smaller than the content/background, you won't need to adjust the reference box, unless you want to create some kind of offset effect. However, when the specified `border-shape` is larger than the content/background, you will see gaps between the edge of the background and the shape(s). In such cases, you may need to use a different reference box to fix the display (see Handling border-shapes larger than the element's background for more information).

Limitations on border styles applied to border shapes

Not all border styles are applied to elements with a `border-shape` property set. The following list explains how each property is affected:

- `border-color`: This property is applied. However, when multiple element borders have different colors applied, the browser chooses the first edge with a border color, in the following order:
  - Block start edge
  - Inline start edge
  - Block end edge
  - Inline end edge

  The browser then applies that edge's border color to the entire rendered `border-shape`.
- `border-image`: Not applied.

- `border-style`: Not applied. All borders are rendered with a `solid` style.
- `border-width`: In stroke mode, `border-width` is applied directly to the rendered `border-shape`. When multiple edges have different border widths, the browser selects a width to apply to the entire border using the same process as described for `border-color`.

  In fill mode, the border area is defined by the difference between the areas of the outer and inner shapes; therefore, `border-width` doesn't have any direct effect on the width of the rendered border. However, it does have an indirect effect — it still affects the size of the reference boxes the shapes are drawn relative to (unless you set their `<geometry-box>` to `content-box` or `padding-box`). You therefore still need to be mindful of the `border-width` set on the underlying element while using fill mode.

As an example, if an element has the following declarations applied:

```
border-shape: rect(5px 198px 189px 0px round 20px);
border-bottom: 30px dashed blue;
border-left: 40px dotted hotpink;
border-right: 50px double yellow;
```

The rendered box will have a rectangular border with rounded corners. The border style will be `solid` because other styles are ignored. The border width and color will be `40px` and `hotpink`, respectively – this is because the `border-left` property applies styles to the inline start edge (assuming that the page has a horizontal `writing-mode`), which is the first edge with border styles; this gets chosen by the browser per the priority list described earlier.

Interaction with <code>border-radius</code> and <code>corner-shape</code>

The `border-radius` and `corner-shape` properties are incompatible with `border-shape`. When a `border-shape` is set on an element, any set `border-radius` is ignored, therefore `corner-shape` will also have no effect. The `border-shape` and `border-radius`/`corner-shape` properties have different effects, and are used separately.

If you want to use shaped corners in a `border-shape`, you will have to draw them directly as part of the shape.

<code>border-shape</code> versus <code>clip-path</code>

The `clip-path` property takes values similar to `border-shape` and produces similar effects. Both properties can be used to change the shape of an element and therefore the element's hit area, altering the boundary inside which `:hover` effects and pointer-related events activate.

However, there is a fundamental difference in how the two properties work:

- `clip-path` hides the area of the element that sits outside the region defined by the provided shape.
- `border-shape` changes the visual rendering of the element so that it sits inside the region defined by the provided shape.

This means `border-shape` clips the element's content while still letting the `overflow` property control its display, whereas `clip-path` hides the element's content altogether, so overflow control is not possible.

More significantly, properties such as `box-shadow` and `outline` do not follow the shape created by `clip-path` — it chops off the outside of the element, meaning that such effects are truncated in an ugly fashion or removed altogether. The `border-shape` property, on the other hand, creates a differently-shaped border that is neatly followed by such effects.

Handling border-shapes larger than the element's background

As mentioned earlier, one issue with `border-shape` is that when you define a shape that is larger than the element's content/background, you can end up with a gap between the background and the border.

The recommended approach to fixing this is to set the reference `<geometry-box>` to `content-box`. and then use `padding` to fill in the gaps between the content and the border. For example:

```
border-shape: shape(
    from 0% 0%,
    hline to 33%,
    arc by 33% 0% of 16% 20% small cw,
    hline to 100%,
    line to 100% 33%,
    arc by 0% 33% of 20% 16% small cw,
    line to 100% 100%,
    hline to 66%,
    arc by -33% 0% of 16% 20% small ccw,
    hline to 0%,
    line to 0% 66%,
    arc by 0% -33% of 20% 16% small ccw,
    close
  )
  content-box;
padding: 24px;
```

This way, the `padding` will be set outside the shape, causing it to get smaller, and forcing the background to fill up the parts of the shape extending outside the content area. You can see this technique in action in our irregular jigsaw piece navigation menu example.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	by computed value type

Formal syntax

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Box Model Module Level 4, CSS Fill and Stroke Module Level 3, CSS Images Module Level 3, CSS Masking Module Level 1, CSS Shapes Module Level 1, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic <code>border-shape</code> stroke usage

This example shows how to use `border-shape` in stroke mode.

HTML

The markup for this example contains a single `<p>` element.

```
<p>Circle</p>
```

CSS

```
html {
  height: 100%;
}

body {
  margin: 0;
  height: inherit;
  display: flex;
  justify-content: center;
  align-items: center;
}

p {
  box-sizing: border-box;
  font-family: "Helvetica", "Arial";
  font-size: 1.6rem;
  padding: 40px 50px;
  background-color: chartreuse;
  display: flex;
  align-items: center;
}
```

We give the box a `width` of `fit-content` and an `aspect-ratio` of `1/1` to neatly fit the content inside a square. We also set a thick black `border` and a `box-shadow` before setting a `border-shape` of `circle(50%)` to create a circular border that neatly fits the content and background.

```
p {
  width: fit-content;
  aspect-ratio: 1/1;
  border: 15px solid black;
  box-shadow: 5px 5px 10px rgb(0 0 0 / 0.5);
  border-shape: circle(50%);
}
```

Result

Note how the `border` and `box-shadow` neatly follow the defined shape.

Basic <code>border-shape</code> fill usage

This example builds on the previous one, showing how to use `border-shape` in fill mode to create an irregular filled border.

The HTML is the same as in the previous example.

CSS

The CSS is the same as in the previous example, except this time we color the border `hotpink`, and we include two `<basic-shape>` definitions inside the `border-shape` value. There's an outer rectangle that covers the whole area of the content and an inner circle that's the same as in the previous example.

```
p {
  width: fit-content;
  aspect-ratio: 1/1;
  border: 15px solid hotpink;
  box-shadow: 5px 5px 10px rgb(0 0 0 / 0.5);
  border-shape: rect(0% 100% 100% 0% round 20px) circle(50%);
}
```

Result

Note how this time, the border covers the area between the rectangle and the circle, and it adopts the color set in the `border` declaration.

Comparing <code>border-shape</code> values

In this example, we let you select from different `border-shape` values to apply to an element, so you can compare and contrast how they render.

HTML

The HTML is similar to that in the previous example, except this time we include a bit more text in the `<p>` element. We've also included a `<select>` element so you can choose different classes to apply to the `<p>` via JavaScript (we've hidden both the `<select>` and the JavaScript for brevity).

```
<p>Blessed are the cheesemakers.</p>
```

```
<form>
  <label for="shape-select">Select border-shape type:</label>
  <br />
  <select id="shape-select">
    <option>circle</option>
    <option selected>ellipse</option>
    <option>inset</option>
    <option>path</option>
    <option>polygon</option>
    <option>rect</option>
    <option>shape</option>
    <option>two-polygons</option>
    <option>xywh</option>
  </select>
</form>
```

The classes set different `border-shape` values on the `<p>` element. To begin with, a `class` of `ellipse` is set on the `<p>` element, so initially it has an `ellipse()` `border-shape`.

```
const box = document.querySelector("p");
const select = document.querySelector("select");

select.addEventListener("change", selectClass);

function selectClass() {
  box.className = select.value;
}

selectClass();
```

CSS

In the CSS, we give the box a `width` of `550px`, a thick black `border`, and a `box-shadow`.

```
p {
  width: 550px;
  border: 15px solid black;
  box-shadow: 5px 5px 10px rgb(0 0 0 / 0.5);
}
```

Next, we define the rules for each of the classes that will be applied when you select the different options in the `<select>` element:

```
.circle {
  border-shape: circle(60%);
}

.ellipse {
  border-shape: ellipse(50% 40%);
}

.inset {
  border-shape: inset(10px 20px 10px 20px round 20px);
}

.path {
  border-shape: path(
      "M 35,95 C 35,50 60,15 100,20 C 120,5 160,5 180,22 C 200,5 250,5 270,22 C 295,5 340,5 360,22 C 460,10 477,35 496,75 C 515,157 450,120 430,128 C 400,145 360,145 330,130 C 300,145 260,145
230,130 C 200,145 160,145 130,130 C 80,142 35,120 35,95 Z"
    )
    view-box;
}

.polygon {
  border-shape: polygon(0% 60%, 0% 85%, 8% 100%, 18% 88%, 30% 100%, 42% 88%, 55% 100%, 68% 88%, 80% 100%, 86% 88%, 90% 75%, 100% 60%, 90% 30%, 85% 5%, 75% 18%, 65% 3%, 52% 16%, 40% 3%, 27% 16%,
15% 3%, 5% 18%) view-box;
}

.rect {
  border-shape: rect(10px 500px 130px 20px round 20px);
}

.shape {
  border-shape: shape(
    from 0% 64.5%,
    curve to 15.71% 8.26% with 0% 30.76%/6.04% 4.51%,
    curve to 35.05% 9.76% with 20.55% -2.99%/30.21% -2.99%,
    curve to 56.8% 9.76% with 39.88% -2.99%/51.97% -2.99%,
```

```
    curve to 78.56% 9.76% with 62.84% -2.99%/73.72% -2.99%,
    curve to 97.89% 49.5% with 87.02% 0.76%/97.89% 19.51%,
    curve to 95.47% 89.25% with 101.52% 60.75%/100.31% 83.25%,
    curve to 71.3% 90.75% with 88.22% 102%/78.56% 102%,
    curve to 47.13% 90.75% with 64.05% 102%/54.38% 102%,
    curve to 22.96% 90.75% with 39.88% 102%/30.21% 102%,
    curve to 0% 64.5% with 10.88% 99.75%/0% 83.25%,
    close
  );
}

.two-polygons {
  border-shape: polygon(0% 60%, 0% 85%, 8% 100%, 18% 88%, 30% 100%, 42% 88%, 55% 100%, 68% 88%, 80% 105%, 86% 88%, 91% 75%, 101% 60%, 93% 30%, 86% 5%, 75% 18%, 65% 3%, 52% 16%, 40% 3%, 27% 16%,
15% 3%, 5% 18%)
    polygon(0% 55%, 0% 90%, 6% 104%, 17% 93%, 30% 100%, 43% 93%, 56% 102%, 69% 93%, 81% 102%, 88% 93%, 94% 78%, 100% 58%, 94% 24%, 88% -2%, 76% 13%, 64% -4%, 51% 11%, 39% -4%, 26% 11%, 13% -4%,
3% 13%);
}

.xywh {
  border-shape: xywh(5% 5% 90% 90% round 20px);
}
```

```
form {
  position: absolute;
  border: 2px solid black;
  background: white;
  padding: 5px;
  bottom: 0;
  right: 0;
}

form select {
  width: 100%;
  padding: 2px 5px;
  margin-top: 10px;
}
```

Result

Select different options from the drop-down menu to see how the different border shapes render. At any point, feel free to use your browser's developer tools to inspect the `border-shape` values applied to the `<p>` element and edit them to get an idea of how the values work.

Animating a <code>border-shape</code>

This example demonstrates how you can animate the `border-shape` property.

HTML

The same `<p>` element is used as in the previous example, except this time we've included a `tabindex` attribute so it can be focused via the keyboard.

```
<p tabindex="0">Blessed are the cheesemakers.</p>
```

CSS

For this example, we apply a `polygon()` `border-shape` to the `<p>`.

```
p {
  width: 550px;
  border: 15px solid black;
  box-shadow: 5px 5px 10px rgb(0 0 0 / 0.5);
  border-shape: polygon(0% 60%, 0% 85%, 8% 100%, 18% 88%, 30% 100%, 42% 88%, 55% 100%, 68% 88%, 80% 100%, 86% 88%, 90% 75%, 100% 60%, 90% 30%, 85% 5%, 75% 18%, 65% 3%, 52% 16%, 40% 3%, 27% 16%,
15% 3%, 5% 18%) view-box;
}
```

We also set an `animation` on the `<p>` element's `:hover` and `:focus` states, so that when the element is hovered or focused, it smoothly animates back and forth between two polygon border shapes for infinite iterations.

```
p:hover,
p:focus {
  animation: morph 1s ease-in-out infinite alternate;
}

@keyframes morph {
  from {
    border-shape: polygon(0% 60%, 0% 85%, 8% 100%, 18% 88%, 30% 100%, 42% 88%, 55% 100%, 68% 88%, 80% 100%, 86% 88%, 90% 75%, 100% 60%, 90% 30%, 85% 5%, 75% 18%, 65% 3%, 52% 16%, 40% 3%, 27%
16%, 15% 3%, 5% 18%) view-box;
  }
  to {
    border-shape: polygon(0% 55%, 0% 90%, 6% 104%, 17% 93%, 30% 100%, 43% 93%, 56% 102%, 69% 93%, 81% 102%, 88% 93%, 94% 78%, 100% 58%, 94% 24%, 88% -2%, 76% 13%, 64% -4%, 51% 11%, 39% -4%, 26%
11%, 13% -4%, 3% 13%) view-box;
  }
}
```

Result

Hover over or focus the paragraph to see the animation.

```
@supports not (border-shape: circle(50%)) {
  body::before {
    content: "Your browser does not support the 'border-shape' property.";
    font-family: sans-serif;
    background-color: wheat;
    padding: 1rem 0;
    text-align: center;

    z-index: 1;
    position: fixed;
    inset: 40% 0 auto;
```

```
  }
}
```

border-spacing CSS property

The **`border-spacing`** CSS property sets the distance between the borders of adjacent cells in a `<table>`. This property applies only when `border-collapse` is `separate`.

Try it

```
border-spacing: 0;
```

```
border-spacing: 5px;
```

```
border-spacing: 5px 1rem;
```

```
<section class="default-example" id="default-example">
  <table class="transition-all" id="example-element">
    <tbody>
      <tr>
        <td>Cell 1.1</td>
        <td>Cell 1.2</td>
      </tr>
      <tr>
        <td>Cell 2.1</td>
        <td>Cell 2.2</td>
      </tr>
      <tr>
        <td>Cell 3.1</td>
        <td>Cell 3.2</td>
      </tr>
    </tbody>
  </table>
</section>
```

```
table {
  width: 15rem;
  table-layout: fixed;
}

td {
  border: 5px solid;
  border-color: crimson dodgerblue;
  padding: 0.75rem;
}
```

Syntax

```
/* <length> */
border-spacing: 2px;

/* horizontal <length> | vertical <length> */
border-spacing: 1cm 2em;

/* Global values */
border-spacing: inherit;
border-spacing: initial;
border-spacing: revert;
border-spacing: revert-layer;
border-spacing: unset;
```

The `border-spacing` property may be specified as either one or two values.

- When **one** `<length>` value is specified, it defines both the horizontal and vertical spacings between cells.
- When **two** `<length>` values are specified, the first value defines the horizontal spacing between cells (i.e., the space between cells in adjacent *columns*), and the second value defines the vertical spacing between cells (i.e., the space between cells in adjacent *rows*).

Values

`<length>`

The size of the spacing as a fixed value.

Description

The `border-spacing` value is also used along the outside edge of the table, where the distance between the table's border and the cells in the first/last column or row is the sum of the relevant (horizontal or vertical) `border-spacing` and the relevant (top, right, bottom, or left) `padding` on the table.

> **Note:** The `border-spacing` property is equivalent to the deprecated `cellspacing` attribute of the `<table>` element, except that `border-spacing` has an optional second value that can be used to set different horizontal and vertical spacing.

Formal definition

Initial value	`0`
Applies to	`table` and `inline-table` elements

Inherited	yes
Computed value	two absolute lengths
Animation type	by computed value type

Formal syntax

```
border-spacing =
  <length [0,∞]>{1,2}
```

This syntax reflects the latest standard as per CSS Table Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Spacing and padding table cells

This example applies a spacing of `.5em` vertically and `1em` horizontally between a table's cells. Note how, along its outside edges, the table's `padding` values are added to its `border-spacing` values.

HTML

```
<table>
  <tbody>
    <tr>
      <td>1</td>
      <td>2</td>
      <td>3</td>
    </tr>
    <tr>
      <td>4</td>
      <td>5</td>
      <td>6</td>
    </tr>
    <tr>
      <td>7</td>
      <td>8</td>
      <td>9</td>
    </tr>
  </tbody>
</table>
```

CSS

```
table {
  border-spacing: 1em 0.5em;
  padding: 0 2em 1em 0;
  border: 1px solid orange;
}

td {
  width: 1.5em;
  height: 1.5em;
  background: #d2d2d2;
  text-align: center;
  vertical-align: middle;
}
```

border-start-end-radius CSS property

The **`border-start-end-radius`** CSS property defines a logical border radius on an element, which maps to a physical border radius depending on the element's `writing-mode`, `direction`, and `text-orientation`. This is useful when building styles to work regardless of the text orientation and writing mode.

This property affects the corner between the block-start and the inline-end sides of the element. For instance, in a `horizontal-tb` writing mode with `ltr` direction, it corresponds to the `border-top-right-radius` property.

Try it

```
border-start-end-radius: 80px 80px;
```

```
border-start-end-radius: 250px 100px;
direction: rtl;
```

```
border-start-end-radius: 50%;
writing-mode: vertical-lr;
```

```
border-start-end-radius: 50%;
writing-mode: vertical-rl;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a top right rounded corner.
  </div>
</section>
```

```
#example-element {
  width: 80%;
  height: 80%;
  display: flex;
  justify-content: center;
  flex-direction: column;
  background-color: #5b6dcd;
```

```
  color: white;
  padding: 10px;
}
```

Syntax

```
/* <length> values */
/* With one value the corner will be a circle */
border-start-end-radius: 10px;
border-start-end-radius: 1em;

/* With two values the corner will be an ellipse */
border-start-end-radius: 1em 2em;

/* Global values */
border-start-end-radius: inherit;
border-start-end-radius: initial;
border-start-end-radius: revert;
border-start-end-radius: revert-layer;
border-start-end-radius: unset;
```

Values

`<length-percentage>`

Denotes the size of the circle radius or the semi-major and semi-minor axes of the ellipse. As absolute length it can be expressed in any unit allowed by the CSS `<length>` data type. Percentages for the horizontal axis refer to the width of the box, percentages for the vertical axis refer to the height of the box. Negative values are invalid.

Formal definition

Initial value	`0`
Applies to	all elements; but User Agents are not required to apply to `table` and `inline-table` elements when `border-collapse` is `collapse`. The behavior on internal table elements is undefined for the moment.. It also applies to `::first-letter`.
Inherited	no
Percentages	refer to the corresponding dimension of the border box
Computed value	two absolute `<length>`s or `<percentage>`s
Animation type	a length, percentage or calc();

Formal syntax

```
border-start-end-radius =
  <border-radius>

<border-radius> =
  <slash-separated-border-radius-syntax>  |
  <legacy-border-radius-syntax>

<slash-separated-border-radius-syntax> =
  <length-percentage [0,∞]> [ / <length-percentage [0,∞]> ]?

<legacy-border-radius-syntax> =
  <length-percentage [0,∞]>{1,2}

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Border radius with vertical text

HTML

```
<div>
  <p class="exampleText">Example</p>
</div>
```

CSS

```
div {
  background-color: rebeccapurple;
  width: 120px;
  height: 120px;
  border-start-end-radius: 10px;
}

.exampleText {
  writing-mode: vertical-rl;
  padding: 10px;
  background-color: white;
  border-start-end-radius: 10px;
}
```

border-start-start-radius CSS property

The **`border-start-start-radius`** CSS property defines a logical border radius on an element, which maps to a physical border radius that depends on the element's `writing-mode`, `direction`, and `text-orientation`. This is useful when building styles to work regardless of the text orientation and writing mode.

This property affects the corner between the block-start and the inline-start sides of the element. For instance, in a `horizontal-tb` writing mode with `ltr` direction, it corresponds to the `border-top-left-radius` property.

Try it

```
border-start-start-radius: 80px 80px;
```

```
border-start-start-radius: 250px 100px;
direction: rtl;
```

```
border-start-start-radius: 50%;
writing-mode: vertical-lr;
```

```
border-start-start-radius: 50%;
writing-mode: vertical-rl;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a top left rounded corner.
  </div>
</section>
```

```
#example-element {
  width: 80%;
  height: 80%;
  display: flex;
  justify-content: center;
  flex-direction: column;
  background-color: #5b6dcd;
  color: white;
  padding: 10px;
}
```

Syntax

```
/* <length> values */
/* With one value the corner will be a circle */
border-start-start-radius: 10px;
border-start-start-radius: 1em;

/* With two values the corner will be an ellipse */
border-start-start-radius: 1em 2em;

/* Global values */
border-start-start-radius: inherit;
border-start-start-radius: initial;
border-start-start-radius: revert;
border-start-start-radius: revert-layer;
border-start-start-radius: unset;
```

Values

`<length-percentage>`

> Denotes the size of the circle radius or the semi-major and semi-minor axes of the ellipse. As absolute length it can be expressed in any unit allowed by the CSS `<length>` data type. Percentages for the horizontal axis refer to the width of the box, percentages for the vertical axis refer to the height of the box. Negative values are invalid.

Formal definition

Initial value	`0`
Applies to	all elements; but User Agents are not required to apply to `table` and `inline-table` elements when `border-collapse` is `collapse`. The behavior on internal table elements is undefined for the moment.. It also applies to `::first-letter`.
Inherited	no
Percentages	refer to the corresponding dimension of the border box
Computed value	two absolute `<length>`s or `<percentage>`s
Animation type	a length, percentage or calc();

Formal syntax

```
border-start-start-radius =
  <border-radius>

<border-radius> =
  <slash-separated-border-radius-syntax>  |
  <legacy-border-radius-syntax>

<slash-separated-border-radius-syntax> =
  <length-percentage [0,∞]> [ / <length-percentage [0,∞]> ]?

<legacy-border-radius-syntax> =
  <length-percentage [0,∞]>{1,2}

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Border radius with vertical text

HTML

```
<div>
  <p class="exampleText">Example</p>
</div>
```

CSS

```
div {
  background-color: rebeccapurple;
  width: 120px;
  height: 120px;
  border-start-start-radius: 10px;
}

.exampleText {
  writing-mode: vertical-rl;
  padding: 10px;
  background-color: white;
  border-start-start-radius: 10px;
}
```

border-style CSS property

The **`border-style`** CSS shorthand property sets the line style for all four sides of an element's border.

Try it

```
border-style: none;
```

```
border-style: dotted;
```

```
border-style: inset;
```

```
border-style: dashed solid;
```

```
border-style: dashed double none;
```

```
border-style: dashed groove none dotted;
```

```
<section id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: black;
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}

body {
  background-color: white;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `border-bottom-style`
- `border-left-style`
- `border-right-style`
- `border-top-style`

Syntax

```
/* Keyword values */
border-style: none;
border-style: hidden;
border-style: dotted;
border-style: dashed;
border-style: solid;
border-style: double;
border-style: groove;
border-style: ridge;
border-style: inset;
border-style: outset;

/* top and bottom | left and right */
border-style: dotted solid;
```

```
/* top | left and right | bottom */
border-style: hidden double dashed;

/* top | right | bottom | left */
border-style: none solid dotted dashed;

/* Global values */
border-style: inherit;
border-style: initial;
border-style: revert;
border-style: revert-layer;
border-style: unset;
```

The `border-style` property may be specified using one, two, three, or four values.

- When **one** value is specified, it applies the same style to **all four sides**.
- When **two** values are specified, the first style applies to the **top and bottom**, the second to the **left and right**.
- When **three** values are specified, the first style applies to the **top**, the second to the **left and right**, the third to the **bottom**.
- When **four** values are specified, the styles apply to the **top**, **right**, **bottom**, and **left** in that order (clockwise).

Each value is a keyword chosen from the list below.

Values

`<line-style>`

Describes the style of the border. It can have the following values:

`none`

Like the `hidden` keyword, displays no border. Unless a `background-image` is set, the used value of the same side's `border-width` will be `0`, even if the specified value is something else. In the case of table cell and border collapsing, the `none` value has the *lowest* priority: if any other conflicting border is set, it will be displayed.

`hidden`

Like the `none` keyword, displays no border. Unless a `background-image` is set, the used value of the same side's `border-width` will be `0`, even if the specified value is something else. In the case of table cell and border collapsing, the `hidden` value has the *highest* priority: if any other conflicting border is set, it won't be displayed.

`dotted`

Displays a series of rounded dots. The spacing of the dots is not defined by the specification and is implementation-specific. The radius of the dots is half the computed value of the same side's `border-width`.

`dashed`

Displays a series of short square-ended dashes or line segments. The exact size and length of the segments are not defined by the specification and are implementation-specific.

`solid`

Displays a single, straight, solid line.

`double`

Displays two straight lines that add up to the pixel size defined by `border-width`.

`groove`

Displays a border with a carved appearance. It is the opposite of `ridge`.

`ridge`

Displays a border with an extruded appearance. It is the opposite of `groove`.

`inset`

Displays a border that makes the element appear embedded. It is the opposite of `outset`. When applied to a table cell with `border-collapse` set to `collapsed`, this value behaves like `ridge`.

`outset`

Displays a border that makes the element appear embossed. It is the opposite of `inset`. When applied to a table cell with `border-collapse` set to `collapsed`, this value behaves like `groove`.

Formal definition

Initial value	as each of the properties of the shorthand: • `border-top-style`: none • `border-right-style`: none • `border-bottom-style`: none • `border-left-style`: none
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	as each of the properties of the shorthand: • `border-top-style`: as specified • `border-right-style`: as specified • `border-bottom-style`: as specified • `border-left-style`: as specified
Animation type	discrete

Formal syntax

```
border-style =
  <'border-top-style'>{1,4}

<border-top-style> =
  <line-style>
```

```
<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

All property values

Here is an example of all the property values.

HTML

```
<pre class="b1">none</pre>
<pre class="b2">hidden</pre>
<pre class="b3">dotted</pre>
<pre class="b4">dashed</pre>
<pre class="b5">solid</pre>
<pre class="b6">double</pre>
<pre class="b7">groove</pre>
<pre class="b8">ridge</pre>
<pre class="b9">inset</pre>
<pre class="b10">outset</pre>
```

CSS

```
pre {
  height: 80px;
  width: 120px;
  margin: 20px;
  padding: 20px;
  display: inline-block;
  background-color: palegreen;
  border-width: 5px;
  box-sizing: border-box;
}

/* border-style example classes */
.b1 {
  border-style: none;
}

.b2 {
  border-style: hidden;
}

.b3 {
  border-style: dotted;
}

.b4 {
  border-style: dashed;
}

.b5 {
  border-style: solid;
}

.b6 {
  border-style: double;
}

.b7 {
  border-style: groove;
}

.b8 {
  border-style: ridge;
}

.b9 {
  border-style: inset;
}

.b10 {
  border-style: outset;
}
```

Result

See also

- The border-related shorthand CSS properties: `border`, `border-width`, `border-color`, `border-radius`

border-top CSS property

The **`border-top`** CSS shorthand property sets all the properties of an element's top border.

Try it

```
border-top: solid;
```

```
border-top: dashed red;
```

```
border-top: 1rem solid;
```

```
border-top: thick double #32a1ce;
```

```
border-top: 4mm ridge rgb(211 220 50 / 0.6);
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: darkmagenta;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `border-top-color`
- `border-top-style`
- `border-top-width`

Syntax

```
border-top: 1px;
border-top: 2px dotted;
border-top: medium dashed green;

/* Global values */
border-top: inherit;
border-top: initial;
border-top: revert;
border-top: revert-layer;
border-top: unset;
```

The three values of the shorthand property can be specified in any order, and one or two of them may be omitted.

Values

`<br-width>`

See `border-top-width`.

`<br-style>`

See `border-top-style`.

`<color>`

See `border-top-color`.

Description

As with all shorthand properties, `border-top` always sets the values of all of the properties that it can set, even if they are not specified. It sets those that are not specified to their default values. Consider the following code:

```
border-top-style: dotted;
border-top: thick green;
```

It is actually the same as this one:

```
border-top-style: dotted;
border-top: none thick green;
```

The value of `border-top-style` given before `border-top` is ignored. Since the default value of `border-top-style` is `none`, not specifying the `border-style` part results in no border.

Formal definition

Initial value	as each of the properties of the shorthand: • `border-top-width`: `medium` • `border-top-style`: `none` • `border-top-color`: `currentcolor`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	as each of the properties of the shorthand: • `border-top-width`: the absolute `<length>`, snapped as a line width • `border-top-style`: as specified • `border-top-color`: computed color
Animation type	as each of the properties of the shorthand: • `border-top-width`: a length • `border-top-style`: discrete • `border-top-color`: a color

Formal syntax

```
border-top =
  <line-width> ||
  <line-style> ||
  <color>

<line-width> =
  <length [0,∞]> |
  hairline       |
  thin           |
  medium         |
  thick

<line-style> =
  none   |
  hidden |
  dotted |
  dashed |
  solid  |
  double |
  groove |
  ridge  |
  inset  |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Applying a top border

HTML

```
<div>This box has a border on the top side.</div>
```

CSS

```
div {
  border-top: 4px dashed blue;
  background-color: gold;
  height: 100px;
  width: 100px;
  font-weight: bold;
  text-align: center;
}
```

border-top-color CSS property

The **`border-top-color`** CSS property sets the color of an element's top border. It can also be set with the shorthand CSS properties `border-color` or `border-top`.

Try it

```
border-top-color: red;
```

```
border-top-color: #32a1ce;
```

```
border-top-color: rgb(170 50 220 / 0.6);
```

```
border-top-color: hsl(60 90% 50% / 0.8);
```

```
border-top-color: transparent;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: black;
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}
```

Syntax

```
/* <color> values */
border-top-color: red;
border-top-color: #ffbb00;
border-top-color: rgb(255 0 0);
border-top-color: hsl(100deg 50% 25% / 75%);
border-top-color: currentColor;
border-top-color: transparent;

/* Global values */
border-top-color: inherit;
border-top-color: initial;
```

```
border-top-color: revert;
border-top-color: revert-layer;
border-top-color: unset;
```

Values

This property is specified as one `<color>` value:

`<color>`

The color of the top border.

Formal definition

Initial value	`currentcolor`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	computed color
Animation type	a color

Formal syntax

```
border-top-color =
  <color>     |
  <image-1D>

<image-1D> =
  <stripes()>

<stripes()> =
  stripes( <color-stripe># )

<color-stripe> =
  <color>                          &&
  [ <length-percentage> | <flex> ]?

<length-percentage> =
  <length>     |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Images Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

A div with a border

HTML

```
<div class="my-box">
  <p>
    This is a box with a border around it. Note which side of the box is
    <span class="red-text">red</span>.
  </p>
</div>
```

CSS

```
.my-box {
  border: solid 0.3em gold;
  border-top-color: red;
  width: auto;
}

.red-text {
  color: red;
}
```

Result

See also

- The color-related CSS properties for the other borders: `border-right-color`, `border-bottom-color`, and `border-left-color`.
- The other border-related CSS properties applying to the same border: `border-top-style` and `border-top-width`.
- The default `currentColor` color value.

border-top-left-radius CSS property

The **`border-top-left-radius`** CSS property rounds the top-left corner of an element by specifying the radius (or the radius of the semi-major and semi-minor axes) of the ellipse defining the curvature of the corner.

Try it

```
border-top-left-radius: 80px 80px;
```

```
border-top-left-radius: 250px 100px;
```

```
border-top-left-radius: 50%;
```

```
border-top-left-radius: 50%;
border: black 10px double;
background-clip: content-box;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
```

```
    This is a box with a top left rounded corner.
  </div>
</section>
```

```
#example-element {
  width: 80%;
  height: 80%;
  display: flex;
  justify-content: center;
  flex-direction: column;
  background-color: #5b6dcd;
  color: white;
  padding: 10px;
}
```

Syntax

```
/* the corner is a circle */
/* border-top-left-radius: radius */
border-top-left-radius: 3px;

/* the corner is an ellipse */
/* border-top-left-radius: horizontal vertical */
border-top-left-radius: 0.5em 1em;

border-top-left-radius: inherit;

/* Global values */
border-top-left-radius: inherit;
border-top-left-radius: initial;
border-top-left-radius: revert;
border-top-left-radius: revert-layer;
border-top-left-radius: unset;
```

With one value:

- the value is a `<length>` or a `<percentage>` denoting the radius of the circle to use for the border in that corner.

With two values:

- the first value is a `<length>` or a `<percentage>` denoting the horizontal semi-major axis of the ellipse to use for the border in that corner.
- the second value is a `<length>` or a `<percentage>` denoting the vertical semi-major axis of the ellipse to use for the border in that corner.

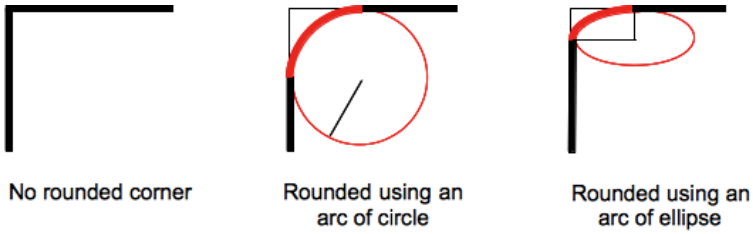
Values

`<length-percentage>`

> Denotes the size of the circle radius or the semi-major and semi-minor axes of the ellipse. As absolute length it can be expressed in any unit allowed by the CSS `<length>` data type. Percentages for the horizontal axis refer to the width of the box, percentages for the vertical axis refer to the height of the box. Negative values are invalid.

Description

The rounding can be a circle or an ellipse, or if one of the values is `0`, no rounding is done and the corner is square.



A background, being an image or a color, is clipped at the border, even a rounded one; the exact location of the clipping is defined by the value of the `background-clip` property.

> **Note:** If the value of this property is not set in a `border-radius` shorthand property that is applied to the element after the `border-top-left-radius` CSS property, the value of this property is then reset to its initial value by the shorthand property.

Formal definition

Initial value	`0`
Applies to	all elements; but User Agents are not required to apply to `table` and `inline-table` elements when `border-collapse` is `collapse`. The behavior on internal table elements is undefined for the moment.. It also applies to `::first-letter`.
Inherited	no
Percentages	refer to the corresponding dimension of the border box
Computed value	two absolute `<length>`s or `<percentage>`s
Animation type	a length, percentage or calc();

Formal syntax

```
border-top-left-radius =
  <border-radius>

<border-radius> =
  <slash-separated-border-radius-syntax>  |
  <legacy-border-radius-syntax>

<slash-separated-border-radius-syntax> =
  <length-percentage [0,∞]> [ / <length-percentage [0,∞]> ]?
```

```
<legacy-border-radius-syntax> =
  <length-percentage [0,∞]>{1,2}

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Arc of a circle

A single `<length>` value produces an arc of a circle.

```
<div></div>
```

```
div {
  border-top-left-radius: 40px;
  background-color: lightgreen;
  border: solid 1px black;
  width: 100px;
  height: 100px;
}
```

Arc of an ellipse

Two different `<length>` values produce an arc of an ellipse.

```
<div></div>
```

```
div {
  border-top-left-radius: 40px 20px;
  background-color: lightgreen;
  border: solid 1px black;
  width: 100px;
  height: 100px;
}
```

Square element with percentage radius

A square element with a single `<percentage>` value produces an arc of a circle.

```
<div></div>
```

```
div {
  border-top-left-radius: 40%;
  background-color: lightgreen;
  border: solid 1px black;
  width: 100px;
  height: 100px;
}
```

Non-square element with percentage radius

A non-square element with a single `<percentage>` value produces an arc of an ellipse.

```
<div></div>
```

```
div {
  border-top-left-radius: 40%;
  background-color: lightgreen;
  border: solid 1px black;
  width: 200px;
  height: 100px;
}
```

See also

- `border-radius` shorthand property
- `border-top-right-radius`, `border-bottom-right-radius`, and `border-bottom-left-radius`

border-top-right-radius CSS property

The **`border-top-right-radius`** CSS property rounds the top-right corner of an element by specifying the radius (or the radius of the semi-major and semi-minor axes) of the ellipse defining the curvature of the corner.

Try it

```
border-top-right-radius: 80px 80px;
```

```
border-top-right-radius: 250px 100px;
```

```
border-top-right-radius: 50%;
```

```
border-top-right-radius: 50%;
border: black 10px double;
background-clip: content-box;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a top right rounded corner.
  </div>
</section>
```

```
#example-element {
  width: 80%;
  height: 80%;
  display: flex;
  justify-content: center;
  flex-direction: column;
  background-color: #5b6dcd;
  color: white;
  padding: 10px;
}
```

Syntax

```
/* the corner is a circle */
/* border-top-right-radius: radius */
border-top-right-radius: 3px;

/* the corner is an ellipse */
/* border-top-right-radius: horizontal vertical */
border-top-right-radius: 0.5em 1em;

border-top-right-radius: inherit;

/* Global values */
border-top-right-radius: inherit;
border-top-right-radius: initial;
border-top-right-radius: revert;
border-top-right-radius: revert-layer;
border-top-right-radius: unset;
```

With one value:

- the value is a `<length>` or a `<percentage>` denoting the radius of the circle to use for the border in that corner.

With two values:

- the first value is a `<length>` or a `<percentage>` denoting the horizontal semi-major axis of the ellipse to use for the border in that corner.
- the second value is a `<length>` or a `<percentage>` denoting the vertical semi-major axis of the ellipse to use for the border in that corner.

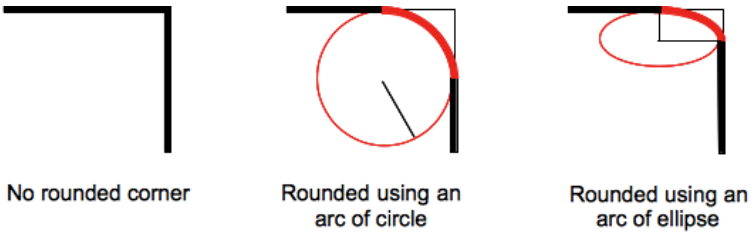
Values

`<length-percentage>`

> Denotes the size of the circle radius or the semi-major and semi-minor axes of the ellipse. As absolute length it can be expressed in any unit allowed by the CSS `<length>` data type. Percentages for the horizontal axis refer to the width of the box, percentages for the vertical axis refer to the height of the box. Negative values are invalid.

Description

The rounding can be a circle or an ellipse, or if one of the values is `0` no rounding is done and the corner is square.



A background, being an image or a color, is clipped at the border, even a rounded one; the exact location of the clipping is defined by the value of the `background-clip` property.

> **Note:** If the value of this property is not set in a `border-radius` shorthand property that is applied to the element after the `border-top-right-radius` CSS property, the value of this property is then reset to its initial value by the shorthand property.

Formal definition

Initial value	`0`
Applies to	all elements; but User Agents are not required to apply to `table` and `inline-table` elements when `border-collapse` is `collapse`. The behavior on internal table elements is undefined for the moment.. It also applies to `::first-letter`.
Inherited	no
Percentages	refer to the corresponding dimension of the border box
Computed value	two absolute `<length>`s or `<percentage>`s
Animation type	a length, percentage or calc();

Formal syntax

```
border-top-right-radius =
  <border-radius>

<border-radius> =
  <slash-separated-border-radius-syntax>  |
  <legacy-border-radius-syntax>

<slash-separated-border-radius-syntax> =
  <length-percentage [0,∞]> [ / <length-percentage [0,∞]> ]?

<legacy-border-radius-syntax> =
  <length-percentage [0,∞]>{1,2}

<length-percentage> =
```

```
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Arc of a circle

A single `<length>` value produces an arc of a circle.

```
<div></div>
```

```
div {
  border-top-right-radius: 40px;
  background-color: lightgreen;
  border: solid 1px black;
  width: 100px;
  height: 100px;
}
```

Arc of an ellipse

Two different `<length>` values produce an arc of an ellipse.

```
<div></div>
```

```
div {
  border-top-right-radius: 40px 20px;
  background-color: lightgreen;
  border: solid 1px black;
  width: 100px;
  height: 100px;
}
```

Square element with percentage radius

A square element with a single `<percentage>` value produces an arc of a circle.

```
<div></div>
```

```
div {
  border-top-right-radius: 40%;
  background-color: lightgreen;
  border: solid 1px black;
  width: 100px;
  height: 100px;
}
```

Non-square element with percentage radius

A non-square element with a single `<percentage>` value produces an arc of an ellipse.

```
<div></div>
```

```
div {
  border-top-right-radius: 40%;
  background-color: lightgreen;
  border: solid 1px black;
  width: 200px;
  height: 100px;
}
```

border-top-style CSS property

The **`border-top-style`** CSS property sets the line style of an element's top `border`.

> **Note:** The specification doesn't define how borders of different styles connect in the corners.

Try it

```
border-top-style: none;
```

```
border-top-style: dotted;
```

```
border-top-style: dashed;
```

```
border-top-style: solid;
```

```
border-top-style: groove;
```

```
border-top-style: inset;
```

```
<section id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
```

```
  </div>
</section>
```

```
#example-element {
  background-color: #eeeeee;
  color: black;
  border: 0.75em solid;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}

body {
  background-color: white;
}
```

Syntax

```
/* Keyword values */
border-top-style: none;
border-top-style: hidden;
border-top-style: dotted;
border-top-style: dashed;
border-top-style: solid;
border-top-style: double;
border-top-style: groove;
border-top-style: ridge;
border-top-style: inset;
border-top-style: outset;

/* Global values */
border-top-style: inherit;
border-top-style: initial;
border-top-style: revert;
border-top-style: revert-layer;
border-top-style: unset;
```

The `border-top-style` property is specified as a single `<line-style>` keyword value.

Formal definition

Initial value	none
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
border-top-style =
  <line-style>

<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting border-top-style

HTML

```
<table>
  <tbody>
    <tr>
      <td class="b1">none</td>
      <td class="b2">hidden</td>
      <td class="b3">dotted</td>
      <td class="b4">dashed</td>
    </tr>
    <tr>
      <td class="b5">solid</td>
      <td class="b6">double</td>
      <td class="b7">groove</td>
      <td class="b8">ridge</td>
    </tr>
    <tr>
      <td class="b9">inset</td>
      <td class="b10">outset</td>
    </tr>
  </tbody>
</table>
```

CSS

```
/* Define look of the table */
table {
  border-width: 2px;
  background-color: #52e385;
```

```
}
tr,
td {
  padding: 3px;
}

/* border-top-style example classes */
.b1 {
  border-top-style: none;
}
.b2 {
  border-top-style: hidden;
}
.b3 {
  border-top-style: dotted;
}
.b4 {
  border-top-style: dashed;
}
.b5 {
  border-top-style: solid;
}
.b6 {
  border-top-style: double;
}
.b7 {
  border-top-style: groove;
}
.b8 {
  border-top-style: ridge;
}
.b9 {
  border-top-style: inset;
}
.b10 {
  border-top-style: outset;
}
```

Result

See also

- The other style-related border properties: `border-left-style`, `border-right-style`, `border-bottom-style`, and `border-style`.
- The other top-border-related properties: `border-top`, `border-top-color`, and `border-top-width`.

border-top-width CSS property

The **`border-top-width`** CSS property sets the width of the top border of an element.

Try it

```
border-top-width: thick;
```

```
border-top-width: 2em;
```

```
border-top-width: 4px;
```

```
border-top-width: 2ex;
```

```
border-top-width: 0;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: palegreen;
  color: black;
  border: 0 solid crimson;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}
```

Syntax

```
/* Keyword values */
border-top-width: thin;
border-top-width: medium;
border-top-width: thick;

/* <length> values */
border-top-width: 10em;
border-top-width: 3vmax;
border-top-width: 6px;

/* Global keywords */
border-top-width: inherit;
border-top-width: initial;
border-top-width: revert;
border-top-width: revert-layer;
border-top-width: unset;
```

Values

`<line-width>`

Defines the width of the border, either as an explicit non-negative `<length>` or the keywords: `thin`, `medium`, or `thick`. The default is `medium`.

Formal definition

Initial value	`medium`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	the absolute `<length>`, snapped as a line width
Animation type	a length

Formal syntax

```
border-top-width =
  <line-width>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

HTML

```
<div>Element 1</div>
<div>Element 2</div>
```

CSS

```
div {
  border: 1px solid red;
  margin: 1em 0;
}

div:nth-child(1) {
  border-top-width: thick;
}
div:nth-child(2) {
  border-top-width: 2em;
}
```

Result

See also

- The other border-width-related CSS properties: `border-left-width`, `border-right-width`, `border-bottom-width`, and `border-width`.
- The other border-top-related CSS properties: `border`, `border-top`, `border-top-style`, and `border-top-color`.

border-width CSS property

The **`border-width`** CSS shorthand property sets the width of an element's border.

Try it

```
border-width: thick;
```

```
border-width: 1em;
```

```
border-width: 4px 1.25em;
```

```
border-width: 2ex 1.25ex 0.5ex;
```

```
border-width: 0 4px 8px 12px;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    This is a box with a border around it.
  </div>
</section>
```

```
#example-element {
  background-color: palegreen;
  color: black;
  border: 0 solid crimson;
  padding: 0.75em;
  width: 80%;
  height: 100px;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `border-bottom-width`
- `border-left-width`
- `border-right-width`
- `border-top-width`

Syntax

```
/* Keyword values */
border-width: thin;
border-width: medium;
border-width: thick;

/* <length> values */
border-width: 4px;
border-width: 1.2rem;

/* top and bottom | left and right */
border-width: 2px 1.5em;

/* top | left and right | bottom */
border-width: 1px 2em 1.5cm;

/* top | right | bottom | left */
border-width: 1px 2em 0 4rem;

/* Global values */
border-width: inherit;
border-width: initial;
border-width: revert;
border-width: revert-layer;
border-width: unset;
```

The `border-width` property may be specified using one, two, three, or four values.

- When **one** value is specified, it applies the same width to **all four sides**.
- When **two** values are specified, the first width applies to the **top and bottom**, the second to the **left and right**.
- When **three** values are specified, the first width applies to the **top**, the second to the **left and right**, the third to the **bottom**.
- When **four** values are specified, the widths apply to the **top**, **right**, **bottom**, and **left** in that order (clockwise).

Values

`<line-width>`

Defines the width of the border, either as an explicit non-negative `<length>` or the keywords: `thin`, `medium`, or `thick`. The default is `medium`.

Formal definition

Initial value	as each of the properties of the shorthand: • `border-top-width`: `medium` • `border-right-width`: `medium` • `border-bottom-width`: `medium` • `border-left-width`: `medium`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	as each of the properties of the shorthand: • `border-top-width`: the absolute `<length>`, snapped as a line width • `border-right-width`: the absolute `<length>`, snapped as a line width • `border-bottom-width`: the absolute `<length>`, snapped as a line width • `border-left-width`: the absolute `<length>`, snapped as a line width
Animation type	as each of the properties of the shorthand: • `border-top-width`: a length • `border-right-width`: a length • `border-bottom-width`: a length • `border-left-width`: a length

Formal syntax

```
border-width =
  <'border-top-width'>{1,4}

<border-top-width> =
  <line-width>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

A mix of values and lengths

HTML

```
<p id="one-value">one value: 6px wide border on all 4 sides</p>
<p id="two-values">
  two different values: 2px wide top and bottom border, 10px wide right and left
  border
</p>
<p id="three-values">
  three different values: 0.3em top, 9px bottom, and zero width right and left
</p>
<p id="four-values">
```

```
  four different values: "thin" top, "medium" right, "thick" bottom, and 1em
  left
</p>
```

CSS

```
#one-value {
  border: ridge #cccccc;
  border-width: 6px;
}
#two-values {
  border: solid red;
  border-width: 2px 10px;
}
#three-values {
  border: dotted orange;
  border-width: 0.3em 0 9px;
}
#four-values {
  border: solid lightgreen;
  border-width: thin medium thick 1em;
}
p {
  width: auto;
  margin: 0.25em;
  padding: 0.25em;
}
```

Result

See also

- The border-related shorthand properties: `border`, `border-style`, `border-color`
- The border-width-related properties: `border-bottom-width`, `border-left-width`, `border-right-width`, `border-top-width`

bottom CSS property

The **`bottom`** CSS property participates in setting the vertical position of a positioned element. This inset property has no effect on non-positioned elements.

Try it

```
bottom: 0;
```

```
bottom: 4em;
```

```
bottom: 10%;
```

```
bottom: 20px;
```

```
<section id="default-example">
  <div class="example-container">
    <div id="example-element">I am absolutely positioned.</div>
    <p>
      As much mud in the streets as if the waters had but newly retired from the
      face of the earth, and it would not be wonderful to meet a Megalosaurus,
      forty feet long or so, waddling like an elephantine lizard up Holborn
      Hill.
    </p>
  </div>
</section>
```

```
.example-container {
  border: 0.75em solid;
  padding: 0.75em;
  text-align: left;
  position: relative;
  width: 100%;
  min-height: 200px;
}

#example-element {
  background-color: #264653;
  border: 4px solid #ffb500;
  color: white;
  position: absolute;
  width: 140px;
  height: 60px;
}
```

Syntax

```
/* <length> values */
bottom: 3px;
bottom: 2.4em;
bottom: calc(anchor(--my-anchor 50%) + 5px);
bottom: anchor-size(width);

/* <percentage>s of the height of the containing block */
bottom: 10%;

/* Keyword value */
bottom: auto;

/* Global values */
bottom: inherit;
bottom: initial;
bottom: revert;
```

```
bottom: revert-layer;
bottom: unset;
```

Values

`<length>`

A negative, null, or positive `<length>`:

- for *absolutely positioned elements*, it represents the distance to the bottom edge of the containing block.
- for *relatively positioned elements*, it represents the distance that the element is moved above its normal position.
- for *anchor-positioned elements*, the `anchor()` function resolves to a `<length>` value relative to the position of the associated *anchor element*'s top or bottom edge (see Using inset properties with `anchor()` function values), and the `anchor-size()` function resolves to a `<length>` value relative to the associated anchor element's width or height (see Setting element position based on anchor size).

`<percentage>`

A `<percentage>` of the containing block's height.

`auto`

Specifies that:

- for *absolutely positioned elements*, the position of the element is based on the `top` property, while `height: auto` is treated as a height based on the content; or if `top` is also `auto`, the element is positioned where it should vertically be positioned if it were a static element.
- for *relatively positioned elements*, the distance of the element from its normal position is based on the `top` property; or if `top` is also `auto`, the element is not moved vertically at all.

Description

The effect of `bottom` depends on how the element is positioned (i.e., the value of the `position` property):

- When `position` is set to `absolute` or `fixed`, the `bottom` property specifies the distance between the outer edge of the element's bottom margin and the outer edge of the containing block's bottom padding, or, in the case of anchor positioned elements when the `anchor()` function is used within the value, relative to the position of the specified `<anchor-side>` edge. The `bottom` property is compatible with the `top`, `bottom`, `start`, `end`, `self-start`, `self-end`, `center`, and `<percentage>` values.
- When `position` is set to `relative`, the `bottom` property specifies the distance the element's bottom edge is moved above its normal position.
- When `position` is set to `sticky`, the `bottom` property is used to compute the sticky-constraint rectangle.
- When `position` is set to `static`, the `bottom` property has *no effect*.

When both `top` and `bottom` are specified, `position` is set to `absolute` or `fixed`, *and* `height` is unspecified (either `auto` or `100%`) both the `top` and `bottom` distances are respected. In all other situations, if `height` is constrained in any way or `position` is set to `relative`, the `top` property takes precedence and the `bottom` property is ignored.

Formal definition

Initial value	`auto`
Applies to	positioned elements
Inherited	no
Percentages	refer to the height of the containing block
Computed value	if specified as a length, the corresponding absolute length; if specified as a percentage, the specified value; otherwise, `auto`
Animation type	a length, percentage or calc();

Formal syntax

```
bottom =
  auto                |
  <length-percentage>  |
  <anchor()>           |
  <anchor-size()>

<length-percentage> =
  <length>     |
  <percentage>

<anchor()> =
  anchor( <anchor-name>?                 &&
  <anchor-side> , <length-percentage>? )

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<anchor-name> =
  <dashed-ident>

<anchor-side> =
  inside       |
  outside      |
  top          |
  left         |
  right        |
  bottom       |
  start        |
  end          |
  self-start   |
  self-end     |
  <percentage>  |
  center

<anchor-size> =
  width       |
  height      |
  block       |
  inline      |
  self-block  |
  self-inline
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Positioned Layout Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Absolute and fixed positioning

This example demonstrates the difference in behavior of the `bottom` property, when `position` is `absolute` versus `fixed`.

HTML

```
<p>
  This<br />is<br />some<br />tall,<br />tall,<br />tall,<br />tall,<br />tall<br />content.
</p>
<div class="fixed"><p>Fixed</p></div>
<div class="absolute"><p>Absolute</p></div>
```

CSS

```
p {
  font-size: 30px;
  line-height: 2em;
}

div {
  width: 48%;
  text-align: center;
  background: rgb(55 55 55 / 20%);
  border: 1px solid blue;
}

.absolute {
  position: absolute;
  bottom: 0;
  left: 0;
}

.fixed {
  position: fixed;
  bottom: 0;
  right: 0;
}
```

box-align CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

> **Warning:** This is a property of the original CSS flexible box layout Module draft, and has been replaced by a newer standard.

The **`box-align`** CSS property specifies how an element aligns its contents across its layout in a perpendicular direction. The effect of the property is only visible if there is extra space in the box.

See flexbox for information about the current standard.

The direction of layout depends on the element's orientation: horizontal or vertical.

Syntax

```
/* Keyword values */
box-align: start;
box-align: center;
box-align: end;
box-align: baseline;
box-align: stretch;

/* Global values */
box-lines: inherit;
box-lines: initial;
box-lines: unset;
```

Values

This property is specified as one of the following keyword values:

`start`

The box aligns contents at the start, leaving any extra space at the end.

`center`

The box aligns contents in the center, dividing any extra space equally between the start and the end.

`end`

The box aligns contents at the end, leaving any extra space at the start.

`baseline`

The box aligns the baselines of the contents (lining up the text). This only applies if the box's orientation is horizontal.

`stretch`

The box stretches the contents so that there is no extra space in the box.

Notes

The edge of the box designated the *start* for alignment purposes depends on the box's orientation:

- For horizontal elements, the *start* is the top edge.
- For vertical elements, the *start* is the left edge.

The edge opposite to the start is designated the *end*.

If the alignment is set using the element's `align` attribute, then the style is ignored.

Formal definition

Initial value	`stretch`
Applies to	elements with a CSS `display` value of `box` or `inline-box`
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
box-align =
  start    |
  center   |
  end      |
  baseline |
  stretch
```

Examples

Setting box alignment

```
<div class="example">
  <p>I will be second from the bottom of div.example, centered horizontally.</p>
  <p>I will be on the bottom of div.example, centered horizontally.</p>
</div>
```

```
div.example {
  display: box; /* As specified */
  display: -moz-box; /* Mozilla */
  display: -webkit-box; /* WebKit */

  /* Make this box taller than the children,
     so there is room for the box-pack */
  height: 400px;

  /* Make this box wider than the children
     so there is room for the box-align */
  width: 300px;

  /* Children should be oriented vertically */
  box-orient: vertical; /* As specified */
  -moz-box-orient: vertical; /* Mozilla */
  -webkit-box-orient: vertical; /* WebKit */

  /* Align children to the horizontal center of this box */
  box-align: center; /* As specified */
  -moz-box-align: center; /* Mozilla */
  -webkit-box-align: center; /* WebKit */

  /* Pack children to the bottom of this box */
  box-pack: end; /* As specified */
  -moz-box-pack: end; /* Mozilla */
  -webkit-box-pack: end; /* WebKit */
}

div.example > p {
  /* Make children narrower than their parent,
     so there is room for the box-align */
  width: 200px;
}
```

Specifications

Not part of any standard.

- `align-items`, `box-orient`, `box-direction`, `box-pack`

box-decoration-break CSS property

The **`box-decoration-break`** CSS property specifies how an element's fragments should be rendered when broken across multiple lines, columns, or pages.

Try it

```
-webkit-box-decoration-break: slice;
box-decoration-break: slice;
```

```
-webkit-box-decoration-break: clone;
box-decoration-break: clone;
```

```
<section id="default-example">
  <div id="example-container">
    <span id="example-element">This text breaks across multiple lines.</span>
  </div>
</section>
```

```
#example-container {
  width: 14rem;
}

#example-element {
  background: linear-gradient(to bottom right, #6f6f6f, black);
  color: white;
  box-shadow:
    8px 8px 10px 0 #ff1492,
    -5px -5px 5px 0 blue,
    5px 5px 15px 0 yellow;
  padding: 0 1em;
  border-radius: 16px;
  border-style: solid;
  margin-left: 10px;
  font: 24px sans-serif;
  line-height: 2;
}
```

Syntax

```
/* Keyword values */
box-decoration-break: slice;
box-decoration-break: clone;

/* Global values */
box-decoration-break: inherit;
box-decoration-break: initial;
box-decoration-break: revert;
box-decoration-break: revert-layer;
box-decoration-break: unset;
```

Values

This property is specified as one of the following keyword values:

`slice`

> The element is initially rendered as if its box were not fragmented, after which the rendering for this hypothetical box is sliced into pieces for each line/column/page. Note that the hypothetical box can be different for each fragment since it uses its own height if the break occurs in the inline direction, and its own width if the break occurs in the block direction. See the CSS specification for details.

`clone`

> Each box fragment is rendered independently with the specified border, padding, and margin wrapping each fragment. The `border-radius`, `border-image`, and `box-shadow` are applied to each fragment independently. The background is also drawn independently for each fragment, which means that a background image with `background-repeat: no-repeat` may nevertheless repeat multiple times.

Description

The specified value will impact the appearance of the following properties:

- `background`
- `border`
- `border-image`
- `box-shadow`
- `clip-path`
- `margin`
- `padding`

Formal definition

Initial value	`slice`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
box-decoration-break =
  slice  |
  clone
```

This syntax reflects the latest standard as per CSS Fragmentation Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Inline box fragments

An inline element with a box decoration may have unexpected appearance when it contains line breaks due to the initial `slice` value. The following example shows the effect of adding `box-decoration-break: clone` to a `<span>` that contains `<br>` tags:

```
body {
  display: flex;
  background-color: grey;
  justify-content: space-around;
}

span {
  padding: 0em 1em;
  border-radius: 1rem;
```

```
  border-style: solid;
  margin: 1rem;
  font: 22px sans-serif;
  line-height: 2;
}
```

```
span {
  background: linear-gradient(to bottom right, yellow, green);
  box-shadow:
    8px 8px 10px 0px deeppink,
    -5px -5px 5px 0px blue,
    5px 5px 15px 0px yellow;
}

#clone {
  -webkit-box-decoration-break: clone;
  box-decoration-break: clone;
}
```

```
<p>
  <span>The<br />quick<br />orange fox</span>
</p>
<p>
  <span id="clone">The<br />quick<br />orange fox</span>
</p>
```

Block box fragments

The following example shows how block elements with box decoration look when they contain line breaks in a multi-column layout. Notice how the result of `box-decoration-break: slice` would be the equivalent of the first `<div>` if stacked vertically.

```
body {
  background-color: grey;
}
span {
  padding: 0em 2em;
  border-radius: 250px;
  border-style: solid;
  margin-left: 1em;
  font: 20px sans-serif;
  line-height: 1.5;
}
```

```
span {
  display: block;
  background: linear-gradient(to bottom right, yellow, green);
  box-shadow:
    inset 8px 8px 10px 0px deeppink,
    inset -5px -5px 5px 0px blue,
    inset 5px 5px 15px 0px yellow;
}
#base {
  width: 33%;
}
.columns {
  columns: 3;
}

.clone {
  -webkit-box-decoration-break: clone;
  box-decoration-break: clone;
}
```

```
<div id="base">
  <span>The<br />quick<br />orange fox</span>
</div>
<br />

<h2>'box-decoration-break: slice'</h2>
<div class="columns">
  <span>The<br />quick<br />orange fox</span>
</div>

<h2>'box-decoration-break: clone'</h2>
<div class="columns">
  <span class="clone">The<br />quick<br />orange fox</span>
</div>
```

box-direction CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

> **Warning:** This is a property of the original CSS flexible box layout Module draft, and has been replaced by a newer standard. The `-moz-box-direction` will only be used for XUL while the previous standard `box-direction` has been replaced by `flex-direction`. See flexbox for information about the current standard.

The **`box-direction`** CSS property specifies whether a box lays out its contents normally (from the top or left edge), or in reverse (from the bottom or right edge).

Syntax

```
/* Keyword values */
box-direction: normal;
```

```
box-direction: reverse;

/* Global values */
box-direction: inherit;
box-direction: initial;
box-direction: revert;
box-direction: revert-layer;
box-direction: unset;
```

Values

This property is specified as one of the following keyword values:

`normal`

The box lays out its contents from the start (the left or top edge).

`reverse`

The box lays out its contents from the end (the right or bottom edge).

Notes

The edge of the box designated the *start* for layout purposes depends on the box's orientation:

- For horizontal elements, the *start* is the top edge.
- For vertical elements, the *start* is the left edge.

The edge opposite to the start is designated the *end*.

If the direction is set using the element's `dir` attribute, then the style is ignored.

Formal definition

Initial value	`normal`
Applies to	elements with a CSS `display` value of `box` or `inline-box`
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
box-direction =
  normal   |
  reverse
```

Examples

Setting box direction

```
.example {
  /* bottom-to-top layout */
  -moz-box-direction: reverse; /* Mozilla */
  -webkit-box-direction: reverse; /* WebKit */
  box-direction: reverse; /* As specified */
}
```

Specifications

Not part of any standard.

See also

- `box-orient`
- `box-pack`

- `flex-direction`

box-flex CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

> **Warning:** This is a property for controlling parts of the XUL box model. It does not match either the old CSS flexible box layout Module drafts for `box-flex` (which were based on this property) or the behavior of `-webkit-box-flex` (which is based on those drafts). See flexbox for information about the current standard.

The **`-moz-box-flex`** and **`-webkit-box-flex`** CSS properties specify how a `-moz-box` or `-webkit-box` grows to fill the box that contains it, in the direction of the containing box's layout.

Syntax

```
/* <number> values */
-moz-box-flex: 0;
-moz-box-flex: 2;
-moz-box-flex: 3.5;
-webkit-box-flex: 0;
-webkit-box-flex: 2;
-webkit-box-flex: 3.5;

/* Global values */
-moz-box-flex: inherit;
-moz-box-flex: initial;
-moz-box-flex: revert;
-moz-box-flex: revert-layer;
-moz-box-flex: unset;
```

```
-webkit-box-flex: inherit;
-webkit-box-flex: initial;
-webkit-box-flex: revert;
-webkit-box-flex: revert-layer;
-webkit-box-flex: unset;
```

The `box-flex` property is specified as a `<number>`. If the value is 0, the box does not grow. If it is greater than 0, the box grows to fill a proportion of the available space.

Notes

The containing box allocates the available extra space in proportion to the flex value of each of the content elements.

Content elements that have zero flex do not grow.

If only one content element has nonzero flex, then it grows to fill the available space.

Content elements that have the same flex grow by the same absolute amounts.

If the flex value is set using the element's `flex` attribute, then the style is ignored.

To make XUL elements in a containing box the same size, set the containing box's `equalsize` attribute to the value `always`. This attribute does not have a corresponding CSS property.

A trick to make all content elements in a containing box the same size, is to give them all a fixed size (e.g., `height: 0`), and the same `box-flex` value greater than zero (e.g., `-moz-box-flex: 1`).

Formal definition

Initial value	`0`
Applies to	elements that are direct children of an element with a CSS `display` value of `-moz-box` or `-moz-inline-box` or `-webkit-box` or `-webkit-inline-box`
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
box-flex =
  <number>
```

Examples

Setting box-flex

```
<div class="example">
  <p>I will expand to fill extra space</p>
  <p>I will not expand</p>
</div>
```

```
div.example {
  display: -moz-box;
  display: -webkit-box;
  border: 1px solid black;
  width: 100%;
}
div.example > p:nth-child(1) {
  -moz-box-flex: 1; /* Mozilla */
  -webkit-box-flex: 1; /* WebKit */
  border: 1px solid black;
}
div.example > p:nth-child(2) {
  -moz-box-flex: 0; /* Mozilla */
  -webkit-box-flex: 0; /* WebKit */
  border: 1px solid black;
}
```

Specifications

Not part of any standard.

box-flex-group CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

> **Warning:** This is a property of the original CSS flexible box layout Module draft. It has been replaced in the specification. See flexbox for information about the current standard.

The **`box-flex-group`** CSS property assigns the flexbox's child elements to a flex group.

For flexible elements assigned to flex groups, the first flex group is 1 and higher values specify subsequent flex groups. The initial value is 1. When dividing up the box's extra space, the browser first considers all elements within the first flex group. Each element within that group is given extra space based on the ratio of that element's flexibility compared to the flexibility of other elements within the same flex group. If the space of all flexible children within the group has been increased to the maximum, the process repeats for the children within the next flex group, using any space left over from the previous flex group. Once there are no more flex groups, and there is still space remaining, the extra space is divided within the containing box according to the `box-pack` property.

If the box would overflow after the preferred space of the children has been computed, then space is removed from flexible elements in a manner similar to that used when adding extra space. Each flex group is examined in turn and space is removed according to the ratio of the flexibility of each element. Elements do not shrink below their minimum widths.

Syntax

```
/* <integer> values */
box-flex-group: 1;
box-flex-group: 5;

/* Global values */
box-flex-group: inherit;
box-flex-group: initial;
box-flex-group: unset;
```

The `box-flex-group` property is specified as any positive `<integer>`.

Formal definition

Initial value	`1`
Applies to	in-flow children of box elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
box-flex-group =
  <integer>

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage example

In the original flexbox spec, `box-flex-group` could be used to assign flex children to different groups to distribute flexible space between:

```
article:nth-child(1) {
  -webkit-box-flex-group: 1;
}

article:nth-child(2) {
  -webkit-box-flex-group: 2;
}
```

This was only ever supported in WebKit-based browsers, with a prefix, and in subsequent versions of the spec this functionality does not have an equivalent. Instead, distribution of space inside the flex container is now handled using `flex-basis`, `flex-grow`, and `flex-shrink`.

Specifications

Not part of any standard.

See also

- `flex`
- `flex-basis`
- `flex-grow`
- `flex-shrink`

box-lines CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

> **Warning:** This is a property of the original CSS flexible box layout Module draft. It has been replaced in the specification. See flexbox for information about the current standard.

The **`box-lines`** CSS property determines whether the box may have a single or multiple lines (rows for horizontally oriented boxes, columns for vertically oriented boxes).

By default a horizontal box will lay out its children in a single row, and a vertical box will lay out its children in a single column. This behavior can be changed using the `box-lines` property. The default value is `single`, which means that all elements will be placed in a single row or column, and any elements that don't fit will be considered overflow.

If a value of `multiple` is specified, however, then the box is allowed to expand to multiple lines (that is, multiple rows or columns) in order to accommodate all of its children. The box must attempt to fit its children on as few lines as possible by shrinking all elements down to their minimum widths or heights if necessary.

If the children in a horizontal box still do not fit on a line after being reduced to their minimum widths, then children are moved one by one onto a new line, until the elements remaining on the previous line fit. This process can repeat to an arbitrary number of lines. If a line contains only a single element that doesn't fit, then the element should stay on that line and overflow out of the box. The later lines are placed below the earlier lines in normal direction boxes and above in reverse direction boxes. The height of a line is the height of the largest child in that line. No additional space appears between the lines apart from the margins on the largest elements in each line. For calculating the height of a line, margins with a computed value of auto should be treated as having a value of 0.

A similar process occurs for children in a vertical box. Later lines in normal direction boxes are placed to the right of earlier lines and to the left in reverse direction boxes.

Once the number of lines has been determined, elements with a computed value for `box-flex` other than `0` stretch as necessary in an attempt to fill the remaining space on the lines. Each line computes flexes independently, so only elements on that line are considered when evaluating `box-flex` and `box-flex-group`. The packing of elements in a line, as specified by the `box-pack` property, is also computed independently for each line.

Syntax

```
/* Keyword values */
box-lines: single;
box-lines: multiple;

/* Global values */
box-lines: inherit;
```

```
box-lines: initial;
box-lines: unset;
```

Values

This property is specified as one of the following keyword values:

`single`

Box elements lay out in a single row or column.

`multiple`

Box elements layout in multiple rows or columns.

Formal definition

Initial value	`single`
Applies to	box elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
box-lines =
  single    |
  multiple
```

Examples

Basic usage example

In the original version of the spec, `box-lines` allowed you to specify that you wanted your flex container's children to wrap onto multiple lines. This was only supported in WebKit-based browsers, with a prefix.

```
div {
  display: box;
  box-orient: horizontal;
  box-lines: multiple;
}
```

The modern flexbox equivalent is `flex-wrap`.

Specifications

Not part of any standard.

- `flex`
- `flex-basis`
- `flex-grow`
- `flex-shrink`

box-ordinal-group CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

> **Warning:** This is a property of the original CSS flexible box layout Module draft. It has been replaced in the specification. See flexbox for information about the current standard.

The **`box-ordinal-group`** CSS property assigns the flexbox's child elements to an ordinal group.

Ordinal groups may be used in conjunction with the `box-direction` property to control the order in which the direct children of a box appear. When the computed `box-direction` is normal, a box will display its elements starting from the lowest numbered ordinal group and ensure that those elements appear to the left (for horizontal boxes) or at the top (for vertical boxes) of the container. Elements with the same ordinal group are flowed in the order they appear in the source document tree. In the reverse direction, the ordinal groups are examined in the same order, except the elements appear reversed.

Syntax

```
/* <integer> values */
box-ordinal-group: 1;
box-ordinal-group: 5;

/* Global values */
box-ordinal-group: inherit;
box-ordinal-group: initial;
box-ordinal-group: unset;
```

The `box-ordinal-group` property is specified as any positive `<integer>`.

Formal definition

Initial value	`1`
Applies to	children of box elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
box-ordinal-group =
  <integer>

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage example

In an older version of the spec, `box-ordinal-group` was included to allow you to change the display order of flex children inside a flex container:

```
article:nth-child(1) {
  -webkit-box-ordinal-group: 2;
  -moz-box-ordinal-group: 2;
  box-ordinal-group: 2;
}

article:nth-child(2) {
  -webkit-box-ordinal-group: 1;
  -moz-box-ordinal-group: 1;
  box-ordinal-group: 1;
}
```

The modern flexbox equivalent is `order`.

Specifications

Not part of any standard.

box-orient CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

> **Warning:** This is a property of the original CSS flexible box layout Module draft, and has been replaced by a newer standard. See flexbox for information about the current standard.

The **`box-orient`** CSS property sets whether an element lays out its contents horizontally or vertically.

Syntax

```
/* Keyword values */
box-orient: horizontal;
box-orient: vertical;
box-orient: inline-axis;
box-orient: block-axis;

/* Global values */
box-orient: inherit;
box-orient: initial;
box-orient: unset;
```

Values

This property is specified as one of the following keyword values:

`horizontal`

: The box lays out its contents horizontally.

`vertical`

: The box lays out its contents vertically.

`inline-axis` (HTML)

: The box displays its children along the inline axis.

`block-axis` (HTML)

: The box displays its children along the block axis.

The inline and block axes are the writing-mode dependent keywords which, in English, map to `horizontal` and `vertical` respectively.

Description

HTML DOM elements lay out their contents along the inline-axis by default. This CSS property will only apply to HTML elements with a CSS `display` value of `box` or `inline-box`.

Formal definition

Initial value	`inline-axis`
Applies to	elements with a CSS `display` value of `box` or `inline-box`
Inherited	no
Computed value	as specified

Animation type	discrete

Formal syntax

```
box-orient =
  horizontal   |
  vertical     |
  inline-axis  |
  block-axis
```

Examples

Setting horizontal box orientation

Here, the `box-orient` property will cause the two `<p>` sections in the example to display in the same line.

HTML

```
<div class="example">
  <p>I will be to the left of my sibling.</p>
  <p>I will be to the right of my sibling.</p>
</div>
```

CSS

```
div.example {
  display: -moz-box; /* Mozilla */
  display: -webkit-box; /* WebKit */
  display: box; /* As specified */

  /* Children should be oriented vertically */
  -moz-box-orient: horizontal; /* Mozilla */
  -webkit-box-orient: horizontal; /* WebKit */
  box-orient: horizontal; /* As specified */
}
```

Result

Specifications

Not part of any standard.

- `flex-direction`

box-pack CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

> **Warning:** This is a property of the original CSS flexible box layout Module draft, and has been replaced by a newer standard. See flexbox for information about the current standard.

The **`-moz-box-pack`** and **`-webkit-box-pack`** CSS properties specify how a `-moz-box` or `-webkit-box` packs its contents in the direction of its layout. The effect of this is only visible if there is extra space in the box.

The direction of layout depends on the element's orientation: horizontal or vertical.

Syntax

```
/* Keyword values */
box-pack: start;
box-pack: center;
box-pack: end;
box-pack: justify;

/* Global values */
box-pack: inherit;
box-pack: initial;
box-pack: unset;
```

Values

This property is specified as one of the following keyword values:

`start`

The box packs contents at the start, leaving any extra space at the end.

`center`

The box packs contents in the center, dividing any extra space equally between the start and the end.

`end`

The box packs contents at the end, leaving any extra space at the start.

`justify`

The space is divided evenly in-between each child, with none of the extra space placed before the first child or after the last child. If there is only one child, treat the value as if it were `start`.

Notes

The edge of the box designated the *start* for packing purposes depends on the box's orientation and direction:

- For horizontal elements, the *start* is the top edge.
- For vertical elements, the *start* is the left edge.

	Normal	**Reverse**
Horizontal	left	right
Vertical	top	bottom

The edge opposite to the start is designated the *end*.

If the packing is set using the element's `pack` attribute, then the style is ignored.

Formal definition

Initial value	`start`
Applies to	elements with a CSS `display` value of `-moz-box`, `-moz-inline-box`, `-webkit-box` or `-webkit-inline-box`
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
box-pack =
  start    |
  center   |
  end      |
  justify
```

Examples

Examples of box-pack

```
div.example {
  border-style: solid;

  display: -moz-box; /* Mozilla */
  display: -webkit-box; /* WebKit */

  /* Make this box taller than the children,
     so there is room for the box-pack */
  height: 300px;
  /* Make this box wide enough to show the contents
     are centered horizontally */
  width: 300px;

  /* Children should be oriented vertically */
  -moz-box-orient: vertical; /* Mozilla */
  -webkit-box-orient: vertical; /* WebKit */

  /* Align children to the horizontal center of this box */
  -moz-box-align: center; /* Mozilla */
  -webkit-box-align: center; /* WebKit */

  /* Pack children to the bottom of this box */
  -moz-box-pack: end; /* Mozilla */
  -webkit-box-pack: end; /* WebKit */
}

div.example p {
  /* Make children narrower than their parent,
     so there is room for the box-align */
  width: 200px;
}
```

```
<div class="example">
  <p>I will be second from the bottom of div.example, centered horizontally.</p>
  <p>I will be on the bottom of div.example, centered horizontally.</p>
</div>
```

Specifications

Not part of any standard.

box-shadow CSS property

The **`box-shadow`** CSS property adds shadow effects around an element's frame. You can set multiple effects separated by commas. A box shadow is described by X and Y offsets relative to the element, blur and spread radius, and color.

Try it

```
box-shadow: 10px 5px 5px red;
```

```
box-shadow: 60px -16px teal;
```

```
box-shadow: 12px 12px 2px 1px rgb(0 0 255 / 0.2);
```

```
box-shadow: inset 5em 1em gold;
```

```
box-shadow:
  3px 3px red,
  -1em 0 0.4em olive;
```

```
<section id="default-example">
  <div class="transition-all" id="example-element">
    <p>This is a box with a box-shadow around it.</p>
  </div>
</section>
```

```
#example-element {
  margin: 20px auto;
  padding: 0;
  border: 2px solid #333333;
  width: 80%;
  text-align: center;
}
```

Syntax

```
/* Keyword value */
box-shadow: none;

/* A color and two length values */
box-shadow: red 60px -16px;

/* Three length values and a color */
box-shadow: 10px 5px 5px black;

/* Four length values and a color */
box-shadow: 2px 2px 2px 1px rgb(0 0 0 / 20%);

/* inset, length values, and a color */
box-shadow: inset 5em 1em gold;

/* Multiple shadows, separated by commas */
box-shadow:
  3px 3px red inset,
  -1em 0 0.4em olive;

/* Global values */
box-shadow: inherit;
box-shadow: initial;
box-shadow: revert;
box-shadow: revert-layer;
box-shadow: unset;
```

Specify a single box-shadow using:

- Two, three, or four `<length>` values.
    - If only two values are given, they are interpreted as `<offset-x>` and `<offset-y>` values.
    - If a third value is given, it is interpreted as a `<blur-radius>`.
    - If a fourth value is given, it is interpreted as a `<spread-radius>`.
- Optionally, the `inset` keyword.
- Optionally, a `<color>` value.

To specify multiple shadows, provide a comma-separated list of shadows.

Values

`<color>` Optional

Specifies color for the shadow. See `<color>` values for possible keywords and notations. If not specified, the value of the `color` property defined in the parent element is used.

`<length>`

Specifies the offset length of the shadow. This parameter accepts two, three, or four values. Third and fourth values are optional. They are interpreted as follows:

- If two values are specified, they are interpreted as `<offset-x>` (horizontal offset) and `<offset-y>` (vertical offset) values. Negative `<offset-x>` value places the shadow to the left of the element. Negative `<offset-y>` value places the shadow above the element.
  If not specified, the value of `0` is used for the missing length. If both `<offset-x>` and `<offset-y>` are set to `0`, the shadow is placed behind the element (and may generate a blur effect if `<blur-radius>` and/or `<spread-radius>` is set).
- If three values are specified, the third value is interpreted as `<blur-radius>`. The larger this value, the bigger the blur, so the shadow becomes bigger and lighter. Negative values are not allowed. If not specified, it will be set to `0` (meaning that the shadow's edge will be sharp). The specification does not include an exact algorithm for how the blur radius should be calculated; however, it does elaborate as follows:

  > ...for a long, straight shadow edge, this should create a color transition the length of the blur distance that is perpendicular to and centered on the shadow's edge, and that ranges from the full shadow color at the radius endpoint inside the shadow to fully transparent at the endpoint outside it.
- If four values are specified, the fourth value is interpreted as `<spread-radius>`. Positive values will cause the shadow to expand and grow bigger, negative values will cause the shadow to shrink. If not specified, it will be set to `0` (that is, the shadow will be the same size as the element).

`inset` Optional

Changes the shadow from an outer box-shadow to an inner box-shadow (as if the content is pressed into the box). Inset shadows are clipped to the element's padding box and appear above the background but below the content. By default, the shadow behaves like a drop shadow, giving the appearance that the box is elevated above its content. This is the default behavior when `inset` is not specified.

Interpolation

When animating shadows, such as when multiple shadow values on a box transition to new values on hover, the values are interpolated. Interpolation determines intermediate values of properties, such as the blur radius, spread radius, and color, as shadows transition. For each shadow in a list of shadows, the color, x, y, blur, and spread transition; the color as `<color>`, and the other values as `<length>`s.

In interpolating multiple shadows between two comma-separated lists of multiple box shadows, the shadows are paired, in order, with interpolation occurring between paired shadows. If the lists of shadows have different lengths, then the shorter list is padded at the end with shadows whose color is `transparent`, and X, Y, and blur are `0`, with the inset, or lack of inset, being set to match. If in any pair of shadows, one

has `inset` set and the other does not, the entire shadow list is uninterpolated; the shadows will change to the new values without an animating effect.

Description

The `box-shadow` property enables you to cast a drop shadow from the frame of almost any element. If a `border-radius` is specified on the element with a box shadow, the box shadow takes on the same rounded corners. The z-ordering of multiple box shadows is the same as multiple text shadows (the first specified shadow is on top).

Box-shadow generator is an interactive tool allowing you to generate a `box-shadow`.

Formal definition

Initial value	none
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	any length made absolute; any specified color computed; otherwise as specified
Animation type	a shadow list

Formal syntax

```
box-shadow =
  <spread-shadow>#

<spread-shadow> =
  <'box-shadow-color'>?                              &&
  [ [ none | <length>{2} ] [ <'box-shadow-blur'> <'box-shadow-spread'>? ]? ]  &&
  <'box-shadow-position'>?

<box-shadow-color> =
  <color>#

<box-shadow-blur> =
  <length [0,∞]>#

<box-shadow-spread> =
  <length>#

<box-shadow-position> =
  [ outset | inset ]#
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting three shadows

In this example, we include three shadows: an inset shadow, a regular drop shadow, and a 2px shadow that creates a border effect (we could have used an `outline` instead for that third shadow).

HTML

```
<blockquote>
  <q>
    You may shoot me with your words,<br />
    You may cut me with your eyes,<br />
    You may kill me with your hatefulness,<br />
    But still, like air, I'll rise.
  </q>
  <p>&mdash; Maya Angelou</p>
</blockquote>
```

CSS

```
blockquote {
  padding: 20px;
  box-shadow:
    inset 0 -3em 3em rgb(0 200 0 / 30%),
    0 0 0 2px white,
    0.3em 0.3em 1em rgb(200 0 0 / 60%);
}
```

Result

Setting zero for offset and blur

When the `x-offset`, `y-offset`, and `blur` are all zero, the box shadow will be a solid-colored outline of equal-size on all sides. The shadows are drawn back to front, so the first shadow sits on top of subsequent shadows. When the `border-radius` is set to 0, as is the default, the corners of the shadow will be, well, corners. Had we put in a `border-radius` of any other value, the corners would have been rounded.

We added a margin the size of the widest box-shadow to ensure the shadow doesn't overlap adjacent elements or go beyond the border of the containing box. A box-shadow does not impact box model dimensions.

HTML

```
<div><p>Hello World</p></div>
```

CSS

```
p {
  box-shadow:
    0 0 0 2em #f4aab9,
    0 0 0 4em #66ccff;
  margin: 4em;
  padding: 1em;
}
```

box-sizing CSS property

The **`box-sizing`** CSS property sets how the total width and height of an element is calculated.

Try it

```
box-sizing: content-box;
width: 100%;
```

```
box-sizing: content-box;
width: 100%;
border: solid #5b6dcd 10px;
padding: 5px;
```

```
box-sizing: border-box;
width: 100%;
border: solid #5b6dcd 10px;
padding: 5px;
```

```
<section id="default-example">
  <div id="example-element-parent">
    <p>Parent container</p>
    <div class="transition-all" id="example-element">
      <p>Child container</p>
    </div>
  </div>
</section>
```

```
#example-element-parent {
  width: 220px;
  height: 200px;
  border: solid 10px #ffc129;
  margin: 0.8em;
}

#example-element {
  height: 60px;
  margin: 2em auto;
  background-color: rgb(81 81 81 / 0.6);
}

#example-element > p {
  margin: 0;
}
```

Syntax

```
box-sizing: border-box;
box-sizing: content-box;

/* Global values */
box-sizing: inherit;
box-sizing: initial;
box-sizing: revert;
box-sizing: revert-layer;
box-sizing: unset;
```

Values

This property is specified as one of the following keyword values:

`content-box`

> This is the initial and default value as specified by the CSS standard. The `width` and `height` properties include the content, but does not include the padding, border, or margin. For example, `.box {width: 350px; border: 10px solid black;}` renders a box that is 370px wide.
>
> Here, the dimensions of the element are calculated as: *width = width of the content*, and *height = height of the content*. (Borders and padding are not included in the calculation.)

`border-box`

> The `width` and `height` properties include the content, padding, and border, but do not include the margin. Note that padding and border will be inside of the box. For example, `.box {width: 350px; border: 10px solid black;}` renders a box that is 350px wide, with the area for content being 330px wide. The content box can't be negative and is floored to 0, making it impossible to use `border-box` to make the element disappear.
>
> Here the dimensions of the element are calculated as: *width = border + padding + width of the content*, and *height = border + padding + height of the content*.

Description

By default in the CSS box model, the `width` and `height` you assign to an element is applied only to the element's content box. If the element has any border or padding, this is then added to the `width` and `height` to arrive at the size of the box that's rendered on the screen. This means that when you set `width` and `height`, you have to adjust the value you give to allow for any border or padding that may be added. For example, if you have four boxes with `width: 25%;`, if any has left or right padding or a left or right border, they will not by default fit on one line within the constraints of the parent container.

The `box-sizing` property can be used to adjust this behavior:

- `content-box` gives you the default CSS box-sizing behavior. If you set an element's width to 100 pixels, then the element's content box will be 100 pixels wide, and the width of any border or padding will be added to the final rendered width, making the element wider than 100px.
- `border-box` tells the browser to account for any border and padding in the values you specify for an element's width and height. If you set an element's width to 100 pixels, that 100 pixels will include any border or padding you added, and the content box will shrink to absorb that extra width. This typically makes it much easier to size elements.

  `box-sizing: border-box` is the default styling that browsers use for the `<table>`, `<select>`, and `<button>` elements, and for `<input>` elements whose type is `radio`, `checkbox`, `reset`, `button`, `submit`, `color`, or `search`.

> **Note:** It is often useful to set `box-sizing` to `border-box` to lay out elements. This makes dealing with the sizes of elements much easier, and generally eliminates a number of pitfalls you can stumble on while laying out your content. On the other hand, when using `position: relative` or `position: absolute`, use of `box-sizing: content-box` allows the positioning values to be relative to the content, and independent of changes to border and padding sizes, which is sometimes desirable.

Formal definition

Initial value	`content-box`
Applies to	all elements that accept width or height
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
box-sizing =
  content-box  |
  border-box
```

This syntax reflects the latest standard as per CSS Box Sizing Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Box sizes with content-box and border-box

This example shows how different `box-sizing` values alter the rendered size of two otherwise identical elements.

HTML

```
<div class="content-box">Content box</div>
<br />
<div class="border-box">Border box</div>
```

CSS

```
div {
  width: 160px;
  height: 80px;
  padding: 20px;
  border: 8px solid red;
  background: yellow;
}

.content-box {
  box-sizing: content-box;
  /* Total width: 160px + (2 * 20px) + (2 * 8px) = 216px
     Total height: 80px + (2 * 20px) + (2 * 8px) = 136px
     Content box width: 160px
     Content box height: 80px */
}

.border-box {
  box-sizing: border-box;
  /* Total width: 160px
     Total height: 80px
     Content box width: 160px - (2 * 20px) - (2 * 8px) = 104px
     Content box height: 80px - (2 * 20px) - (2 * 8px) = 24px */
}
```

Result

break-after CSS property

The **`break-after`** CSS property sets how page, column, or region breaks should behave after a generated box. If there is no generated box, the property is ignored.

Try it

```
break-after: auto;
```

```
break-after: page;
```

```
<div>
  <p>
    The effect of this property can be noticed when the document is being
    printed or a preview of a print is displayed.
  </p>
  <button id="print-btn">Show Print Preview</button>
  <div class="box-container">
    <div class="box">Content before the property</div>
    <div class="box" id="example-element">Content with 'break-after'</div>
    <div class="box">Content after the property</div>
  </div>
</div>
```

```
.box {
  border: solid #5b6dcd 5px;
  background-color: #5b6dcd;
  margin: 10px 0;
  padding: 5px;
}

#example-element {
```

```
  border: solid 5px #ffc129;
  background-color: #ffc129;
  color: black;
}
```

```
const btn = document.getElementById("print-btn");

btn.addEventListener("click", () => {
  window.print();
});
```

Syntax

```
/* Generic break values */
break-after: auto;
break-after: avoid;
break-after: always;
break-after: all;

/* Page break values */
break-after: avoid-page;
break-after: page;
break-after: left;
break-after: right;
break-after: recto;
break-after: verso;

/* Column break values */
break-after: avoid-column;
break-after: column;

/* Region break values */
break-after: avoid-region;
break-after: region;

/* Global values */
break-after: inherit;
break-after: initial;
break-after: revert;
break-after: revert-layer;
break-after: unset;
```

Each possible break point (in other words, each element boundary) is affected by three properties: the `break-after` value of the previous element, the `break-before` value of the next element, and the `break-inside` value of the containing element.

To determine if a break must be done, the following rules are applied:

1. If any of the three concerned values is a *forced break value* (`always`, `left`, `right`, `page`, `column`, or `region`), it has precedence. If more than one of them are such a break, the one of the element that appears the latest in the flow is taken (i.e., the `break-before` value has precedence over the `break-after` value, which itself has precedence over the `break-inside` value).
2. If any of the three concerned values is an *avoid break value* (`avoid`, `avoid-page`, `avoid-region`, or `avoid-column`), no such break will be applied at that point.

Once forced breaks have been applied, soft breaks may be added if needed, but not on element boundaries that resolve in a corresponding `avoid` value.

Values

Generic break values

`auto`

Allows, but does not force, any break (page, column, or region) to be inserted right after the principal box.

`avoid`

Avoids any break (page, column, or region) from being inserted right after the principal box.

`always`

Forces a page break right after the principal box. The type of this break is that of the immediately-containing fragmentation context. If we are inside a multicol container then it would force a column break, inside paged media (but not inside a multicol container) a page break.

`all`

Forces a page break right after the principal box. Breaking through all possible fragmentation contexts. So a break inside a multicol container, which was inside a page container would force a column and page break.

Page break values

`avoid-page`

Avoids any page break right after the principal box.

`page`

Forces a page break right after the principal box.

`left`

Forces one or two page breaks right after the principal box, whichever will make the next page into a left page. It's the page placed on the left side of the spine of the book or the back side of the page in duplex printing.

`right`

Forces one or two page breaks right after the principal box, whichever will make the next page into a right page. It's the page placed on the right side of the spine of the book or the front side of the page in duplex printing.

`recto`

Forces one or two page breaks right after the principal box, whichever will make the next page into a recto page. (A recto page is a right page in a left-to-right spread or a left page in a right-to-left spread.)

`verso`

Forces one or two page breaks right after the principal box, whichever will make the next page into a verso page. (A verso page is a left page in a left-to-right spread or a right page in a right-to-left spread.)

Column break values

`avoid-column`

Avoids any column break right after the principal box.

`column`

Forces a column break right after the principal box.

Region break values

`avoid-region`

Avoids any region break right after the principal box.

`region`

Forces a region break right after the principal box.

Page break aliases

For compatibility reasons, the legacy `page-break-after` property should be treated by browsers as an alias of `break-after`. This ensures that sites using `page-break-after` continue to work as designed. A subset of values should be aliased as follows:

page-break-after	break-after
`auto`	`auto`
`left`	`left`
`right`	`right`
`avoid`	`avoid`
`always`	`page`

> **Note:** The `always` value of `page-break-*` was implemented by browsers as a page break, and not as a column break. Therefore the aliasing is to `page`, rather than the `always` value in the Level 4 spec.

Formal definition

Initial value	`auto`
Applies to	block-level elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
break-after =
  auto          |
  avoid         |
  always        |
  all           |
  avoid-page    |
  page          |
  left          |
  right         |
  recto         |
  verso         |
  avoid-column  |
  column        |
  avoid-region  |
  region
```

This syntax reflects the latest standard as per CSS Fragmentation Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Breaking into neat columns

In the following example we have a container that contains an `<h1>` spanning all columns (achieved using `column-span: all`) and a series of `<h2>`s and paragraphs laid out in multiple columns using `column-width: 200px`.

By default, the subheadings and paragraphs were laid out rather messily because the headings were not in a uniform place. However, we used `break-after: column` on the `<p>` elements to force a column break after each one, meaning that you end up with an `<h2>` neatly at the top of each column.

HTML

```
<article>
  <h1>Main heading</h1>

  <h2>Subheading</h2>

  <p>
    Lorem ipsum dolor sit amet, consectetur adipiscing elit. Nulla vitae
    fringilla mauris. Quisque commodo eget nisi sed pretium. Mauris luctus nec
    lacus in ultricies. Mauris vitae hendrerit arcu, ac scelerisque lacus.
    Aliquam lobortis in lacus sit amet posuere. Fusce iaculis urna id neque
    dapibus, eu lacinia lectus dictum.
  </p>

  <h2>Subheading</h2>

  <p>
    Praesent condimentum dui dui, sit amet rutrum diam tincidunt eu. Cras
    suscipit porta leo sit amet rutrum. Sed vehicula ornare tincidunt. Curabitur
    a ipsum ac diam mattis volutpat ac ut elit. Nullam luctus justo non
    vestibulum gravida. Morbi metus libero, pharetra non porttitor a, molestie
```

```
    nec nisi.
  </p>

  <h2>Subheading</h2>

  <p>
    Vivamus eleifend metus vitae neque placerat, eget interdum elit mattis.
    Donec eu vulputate nibh. Ut turpis leo, malesuada quis nisl nec, volutpat
    egestas tellus.
  </p>

  <h2>Subheading</h2>

  <p>
    In finibus viverra enim vel suscipit. Quisque consequat velit eu orci
    malesuada, ut interdum tortor molestie. Proin sed pellentesque augue. Nam
    risus justo, faucibus non porta a, congue vel massa. Cras luctus lacus nisl,
    sed tincidunt velit pharetra ac. Duis suscipit faucibus dui sed ultricies.
  </p>
</article>
```

CSS

```
html {
  font-family: "Helvetica", "Arial", sans-serif;
}

h1 {
  font-size: 3rem;
  letter-spacing: 2px;
  column-span: all;
}

h2 {
  font-size: 1.2rem;
  color: red;
  letter-spacing: 1px;
}

p {
  line-height: 1.5;
  break-after: column;
}

article {
  column-width: 200px;
  gap: 20px;
}
```

break-before CSS property

The **`break-before`** CSS property sets how page, column, or region breaks should behave before a generated box. If there is no generated box, the property is ignored.

Try it

```
break-before: auto;
```

```
break-before: page;
```

```
<div>
  <p>
    The effect of this property can be noticed when the document is being
    printed or a preview of a print is displayed.
  </p>
  <button id="print-btn">Show Print Preview</button>
  <div class="box-container">
    <div class="box">Content before the property</div>
    <div class="box" id="example-element">Content with 'break-before'</div>
    <div class="box">Content after the property</div>
  </div>
</div>
```

```
.box {
  border: solid #5b6dcd 5px;
  background-color: #5b6dcd;
  margin: 10px 0;
  padding: 5px;
}

#example-element {
  border: solid 5px #ffc129;
  background-color: #ffc129;
  color: black;
}
```

```
const btn = document.getElementById("print-btn");

btn.addEventListener("click", () => {
  window.print();
});
```

Syntax

```
/* Generic break values */
break-before: auto;
break-before: avoid;
break-before: always;
break-before: all;

/* Page break values */
break-before: avoid-page;
break-before: page;
break-before: left;
break-before: right;
break-before: recto;
break-before: verso;

/* Column break values */
break-before: avoid-column;
break-before: column;

/* Region break values */
break-before: avoid-region;
break-before: region;

/* Global values */
break-before: inherit;
break-before: initial;
break-before: revert;
break-before: revert-layer;
break-before: unset;
```

Each possible break point (in other words, each element boundary) is affected by three properties: the `break-after` value of the previous element, the `break-before` value of the next element, and the `break-inside` value of the containing element.

To determine if a break must be done, the following rules are applied:

1. If any of the three concerned values is a *forced break value* (`always`, `left`, `right`, `page`, `column`, or `region`), it has precedence. If more than one of them are such a break, the one of the element that appears the latest in the flow is taken (i.e., the `break-before` value has precedence over the `break-after` value, which itself has precedence over the `break-inside` value).
2. If any of the three concerned values is an *avoid break value* (`avoid`, `avoid-page`, `avoid-region`, or `avoid-column`), no such break will be applied at that point.

Once forced breaks have been applied, soft breaks may be added if needed, but not on element boundaries that resolve in a corresponding `avoid` value.

Values

Generic break values

`auto`

Allows, but does not force, any break (page, column, or region) to be inserted right before the principal box.

`avoid`

Avoids any break (page, column, or region) from being inserted right before the principal box.

`always`

Forces a page break right before the principal box. The type of this break is that of the immediately-containing fragmentation context. If we are inside a multicol container then it would force a column break, inside paged media (but not inside a multicol container) a page break.

`all`

Forces a page break right before the principal box. Breaking through all possible fragmentation contexts. So a break inside a multicol container, which was inside a page container would force a column and page break.

Page break values

`avoid-page`

Avoids any page break right before the principal box.

`page`

Forces a page break right before the principal box.

`left`

Forces one or two page breaks right before the principal box, whichever will make the next page into a left page. It's the page placed on the left side of the spine of the book or the back side of the page in duplex printing.

`right`

Forces one or two page breaks right before the principal box, whichever will make the next page into a right page. It's the page placed on the right side of the spine of the book or the front side of the page in duplex printing.

`recto`

Forces one or two page breaks right before the principal box, whichever will make the next page into a recto page. (A recto page is a right page in a left-to-right spread or a left page in a right-to-left spread.)

`verso`

Forces one or two page breaks right before the principal box, whichever will make the next page into a verso page. (A verso page is a left page in a left-to-right spread or a right page in a right-to-left spread.)

Column break values

`avoid-column`

Avoids any column break right before the principal box.

`column`

Forces a column break right before the principal box.

Region break values

`avoid-region`

Avoids any region break right before the principal box.

`region`

Forces a region break right before the principal box.

Page break aliases

For compatibility reasons, the legacy `page-break-before` property should be treated by browsers as an alias of `break-before`. This ensures that sites using `page-break-before` continue to work as designed. A subset of values should be aliased as follows:

page-break-before	break-before
`auto`	`auto`
`left`	`left`
`right`	`right`
`avoid`	`avoid`
`always`	`page`

> **Note:** The `always` value of `page-break-*` was implemented by browsers as a page break, and not as a column break. Therefore the aliasing is to `page`, rather than the `always` value in the Level 4 spec.

Formal definition

Initial value	`auto`
Applies to	block-level elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
break-before =
  auto          |
  avoid         |
  always        |
  all           |
  avoid-page    |
  page          |
  left          |
  right         |
  recto         |
  verso         |
  avoid-column  |
  column        |
  avoid-region  |
  region
```

This syntax reflects the latest standard as per CSS Fragmentation Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Breaking into neat columns

In the following example we have a container that contains an `<h1>` spanning all columns (achieved using `column-span: all`) and a series of `<h2>`s and paragraphs laid out in multiple columns using `column-width: 200px`.

By default, the subheadings and paragraphs were laid out rather messily because the headings were not in a uniform place. However, we used `break-before: column` on the `<h2>` elements to force a column break before each one, meaning that you end up with an `<h2>` neatly at the top of each column.

HTML

```
<article>
  <h1>Main heading</h1>

  <h2>Subheading</h2>

  <p>
    Lorem ipsum dolor sit amet, consectetur adipiscing elit. Nulla vitae
    fringilla mauris. Quisque commodo eget nisi sed pretium. Mauris luctus nec
    lacus in ultricies. Mauris vitae hendrerit arcu, ac scelerisque lacus.
    Aliquam lobortis in lacus sit amet posuere. Fusce iaculis urna id neque
    dapibus, eu lacinia lectus dictum.
  </p>

  <h2>Subheading</h2>

  <p>
    Praesent condimentum dui dui, sit amet rutrum diam tincidunt eu. Cras
    suscipit porta leo sit amet rutrum. Sed vehicula ornare tincidunt. Curabitur
    a ipsum ac diam mattis volutpat ac ut elit. Nullam luctus justo non
    vestibulum gravida. Morbi metus libero, pharetra non porttitor a, molestie
    nec nisi.
  </p>

  <h2>Subheading</h2>

  <p>
    Vivamus eleifend metus vitae neque placerat, eget interdum elit mattis.
    Donec eu vulputate nibh. Ut turpis leo, malesuada quis nisl nec, volutpat
```

```
    egestas tellus.
  </p>

  <h2>Subheading</h2>

  <p>
    In finibus viverra enim vel suscipit. Quisque consequat velit eu orci
    malesuada, ut interdum tortor molestie. Proin sed pellentesque augue. Nam
    risus justo, faucibus non porta a, congue vel massa. Cras luctus lacus nisl,
    sed tincidunt velit pharetra ac. Duis suscipit faucibus dui sed ultricies.
  </p>
</article>
```

CSS

```
html {
  font-family: "Helvetica", "Arial", sans-serif;
}

h1 {
  font-size: 3rem;
  letter-spacing: 2px;
  column-span: all;
}

h2 {
  font-size: 1.2rem;
  color: red;
  letter-spacing: 1px;
  break-before: column;
}

p {
  line-height: 1.5;
}

article {
  column-width: 200px;
  gap: 20px;
}
```

break-inside CSS property

The **`break-inside`** CSS property sets how page, column, or region breaks should behave inside a generated box. If there is no generated box, the property is ignored.

Try it

```
break-inside: auto;
```

```
break-inside: avoid;
```

```
<div>
  <p>
    The effect of this property can be noticed when the document is being
    printed or a preview of a print is displayed.
  </p>
  <button id="print-btn">Show Print Preview</button>
  <div class="box-container">
    <div class="box">Content before the property</div>
    <div class="box" id="example-element">Content with 'break-inside'</div>
    <div class="box">Content after the property</div>
  </div>
</div>
```

```
.box {
  border: solid #5b6dcd 5px;
  background-color: #5b6dcd;
  margin: 10px 0;
  padding: 5px;
}

#example-element {
  border: solid 5px #ffc129;
  background-color: #ffc129;
  color: black;
}

@media print {
  #example-element {
    height: 25cm;
  }
}
```

```
const btn = document.getElementById("print-btn");

btn.addEventListener("click", () => {
  window.print();
});
```

Syntax

```
/* Keyword values */
break-inside: auto;
break-inside: avoid;
break-inside: avoid-page;
break-inside: avoid-column;
break-inside: avoid-region;

/* Global values */
break-inside: inherit;
break-inside: initial;
break-inside: revert;
break-inside: revert-layer;
break-inside: unset;
```

Each possible break point (in other words, each element boundary) is affected by three properties: the `break-after` value of the previous element, the `break-before` value of the next element, and the `break-inside` value of the containing element.

To determine if a break must be done, the following rules are applied:

1. If any of the three concerned values is a *forced break value* (`always`, `left`, `right`, `page`, `column`, or `region`), it has precedence. If more than one of them are such a break, the value of the element that appears the latest in the flow is used. Thus, the `break-before` value has precedence over the `break-after` value, which in turn has precedence over the `break-inside` value.
2. If any of the three concerned values is an *avoid break value* (`avoid`, `avoid-page`, `avoid-region`, or `avoid-column`), no such break will be applied at that point.

Once forced breaks have been applied, soft breaks may be added if needed, but not on element boundaries that resolve in a corresponding `avoid` value.

Values

`auto`

Allows, but does not force, any break (page, column, or region) to be inserted within the principal box.

`avoid`

Avoids any break (page, column, or region) from being inserted within the principal box.

`avoid-page`

Avoids any page break within the principal box.

`avoid-column`

Avoids any column break within the principal box.

`avoid-region`

Avoids any region break within the principal box.

Page break aliases

For compatibility reasons, the legacy `page-break-inside` property should be treated by browsers as an alias of `break-inside`. This ensures that sites using `page-break-inside` continue to work as designed. A subset of values should be aliased as follows:

page-break-inside	break-inside
`auto`	`auto`
`avoid`	`avoid`

Formal definition

Initial value	`auto`
Applies to	block-level elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
break-inside =
  auto          |
  avoid         |
  avoid-page    |
  avoid-column  |
  avoid-region
```

This syntax reflects the latest standard as per CSS Fragmentation Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Avoiding breaking inside a figure

In the following example we have a container that contains an `<h1>` spanning all columns (achieved using `column-span: all`) and a series of paragraphs laid out in multiple columns using `column-width: 200px`. We also have a `<figure>` containing an image and a caption.

By default, it is possible for you to get a break between the image and its caption, which is not what we want. To avoid this, we have set `break-inside: avoid` on the `<figure>`, which causes them to always stay together.

HTML

```
<article>
  <h1>Main heading</h1>

  <p>
    Lorem ipsum dolor sit amet, consectetur adipiscing elit. Nulla vitae
    fringilla mauris. Quisque commodo eget nisi sed pretium. Mauris luctus nec
    lacus in ultricies. Mauris vitae hendrerit arcu, ac scelerisque lacus.
    Aliquam lobortis in lacus sit amet posuere. Fusce iaculis urna id neque
```

```
    dapibus, eu lacinia lectus dictum.
  </p>

  <figure>
    <img
      src="https://mdn.dev/archives/media/attachments/2020/07/29/17350/3b4892b7e820122ac6dd7678891d4507/firefox.png" />
    <figcaption>The Firefox logo — fox wrapped around the world</figcaption>
  </figure>

  <p>
    Praesent condimentum dui dui, sit amet rutrum diam tincidunt eu. Cras
    suscipit porta leo sit amet rutrum. Sed vehicula ornare tincidunt. Curabitur
    a ipsum ac diam mattis volutpat ac ut elit. Nullam luctus justo non
    vestibulum gravida. Morbi metus libero, pharetra non porttitor a, molestie
    nec nisi.
  </p>

  <p>
    In finibus viverra enim vel suscipit. Quisque consequat velit eu orci
    malesuada, ut interdum tortor molestie. Proin sed pellentesque augue. Nam
    risus justo, faucibus non porta a, congue vel massa. Cras luctus lacus nisl,
    sed tincidunt velit pharetra ac. Duis suscipit faucibus dui sed ultricies.
  </p>
</article>
```

CSS

```
html {
  font-family: "Helvetica", "Arial", sans-serif;
}

body {
  width: 80%;
  margin: 0 auto;
}

h1 {
  font-size: 3rem;
  letter-spacing: 2px;
  column-span: all;
}

h1 + p {
  margin-top: 0;
}

p {
  line-height: 1.5;
  break-after: column;
}

figure {
  break-inside: avoid;
}

img {
  max-width: 70%;
  display: block;
  margin: 0 auto;
}

figcaption {
  font-style: italic;
  font-size: 0.8rem;
  width: 70%;
}

article {
  column-width: 200px;
  gap: 20px;
}
```

caption-side CSS property

The **`caption-side`** CSS property puts the content of a table's `<caption>` on the specified side. The values are relative to the `writing-mode` of the table.

Try it

```
caption-side: top;
```

```
caption-side: bottom;
```

```
<section class="default-example" id="default-example">
  <table class="transition-all" id="example-element">
    <caption>
      Famous animals
    </caption>
    <tbody>
      <tr>
        <th>Name</th>
        <th>Location</th>
      </tr>
      <tr>
        <td>Giraffe</td>
```

```
        <td>Africa</td>
      </tr>
      <tr>
        <td>Penguin</td>
        <td>Antarctica</td>
      </tr>
      <tr>
        <td>Sloth</td>
        <td>South America</td>
      </tr>
      <tr>
        <td>Tiger</td>
        <td>Asia</td>
      </tr>
    </tbody>
  </table>
</section>
```

```
table {
  font-size: 1.2rem;
  text-align: left;
  color: black;
}

th,
td {
  padding: 0.2rem 1rem;
}

caption {
  background: #ffcc33;
  padding: 0.5rem 1rem;
}

tr {
  background: #eeeeee;
}

tr:nth-child(even) {
  background: #cccccc;
}
```

Syntax

```
/* Directional values */
caption-side: top;
caption-side: bottom;

/* Global values */
caption-side: inherit;
caption-side: initial;
caption-side: revert;
caption-side: revert-layer;
caption-side: unset;
```

Values

This property is specified as one of the following keyword values:

`top`

The caption box should be positioned at the block start side of the table.

`bottom`

The caption box should be positioned at the block end side of the table.

> **Note:** The CSS logical properties and values module defines two logical values, `inline-start` and `inline-end`, to position the caption box at the inline start edge and inline end edge of the table, respectively. These values are not supported in any browsers.

Formal definition

Initial value	`top`
Applies to	table-caption elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
caption-side =
  top    |
  bottom
```

This syntax reflects the latest standard as per CSS Table Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting captions above and below

HTML

```
<table class="top">
  <caption>
    Caption ABOVE the table
  </caption>
  <tbody>
```

```
    <tr>
      <td>Some data</td>
      <td>Some more data</td>
    </tr>
  </tbody>
</table>

<br />

<table class="bottom">
  <caption>
    Caption BELOW the table
  </caption>
  <tbody>
    <tr>
      <td>Some data</td>
      <td>Some more data</td>
    </tr>
  </tbody>
</table>
```

CSS

```
.top caption {
  caption-side: top;
}

.bottom caption {
  caption-side: bottom;
}

table {
  border: 1px solid red;
}

td {
  border: 1px solid blue;
}
```

caret CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`caret`** CSS shorthand property sets the appearance and behavior of the **insertion caret** in a single declaration.

Try it

```
caret: red;
```

```
caret: block manual;
```

```
caret: underscore auto green;
```

```
caret: bar manual orange;
```

```
<section class="default-example container" id="default-example">
  <div>
    <label for="example-element">Edit text field:</label>
    <input id="example-element" type="text" value="Sample text" />
  </div>
</section>
```

```
div {
  text-align: left;
}

#example-element {
  font-size: 1.2rem;
  padding: 8px;
  width: 300px;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `caret-color`
- `caret-animation`
- `caret-shape`

Syntax

```
/* Individual values */
caret: red; /* caret-color only */
caret: block; /* caret-shape only */
caret: manual; /* caret-animation only */

/* Two values */
```

```
caret: red manual; /* caret-color + caret-animation */
caret: block auto; /* caret-shape + caret-animation */
caret: underscore orange; /* caret-shape + caret-color */

/* Three values */
caret: bar manual red; /* caret-shape + caret-animation + caret-color */
caret: block auto #00ff00; /* caret-shape + caret-animation + caret-color */

/* Global values */
caret: inherit;
caret: initial;
caret: revert;
caret: revert-layer;
caret: unset;
```

The `caret` property is specified as one, two, or three values from the constituent properties. Values can be specified in any order, and omitted values are set to their initial values.

Values

`caret-color`

Sets the color of the caret.

`caret-animation`

Controls whether the caret blinks.

`caret-shape`

Sets the visual shape of the caret.

Description

The `caret` shorthand allows you to set multiple caret properties in a single declaration, making it convenient to customize the complete appearance and behavior of the insertion caret.

Value resolution

When values are omitted from the shorthand, they reset to their initial values:

- `caret-color`: `auto` (resolves to `currentColor`).
- `caret-animation`: `auto` (caret blinks).
- `caret-shape`: `auto` (browser-determined shape).

Order independence

Unlike some CSS shorthands, the `caret` property accepts values in any order. The browser determines which value applies to which property based on the value type:

- `<color>` values apply to `caret-color`.
- `auto`/`manual` keywords apply to `caret-animation`.
- Shape keywords (`bar`, `block`, `underscore`) apply to `caret-shape`.

Formal definition

Initial value	as each of the properties of the shorthand: • `caret-color`: `auto` • `caret-animation`: `auto` • `caret-shape`: `auto`
Applies to	Text or elements that accept text input
Inherited	yes
Computed value	as each of the properties of the shorthand: • `caret-color`: `auto` is computed as specified and `<color>` values are computed as defined for the `color` property. • `caret-animation`: as specified • `caret-shape`: as specified
Animation type	as each of the properties of the shorthand: • `caret-color`: a color • `caret-animation`: discrete • `caret-shape`: by computed value type

Formal syntax

```
caret =
  <'caret-color'>      ||
  <'caret-animation'>  ||
  <'caret-shape'>

<caret-color> =
  auto                        |
  <color> [ auto | <color> ]?

<caret-animation> =
  auto    |
  manual

<caret-shape> =
  auto        |
  bar         |
  block       |
  underscore
```

This syntax reflects the latest standard as per CSS Basic User Interface Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Retro terminal with animated caret

This example creates a vintage terminal interface using the `caret` shorthand to combine multiple caret properties, demonstrating how it replaces older border-based techniques.

The main advantage of the `caret` shorthand is combining multiple properties in one declaration. Here we set the shape to `block`, disable default blinking, and set the color to `green`, all in a single line.

HTML

```
<label for="terminal">Enter a command</label>
<div class="old-screen">
  <span>></span>
  <textarea id="terminal" class="terminal-input"></textarea>
</div>
```

CSS

```
label {
  background: #092104;
  display: block;
  padding: 10px 20px;
  color: #00ad00;
  font-weight: bold;
  font-family: monospace;
}

.old-screen {
  background: repeating-linear-gradient(
    #092104,
    #092104 2px,
    #123208 2px,
    #123208 4px
  );
  height: 140px;
  display: flex;
  align-items: flex-start;
  padding: 20px;
  font-family: monospace;
}

span {
  display: inline-block;
  padding: 2px 5px;
  color: #00ad00;
  font-weight: bold;
  margin-right: 8px;
}

.terminal-input {
  background: transparent;
  height: 100%;
  border: none;
  color: #00ad00;
  font-family: inherit;
  font-size: 1rem;
  outline: none;
  flex: 1;
  resize: none;
}
```

```
.terminal-input {
  caret: block manual green;
  animation: vintage-caret 2s infinite;
}

@keyframes vintage-caret {
  0%,
  50% {
    caret-color: #00ad00;
  }
  75%,
  100% {
    caret-color: transparent;
  }
}
```

caret-animation CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`caret-animation`** CSS property is used to enable or disable the blinking behavior of the **insertion caret**, the visible marker that appears in editable elements to indicate where the next character will be inserted or deleted.

The `caret-animation` property can also be set as part of the `caret` shorthand property.

> **Note:** When applying a custom animation to the caret, you should stop the default blinking so that it doesn't interfere with the animation.

Syntax

```
/* Keyword values */
caret-animation: auto;
caret-animation: manual;

/* Global values */
caret-animation: inherit;
caret-animation: initial;
caret-animation: revert;
caret-animation: revert-layer;
caret-animation: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

The caret blinks on and off. This is the default (initial) value.

`manual`

The caret does not blink on and off.

Formal definition

Initial value	`auto`
Applies to	Text or elements that accept text input
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
caret-animation =
  auto    |
  manual
```

This syntax reflects the latest standard as per CSS Basic User Interface Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic <code>caret-animation</code> usage

This example shows the difference between having `caret-animation` set to `auto` versus `manual` on an editable element.

HTML

The markup features two `<p>` elements with `contenteditable` set to make them editable.

```
<p contenteditable="true">
  My caret animates because <code>caret-animation</code> is set to
  <code>auto</code>.
</p>
<p contenteditable="true">
  My caret doesn't animate because <code>caret-animation</code> is set to
  <code>manual</code>.
</p>
```

CSS

The CSS sets the `caret-color` value to `red`. It then gives the first paragraph a `caret-animation` value of `auto` and the second paragraph a `caret-animation` value of `manual`.

```
p {
  caret-color: red;
}

p:first-of-type {
  caret-animation: auto;
}

p:last-of-type {
  caret-animation: manual;
}
```

Result

The rendered result looks like so:

Try focusing the two paragraphs to see the difference in caret behavior.

Creating a custom caret animation

In this example, a custom caret animation is applied to an editable paragraph and a text input.

HTML

The markup features a `<p>` element and two text `<input>` elements. The `<p>` element has the `contenteditable` attribute set on it to make it editable. The paragraph and first text input have a `class` of `custom-caret` set on them.

```
<p contenteditable="true" class="custom-caret">
  This paragraph has a custom animation applied to it, plus
  <code>caret-animation: manual</code> to stop the default caret blinking and
  allow the smooth animation to be seen.
</p>

<input
```

```
  type="text"
  class="custom-caret"
  value="I've got a custom caret animation" />

<input type="text" value="I've got the default blinking caret" />
```

CSS

We first define a set of `@keyframes` that change the `caret-color` from `transparent` to `darkblue`.

```
@keyframes custom-caret-animation {
  from {
    caret-color: transparent;
  }

  to {
    caret-color: darkblue;
  }
}
```

We then style the `<p>` and the first `<input>` with the custom `@keyframes` animation, a `caret-color`, and a `caret-animation` value of `manual` to turn the default caret blinking behavior off.

```
body {
  display: flex;
  flex-direction: column;
}

input {
  margin-bottom: 20px;
}
```

```
.custom-caret {
  animation: custom-caret-animation infinite linear alternate 0.75s;
  caret-color: darkblue;
  caret-animation: manual;
}

p,
input {
  font-size: 1.6rem;
}
```

Result

The rendered result looks like so:

Try focusing the first two elements to see what the custom caret animation looks like. To compare it with the default blinking caret, you can focus the third element.

caret-color CSS property

The **`caret-color`** CSS property sets the color of the **insertion caret**, sometimes referred to as the **text input cursor**. This is the visible marker appearing at the insertion point where the next character typed will be added or where the next character deleted will be removed.

The `caret-color` property can also be set as part of the `caret` shorthand property.

Try it

```
caret-color: red;
```

```
caret-color: auto;
```

```
caret-color: transparent;
```

```
<section class="default-example container" id="default-example">
  <div>
    <p>Enter text in the field to see the caret:</p>
    <p><input id="example-element" type="text" /></p>
  </div>
</section>
```

```
#example-element {
  font-size: 1.2rem;
}
```

Syntax

```
/* Keyword values */
caret-color: auto;
caret-color: transparent;
caret-color: currentColor;

/* <color> values */
caret-color: red;
caret-color: #5729e9;
caret-color: rgb(0 200 0);
caret-color: hsl(228deg 4% 24% / 80%);

/* Global values */
caret-color: inherit;
caret-color: initial;
caret-color: revert;
```

```
caret-color: revert-layer;
caret-color: unset;
```

Values

This property is specified as a single value from the following list:

`auto`

Generally resolves to `currentColor`, the `color` of the text that will be modified.

`<color>`

The color of the caret.

Description

An insertion caret is a visible indicator of the spot within editable text — or within an element that accepts text input — where content will be inserted (or deleted) by the user. The caret is typically a thin vertical line indicating where the addition or deletion of characters will occur. It generally blinks (flashes on and off), so it is more noticeable. The caret only appears when the editable element has focus. By default, this caret is the color of the text. The `caret-color` property can be used to set the color of this caret to something other than the `currentColor`, or to reset a colored caret back to its default.

The `auto` value sets the insertion caret to `currentColor`, which is the `color` of the text that is being added or deleted. User agents may choose a different color to ensure good visibility and contrast with the surrounding content, taking into account the `color`, `background-color`, shadows, and other factors. In practice, however, all browsers use the current color by default, and when `caret-color` is set to `auto`. You can set any valid `<color>` as the value.

Understanding insertion carets

The insertion caret, and therefore this property, only applies to text or elements that can accept text input. The caret appears in focused user interface elements where users can update content, such as `<input>` elements that accept freeform text, the `<textarea>` element, and elements with the `contenteditable` attribute set.

The caret may appear in `<input>` elements of type `password`, `text`, `search`, `tel`, and `email`. No caret exists with date, `color`, `hidden`, `radio`, or `checkbox` input types. Some browsers display a caret with the `number` input type. It is possible in some browsers to make a caret appear in elements that never have text content — for example, by setting `appearance: none` and adding the `contenteditable` attribute. However, this is not recommended.

A caret may be displayed in an editable element or its descendants, provided the editability is not disabled, for example by setting a descendant element's `contentEditable` attribute to `false`. If an element is not editable or selectable, for example if `user-select` is set to `none`, the caret should not appear.

Caret versus cursor

There are multiple types of carets. The insertion caret is the only type affected by the `caret-color` property.

Many browsers have a **navigation caret**, which acts similarly to an insertion caret but can be moved around in non-editable text.

The mouse cursor image shown for certain `cursor` property values (for example, `auto` or `text`) may resemble a caret, but it's not. It's a cursor.

Animating from <code>auto</code>

Generally, when the `caret-color` is set to or defaults to `auto`, user agents use `currentColor`, which is animatable. However, `auto` is not an animatable value by default: when animating or transitioning the `caret-color` from `auto` to any color value, no interpolation happens. The animation is discrete; the color switches from or to the `currentColor` color at the midpoint of the `animation-duration` or `transition-duration`.

Formal definition

Initial value	`auto`
Applies to	Text or elements that accept text input
Inherited	yes
Computed value	`auto` is computed as specified and `<color>` values are computed as defined for the `color` property.
Animation type	a color

Formal syntax

```
caret-color =
  auto                        |
  <color> [ auto | <color> ]?
```

This syntax reflects the latest standard as per CSS Basic User Interface Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting a custom caret color

HTML

```
<input value="This field uses a default caret." size="64" />
<input class="custom" value="I have a custom caret color!" size="64" />
<p contenteditable class="custom">
  This paragraph can be edited, and its caret has a custom color as well!
</p>
```

CSS

```
input {
  caret-color: auto;
  display: block;
  margin-bottom: 0.5em;
}

input.custom {
  caret-color: orange;
}

p.custom {
  caret-color: green;
}
```

caret-shape CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`caret-shape`** CSS property sets the shape of the **insertion caret**, the visible marker that appears in editable elements to indicate where the next character will be inserted or deleted.

The `caret-shape` property can also be set as part of the `caret` shorthand property.

Try it

```
caret-shape: auto;
```

```
caret-shape: bar;
```

```
caret-shape: block;
```

```
caret-shape: underscore;
```

```
<section class="default-example container" id="default-example">
  <div>
    <label for="example-element">Edit text field:</label>
    <input id="example-element" type="text" value="Sample text" />
  </div>
</section>
```

```
div {
  text-align: left;
}

#example-element {
  font-size: 1.2rem;
  padding: 8px;
  width: 300px;
}
```

Syntax

```
/* Keyword values */
caret-shape: auto;
caret-shape: bar;
caret-shape: block;
caret-shape: underscore;

/* Global values */
caret-shape: inherit;
caret-shape: initial;
caret-shape: revert;
caret-shape: revert-layer;
caret-shape: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

The default value. The browser determines the caret shape. This typically follows platform conventions and may change based on context.

`bar`

The caret appears as a thin vertical line at the insertion point, positioned between characters rather than over them.

`block`

The caret appears as a rectangle that overlaps the next character after the insertion point. If no character follows, it appears after the last character.

`underscore`

The caret appears as a thin horizontal line underneath the next character after the insertion point. If no character follows, it appears after the last character.

Description

The insertion caret is the blinking cursor that indicates where text will be inserted when typing. Different caret shapes can provide visual feedback about the current editing mode or offer visual customization.

Editing modes and caret shapes

Text editors typically operate in one of two modes:

- **Insert mode**: New characters are inserted at the caret position, pushing existing text to the end of the line. This is the default behavior in most modern applications.
- **Overtype mode** (also called "overwrite mode"): New characters replace existing characters at the caret position instead of being inserted between them. This mode is often toggled with the `Insert` key.

Different caret shapes have traditional uses, for example:

- **Bar carets** are positioned between characters and are most common in modern interfaces.
- **Block carets** overlay the next character and are often used in terminal applications or to indicate overtype mode.
- **Underscore carets** appear below characters and can be useful for certain design aesthetics, such as mimicking typewriter or underline text input styles.

Caret positioning and behavior

The `caret-shape` property affects how the caret is visually rendered but doesn't change its logical position in the text. The caret always represents the insertion point between characters, regardless of its visual shape.

Interaction with writing modes

The caret shape adapts to the `writing-mode` of the text. In vertical writing modes, bar carets become horizontal, and underscore carets position themselves appropriately relative to the text direction.

Formal definition

Initial value	`auto`
Applies to	Text or elements that accept text input
Inherited	yes
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
caret-shape =
  auto        |
  bar         |
  block       |
  underscore
```

This syntax reflects the latest standard as per CSS Basic User Interface Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Retro terminal with animated caret

This example shows how to create a vintage terminal interface using `caret-shape: block` with animated caret color, replacing the old technique of using borders.

The key part is using the modern caret properties instead of the old border-based technique. We set the caret to block shape, disable the default blinking, and create our own custom animation.

HTML

```
<label for="terminal">Enter a command</label>
<div class="old-screen">
  <span>></span>
  <textarea id="terminal" class="terminal-input"></textarea>
</div>
```

CSS

```
label {
  background: #092104;
  display: block;
  padding: 10px 20px;
  color: #00ad00;
  font-weight: bold;
  font-family: monospace;
}

.old-screen {
  background: repeating-linear-gradient(
    #092104,
    #092104 2px,
    #123208 2px,
    #123208 4px
  );
  height: 140px;
  display: flex;
  align-items: flex-start;
  padding: 20px;
  font-family: monospace;
}

span {
  display: inline-block;
  padding: 2px 5px;
  color: #00ad00;
  font-weight: bold;
  margin-right: 8px;
}

.terminal-input {
  background: transparent;
  height: 100%;
  border: none;
  color: #00ad00;
  font-family: inherit;
  font-size: 1rem;
  outline: none;
  flex: 1;
  resize: none;
}
```

```
.terminal-input {
  caret-shape: block;
  caret-animation: manual;
  animation: old-caret 2s infinite;
}

@keyframes old-caret {
```

```
  0%,
  50% {
    caret-color: #00ad00;
  }
  75%,
  100% {
    caret-color: transparent;
  }
}
```

Result

Console interface with underscore caret

This example demonstrates using `caret-shape: underscore` to create a console-style interface where the underscore caret complements the terminal aesthetic.

HTML

```
<label for="console">Enter a command</label>
<div class="console-demo">
  <div class="console-output">
    <p>user@host:css-ui-4 $ ls -a</p>
    <p>. .. Overview.bs Overview.html</p>
  </div>
  <div class="console-input">
    <span class="prompt">user@host:css-ui-4 $ </span>
    <input type="text" id="console" class="console" value="cd" />
  </div>
</div>
```

CSS

```
label {
  background: #2a2a2c;
  color: white;
  display: block;
  padding: 10px 20px;
  font-weight: bold;
  font-family: monospace;
}

.console-demo {
  background: black;
  color: white;
  font-family: monospace;
  padding: 10px 20px;
  height: 60px;
}

.console-output {
  margin-bottom: 0.5rem;
}

.console-output p {
  margin: 0 0.25rem;
}

.console-input {
  display: flex;
  align-items: center;
}

.prompt {
  margin-right: 0;
}

.console {
  background: transparent;
  border: none;
  color: white;
  padding-left: 1ch;
  font-family: inherit;
  outline: none;
  flex: 1;
}
```

```
.console {
  caret-shape: underscore;
}
```

clear CSS property

The **`clear`** CSS property sets whether an element must be moved below (cleared) floating elements that precede it. The `clear` property applies to floating and non-floating elements.

Try it

```
clear: none;
```

```
clear: left;
```

```
clear: right;
```

```
clear: both;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="floated-left">Left</div>
    <div class="floated-right">Right</div>
    <div class="transition-all" id="example-element">
      As much mud in the streets as if the waters had but newly retired from the
      face of the earth, and it would not be wonderful to meet a Megalosaurus,
      forty feet long or so, waddling like an elephantine lizard up Holborn
      Hill.
    </div>
  </div>
</section>
```

```
.example-container {
  border: 1px solid #c5c5c5;
  padding: 0.75em;
  text-align: left;
  line-height: normal;
}

.floated-left {
  border: solid 10px #ffc129;
  background-color: rgb(81 81 81 / 0.6);
  padding: 1em;
  float: left;
}

.floated-right {
  border: solid 10px #ffc129;
  background-color: rgb(81 81 81 / 0.6);
  padding: 1em;
  float: right;
  height: 150px;
}
```

Syntax

```
/* Keyword values */
clear: none;
clear: left;
clear: right;
clear: both;
clear: inline-start;
clear: inline-end;

/* Global values */
clear: inherit;
clear: initial;
clear: revert;
clear: revert-layer;
clear: unset;
```

Values

This property is specified as one of the following keyword values:

`none`

Is a keyword indicating that the element is *not* moved down to clear past floating elements.

`left`

Is a keyword indicating that the element is moved down to clear past *left* floats.

`right`

Is a keyword indicating that the element is moved down to clear past *right* floats.

`both`

Is a keyword indicating that the element is moved down to clear past *both* left and right floats.

`inline-start`

Is a keyword indicating that the element is moved down to clear floats on *start side of its containing block*, that is the *left* floats on ltr scripts and the *right* floats on rtl scripts.

`inline-end`

Is a keyword indicating that the element is moved down to clear floats on *end side of its containing block*, that is the *right* floats on ltr scripts and the *left* floats on rtl scripts.

Description

When applied to non-floating blocks, it moves the border edge of the element down until it is below the margin edge of all relevant floats. The non-floated block's top margin collapses.

Vertical margins between two floated elements on the other hand will not collapse. When applied to floating elements, the margin edge of the bottom element is moved below the margin edge of all relevant floats. This affects the position of later floats, since later floats cannot be positioned higher than earlier ones.

The floats that are relevant to be cleared are the earlier floats within the same block formatting context.

> **Note:** If an element contains only floated elements, its height collapses to nothing. If you want it to always be able to resize, so that it contains floating elements inside it, set the value of the element's `display` property to `flow-root`.
>
> ```
> #container {
>   display: flow-root;
> }
> ```

Formal definition

Initial value	none
Applies to	block-level elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
clear =
  inline-start  |
  inline-end    |
  block-start   |
  block-end     |
  left          |
  right         |
  top           |
  bottom        |
  both-inline   |
  both-block    |
  both          |
  none
```

This syntax reflects the latest standard as per CSS Page Floats. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

clear: left

HTML

```
<div class="wrapper">
  <p class="black">
    Lorem ipsum dolor sit amet, consectetuer adipiscing elit. Phasellus sit amet
    diam. Duis mattis varius dui. Suspendisse eget dolor.
  </p>
  <p class="red">Lorem ipsum dolor sit amet, consectetuer adipiscing elit.</p>
  <p class="left">This paragraph clears left.</p>
</div>
```

CSS

```
.wrapper {
  border: 1px solid black;
  padding: 10px;
}
.left {
  border: 1px solid black;
  clear: left;
}
.black {
  float: left;
  margin: 0;
  background-color: black;
  color: white;
  width: 20%;
}
.red {
  float: left;
  margin: 0;
  background-color: pink;
  width: 20%;
}
p {
  width: 50%;
}
```

clear: right

HTML

```
<div class="wrapper">
  <p class="black">
    Lorem ipsum dolor sit amet, consectetuer adipiscing elit. Phasellus sit amet
    diam. Duis mattis varius dui. Suspendisse eget dolor.
  </p>
  <p class="red">Lorem ipsum dolor sit amet, consectetuer adipiscing elit.</p>
  <p class="right">This paragraph clears right.</p>
</div>
```

CSS

```
.wrapper {
  border: 1px solid black;
  padding: 10px;
}
.right {
  border: 1px solid black;
  clear: right;
}
.black {
  float: right;
  margin: 0;
  background-color: black;
  color: white;
  width: 20%;
}
.red {
```

```
  float: right;
  margin: 0;
  background-color: pink;
  width: 20%;
}
p {
  width: 50%;
}
```

clear: both

HTML

```
<div class="wrapper">
  <p class="black">
    Lorem ipsum dolor sit amet, consectetuer adipiscing elit. Phasellus sit amet
    diam. Duis mattis varius dui. Suspendisse eget dolor. Fusce pulvinar lacus
    ac dui.
  </p>
  <p class="red">
    Lorem ipsum dolor sit amet, consectetuer adipiscing elit. Phasellus sit amet
    diam. Duis mattis varius dui. Suspendisse eget dolor.
  </p>
  <p class="both">This paragraph clears both.</p>
</div>
```

CSS

```
.wrapper {
  border: 1px solid black;
  padding: 10px;
}
.both {
  border: 1px solid black;
  clear: both;
}
.black {
  float: left;
  margin: 0;
  background-color: black;
  color: white;
  width: 20%;
}
.red {
  float: right;
  margin: 0;
  background-color: pink;
  width: 20%;
}
p {
  width: 45%;
}
```

- CSS basic box model

clip CSS property

> **Warning:** Authors are encouraged to use the `clip-path` property instead.

The **`clip`** CSS property defines a visible portion of an element. The `clip` property applies only to absolutely positioned elements — that is, elements with `position:absolute` or `position:fixed`.

Syntax

```
/* Keyword value */
clip: auto;

/* <shape> values */
clip: rect(1px, 10em, 3rem, 2ch);

/* Global values */
clip: inherit;
clip: initial;
clip: revert;
clip: revert-layer;
clip: unset;
```

Values

This property is specified as a single value from the following list:

`rect()`

A rectangle defined using a `rect()` function of the form `rect(<top>, <right>, <bottom>, <left>)`. The `<top>` and `<bottom>` values are offsets from the *inside top border edge* of the box, while `<right>` and `<left>` are offsets from the *inside left border edge* of the box — that is, the extent of the padding box.

The `<top>`, `<right>`, `<bottom>`, and `<left>` values may be either a `<length>` or `auto`. If any side's value is `auto`, the element is clipped to that side's *inside border edge*.

> **Note:** The `rect()` `<shape>` function used in the deprecated `clip` property is different from the CSS `rect()` function used to define a CSS `<basic-shape>`.

`auto`

The element does not clip (default). This is different from `rect(auto, auto, auto, auto)`, which clips to the element's inside border edges.

Formal definition

Initial value	`auto`
Applies to	absolutely positioned elements
Inherited	no
Computed value	`auto` if specified as `auto`, otherwise a rectangle with four values, each of which is `auto` if specified as `auto` or the computed length otherwise
Animation type	a rectangle

Formal syntax

```
clip =
  <rect()>  |
  auto

<rect()> =
  rect( <top> , <right> , <bottom> , <left> )
```

This syntax reflects the latest standard as per CSS Masking Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Clipping an image

```
<p class="dotted-border">
  <img src="macarons.png" alt="Original graphic" />
  <img id="top-left" src="macarons.png" alt="Graphic clipped to upper left" />
  <img id="middle" src="macarons.png" alt="Graphic clipped towards middle" />
  <img
    id="bottom-right"
    src="macarons.png"
    alt="Graphic clipped to bottom right" />
</p>
```

```
.dotted-border {
  border: dotted;
  position: relative;
  width: 390px;
  height: 400px;
}

#top-left,
#middle,
#bottom-right {
  position: absolute;
  top: 0;
}

#top-left {
  left: 400px;
  clip: rect(0, 130px, 90px, 0);
}

#middle {
  left: 270px;
  clip: rect(100px, 260px, 190px, 130px);
}

#bottom-right {
  left: 140px;
  clip: rect(200px, 390px, 290px, 260px);
}
```

clip-path CSS property

The **`clip-path`** CSS property creates a clipping region that sets what part of an element should be shown. Parts that are inside the region are shown, while those outside are hidden.

Try it

```
clip-path: circle(40%);
```

```
clip-path: ellipse(130px 140px at 10% 20%);
```

```
clip-path: polygon(50% 0, 100% 50%, 50% 100%, 0 50%);
```

```
clip-path: path("M 0 200 L 0,75 A 5,5 0,0,1 150,75 L 200 200 z");
```

```
clip-path: rect(5px 145px 160px 5px round 20%);
```

```
clip-path: xywh(0 5px 100% 75% round 15% 0);
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <img
      class="transition-all"
      id="example-element"
      src="/shared-assets/images/examples/balloon-small.jpg"
      width="150" />
```

```
    We had agreed, my companion and I, that I should call for him at his house,
    after dinner, not later than eleven o'clock. This athletic young Frenchman
    belongs to a small set of Parisian sportsmen, who have taken up "ballooning"
    as a pastime. After having exhausted all the sensations that are to be found
    in ordinary sports, even those of "automobiling" at a breakneck speed, the
    members of the "Aéro Club" now seek in the air, where they indulge in all
    kinds of daring feats, the nerve-racking excitement that they have ceased to
    find on earth.
  </div>
</section>
```

```
section {
  align-items: flex-start;
}

.example-container {
  text-align: left;
  padding: 20px;
}

#example-element {
  float: left;
  width: 150px;
  margin: 20px;
}
```

Syntax

```
/* Keyword value */
clip-path: none;

/* <clip-source> values */
clip-path: url("resources.svg#c1");

/* <geometry-box> values */
clip-path: margin-box;
clip-path: border-box;
clip-path: padding-box;
clip-path: content-box;
clip-path: fill-box;
clip-path: stroke-box;
clip-path: view-box;

/* <basic-shape> values */
clip-path: inset(100px 50px);
clip-path: circle(50px at 0 100px);
clip-path: ellipse(50px 60px at 10% 20%);
clip-path: polygon(50% 0%, 100% 50%, 50% 100%, 0% 50%);
clip-path: path(
  "M0.5,1 C0.5,1,0,0.7,0,0.3 A0.25,0.25,1,1,1,0.5,0.3 A0.25,0.25,1,1,1,1,0.3 C1,0.7,0.5,1,0.5,1 Z"
);
clip-path: rect(5px 5px 160px 145px round 20%);
clip-path: shape(from 0% 0%, line to 100% 0%, line to 50% 100%, close);
clip-path: xywh(0 5px 100% 75% round 15% 0);

/* Box and shape values combined */
clip-path: padding-box circle(50px at 0 100px);

/* Global values */
clip-path: inherit;
clip-path: initial;
clip-path: revert;
clip-path: revert-layer;
clip-path: unset;
```

The `clip-path` property is specified as one or a combination of the values listed below.

Values

`<clip-source>`

A `<url>` referencing an SVG `<clipPath>` element.

`<basic-shape>`

A shape whose size and position is defined by the `<geometry-box>` value. If no geometry box is specified, the `border-box` will be used as the reference box. One of:

`inset()`

Defines an inset rectangle.

`circle()`

Defines a circle using a radius and a position.

`ellipse()`

Defines an ellipse using two radii and a position.

`polygon()`

Defines a polygon using an SVG filling rule and a set of vertices.

`path()`

Defines a shape using an optional SVG filling rule and an SVG path definition.

`rect()`

Defines a rectangle using the specified distances from the edges of the reference box.

`shape()`

Defines a shape using an optional SVG filling rule and shape commands for lines, curves, and arcs.

`xywh()`

Defines a rectangle using the specified distances from the top and left edges of the reference box and the specified width and height of the rectangle.

`<geometry-box>`

If specified in combination with a `<basic-shape>`, this value defines the reference box for the basic shape. If specified by itself, it causes the edges of the specified box, including any corner shaping (such as a `border-radius`), to be the clipping path. The geometry box can be one of the following values:

`margin-box`

Uses the margin box as the reference box.

`border-box`

Uses the border box as the reference box.

`padding-box`

Uses the padding box as the reference box.

`content-box`

Uses the content box as the reference box.

`fill-box`

Uses the object bounding box as the reference box.

`stroke-box`

Uses the stroke bounding box as the reference box.

`view-box`

Uses the nearest SVG viewport as the reference box. If a `viewBox` attribute is specified for the element creating the SVG viewport, the reference box is positioned at the origin of the coordinate system established by the `viewBox` attribute and the dimension of the size of the reference box is set to the width and height values of the `viewBox` attribute.

`none`

No clipping path is created.

> **Note:** A computed value other than `none` results in the creation of a new stacking context the same way that CSS `opacity` does for values other than `1`.

Formal definition

Initial value	none
Applies to	all elements; In SVG, it applies to container elements excluding the `<defs>` element and all graphics elements
Inherited	no
Percentages	refer to reference box when specified, otherwise border-box
Computed value	as specified, but with `<url>` values made absolute
Animation type	yes, as specified for `<basic-shape>`, otherwise no

Formal syntax

```
clip-path =
  <clip-source>                      |
  [ <basic-shape> || <geometry-box> ]  |
  none

<clip-source> =

<arc-sweep> =
  cw   |
  ccw

<arc-size> =
  large  |
  small
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Box Model Module Level 4, CSS Fill and Stroke Module Level 3, CSS Images Module Level 3, CSS Masking Module Level 1, CSS Shapes Module Level 1, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Shapes and geometry boxes

In this example, two triangles are created by defining a `polygon()` as the clip path on `<div>` elements. Each one has a solid colored background and a thick `border`. The second `<div>` element has its reference box set to `content-box`:

HTML

```
<div></div>
<div></div>
```

CSS

```
body {
  display: flex;
  gap: 20px;
  flex-flow: row wrap;
}
```

```
div {
  height: 200px;
  width: 200px;
  box-sizing: border-box;
  background-color: rebeccapurple;
  border: 20px solid magenta;

  clip-path: polygon(50% 0, 100% 100%, 0 100%);
}

div:last-of-type {
  clip-path: content-box polygon(50% 0, 100% 100%, 0 100%);
}
```

Results

For the first triangle, we didn't specify a reference box; it therefore defaults to `border-box`, with the 0% and 100% positions located on the outside edge of the border. In the second example, we set the `<geometry-box>` to `content-box`, meaning the reference box for the basic shape is the outer edge of the content area, which is inside the padding box. Because our example has no `padding`, this is the inner edge of the border.

<code>shape()</code> versus <code>path()</code> functions

Expanding on the previous example, we create the same triangle with different `<basic-shape>` values, demonstrating how the `shape()` and `path()` functions can also be used to create clipping paths, with `shape()` being a more flexible solution.

We use `path()` to define the first element's clipping path, and `shape()` for the second, both using the default `border-box` as their reference box:

```
div {
  clip-path: path("M100 0 L200 200 L0 200 Z");
}

div:last-of-type {
  clip-path: shape(from 50% 0, line to 100% 100%, line to 0 100%, close);
}
```

As a result, the path defined with the shape() function grows with the element, whereas the path() version does not:

Because the `shape()` function allows using `<percentage>` values (and custom properties too), it is more robust.

We'll demonstrate this by increasing the size of the underlying element:

```
div {
  width: 250px;
  height: 250px;
}
```

The visibility, or at least partial visibility, of the four border sides in the clip path example defined by the `shape()` function is due to the percentage values allowing the path to grow with the element. In the `path()` version, the element grew, but not the shape. As a result, the top and left borders are partially visible while the right and bottom borders are clipped out.

SVG as clip source

In this example, we define SVG `<clipPath>` elements to use as a `clip-path` source.

HTML

We include two `<div>` elements and an `<svg>` element containing two `<clipPath>` elements. One `<clipPath>` contains four `<rect>` elements that together define window panes, leaving a cross of blank space in the middle, and the other contains two crossing `<rect>` elements.

```
<svg height="0" width="0">
  <defs>
```

```
    <clipPath id="window">
      <rect y="0" x="0" width="80" height="80" />
      <rect y="0" x="120" width="80" height="80" />
      <rect y="120" x="0" width="80" height="80" />
      <rect y="120" x="120" width="80" height="80" />
    </clipPath>
    <clipPath id="cross">
      <rect y="0" x="80" width="40" height="200" />
      <rect y="80" x="0" width="200" height="40" />
    </clipPath>
  </defs>
</svg>

<div class="window">Window</div>
<div class="cross">Cross</div>
```

CSS

We use flexbox to allow our elements to sit side-by-side with a gap between them, if there is space available. We define a `conic-gradient()` background image on both `<div>` elements, providing an interesting visual to clip, along with a `border`.

```
body {
  display: flex;
  gap: 20px;
  flex-flow: row wrap;
  font: 2em sans-serif;
}

div {
  width: 200px;
  height: 200px;
  background-image: conic-gradient(
    at center,
    rebeccapurple,
    green,
    lightblue,
    rebeccapurple
  );

  border: 5px solid;
  box-sizing: border-box;
}
```

We then set the `id` of the `<clipPath>` as the `<clip-source>`. We center the text in the `cross` example vertically using `align-content`, as otherwise the text would be clipped, as is happening in the `window` example.

```
.window {
  clip-path: url("#window");
}

.cross {
  clip-path: url("#cross");
  align-content: center;
}
```

Results

The elements, including their border and text, are clipped, with only the parts overlapping the `<clipPath>` elements being drawn to the page.

The various value types

This example demonstrates the various values of the `clip-path` property clipping an HTML `<img>`.

HTML

The HTML includes an `<img>` that will be clipped, a star-shaped `<clipPath>`, and a `<select>` element to choose a `clip-path` property value from.

```
<img
  id="clipped"
  src="https://mdn.github.io/shared-assets/images/examples/progress-pride-flag.jpg"
  alt="Pride flag" />
<svg height="0" width="0">
  <defs>
    <clipPath id="star">
      <path d="M100,0 42,180 196,70 4,70 158,180z" />
    </clipPath>
  </defs>
</svg>

<select id="clipPath">
  <option value="none">none</option>
  <option value="circle(100px at 110px 100px)">circle</option>
  <option value="url(#star)" selected>star</option>
  <option value="inset(20px round 20px)">inset</option>
  <option value="rect(20px 150px 200px 20px round 10%)">rect</option>
  <option value="xywh(0 20% 90% 67% round 0 0 5% 5px)">xywh</option>
  <option value="path('M 0 200 L 0,110 A 110,90 0,0,1 240,100 L 200 340 z')">
    path
  </option>
</select>
```

```
<pre id="log"></pre>
```

CSS

The initial rendering includes the star as the `clip-path` source.

```
#clipped {
  margin-bottom: 20px;
```

```
  clip-path: url("#star");
}
```

JavaScript

When you select a new option from the `<select>` menu, an event handler updates the value of the `clip-path` set on the `<img>`.

```
const clipPathSelect = document.getElementById("clipPath");
clipPathSelect.addEventListener("change", (evt) => {
  const path = evt.target.value;
  document.getElementById("clipped").style.clipPath = path;
  log(`clip-path: ${path};`);
});
```

```
function log(text) {
  const logElement = document.querySelector("#log");
  logElement.innerText = `${text}`;
  logElement.scrollTop = logElement.scrollHeight;
}
```

Result

Select different options to change the `clip-path` value.

> **Note:** While it is possible to define a path of text, if you want to clip a background image to text rather than a shape, see the `background-clip` property.

clip-rule CSS property

The **`clip-rule`** CSS property determines, when parts of the path overlap other parts, which pixels in a mask's box are inside the clipping shape defined by a clip path and which are outside.

The `clip-rule` property only applies to SVG elements that are contained within a `<clipPath>` element, overriding the element's `clip-rule` attribute value if present. The `clip-rule` property basically works as the `fill-rule` property, except that it applies to `<clipPath>` definitions. It does not have any effect on CSS `<basic-shape>`s.

Syntax

```
/* Keyword values */
clip-rule: nonzero;
clip-rule: evenodd;

/* Global values */
clip-rule: inherit;
clip-rule: initial;
clip-rule: revert;
clip-rule: revert-layer;
clip-rule: unset;
```

Values

This property is specified as one of the following keyword values:

`nonzero`

> For every point in the clipping mask's box, a ray is drawn in a random direction. Every time the ray intersects with any part of the clipping path, a tally is increased by one if the clipping path's part is moving from left to right across the ray, whereas it is decreased by one if the path part is moving right to left across the ray. If the final total of the tally is zero, the point is outside the path's shape. Otherwise, it's inside the path's shape.

`even-odd`

> For every point in the clipping mask's box, a ray is drawn in a random direction. Every time the ray intersects with any part of the clipping path, a tally is increased by one. If the final total of the tally is even, the point is outside the path's shape; otherwise, it's inside the path's shape. Zero is taken to be even.

Formal syntax

```
clip-rule =
  nonzero  |
  evenodd
```

This syntax reflects the latest standard as per CSS Masking Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Value comparison

In this example, we will apply different CSS `clip-rule` values to similar SVG `<path>` elements to demonstrate the difference between `evenodd` and `non-zero`.

HTML

The markup has multiple `<svg>` containers, each containing a `<clipPath>` element that defines a star shape, and a `<rect>` element to draw the star inside. The stars are created with overlapping lines. Other than the `id`, the markup of the first two SVG elements is identical. The third SVG includes just the `<path>` element, showing how the lines of the path that created the star overlap.

```
<svg>
  <clipPath id="star1">
    <path d="M50,0 21,90 98,35 2,35 79,90z" />
  </clipPath>
  <rect clip-path="url(#star1)" width="95" height="95" />
</svg>
```

```
<svg>
  <clipPath id="star2">
    <path d="M50,0 21,90 98,35 2,35 79,90z" />
  </clipPath>
  <rect clip-path="url(#star2)" width="95" height="95" />
</svg>

<svg id="star3">
  <path d="M50,0 21,90 98,35 2,35 79,90z" />
</svg>
```

CSS

The `clip-rule` for the `<path>` in the first SVG is set to `evenodd`; `nonzero` in the second SVG. For the path-only SVG, we removed the default `fill` and defined both a `stroke` color and `stroke-width` to make the overlapping path lines visible:

```
body {
  display: flex;
  gap: 20px;
}
svg {
  width: 110px;
  height: 110px;
}
```

```
#star1 path {
  clip-rule: evenodd;
}

#star2 path {
  clip-rule: nonzero;
}

#star3 path {
  fill: none;
  stroke: black;
  stroke-width: 1;
}
```

Results

Within basic shape definitions

This example demonstrates that, while the `clip-rule` does not have any effect on CSS `<basic-shape>`s, it can affect a `<clipPath>` used as the source of a shape.

HTML

We include an SVG with two `<clipPath>` elements that define star shapes, which are identical except for their `id` attribute values. We also include two `<div>` elements that will contain our star shapes.

```
<svg height="0" width="0">
  <defs>
    <clipPath id="star1">
      <path d="M100,0 42,180 196,70 4,70 158,180z" />
    </clipPath>
    <clipPath id="star2">
      <path d="M100,0 42,180 196,70 4,70 158,180z" />
    </clipPath>
  </defs>
</svg>

<div></div>
<div></div>
```

CSS

We provide the `<div>` elements with a set `width` and `height`, adding a `conic-gradient()` for their `background-image` value:

```
body {
  display: flex;
  gap: 20px;
}
```

```
div {
  height: 200px;
  width: 200px;
  background-image: conic-gradient(
    at center,
    rebeccapurple,
    green,
    lightblue,
    rebeccapurple
  );
}
```

We use the `clip-path` property to set the different `<clipPath>` elements as the clipping path for each `<div>`:

```
div:first-of-type {
  clip-path: url("#star1");
}
div:last-of-type {
  clip-path: url("#star2");
}
```

Finally, we set the different `clip-rule` values for each of the `<clipPath>` element's `<path>`s:

```
#star1 path {
  clip-rule: evenodd;
}
```

```
#star2 path {
  clip-rule: nonzero;
}
```

Results

Choosing between rules for a path with all clockwise paths

In this SVG image, we have two rectangles that are clipped, once with each clipping rule. There are two `<clipPath>` elements, so that one can be set to use the non-zero clipping rule and the other uses the even-odd rule. Both paths are drawn in a clockwise direction for both its inner and outer parts.

```
<svg xmlns="http://www.w3.org/2000/svg" viewBox="0 0 200 50">
  <g stroke="#112233" fill="#bbccdd">
    <!-- basic rectangle and clipping path visualization follow -->
    <rect x="10" y="10" width="30" height="30" />
    <path
      d="M 65,5 l 20,20 -20,20 -20,-20 20,-20 m 0,10 l 10,10 -10,10 -10,-10 10,-10 z"
      fill="none"
      stroke-width="0.5" />
    <!-- rectangles to be clipped follow -->
    <rect x="110" y="10" width="30" height="30" clip-path="url(#clipper1)" />
    <rect x="160" y="10" width="30" height="30" clip-path="url(#clipper2)" />
  </g>
  <!-- clipping paths follow -->
  <clipPath id="clipper1" clipPathUnits="objectBoundingBox">
    <path
      d="M 0.5 -0.15 l 0.65 0.65 -0.65,0.65 -0.65,-0.65 0.65,-0.65 m 0,0.33 l 0.33,0.33 -0.33,0.33 -0.33,-0.33 0.33,-0.33 z"
      clip-rule="evenodd" />
  </clipPath>
  <clipPath id="clipper2" clipPathUnits="objectBoundingBox">
    <path
      d="M 0.5 -0.15 l 0.65 0.65 -0.65,0.65 -0.65,-0.65 0.65,-0.65 m 0,0.33 l 0.33,0.33 -0.33,0.33 -0.33,-0.33 0.33,-0.33 z"
      clip-rule="nonzero" />
  </clipPath>
</svg>
```

To the clipping paths that are applied to the clipped rectangles, the CSS `clip-rule` property is used to set one path to use the `nonzero` rules, and the other to use the `evenodd` rule. These override the values of the `clip-path` attributes in the SVG, which have been intentionally set to the opposite values as the CSS imposes.

```
#clipper1 {
  clip-rule: nonzero;
}
#clipper2 {
  clip-rule: evenodd;
}
```

Because both the inner and outer parts of the path move in a clockwise (left-to-right) direction, the resulting clip shape will be different between the two clipping rules. For `nonzero`, any ray inside the outer part of the shape will tally to a value above zero, because it will encounter one or more left-to-right path fragments. For `even-odd`, points between the two parts of the path will have an odd-numbered tally, whereas any point either inside the inner path or outside the outer part will have an even-numbered tally.

Choosing between rules for a path with different winding paths

This example uses the same SVG as the previous example, with the change that the interior part of the clipping path winds in a counterclockwise direction.

```
<svg xmlns="http://www.w3.org/2000/svg" viewBox="0 0 200 50">
  <g stroke="#112233" fill="#bbccdd">
    <!-- basic rectangle and clipping path visualization follow -->
    <rect x="10" y="10" width="30" height="30" />
    <path
      d="M 65,5 l 20,20 -20,20 -20,-20 20,-20 m 0,10 l 10,10 -10,10 -10,-10 10,-10 z"
      fill="none"
      stroke-width="0.5" />
    <!-- rectangles to be clipped follow -->
    <rect x="110" y="10" width="30" height="30" clip-path="url(#clipper1)" />
    <rect x="160" y="10" width="30" height="30" clip-path="url(#clipper2)" />
  </g>
  <!-- clipping paths follow -->
  <clipPath id="clipper1" clipPathUnits="objectBoundingBox">
    <path
      d="M 0.5 -0.15 l 0.65 0.65 -0.65,0.65 -0.65,-0.65 0.65,-0.65 m 0,0.33 l -0.33,0.33 0.33,0.33 0.33,-0.33 -0.33,-0.33 z" />
  </clipPath>
  <clipPath id="clipper2" clipPathUnits="objectBoundingBox">
    <path
      d="M 0.5 -0.15 l 0.65 0.65 -0.65,0.65 -0.65,-0.65 0.65,-0.65 m 0,0.33 l 0.33,0.33 -0.33,0.33 -0.33,-0.33 0.33,-0.33 z" />
  </clipPath>
</svg>
```

We apply the same CSS as before.

```
#clipper1 {
  clip-rule: nonzero;
}
#clipper2 {
  clip-rule: evenodd;
}
```

In this case, because the outer part of the path moves in a clockwise (left-to-right) direction and the interior part of the path moves in a counterclockwise (right-to-left) direction, the resulting clip shape will be the same regardless of which clipping rule is used.

color CSS property

The **`color`** CSS property sets the foreground color value of an element's text and text decorations, and sets the `currentColor` value. `currentColor` may be used as an indirect value on *other* properties and is the default for other color properties, such as `border-color`.

For an overview of using color in HTML, see Applying color to HTML elements using CSS.

Try it

```
color: rebeccapurple;
```

```
color: #00a400;
```

```
color: rgb(214 122 127);
```

```
color: hsl(30deg 82% 43%);
```

```
color: hsl(237deg 74% 33% / 61%);
```

```
color: hwb(152deg 0% 58% / 70%);
```

```
<section id="default-example">
  <div class="example-container">
    <p id="example-element">
      London. Michaelmas term lately over, and the Lord Chancellor sitting in
      Lincoln's Inn Hall. Implacable November weather.
    </p>
  </div>
</section>
```

```
#example-element {
  font-size: 1.5em;
}

.example-container {
  background-color: white;
  padding: 10px;
}
```

Syntax

```
/* Keyword value */
color: currentColor;

/* <named-color> values */
color: red;
color: orange;
color: tan;
color: rebeccapurple;

/* <hex-color> values */
color: #090;
color: #009900;
color: #090a;
color: #009900aa;

/* <rgb()> values and legacy <rgba()> values*/
color: rgb(34, 12, 64);
color: rgb(34, 12, 64, 0.6);
color: rgba(34, 12, 64, 0.6);
color: rgb(34 12 64 / 0.6);
color: rgba(34 12 64 / 0.6);
color: rgb(34.6 12 64 / 60%);
color: rgba(34.6 12 64 / 60%);

/* <hsl()> values and legacy <hsla()> values */
color: hsl(30, 100%, 50%);
color: hsl(30, 100%, 50%, 0.6);
color: hsla(30, 100%, 50%, 0.6);
color: hsl(30 100% 50% / 0.6);
color: hsla(30 100% 50% / 0.6);
color: hsl(30.2 100% 50% / 60%);
color: hsla(30.2 100% 50% / 60%);

/* <hwb()> values */
color: hwb(90 10% 10%);
color: hwb(90 10% 10% / 0.5);
color: hwb(90deg 10% 10%);
color: hwb(1.5708rad 60% 0%);
color: hwb(0.25turn 0% 40% / 50%);

/* Global values */
color: inherit;
color: initial;
color: revert;
color: revert-layer;
color: unset;
```

Values

This property is specified as a single value from the following list:

`<color>`

Sets the color of the textual and decorative parts of the element.

`currentColor`

Sets the color to the element's `color` property value. However, if set as the value of `color`, `currentColor` is treated as `inherit`.

Accessibility

It is important to ensure that the contrast ratio between the color of the text and the background the text is placed over is high enough that people experiencing low vision conditions will be able to read the content of the page.

Color contrast ratio is determined by comparing the luminosity of the text and background color values. In order to meet current Web Content Accessibility Guidelines (WCAG), a ratio of 4.5:1 is required for text content and 3:1 for larger text such as headings. Large text is defined as 18.66px and bold or larger, or 24px or larger.

- WebAIM: Color Contrast Checker
- MDN Understanding WCAG, Guideline 1.4 explanations
- Understanding Success Criterion 1.4.3 | W3C Understanding WCAG 2.0

Formal definition

Initial value	`canvastext`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	computed color
Animation type	by computed value type

Formal syntax

```
color =
  <color>
```

This syntax reflects the latest standard as per CSS Color Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Making text red

The following are all ways to make a paragraph's text red:

```
p {
  color: red;
}
p {
  color: #f00;
}
p {
  color: #ff0000;
}
p {
  color: rgb(255 0 0);
}
p {
  color: rgb(100% 0% 0%);
}
p {
  color: hsl(0 100% 50%);
}

/* 50% translucent */
p {
  color: #ff000080;
}
p {
  color: rgb(255 0 0 / 50%);
}
p {
  color: hsl(0 100% 50% / 50%);
}
```

color-interpolation CSS property

The `color-interpolation` CSS property is used in SVG to specify which color space to use for `<linearGradient>` and `<radialGradient>` SVG elements.

Syntax

```
/* Keyword values */
color-interpolation: auto;
color-interpolation: sRGB;
color-interpolation: linearRGB;
```

Values

This property is specified as one of the following keyword values:

`auto`

> Indicates that the user agent can choose either the `sRGB` or `linearRGB` spaces for color interpolation. This option indicates that the author doesn't require that color interpolation occur in a particular color space.

`sRGB`

> Indicates that color interpolation should occur in the sRGB color space. Defaults to this initial value if no `color-interpolation` property is set.

`linearRGB`

Indicates that color interpolation should occur in the linearized RGB color space as described in the sRGB specification.

Formal definition

Value	`auto` | `sRGB` | `linearRGB`
Applies to	`<linearGradient>` and `<radialGradient>`
Default value	`auto`
Animatable	discrete

Formal syntax

```
color-interpolation =
  auto       |
  sRGB       |
  linearRGB
```

This syntax reflects the latest standard as per CSS Specification. Not all browsers may have implemented every part. See Browser compatibility for support information.

Example

In the first SVG, the `color-interpolation` property is not included on the `<linearGradient>` element and color interpolation defaults to `sRGB`. The second example shows color interpolation using the `linearRGB` value.

```
<svg width="450" height="70">
  <title>Example of using the color-interpolation CSS Property</title>
  <defs>
    <linearGradient id="sRGB">
      <stop offset="0%" stop-color="white" />
      <stop offset="25%" stop-color="blue" />
      <stop offset="50%" stop-color="white" />
      <stop offset="75%" stop-color="red" />
      <stop offset="100%" stop-color="white" />
    </linearGradient>
  </defs>
  <rect x="0" y="0" width="400" height="40" fill="url(#sRGB)" stroke="black" />
  <text x="0" y="60" font-family="courier" font-size="16">
    no color-interpolation (CSS property)
  </text>
</svg>
```

```
<svg width="450" height="70">
  <title>Example of using the color-interpolation CSS Property</title>
  <defs>
    <linearGradient id="linearRGB">
      <stop offset="0%" stop-color="white" />
      <stop offset="25%" stop-color="blue" />
      <stop offset="50%" stop-color="white" />
      <stop offset="75%" stop-color="red" />
      <stop offset="100%" stop-color="white" />
    </linearGradient>
  </defs>
  <rect
    x="0"
    y="0"
    width="400"
    height="40"
    fill="url(#linearRGB)"
    stroke="black" />
  <text x="0" y="60" font-family="courier" font-size="16">
    color-interpolation: linearRGB; (CSS property)
  </text>
</svg>
```

```
svg {
  display: block;
}

#linearRGB {
  color-interpolation: linearRGB;
}
```

See also

- `<linearGradient>`
- `<radialGradient>`
- SVG `color-interpolation` attribute

color-interpolation-filters CSS property

The **`color-interpolation-filters`** CSS property specifies the color space for imaging operations performed via SVG filter effects. If explicitly declared, the value of the CSS property overrides any value given in the element's `color-interpolation-filters` attribute.

> **Note:** The `color-interpolation-filters` property is only relevant to SVG filter operations. It has *no* effect on filter primitives like `<feOffset>`, `<feImage>`, `<feTile>`, and `<feFlood>`, but instead applies to the various filter effect elements (e.g., `<feBlend>`); see the SVG `color-interpolation-filters` page for a full list.

> **Note:** It is important to remember that the SVG `color-interpolation` attribute has an initial value of `sRGB`, while `color-interpolation-filters` has an initial value of `linearRGB`. This means, in the default case, filter effect interpolations occur in a different color space than all other color interpolations.

Syntax

```
color-interpolation-filters: auto;
color-interpolation-filters: linearRGB;
color-interpolation-filters: sRGB;
```

```
/* Global values */
color-interpolation-filters: inherit;
color-interpolation-filters: initial;
color-interpolation-filters: revert;
color-interpolation-filters: revert-layer;
color-interpolation-filters: unset;
```

Values

This property is specified as one of the following keyword values:

`linearRGB`

Indicates that color interpolation should occur in the linearized RGB color space as described in the sRGB specification. This is the default property value.

`sRGB`

Indicates that color interpolation should occur in the gamma-encoded sRGB color space.

`auto`

Indicates that the user agent can choose either the `sRGB` or `linearRGB` spaces for color interpolation. This option indicates that the author doesn't require that color interpolation occur in a particular color space.

Formal definition

Initial value	`linearRGB`
Applies to	The set of elements that control the output of a `<filter>` element in `<svg>`
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
color-interpolation-filters =
  auto       |
  sRGB       |
  linearRGB
```

This syntax reflects the latest standard as per Filter Effects Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

color-scheme CSS property

The **`color-scheme`** CSS property allows an element to indicate which color schemes it can comfortably be rendered in. User agents change the following aspects of the UI chrome to match the used color scheme:

- The color of the canvas surface.
- The default colors of scrollbars and other interaction UI.
- The default colors of form controls.
- The default colors of other browser-provided UI, such as "spellcheck" underlines.

Component authors must use the `prefers-color-scheme` media feature to support the color schemes on the rest of the elements.

Common choices for operating system color schemes are "light" and "dark", or "day mode" and "night mode". When a user selects one of these color schemes, the operating system makes adjustments to the user interface. This includes form controls, scrollbars, and the used values of CSS system colors.

Try it

```
color-scheme: normal;
```

```
color-scheme: dark;
```

```
color-scheme: light;
```

```
<section class="default-example container" id="default-example">
  <textarea id="example-element">Text Area</textarea>
</section>
```

```
#example-element {
  width: 80%;
  height: 50%;
}
```

Syntax

```
color-scheme: normal;
color-scheme: light;
color-scheme: dark;
color-scheme: light dark;
color-scheme: only light;

/* Global values */
color-scheme: inherit;
color-scheme: initial;
color-scheme: revert;
color-scheme: revert-layer;
color-scheme: unset;
```

Values

This property is specified as one of the following keyword values:

`normal`

Indicates that the element can be rendered using the page's color scheme settings. If the page does not have a color scheme set, the element is rendered using the page's default color settings.

`light`

Indicates that the element can be rendered using the operating system *light* color scheme.

`dark`

Indicates that the element can be rendered using the operating system *dark* color scheme.

`only`

Forbids the user agent from overriding the color scheme for the element.

Can be used to turn off color overrides caused by Chrome's Auto Dark Theme, by applying `color-scheme: only light;` on a specific element or `:root`.

Formal definition

Initial value	`normal`
Applies to	all elements and text
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
color-scheme =
  normal                                  |
  [ light | dark | <custom-ident> ]+ && only?
```

This syntax reflects the latest standard as per CSS Color Adjustment Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Declaring color scheme preferences

To opt the entire page into the user's color scheme preferences, declare `color-scheme` on the `:root` element.

```
:root {
  color-scheme: light dark;
}
```

To opt in specific elements to the user's color scheme preferences, declare `color-scheme` on those elements.

```
header {
  color-scheme: only light;
}
main {
  color-scheme: light dark;
}
footer {
  color-scheme: only dark;
}
```

Along with the above CSS, also include the `<meta name="color-scheme">` HTML `<meta>` tag in the `<head>`, before any CSS style information, to inform user agents about the preferred color scheme, helping prevent unwanted screen flashes during the page load.

Styling based on color schemes

To style elements based on color scheme preferences, use the `prefers-color-scheme` media query. The example below opts in the entire page to using both light and dark operating system color schemes via the `color-scheme` property, and then uses `prefers-color-scheme` to specify the desired foreground and background colors for individual elements in those color schemes.

```
:root {
  color-scheme: light dark;
}

@media (prefers-color-scheme: light) {
  .element {
    color: black;
    background-color: white;
  }
}

@media (prefers-color-scheme: dark) {
  .element {
    color: white;
    background-color: black;
  }
}
```

Alternatively, use the `light-dark()` `<color>` function to set the foreground and background colors for the different color schemes using a more compact code structure:

```
:root {
  color-scheme: light dark;
}

.element {
  color: light-dark(black, white);
  background-color: light-dark(white, black);
}
```

See also

- `prefers-color-scheme` media query to detect user preferences for color schemes.
- `light-dark()` color function to set colors for both light and dark color schemes.
- Other color-related properties: `color`, `accent-color`, `background-color`, `border-color`, `outline-color`, `text-decoration-color`, `text-emphasis-color`, `text-shadow`, `caret-color`, and `column-rule-color`
- `background-image`
- `print-color-adjust`
- Using relative colors

column-count CSS property

The **`column-count`** CSS property breaks an element's content into the specified number of columns.

Try it

```
column-count: 2;
```

```
column-count: 3;
```

```
column-count: 4;
```

```
column-count: auto;
column-width: 8rem;
```

```
<section id="default-example">
  <p id="example-element">
    London. Michaelmas term lately over, and the Lord Chancellor sitting in
    Lincoln's Inn Hall. Implacable November weather. As much mud in the streets
    as if the waters had but newly retired from the face of the earth, and it
    would not be wonderful to meet a Megalosaurus, forty feet long or so,
    waddling like an elephantine lizard up Holborn Hill.
  </p>
</section>
```

```
#example-element {
  width: 100%;
  text-align: left;
}
```

Syntax

```
/* Keyword value */
column-count: auto;

/* <integer> value */
column-count: 3;

/* Global values */
column-count: inherit;
column-count: initial;
column-count: revert;
column-count: revert-layer;
column-count: unset;
```

Values

This property is specified as a single value from the following list:

`auto`

> The number of columns is determined by other CSS properties, such as `column-width`.

`<integer>`

> Is a strictly positive `<integer>` describing the ideal number of columns into which the content of the element will be flowed. If the `column-width` is also set to a non-`auto` value, it merely indicates the maximum allowed number of columns.

Description

Setting the `column-count` to a value greater than `1` creates a multi-column layout. The element's content will be evenly distributed between the specified number of columns.

The `column-count` property, along with the `column-height` and `column-width` properties, can also be set by using the `columns` shorthand.

Formal definition

Initial value	`auto`
Applies to	Block containers except table wrapper boxes
Inherited	no
Computed value	as specified
Animation type	an integer

Formal syntax

```
column-count =
  auto             |
  <integer [1,∞]>

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Multi-column Layout Module Level 2, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Splitting a paragraph across three columns

HTML

```
<p class="content-box">
  This is a bunch of text split into three columns using the CSS
  <code>column-count</code>
  property. The text is equally distributed over the columns.
</p>
```

CSS

```
.content-box {
  column-count: 3;
}
```

Result

- Basic Concepts of Multicol

column-fill CSS property

The **`column-fill`** CSS property controls how an element's contents are balanced when broken into columns.

Try it

```
column-fill: auto;
```

```
column-fill: balance;
```

```
<section id="default-example">
  <p id="example-element">
    London. Michaelmas term lately over, and the Lord Chancellor sitting in
    Lincoln's Inn Hall. Implacable November weather.
  </p>
</section>
```

```
#example-element {
  width: 100%;
  height: 90%;
  columns: 3;
  text-align: left;
}
```

Syntax

```
/* Keyword values */
column-fill: auto;
column-fill: balance;

/* Global values */
column-fill: inherit;
column-fill: initial;
column-fill: revert;
column-fill: revert-layer;
column-fill: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

> Columns are filled sequentially. Content takes up only the room it needs, possibly resulting in some columns remaining empty.

`balance`

> Content is equally divided between columns. In fragmented contexts, such as paged media, only the last fragment is balanced. Therefore in paged media, only the last page would be balanced. This is the default value.

The specification defines a `balance-all` value, in which content is equally divided between columns in fragmented contexts, such as paged media. This value is not yet supported in any browser.

Formal definition

Initial value	`balance`
Applies to	multicol elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
column-fill =
  auto         |
  balance      |
  balance-all
```

This syntax reflects the latest standard as per CSS Multi-column Layout Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Balancing column content

HTML

```
<p class="fill-auto">
  This paragraph fills columns one at a time. Since all of the text can fit in
  the first column, the others are empty.
</p>

<p class="fill-balance">
  This paragraph attempts to balance the amount of content in each column.
</p>
```

CSS

```
p {
  height: 7em;
  background: #ffff99;
  columns: 3;
  column-rule: 1px solid;
}

p.fill-auto {
  column-fill: auto;
}

p.fill-balance {
  column-fill: balance;
}
```

Result

> **Warning:** There are some interoperability issues and bugs with `column-fill` across browsers, due to unresolved issues in the specification.
>
> In particular, when using `column-fill: auto` to fill columns sequentially, Chrome will only consult this property if the multicol container has a size in the block dimension (e.g., height in a horizontal writing mode). Firefox will always consult this property, therefore filling the first column with all of the content in cases where there is no size.

column-gap CSS property

The **`column-gap`** CSS property sets the size of the gap (gutter) between an element's columns in multi-column, flexible box, and grid layouts.

Try it

```
column-gap: 0;
```

```
column-gap: 10%;
```

```
column-gap: 1em;
```

```
column-gap: 20px;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">
      <div>One</div>
      <div>Two</div>
      <div>Three</div>
      <div>Four</div>
      <div>Five</div>
    </div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  display: grid;
  grid-template-columns: 1fr 1fr;
  width: 200px;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
}
```

Syntax

```
/* Keyword value */
column-gap: normal;

/* <length-percentage> value */
column-gap: 3px;
column-gap: 2.5em;
column-gap: 3%;
column-gap: calc(3% - 6px);

/* <line-width> keyword value */
```

```
column-gap: thin;
column-gap: medium;
column-gap: thick;

/* Global values */
column-gap: inherit;
column-gap: initial;
column-gap: revert;
column-gap: revert-layer;
column-gap: unset;
```

Values

This property is specified as a single value from the following list:

`normal`

For multi-column layout, sets the gap to `1em`; otherwise `0`. This is the default value.

`<line-width>`

Sets the size of the gap using the keywords `thin`, `medium`, or `thick`, or a positive `<length>` value.

`<length-percentage>`

Sets a non-negative `<length>` or `<percentage>` value. Percentages are relative to the inline-size of the content box.

Description

The `column-gap` property sets the size of the gap between an element's columns. The property specifies a fixed-length gutter between items in a container, separating boxes in the container's inline axis. Negative values are invalid. Column gaps in multi-col containers are `1em` wide by default, while no gap is added between grid columns or flex items or rows. See Defining CSS gaps for more information about gaps by layout type.

Percentages are calculated against the content box size of the container element's inline axis when this size is definite, against `0` otherwise, except in grid layout, for which cyclic percentage sizes resolve against zero for determining intrinsic size contributions but resolve against the element's content box when laying out the contents. See Specifying gap values as percentages for more information.

The column gap may contain a visible separator as a gap decoration. To draw a rule between the columns, use the `column-rule` or the `rule` shorthand. The rule appears in the middle of the gap but has no effect on the size of the gap between the columns.

The `column-gap` property, along with the `row-gap` property, can also be set by using the `gap` shorthand, which sets both `row-gap` and `column-gap` in one declaration, in that order.

The `column-gap` property replaced the `grid-column-gap` property, which was initially defined in CSS grid layout for creating gaps between grid columns. `grid-column-gap` is now an alias for `column-gap`.

Formal definition

Initial value	`normal`
Applies to	multi-column elements, flex containers, grid containers
Inherited	no
Percentages	refer to corresponding dimension of the content area
Computed value	as specified, with <length>s made absolute, and normal computing to zero except on multi-column elements
Animation type	a length, percentage or calc();

Formal syntax

```
column-gap =
  normal                    |
  <length-percentage [0,∞]> |
  <line-width>

<length-percentage> =
  <length>      |
  <percentage>

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Flex layout

This example demonstrates using the `column-gap` property to create horizontal space between adjacent flex items.

HTML

We include six items in a container element:

```
<div class="flexbox">
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
</div>
```

CSS

We set the `display` property to `flex` and the `flex-flow` property to `row wrap` to create a flex container with rows of items. This allows the items to flow onto new lines if needed. The flex items are each given a flex basis of either `200px` or `300px`.

We define a column rule with the `column-rule` property. The `column-gap` value is set to `20px` on the flex container, creating a `20px` gap between the adjacent flex items in each row. The column rule is drawn in the middle of the gap.

```
.flexbox {
  display: flex;
  flex-flow: row wrap;
  column-rule: 1px solid magenta;

  column-gap: 20px;
}

.flexbox > div {
  border: 1px solid green;
  background-color: lime;
  height: 35px;
  flex: 200px;
}
div:nth-of-type(3n) {
  flex: 300px;
}
```

Result

To set vertical space between flex rows, specify a non-zero value for the `row-gap` property, optionally setting both `row-gap` and `column-gap` by using the `gap` shorthand.

Grid layout

This example demonstrates using the `column-gap` property with a `<percentage>` value in a grid layout. It also demonstrates how the `column-gap` size is not affected by the size of the column rule.

HTML

We include seven items in a container element:

```
<div id="grid">
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
</div>
```

CSS

We set the `display` to `grid`, the `width` to `400px` and the `grid-template-columns` to `repeat(3, 1fr)` to create a 400px-wide grid container with three columns and as many rows as needed. Each row is `100px` tall, as defined by the `grid-auto-rows` property. Every odd grid item has a `lime` background color and the even grid items are semi-opaque.

We've also set a very wide, semi-opaque `column-rule` to demonstrate how the rule is painted behind the content, with the width of the rule having no impact on the size of the gap. The `column-gap` is set to `5%`, which creates a gap that is `20px` wide.

```
#grid {
  display: grid;
  width: 400px;
  grid-template-columns: repeat(3, 1fr);
  grid-auto-rows: 100px;
  column-rule: 30px solid #ff00ff33;

  column-gap: 5%;
}

#grid > div {
  outline: 1px solid green;
  background-color: lime;
}
#grid > div:nth-of-type(even) {
  background-color: #00ff0033;
}
```

```
@layer no-support {
  @supports not (column-gap: 5%) {
    body::before {
      content: "Your browser doesn't support percent values";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

Result

The column rule is wider than the column gap, and is visible only where the items drawn on top are semi-transparent.

Multi-column layout

This example demonstrates using the `column-gap` property with a `<line-width>` keyword value in a multi-col layout.

HTML

```
<p class="content-box">
  This is some multi-column text with a thin column gap created with the CSS
  `column-gap` property. The `normal` default value for the `column-gap`
  property in multi-col layout is 1em.
</p>
```

CSS

```
.content-box {
  column-count: 3;
  column-gap: thin;
}
```

```
@layer no-support {
  @supports not (column-gap: thick) {
    body::before {
      content: "Your browser doesn't support the <line-width> keyword values";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

column-height CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`column-height`** CSS property specifies the height of the columns in a CSS multi-column layout.

Syntax

```
/* Keyword value */
column-height: auto;

/* <length> value */
column-height: 300px;
column-height: 25em;
column-height: 70vh;

/* Global values */
column-height: inherit;
column-height: initial;
column-height: revert;
column-height: revert-layer;
column-height: unset;
```

Values

This property is specified as a single value from the following list:

`auto`

> The initial value. If the content container has a set height, the content columns will grow to that height, overflowing to the side if the content doesn't fit inside the container. If the content container does not have a set height, the content will be equally distributed between the columns generated inside the container.

`<length>`

> The height of the columns. Must be non-negative.

Description

The `column-height` property sets the height of the columns in a multi-column layout. This is useful for constraining the column height for readability when setting multiple columns using the `column-count` or `column-width` property.

Without `column-height`, if the height of the multi-col content exceeds the viewport height, readers will need to scroll down to the end of a column and then back up to the top of the next column. One possible fix would be to set a fixed height on the content container, however, excess columns will then overflow to the side, and readers will have to scroll in the inline direction to read all the content.

The `column-height` property, along with `column-wrap`, allows you to set a specific height for the columns and wrap them onto a new row of columns when the container edge is reached.

The default value of `column-wrap` is `auto`, which resolves to `wrap` when `column-height` is set to a `<length>` value; `wrap` allows the fixed-height columns to wrap onto multiple rows. When `column-height` is equal to `auto`, `column-wrap: auto` resolves to `nowrap`, allowing the columns to overflow horizontally if a fixed container height is set. As a result of this default behavior, generally you don't need to explicitly set the `column-wrap` property.

The `column-height` property, along with the `column-count` and `column-width` properties, can also be set by using the `columns` shorthand.

Formal definition

Initial value	`auto`
Applies to	Block containers except table wrapper boxes
Inherited	no
Computed value	`auto` if specified as `auto`, otherwise for `<length>` the absolute value specified
Animation type	by computed value type

Formal syntax

```
column-height =
  auto            |
  <length [0,∞]>
```

This syntax reflects the latest standard as per CSS Multi-column Layout Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates basic usage of the `column-height` property to create a wrapped multi-col layout.

HTML

We include a poem by Dr. Seuss using an `<ol>` containing 28 `<li>`s, followed by the author's name in a `<p>`.

```
<ol>
  <li>One fish</li>
  <li>Two fish</li>
  <li>Red fish</li>
  <li>Blue fish</li>
  ...
</ol>
<p>-- Dr. Seuss</p>
```

```
<ol>
  <li>One fish</li>
  <li>Two fish</li>
  <li>Red fish</li>
  <li>Blue fish</li>
  <li>Black fish</li>
  <li>Blue fish</li>
  <li>Old fish</li>
  <li>New fish.</li>
  <li>This one has a little star.</li>
  <li>This one has a little car.</li>
  <li>Say! What a lot</li>
  <li>Of fish there are.</li>
  <li>Yes. Some are red. And some are blue.</li>
  <li>Some are old. And some are new.</li>
  <li>Some are sad.</li>
  <li>And some are glad.</li>
  <li>And some are very, very bad.</li>
  <li>Why are they</li>
  <li>Sad and glad and bad?</li>
  <li>I do not know.</li>
  <li>Go ask your dad.</li>
  <li>Some are thin.</li>
  <li>And some are fat.</li>
  <li>The fat one has</li>
  <li>A yellow hat.</li>
  <li>From there to here, from here to there,</li>
  <li>Funny things</li>
  <li>Are everywhere.</li>
</ol>
<p>--Dr. Seuss</p>
```

CSS

We define the `<ol>` to be a multi-column container by setting the `column-width` property to `150px`, meaning the container will contain as many columns as possible with each being at least `150px` wide. The `gap` property of `2em` sets a horizontal gap between columns and a vertical gap between rows of columns. We then set the `column-height` to `2em`, causing the `column-wrap` property's default `auto` value to resolve to `wrap` to create wrapped rows of columns.

```
ol {
  column-width: 150px;
  gap: 2em;
  column-height: 3em;
}
```

Result

Scroll-snapped columns

This example combines a wrapped multi-column layout with CSS scroll snapping, creating a usable experience where each scrolling action snaps a new row of columns neatly inside the full height of the viewport for comfortable reading.

HTML

The HTML, which contains multiple paragraphs of content from the MDN HTML, CSS, and JavaScript home pages, has been hidden for brevity.

```
<h1>HTML, CSS, and JavaScript summaries</h1>
<p>
  <strong>HTML</strong> (HyperText Markup Language) is the most basic building
  block of the Web. It defines the meaning and structure of web content. Other
  technologies besides HTML are generally used to describe a web page's
  appearance (CSS) or behavior (JavaScript).
</p>
<p>
  "Hypertext" refers to text containing links that connect web pages to one
  another, either within a single website or between websites. Links are a
  fundamental aspect of the Web. By uploading content to the Internet and
  linking it to pages created by other people, you become an active participant
  in the World Wide Web.
</p>
<p>
  HTML uses "markup" to annotate text, images, and other content for display in
  a Web browser. HTML markup includes special "elements" such as
  <a href="/en-US/docs/Web/HTML/Reference/Elements/head"
    ><code>&lt;head&gt;</code></a
```

```
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/title"
    ><code>&lt;title&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/body"
    ><code>&lt;body&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/header"
    ><code>&lt;header&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/footer"
    ><code>&lt;footer&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/article"
    ><code>&lt;article&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/section"
    ><code>&lt;section&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/p"><code>&lt;p&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/div"
    ><code>&lt;div&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/span"
    ><code>&lt;span&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/img"
    ><code>&lt;img&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/aside"
    ><code>&lt;aside&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/audio"
    ><code>&lt;audio&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/canvas"
    ><code>&lt;canvas&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/datalist"
    ><code>&lt;datalist&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/details"
    ><code>&lt;details&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/embed"
    ><code>&lt;embed&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/nav"
    ><code>&lt;nav&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/search"
    ><code>&lt;search&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/output"
    ><code>&lt;output&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/progress"
    ><code>&lt;progress&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/video"
    ><code>&lt;video&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/ul"
    ><code>&lt;ul&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/ol"
    ><code>&lt;ol&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/li"
    ><code>&lt;li&gt;</code></a
  >
  and many others.
</p>
<p>
  An HTML element is set off from other text in a document by "tags", which
  consist of the element name surrounded by <code>&lt;</code> and
  <code>&gt;</code>. The name of an element inside a tag is case-insensitive.
  That is, it can be written in uppercase, lowercase, or a mixture. For example,
  the <code>&lt;title&gt;</code> tag can be written as
  <code>&lt;Title&gt;</code>, <code>&lt;TITLE&gt;</code>, or in any other way.
  However, the convention and recommended practice is to write tags in
  lowercase.
</p>

<hr />

<p>
  <strong>Cascading Style Sheets</strong> (<strong>CSS</strong>) is a
  <a href="/en-US/docs/Web/API/StyleSheet">stylesheet</a> language used to
  describe the presentation of a document written in
  <a href="/en-US/docs/Web/HTML">HTML</a> or
  <a href="/en-US/docs/Web/XML/Guides/XML_introduction">XML</a> (including XML
  dialects such as <a href="/en-US/docs/Web/SVG">SVG</a>,
  <a href="/en-US/docs/Web/MathML">MathML</a> or
  <a href="/en-US/docs/Glossary/XHTML">XHTML</a>). CSS describes how elements
  should be rendered on screen, on paper, in speech, or on other media.
</p>
<p>
  CSS is among the core languages of the <strong>open web</strong> and is
  standardized across web browsers according to
  <a href="https://www.w3.org/Style/CSS/#specs" class="external" target="_blank"
    >W3C specifications</a
```

```
  >. Previously, the development of various parts of CSS specification was done
  synchronously, which allowed the versioning of the latest recommendations. You
  might have heard about CSS1, CSS2.1, or even CSS3. There will never be a CSS3
  or a CSS4; rather, everything is now just "CSS" with individual CSS modules
  having version numbers.
</p>
<p>
  After CSS 2.1, the scope of the specification increased significantly and the
  progress on different CSS modules started to differ so much, that it became
  more effective to
  <a
    href="https://www.w3.org/Style/CSS/current-work"
    class="external"
    target="_blank"
    >develop and release recommendations separately per module</a
  >. Instead of versioning the CSS specification, W3C now periodically takes a
  snapshot of
  <a href="https://www.w3.org/TR/css/" class="external" target="_blank"
    >the latest stable state of the CSS specification</a
  >
  and individual modules progress. CSS modules now have version numbers, or
  levels, such as
  <a
    href="https://drafts.csswg.org/css-color-5/"
    class="external"
    target="_blank"
    >CSS Color Module Level 5</a
  >.
</p>

<hr />

<p>
  <strong>JavaScript</strong> (<strong>JS</strong>) is a lightweight interpreted
  (or
  <a href="/en-US/docs/Glossary/Just_In_Time_Compilation"
    >just-in-time compiled</a
  >) programming language with
  <a href="/en-US/docs/Glossary/First-class_Function">first-class functions</a>.
  While it is most well-known as the scripting language for Web pages,
  <a
    href="https://en.wikipedia.org/wiki/JavaScript#Other_usage"
    class="external"
    target="_blank"
    >many non-browser environments</a
  >
  also use it, such as <a href="/en-US/docs/Glossary/Node.js">Node.js</a>,
  <a href="https://couchdb.apache.org/" class="external" target="_blank"
    >Apache CouchDB</a
  >
  and
  <a
    href="https://opensource.adobe.com/dc-acrobat-sdk-docs/acrobatsdk/"
    class="external"
    target="_blank"
    >Adobe Acrobat</a
  >. JavaScript is a
  <a href="/en-US/docs/Glossary/Prototype-based_programming">prototype-based</a
  >, <a href="/en-US/docs/Glossary/Garbage_collection">garbage-collected</a>,
  <a href="/en-US/docs/Glossary/Dynamic_typing">dynamic</a> language, supporting
  multiple paradigms such as imperative, functional, and object-oriented.
</p>
<p>
  JavaScript's dynamic capabilities include runtime object construction,
  variable parameter lists, function variables, dynamic script creation (via
  <a href="/en-US/docs/Web/JavaScript/Reference/Global_Objects/eval"
    ><code>eval</code></a
  >), object introspection (via
  <a href="/en-US/docs/Web/JavaScript/Reference/Statements/for...in"
    ><code>for...in</code></a
  >
  and
  <a
    href="/en-US/docs/Web/JavaScript/Reference/Global_Objects/Object#static_methods"
    ><code>Object</code> utilities</a
  >), and source-code recovery (JavaScript functions store their source text and
  can be retrieved through
  <a
    href="/en-US/docs/Web/JavaScript/Reference/Global_Objects/Function/toString"
    ><code>toString()</code></a
  >).
</p>
<p>
  This section is dedicated to the JavaScript language itself, and not the parts
  that are specific to Web pages or other host environments. For information
  about <a href="/en-US/docs/Glossary/API">APIs</a> that are specific to Web
  pages, please see <a href="/en-US/docs/Web/API">Web APIs</a> and
  <a href="/en-US/docs/Glossary/DOM">DOM</a>.
</p>
<p>
  The standards for JavaScript are the
  <a href="https://tc39.es/ecma262/" class="external" target="_blank"
    >ECMAScript Language Specification</a
  >
  (ECMA-262) and the
  <a href="https://tc39.es/ecma402/" class="external" target="_blank"
    >ECMAScript Internationalization API specification</a
  >
  (ECMA-402). As soon as one browser implements a feature, we try to document
  it. This means that cases where some
  <a href="https://github.com/tc39/proposals" class="external" target="_blank"
    >proposals for new ECMAScript features</a
  >
```

```
  have already been implemented in browsers, documentation and examples in MDN
  articles may use some of those new features. Most of the time, this happens
  between the
  <a href="https://tc39.es/process-document/" class="external" target="_blank"
    >stages</a
  >
  3 and 4, and is usually before the spec is officially published.
</p>
<p>
  Do not confuse JavaScript with the

  JavaScript documentation of core language features (pure
  <a
    href="/en-US/docs/Web/JavaScript/Reference/JavaScript_technologies_overview"
    >ECMAScript</a
  >, for the most part) includes the following:
</p>
```

CSS

We start by setting `column-width` on the `<body>` element to define the preferred width for the columns. A `gap` of `3em 2em` results in a `3em` gap between rows and a `2em` gap between columns. The `column-rule` adds a line in the center of the gap between the columns. The `column-height` of `95vh` makes the columns nearly as tall as the viewport.

We explicitly set `column-wrap` to `wrap` as a reminder of the applied wrapping behavior. We could have set the value to `auto` or omitted the property altogether, as, by default, `column-wrap` resolves to `wrap` when the `column-height` is set to a `<length>` value.

```
body {
  column-width: 150px;
  column-rule: 2px solid red;
  gap: 3em 2em;
  padding: 0 2em;
  column-height: 95vh;
  column-wrap: wrap;
}
```

Next, we set the `<h1>` element's `column-span` property to `all`, to make the heading span across all the columns, and set the `margin-top` property of the first `<p>` to `0` so that it lines up with the top of the columns.

```
h1 {
  column-span: all;
}

p:first-of-type {
  margin-top: 0;
}
```

Finally, we add scroll snapping by setting `scroll-snap-type` to `y mandatory` on the `<html>` element, and `scroll-snap-align` to `start` on the `::column` pseudo-elements that represent each generated column. This causes the content to snap to the top of a new column each time it is scrolled.

```
html {
  scroll-snap-type: y mandatory;
}

::column {
  scroll-snap-align: start;
}
```

```
* {
  box-sizing: border-box;
}

html {
  font-family: "Arial", sans-serif;
}

p {
  line-height: 1.5;
}
```

```
@supports not (column-height: 15em) {
  body::before {
    content: "Your browser does not support the 'column-height' property.";
    background-color: wheat;
    position: fixed;
    inset: 40% 0;
    height: fit-content;
    text-align: center;
    padding: 1rem 0;
  }
}
```

Result

Try scrolling the content. Note how each new row of columns fills the viewport, and how the content snaps neatly to the top of a new row with each scroll.

<code>column-height</code> and <code>column-count</code> playground

This example builds upon the previous one by including two range sliders that allow you to adjust the multiple-column layout's column count and column height.

HTML and JavaScript

The HTML is the same as the previous example, with the addition of a form containing two `<input="range">` elements that update the `column-count` and `column-height` values via JavaScript. The HTML and JavaScript are hidden for brevity.

```
<form>
  <div>
    <label for="columns">
      <code>column-count <output id="columns-output">3</output></code>
    </label>
    <input type="range" min="3" max="6" value="3" id="columns" />
  </div>
  <div>
    <label for="column-height">
      <code>column-height <output id="column-height-output">20em</output></code>
    </label>
    <input type="range" min="10" max="30" value="20" id="column-height" />
  </div>
</form>
```

```
const columnsRange = document.getElementById("columns");
const columnsOutput = document.getElementById("columns-output");
const columnHeightRange = document.getElementById("column-height");
const columnHeightOutput = document.getElementById("column-height-output");

columnsRange.addEventListener("input", () => {
  document.body.style.columnCount = columnsRange.value;
  columnsOutput.textContent = columnsRange.value;
});

columnHeightRange.addEventListener("input", () => {
  document.body.style.columnHeight = `${columnHeightRange.value}em`;
  columnHeightOutput.textContent = `${columnHeightRange.value}em`;
});
```

CSS

We specify the `column-rule` and `gap` with the same values as the previous example. We don't specify a `column-width`; instead, we create a multi-column layout using the `column-count` property, interactively setting the number of columns and the height of the column rows using JavaScript. Scroll snapping is not included in this example.

```
body {
  column-count: 3;
  column-height: 20em;
  column-rule: 2px solid red;
  gap: 3em 2em;
  padding: 0 2em;
}
```

```
form {
  border: 1px solid black;
  background-color: white;
  padding: 10px;
  position: fixed;
  bottom: 1px;
  right: 1px;
}

form div {
  display: flex;
  gap: 1em;
  align-items: center;
  justify-content: space-between;
}
```

Result

Adjust the number of columns and the column height to see the effect of these properties.

column-rule CSS property

The **`column-rule`** CSS shorthand property sets the width, style, and color of the lines drawn between columns in multi-column grid, flex, and multi-col layouts.

Try it

```
column-rule: solid;
```

```
column-rule: groove 0.8em teal;
```

```
column-rule:
  dotted thick teal,
  repeat(3, dashed pink 1px, outset olive 5px);
```

```
column-rule:
  dotted thick teal,
  repeat(auto, dashed pink 1px, dashed pink 5px),
  dotted thick teal;
```

```
column-rule:
  dashed medium olive,
```

```
  repeat(auto, dotted pink 1px),
  inset orange 5px;
```

```
<section id="default-example">
  <p id="example-element">
    London. Lady Catnip sitting in Lincoln's Inn Hall. Nice May weather. As much
    mud in the streets as if the waters had but newly retired from the face of
    the earth, and it would not be great to meet a Fred, two feet long or so,
    waddling like an iguana up Holborn Hill.
  </p>
</section>
```

```
#example-element {
  columns: 7;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `column-rule-color`
- `column-rule-style`
- `column-rule-width`

Syntax

```
/* One value */
column-rule: dashed;
column-rule: inset 8px;
column-rule: solid teal;
column-rule: thick outset rgb(18 122 67);

/* Multiple values */
column-rule: groove, dashed, solid;
column-rule:
  dotted medium teal,
  dashed pink 0.5em,
  outset olive 1px;
column-rule:
  solid #0ff,
  repeat(3, dashed pink 1px, outset olive 5px);
column-rule:
  inset 3px yellow,
  repeat(auto, dashed pink 1px, groove olive 5px);

/* Global values */
column-rule: inherit;
column-rule: initial;
column-rule: revert;
column-rule: revert-layer;
column-rule: unset;
```

Values

This property is specified as a comma-separated list of values. Each value can be one of the following value types:

`<gap-rule>`

Specified as one, two, or three of the values listed below, in any order.

`<'line-width'>`

A `<line-width>`: This can be one of the keywords `thin`, `medium`, or `thick`, or a positive `<length>` value, representing the width of the line. The default value is `medium`.

`<'line-style'>`

A `<line-style>`: one of `none`, `hidden`, `dotted`, `dashed`, `solid`, `double`, `groove`, `ridge`, `inset`, or `outset`. The default value is `none`. See `column-rule-style`.

`<'color'>`

A `<color>` value representing the color of the line. The default value is `currentcolor`. See `column-rule-color`.

`<gap-repeat-rule>`

A `repeat()` function, with an `<integer>` of `1` or more as the first argument and one or more `<gap-rule>` values as subsequent arguments. The `<integer>` specifies how many times the list of `<gap-rule>` values should be repeated.

`<gap-auto-repeat-rule>`

A `repeat()` function, with `auto` as the first argument and one or more `<gap-rule>` values as subsequent arguments. The provided list of `<gap-rule>` values is repeated as many times as needed to fill in values for any column-rules that are not explicitly specified by other components of the property value.

Description

The `column-rule` property defines the line style of any rule lines drawn in the gaps between columns in multi-column, flex, and grid containers with more than one column.

The `column-rule` is shorthand for `column-rule-color`, `column-rule-style`, and `column-rule-width`. The `column-rule`, along with the `row-rule` shorthand property, can also be set using the `rule` shorthand.

The property value is a comma-separated list of components, which can include `<gap-rule>`, `<gap-repeat-rule>`, and `<gap-auto-repeat-rule>` types. Each `<gap-rule>` defines the width, color, and style of one or more rule lines.

If the property value consists of only one `<gap-rule>`, all the column rules will be that style. If we declare the following, all column rules will be `dashed maroon 3px`:

```
column-rule: dashed maroon 3px;
```

When more than one `<gap-rule>` is declared, they will be applied to column-rules in the order specified. If there are more gutters between columns than `<gap-rule>` values, the list of values is repeated until every column rule has a gap line. If we declare the following, for example, every odd rule will be `dashed maroon 3px`, and every even rule will be `dotted navy 5px`.

```
column-rule:
  dashed maroon 3px,
```

```
  dotted navy 5px;
```

Repeated line styles

The `repeat()` function, with an integer of `1` or greater as the first argument, can be used to repeat a valid list of CSS `<gap-rule>` values passed as subsequent arguments the specified number of times. This allows the same `<gap-rule>` to be repeated a set number of times without repeating the same CSS multiple times. The following declarations are equivalent:

```
column-rule:
  solid maroon 5px,
  outset navy 10px,
  inset olive 1px,
  outset navy 10px,
  inset olive 1px,
  outset navy 10px,
  inset olive 1px;
column-rule:
  solid maroon 5px,
  repeat(3, outset navy 10px, inset olive 1px);
```

This creates a list of seven rules. If the number of styles in the `column-rule` value's style list exceeds the number of gaps between columns, the excess style values are ignored. If the container on which this is applied has three columns, the rule in the first gutter will be `solid maroon 5px` and the second `outset navy 10px`.

If there are more gutters than styles, the list of styles is repeated. If the container has 8, 15, 22, or 29 columns, this sequence of styles will be repeated one, two, three, or four times, respectively, with the last rule being `inset olive 1px`.

Auto-repeating line styles

The `repeat()` function also accepts `auto` as the first argument instead of a positive integer. With `auto` as the first argument, the `<gap-rule>` values passed as subsequent arguments will be repeated as many times as needed to fill in values for any rules that are not explicitly specified by other components of the property value.

```
column-rule:
  solid maroon 5px,
  repeat(auto, dotted olive 1px, dashed navy 1px),
  solid maroon 5px;
```

In this case, the first and last column rules will be `solid maroon 5px`, and all others will alternate between `dotted olive 1px` and `dashed navy 1px`. It doesn't matter if the container has 3, 6, 11, 16, or 21 columns; the first and last gutters will always have a thick solid maroon line painted between them (unless `column-rule-visibility-items` leads to no line being drawn), and all the other column rules will be thin, dotted olive or dashed navy lines. If there are only 2 or 3 columns, there will be no dotted or dashed lines.

The `auto` keyword within the `repeat()` function creates an auto-repeater that fills in values for column rules that would not otherwise receive values from other parts of the list, preventing the list from being cycled. At most, only one `repeat(auto, <gap-rule>)` can be present in a `column-rule` value.

Formal definition

Initial value	as each of the properties of the shorthand: • `column-rule-width`: `medium` • `column-rule-style`: `none` • `column-rule-color`: `currentcolor`
Applies to	multicol elements
Inherited	no
Computed value	as each of the properties of the shorthand: • `column-rule-width`: the absolute `<length>`, snapped as a line width • `column-rule-style`: as specified • `column-rule-color`: computed color
Animation type	as each of the properties of the shorthand: • `column-rule-width`: a length • `column-rule-style`: discrete • `column-rule-color`: a color

Formal syntax

```
column-rule =
  <gap-rule-list>      |
  <gap-auto-rule-list>

<gap-rule-list> =
  <gap-rule-or-repeat>#

<gap-auto-rule-list> =
  <gap-rule-or-repeat>#? , <gap-auto-repeat-rule> , <gap-rule-or-repeat>#?

<gap-rule-or-repeat> =
  <gap-rule>         |
  <gap-repeat-rule>

<gap-auto-repeat-rule> =
  repeat( auto , <gap-rule># )

<gap-rule> =
  <line-width>  ||
  <line-style>  ||
  <color>

<gap-repeat-rule> =
  repeat( <integer [1,∞]> , <gap-rule># )

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick
```

```
<line-style> =
  none    |
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

In this example, we define a single rule for the lines drawn between flex items.

HTML

We include a list of authors:

```
<ul>
  <li>Kimberlé Crenshaw</li>
  <li>Angela Y. Davis</li>
  <li>Bernardine Evaristo</li>
  <li>Audre Lorde</li>
  <li>Cathy Park Hong</li>
  <li>Zoya Patel</li>
  <li>Juno Mac</li>
  <li>Molly Smith</li>
  <li>Tara Westover</li>
</ul>
```

CSS

We define the list to be a flex container, creating columns by setting the `flex-direction` to `row` using the `flex-flow` shorthand. We include a `gap` of `12px` to provide enough room between the columns to fit our `10px groove maroon` rule:

```
ul {
  display: flex;
  flex-flow: row;
  gap: 12px;
  list-style-type: none;

  column-rule: 10px groove maroon;
}
```

Result

Repeating values

This example demonstrates how the values are repeated when there are fewer values in the list of styles than column rules. It also demonstrates the default values for the width, color, and style of `medium`, `currentcolor` and `none`, respectively.

Using the same HTML and CSS as in the previous example, we include four comma-separated `<gap-rule>` values as the `column-rule` value, omitting the width in the first `<gap-rule>`, the color in the second, and the style from the third, with the fourth including all three components:

```
ul {
  column-rule:
    maroon dashed,
    1px dotted,
    5px teal,
    10px orange solid;
}
```

The maroon line is `3px` wide. The dotted line is the same color as the text. There are no teal lines, as the `<line-style>` of the third `<gap-rule>` defaults to `none`, so no line is painted. There are more gutters than `<gap-rule>` values, so the list of values gets repeated.

Using the <code>repeat()</code> function

This example demonstrates using the `repeat()` function within the `column-rule` property value. We use the same HTML and CSS as in the previous examples. We include a `repeat()` function, setting the list of two `<gap-rule>` values to repeat four times.

```
ul {
  column-rule:
    10px maroon dashed,
    repeat(4, dotted olive 3px, dashed teal 3px),
    10px maroon dashed;
}
```

The flex container has nine columns, so eight gutters. The `repeat()` function repeats two style values four times, creating a list of ten `<gap-rule>` values. As there are fewer column gutters than total `<gap-rule>` values, the last two values in the list are discarded.

Using <code>auto</code> within <code>repeat()</code>

This example demonstrates using the `auto` argument instead of an integer in the `repeat()` function.

Using `repeat(auto, <gap-rule>)`, we set all column rules to `1px dotted` and default to the current color, except the first and last, which we set to `10px groove maroon`.

```
ul {
  column-rule:
    10px groove maroon,
```

```
    repeat(auto, 3px dotted maroon),
    10px groove maroon;
}
```

```
@layer no-support {
  @supports not (column-rule: thin, thick) {
    body::before {
      content: "Your browser doesn't support multiple values for the column-rule property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

column-rule-break CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`column-rule-break`** CSS property sets the behavior for breaking column rules into segments wherever column rules intersect row gaps.

Try it

```
column-rule-break: none;
```

```
column-rule-break: normal;
```

```
column-rule-break: intersection;
```

```
<section id="default-example">
  <div id="example-element">
    <i>A</i>
    <i>B</i>
    <i>C</i>
    <i>D</i>
    <i>E</i>
    <i>F</i>
    <i>G</i>
    <i>H</i>
    <i>I</i>
    <i>J</i>
    <i>K</i>
    <i>L</i>
    <i>M</i>
    <i>N</i>
    <i>O</i>
    <i>P</i>
    <i>Q</i>
    <i>R</i>
    <i>S</i>
    <i>T</i>
    <i>U</i>
    <i>V</i>
    <i>W</i>
    <i>X</i>
    <i>Y</i>
    <i>Z</i>
  </div>
</section>
```

```
#example-element {
  display: grid;
  grid-template-columns: repeat(7, 1fr);
  column-rule: solid thick orange;
  row-rule: solid thick lavender;
  gap: 15px;
  rule-overlap: column-over-row;
}
#example-element i {
  padding: 5px;
}
```

Syntax

```
/* Keyword values */
column-rule-break: none;
column-rule-break: normal;
column-rule-break: intersection;

/* Global values */
column-rule-break: inherit;
column-rule-break: initial;
column-rule-break: revert;
```

```
column-rule-break: revert-layer;
column-rule-break: unset;
```

Values

This property is specified as a single keyword from the following list:

`none`

There are no breaks in column rules when they intersect row gaps; rather, a continuous column rule is painted the whole height of the container, from edge to edge.

`normal`

In grid and flex containers, behaves as `none`. In multi-col, behaves as `intersection`. This is the default value.

`intersection`

Column rules always break when they intersect row gaps, with column rule segments starting and ending at container and gap edges.

Description

The `column-rule-break` property specifies whether or not to break column rules into segments when they cross row gaps.

Column rules are painted within a column gap as one or more segments, with segments occurring between adjacent grid items in separate columns, between flex items or flex lines in flex layouts depending on the `flex-direction`, or between columns in multi-col layouts.

The `column-rule-break` property only determines if the break occurs. By default, the break between column rule segments is the height of the row gap, as each segment starts and ends at the edge of the gap (or edge of the container). If the row gap is `0`, this break may not be visible. The end positions can be controlled with the `column-rule-inset` properties.

If `column-rule-break` is set to `none`, there are no breaks. In this case, the column rule line is continuous, and any `column-rule-inset` values only affect the left and right edges of the column rule at the container's edge. When there are breaks, the `column-rule-inset` properties affect the start and end of every column rule segment.

The `column-rule-break` property, along with the `row-rule-break` property, can be set using the `rule-break` shorthand.

Whether a column rule is by default a single continuous segment or segments that break at row gaps depends on the container type.

Grid containers

In grid containers, by default, column rule segments continue through row gap intersections, equivalent to `column-rule-break: none`. Setting `column-rule-break: intersection` forces the segments to break at every row gap they would otherwise cross.

```
<h1>Default rule breaks in grid</h1>
<div class="grid">
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
  <div></div>
</div>
<p>
  <label
    ><input type="checkbox" /> Set
    <code>column-rule-break: intersection</code></label
  >
</p>
```

```
h1,
div {
  font-family: sans-serif;
  text-align: center;
}
h1 {
  font-size: 1.25em;
}
h2 {
  font-size: 1em;
}

:has(:checked) .grid {
  column-rule-break: intersection;
}
.grid {
  display: grid;
  grid-template-columns: repeat(3, 1fr);
  gap: 20px;
  rule: 5px solid blue;
  row-rule-color: lightblue;
  rule-overlap: column-over-row;
  width: 100%;
}

.grid > div {
  border: 1px solid green;
  background-color: lime;
  height: 30px;
}

@layer no-support {
  @supports not (column-rule-break: intersection) {
    body::before {
      content: "Your browser doesn't support the column-rule-break property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

By default, there are no column rule breaks. Check the checkbox to set the `column-rule-break` to `intersection`, which makes the otherwise continuous rules break at every "cross" intersection. By default, the break between segments is the height of the `row-gap`, which was set to `20px` in this case.

Flex containers

In flexbox, whether the column rules break at every row gap by default depends on the `flex-direction`. In horizontal writing modes, when set to `row` or `row-reverse`, the column rule breaks at every row gap, equivalent to `column-rule-break: intersection`. When the `flex-direction` is `column` or `column-reverse`, the column rule is continuous by default, equivalent to `column-rule-break: none`.

```
<h1>Default rule breaks in flexbox</h1>
<article>
  <section>
    <h2>flex-direction: row</h2>
    <div class="flexbox">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
  <section>
    <h2>flex-direction: column</h2>
    <div class="flexbox column">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
</article>
<p>
  <label
    ><input type="checkbox" /> Set
    <code>column-rule-break: intersection</code></label
  >
</p>
```

```
h1,
article {
  font-family: sans-serif;
  text-align: center;
}
h1 {
  font-size: 1.25em;
}
h2 {
  font-size: 1em;
}

:has(:checked) .flexbox {
  column-rule-break: intersection;
}
article {
  display: flex;
  gap: 5vw;
  rule: 1px solid black;
  width: 100vw;
}
section {
  flex-basis: 45vw;
}
.flexbox {
  display: flex;
  flex-flow: balance;
  flex-line-count: 3;
  gap: 20px;
  rule: 5px solid blue;
  row-rule-color: lightblue;
  width: 100%;
}
.column {
  flex-flow: column balance;
  gap: 20px;
}

.flexbox > div {
  border: 1px solid green;
  background-color: lime;
  flex: 1 1 auto;
  height: 30px;
}

@layer no-support {
  @supports not (column-rule-break: intersection) {
    body::before {
      content: "Your browser doesn't support the column-rule-break property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

In horizontal writing modes, setting the `column-rule-break` to `intersection` only impacts the column rules in the `column` and `column-reverse` scenarios.

Multi-col containers

In multi-col containers, the default `normal` value behaves the same as `intersection`. While the row decorations are continuous by default, column rules break at every intersection. Column rules break into segments at every row gap, with each segment starting and ending at the edge of the gap. These start and end positions can be changed with the `column-rule-inset` properties.

```
<h1>Default rule breaks in multi-col</h1>
<ol>
  <li>One fish</li>
  <li>Two fish</li>
  <li>Red fish</li>
  <li>Blue fish</li>
  <li>Black fish</li>
  <li>Blue fish</li>
  <li>Old fish</li>
  <li>New fish.</li>
  <li>This one has a little star.</li>
  <li>This one has a little car.</li>

      padding: 1rem 0;
    }
  }
}
```

If you select `none`, the column rule will no longer break into segments; rather, it will continue from the top of the container, until it reaches the bottom edge. The `column-rule-inset` properties can be used to offset the ends of the column gap decorations.

Formal definition

Value not found in DB!

Formal syntax

```
column-rule-break =
  none          |
  normal        |
  intersection
```

This syntax reflects the latest standard as per CSS Gap Decorations Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

In this example, we use the `column-rule-break` property to break each rule segment in a grid container, creating column rule segments between row gaps. Changing the `row-gap` property changes the segment size.

HTML

We create a list of 50 items and a slider to select the row gap width. Most of the HTML is hidden for brevity.

```
<ul>
  <li>1</li>
  <li>2</li>
  ...
  <li>49</li>
  <li>50</li>
</ul>
```

```
<p>
  <label
    >Change the width of the row gap.
    <input type="range" min="0" max="32" value="16" id="gap"
  /></label>
  <output id="o"></output>
</p>
<ul id="ul">
  <li>1</li>
  <li>2</li>
  <li>3</li>
  <li>5</li>
  <li>6</li>
  <li>7</li>
  <li>8</li>
  <li>9</li>
  <li>10</li>
  <li>11</li>
  <li>12</li>
  <li>13</li>
  <li>14</li>
  <li>15</li>
  <li>16</li>
  <li>17</li>
  <li>18</li>
  <li>19</li>
  <li>20</li>
  <li>21</li>
  <li>22</li>
  <li>23</li>
  <li>24</li>
  <li>25</li>
  <li>26</li>
  <li>27</li>
  <li>28</li>
  <li>29</li>
  <li>30</li>
  <li>31</li>
  <li>32</li>
  <li>33</li>
  <li>34</li>
  <li>35</li>
  <li>36</li>
  <li>37</li>
  <li>38</li>
  <li>39</li>
  <li>40</li>
  <li>41</li>
  <li>42</li>
  <li>43</li>
  <li>44</li>
  <li>45</li>
  <li>46</li>
  <li>47</li>
  <li>48</li>
  <li>49</li>
  <li>50</li>
</ul>
```

CSS

We define the unordered list as an 8-column container, creating rows and columns with the `grid-template-columns` property and setting `list-style-type` to `none` to remove the bullets. We include a `gap` of `20px` to provide enough room between the rows and columns to fit our `20px` solid row and column rules. We include the `rule-overlap` property to paint the column decoration on top of any row decorations. Last, we set the column rules to break at every intersection.

```
ul {
  display: grid;
  grid-template-columns: repeat(8, 1fr);
  list-style-type: none;
  gap: 20px;

  column-rule: 10px solid olive;
  row-rule: 10px solid palegoldenrod;
```

```
  rule-overlap: column-over-row;

  column-rule-break: intersection;
}
```

The rest of the CSS is hidden for brevity.

```
ol {
  place-items: center;
  width: 95vw;
}
li {
  text-align: center;
  font-family: sans-serif;
  line-height: 50px;
}
@layer no-support {
  @supports not (column-rule-break: intersection) {
    body::before {
      content: "Your browser doesn't support the column-rule-break property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
const gap = document.getElementById("gap");
const ul = document.getElementById("ul");
const output = document.getElementById("o");

gap.addEventListener("input", () => {
  output.innerText = ul.style.rowGap = `${gap.value}px`;
});
```

Result

Make the row gaps wider and note how the breaks between column segments grow. Bring the row gap width down to `0px`, and notice how the column decoration appears continuous. It isn't! The `0px` gap between segments may not be visible, but the segments still start and end at the gap, so any offsets set with `column-rule-inset-*` properties still apply.

column-rule-color CSS property

The **`column-rule-color`** CSS property defines the colors of the lines drawn between columns in multi-column grid, flex, and multi-col layouts.

Try it

```
column-rule-color: purple;
```

```
column-rule-color: rgb(48 125 222), rgb(222 48 125);
```

```
column-rule-color: rgb(48 125 222), repeat(3, rgb(222 48 125));
```

```
column-rule-color: purple, repeat(auto, orange, yellow);
```

```
<section id="default-example">
  <p id="example-element">
    London. Michaelmas term lately over, and the Lord Chancellor sitting in
    Lincoln's Inn Hall. Implacable November weather. As much mud in the streets
    as if the waters had but newly retired from the face of the earth, and it
    would not be wonderful to meet a Megalosaurus, forty feet long or so,
    waddling like an elephantine lizard up Holborn Hill.
  </p>
</section>
```

```
#example-element {
  columns: 7;
  column-rule: solid thick;
  gap: 7px;
}
```

Syntax

```
/* Single <color> value */
column-rule-color: purple;
column-rule-color: rgb(192 56 78);
column-rule-color: transparent;
column-rule-color: hsl(0 100% 50% / 60%);

/* Multiple values */
column-rule-color: purple, magenta;
column-rule-color: repeat(3, purple), repeat(3, transparent);
column-rule-color: repeat(3, purple), repeat(3, yellow, blue);
column-rule-color: purple, repeat(auto, transparent), purple;
column-rule-color: purple, repeat(auto, blue, yellow), purple;
column-rule-color:
  repeat(3, purple), repeat(auto, transparent), repeat(3, purple);
```

```
/* Global values */
column-rule-color: inherit;
column-rule-color: initial;
column-rule-color: revert;
column-rule-color: revert-layer;
column-rule-color: unset;
```

Values

The `column-rule-color` property accepts a comma-separated list of values, including:

`<line-color>`

A `<color>` representing the color of the line.

`<repeat-line-color>`

A `repeat()` function, with an `<integer>` of `1` or more as the first argument and one or more `<color>` values as subsequent arguments. The `<integer>` specifies how many times the `<color>` values should be repeated.

`<auto-repeat-line-color>`

A `repeat()` function, with `auto` as the first argument and one or more `<color>` values as subsequent arguments. The provided `<color>` values are repeated as many times as needed to fill in values for any column-rules that are not explicitly specified by other components of the property value.

Description

The `column-rule-color` property defines the colors of any lines drawn in the gaps between columns in multi-column, flex, and grid containers with more than one column.

The value is a comma-separated list of components, which can include `<line-color>`, `<repeat-line-color>`, and `<auto-repeat-line-color>` types.

The `column-rule-color`, along with the `column-rule-width` and `column-rule-style` properties, can be set using the `column-rule` shorthand. The `column-rule-color`, along with the `row-rule-color` property, can also be set using the `rule-color` shorthand.

A `<line-color>` can be declared as any valid CSS `<color>` value. If the property value consists of only one `<color>`, all the rule lines will be that color. For example, if we declare the following, the lines in the gutters between columns will all be blue:

```
column-rule-color: blue;
```

When more than one `<line-color>` is declared, they will be applied to lines painted in the column gutters in the order specified. If there are more rules than `<line-color>` values, the list of colors is repeated until every column-rule has a color. If we declare the following, for example, every odd rule will be red, and every even rule will be yellow.

```
column-rule-color: red, yellow;
```

Repeated line colors

The `repeat()` function, with an integer of `1` or greater as the first argument, can be used to repeat a valid list of CSS `<color>` values passed as subsequent arguments the specified number of times. This allows the color values to be repeated as many times as you need without having to list them individually. The following declarations are equivalent:

```
column-rule-color: blue, yellow, red, yellow, red;
column-rule-color: blue, repeat(2, yellow, red);
```

This creates a list of five colors. If the number of colors in the `column-rule-color` value's color list exceeds the number of gaps between columns, the excess color values are ignored. If the container has three columns, the rule in the first gutter will be blue and the second yellow.

Auto-repeating line colors

The `repeat()` function also accepts `auto` as the first argument instead of a positive integer. With `auto` as the first argument, the `<color>` values passed as subsequent arguments will be repeated as many times as needed to fill in values for any column-rules that are not explicitly specified by other components of the property value.

```
column-rule-color: blue, repeat(auto, yellow), red;
```

In this case, the first column-rule will be blue, the last will be red, and all others will be yellow. As long as there are at least two column-rules, the first will always be blue and the last will always be red. All the other rules will be yellow, which means if there are only 2 or 3 columns, there will be no yellow lines.

The `auto` keyword within the `repeat()` function creates an auto-repeater that fills in values for the column-rule line colors that would not otherwise receive values from other parts of the list, preventing the list from being cycled. A `column-rule-color` value can include, at most, one `repeat(auto, <color>)`.

Formal definition

Initial value	`currentcolor`
Applies to	multicol elements
Inherited	no
Computed value	computed color
Animation type	a color

Formal syntax

```
column-rule-color =
  <line-color-list>      |
  <auto-line-color-list>

<line-color-list> =
  <line-color-or-repeat>#

<auto-line-color-list> =
  <line-color-or-repeat>#? , <auto-repeat-line-color> , <line-color-or-repeat>#?

<line-color-or-repeat> =
  <color>               |
  <repeat-line-color>

<auto-repeat-line-color> =
  repeat( auto , [ <color> ]# )
```

```
<repeat-line-color> =
  repeat( [ <integer [1,∞]> ] , [ <color> ]# )

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

In this example, we define a single color for the lines drawn between columns in a multi-column layout.

HTML

We include a paragraph of text.

```
<p>
  This is a bunch of text split into three columns. The `column-rule-color`
  property is used to change the color of the line that is drawn between
  columns. Don't you think that's wonderful?
</p>
```

CSS

We define the `<p>` element as a multi-column container. We include a `gap` of `7px` to provide padding for the `3px` dashed rule drawn between the columns:

```
p {
  column-count: 5;
  gap: 7px;
  column-rule-style: dashed;
  column-rule-width: 3px;

  column-rule-color: blue;
}
```

Result

Multiple color values

This example demonstrates declaring more than one color, and how the values are repeated when there are fewer values in the list of colors than gutters between columns.

Using the same HTML and CSS as in the previous example, we include three comma-separated colors as the `column-rule-color` value:

```
<p>
  This is a bunch of text split into three columns. The `column-rule-color`
  property is used to change the color of the line that is drawn between
  columns. Don't you think that's wonderful?
</p>
```

```
p {
  column-count: 5;
  gap: 7px;
  column-rule-style: dashed;
  column-rule-width: 3px;
}

@layer no-support {
  @supports not (column-rule-color: red, blue) {
    body::before {
      content: "Your browser doesn't support multiple values for the column-rule-color property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
p {
  column-rule-color: blue, yellow, red;
}
```

Result

There are four gutters but only three colors, so the list gets repeated, with the first and fourth lines both being blue.

Using the <code>repeat()</code> function

This example demonstrates using the `repeat()` function within the `column-rule-color` property value and how this function can help prevent complex values from becoming unwieldy.

HTML

We include a list of authors:

```
<ul>
  <li>Kimberlé Crenshaw</li>
  <li>Angela Y. Davis</li>
  <li>Bernardine Evaristo</li>
  <li>Audre Lorde</li>
  <li>Cathy Park Hong</li>
  <li>Zoya Patel</li>
  <li>Juno Mac</li>
  <li>Molly Smith</li>
  <li>Tara Westover</li>
</ul>
```

CSS

We start by defining the list as a grid container, creating columns with the `grid-template-columns` property. We include a `gap` of `7px` to provide enough room between the columns to fit our `3px` dashed rule, and remove the bullets with `list-style-type` set to `none`.

Then, to demonstrate how values can become complicated and the utility of the `repeat()` function, we declare two custom properties, which we use in three `color-mix()` color function declarations to create blue, red, and yellow colors. The yellow `color-mix()` color is within a `repeat()` function, set to repeat 3 times.

We also added a border around each grid item so you can see how the line is rule in the middle of the gutter between the columns.

```
ul {
  display: grid;
  grid-template-columns: repeat(9, 1fr);
  gap: 7px;
  list-style-type: none;
  column-rule-style: dashed;
  column-rule-width: 3px;

  --base: yellow;
  --mixin: blue;
  column-rule-color:
    color-mix(in lch decreasing hue, var(--base) 0%, var(--mixin)),
    repeat(3, color-mix(in lch decreasing hue, var(--base) 100%, var(--mixin))),
    color-mix(in lch decreasing hue, var(--base) 58%, var(--mixin));
}
li {
  border: 1px solid #dddddd;
}
```

Result

The grid has nine cells across, so eight gutters. The `repeat()` function repeats our two mixed color three times, creating a color list with seven colors. Since there are as more column gutters than list colors, the last color in the list is not used.

Using <code>auto</code> within <code>repeat()</code>

This example demonstrates using `auto`, instead of an integer, within the `repeat()` function.

We use the same HTML and CSS as in the previous examples, but override the `column-rule-color` value. Here, we use `repeat(auto, <color>)` to set all the lines to be almost transparent black (`#00000033`), except the first and last, which we set to a solid `black`.

```
ul {
  column-rule-color: black, repeat(auto, #00000033), black;
}
```

Result

```
@layer no-support {
  @supports not (column-rule-color: repeat(3, red)) {
    body::before {
      content: "Your browser doesn't support `repeat()` functions within a column-rule-color property value";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

column-rule-inset-cap CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`column-rule-inset-cap`** shorthand CSS property can be used to offset the column rule segment cap endpoints at the container's start and end edges, and endpoints where the segments don't intersect other row or column segments.

Try it

```
column-rule-inset-cap: -20px;
```

```
column-rule-inset-cap: 0;
```

```
column-rule-inset-cap: 1em;
```

```
column-rule-inset-cap: 100%;
```

```
column-rule-inset-cap: overlap-join;
```

```
<section id="default-example">
  <div id="example-element">
    <i>A</i>
```

```
    <i>B</i>
    <i>C</i>
    <i>D</i>
    <i>E</i>
    <i>F</i>
    <i>G</i>
    <i>H</i>
    <i>I</i>
    <i>J</i>
    <i>K</i>
    <i>L</i>
    <i>M</i>
    <i>N</i>
    <i>O</i>
    <i>P</i>
    <i>Q</i>

    <i id="y">Y</i>
    <i id="z">Z</i>
    <i id="bang">!</i>
  </div>
</section>
```

```
#example-element {
  display: grid;
  grid-template-columns: repeat(7, 1fr);
  rule: solid thick rebeccapurple;
  column-rule-color: magenta;
  gap: 1em;
  rule-overlap: column-over-row;
  rule-visibility-items: between;
  border: 1px solid rebeccapurple;
  overflow: visible;
  margin: 1em;
}
#example-element i {
  padding: 8px;
  border: 1px dashed;
}
#y {
  grid-column: 4 / 5;
  grid-row: 4 / 5;
}
#z {
  grid-column: 5 / 6;
  grid-row: 4 / 5;
}
#bang {
  grid-column: 6 / 7;
  grid-row: 4 / 5;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `column-rule-inset-cap-end`
- `column-rule-inset-cap-start`

Syntax

```
/* Keywords */
column-rule-inset-cap: overlap-join;

/* <length-percentage> values */
column-rule-inset-cap: 0;
column-rule-inset-cap: 1em;
column-rule-inset-cap: -5px;
column-rule-inset-cap: -25%;

/* Two values */
column-rule-inset-cap: overlap-join 1em;
column-rule-inset-cap: -5px -25%;

/* Global values */
column-rule-inset-cap: inherit;
column-rule-inset-cap: initial;
column-rule-inset-cap: revert;
column-rule-inset-cap: revert-layer;
column-rule-inset-cap: unset;
```

Values

This property is specified as one or two values from the following list:

`overlap-join`

Resolves to `0`.

`<length-percentage>`

Specifies the size of the inset. Percentage values are relative to the crossing gap width, which is the width of the `row-gap` for segment endpoints at gap junctions and `0` for endpoints at the container's edge.

Description

The `column-rule-inset-cap` shorthand property can be used to set the `column-rule-inset-cap-end` and `column-rule-inset-cap-start` properties, insetting or outsetting both the start and end edges of cap segment endpoints in a single declaration.

If one value is specified, both properties are set to that value. If two values are specified, `-start` is set to the first value and `-end` is set to the second. The default value is `0`, which, in the case of cap endpoints, is the same as `overlap-join`. Positive values reduce (or inset) the segment size, while negative values increase (or outset) it.

Column rules are painted within a column gap as one or more segments, with segments occurring between:

- Adjacent columns in CSS grid layouts.
- Flex items or flex lines in flex layouts, depending on the `flex-direction`.
- Columns in multi-col layouts.

Whether a column rule spans multiple rows or is broken into multiple segments is defined by the `column-rule-break` property, with interior breaks between column rule segments being the size of the `row-gap`.

Length `column-rule-inset-cap` values inset segments by the specified value; with negative length values creating an outset, causing end edge cap segments to extend beyond the container's top and bottom edges. Percentage values for end edge cap segments are relative to `0`, so have no effect.

For interior segments, percentage values are relative to the size of the `row-gap`. Setting `-50%` will extend the segment to the middle of the gap, while `-100%` will extend the segment across the entire gap.

The `column-rule-inset-cap` property is a constituent property of a few shorthand properties:

- To inset the ends of all column segments, the `column-rule-inset-cap` property, along with the `column-rule-inset-junction` property, can be set using the `column-rule-inset` shorthand.
- To inset all row and column cap endpoints, the `column-rule-inset-cap` property, along with the `row-rule-inset-cap` property, can be set using the `rule-inset-cap` shorthand.

All segment endpoints, including this property's `-junction` and `row-` equivalents, can be set using the `rule-inset` shorthand.

Understanding cap endpoints

A *cap segment endpoint* is any segment endpoint that is not a junction segment endpoint. This includes endpoints at the container's content edges, as well as endpoints at a gap junction where no other row or column segments are present.

The `column-rule-inset-cap` property can reduce or extend the top, bottom, or both ends of column segments at the top and bottom edge of the container and the segment end at any interior junction where no other segments are present.

Column cap segments are impacted by the `rule-visibility-items` properties, which define whether row- and column-rule segments are painted in gaps adjacent to empty areas. Changing the value from `auto` to `between` or `around` can create additional interior cap segments.

In the following demonstration, the top of the column segments in the top row and the bottom of the column segments in the bottom row start and end in cap endpoints, respectively. With `column-rule-inset-cap: 16px` set, all the column segment cap endpoints are inset by `16px`. Change the inset `<length>` value to better visualize which segments start or end in cap segment endpoints.

```
<ul id="ul">
  <li>1</li>
  <li>2</li>
  <li>3</li>
  <li>4</li>
  <li>5</li>
  <li>6</li>
  <li>7</li>
  <li>8</li>
  <li>9</li>
  <li>10</li>
  <li>11</li>
  <li>12</li>
  <li>13</li>
  <li>15</li>
  <li>16</li>
</ul>

<p>
  <label>

    ul.style.columnRuleStyle = "repeat(2, inset), double, repeat(2, solid)";
  } else if (visibility.value === "around") {
    ul.style.columnRuleStyle = "repeat(3, inset), repeat(2, double)";
  } else {
    ul.style.columnRuleStyle = "solid";
  }
});
```

Change the inset. When `0px` is set, the ends of the column rules align with the top and bottom edges of the container. This is the default. Setting `-32px` outsets the segments by `32px`, with the lines being drawn `32px` past the edge of the container. As column rules don't impact the box model, these lines have no impact on the layout of the container or the rest of the content.

Select `around` as the `rule-visibility-items` value. This value paints rules in a gap segment if at least one of the two adjacent areas is occupied by an item. The start end of the top-most segments are still cap segment endpoints. The bottom-most segments of the double line-style column rules, which appear when the `rule-visibility-items` property is set to `around` do not end in cap endpoints. Rather, the bottom segment of the last two column rules end at *junctions*: interior gaps where row rule segments are present. Therefore, the `column-rule-inset-cap` property does not affect those segment endpoints.

Select `between` as the `rule-visibility-items` value. This value only paints rules in gap segments if both adjacent areas are occupied by an item. In this example, the bottom row rule ends at the third column gap, with the last row segment being between `9` and `16`. The bottom of the third column rule, shown as a double line, ends at an interior gap. As a row rule segment is present, the column segment does not end in a cap segment endpoint, so it is not affected by the `column-rule-inset-cap` property. The last two column rules, however, end at interior gaps where no other rule segments are present, so these column segments are cap segment endpoints and therefore are affected by the `column-rule-inset-cap` property.

Understanding percentage values

What a percentage value is relative to depends on the endpoint's location. Interior endpoint percentage values are relative to the width of the gap the cap endpoint touches, so generally relative to the `row-gap`, plus any additional spacing added due to `align-content` values. Percentages at container-edge endpoints are relative to `0`. For example, `column-rule-inset-cap: 50%` resolves to half the gap junction size at an interior cap and `0` at the container edges.

This example is not broken. When `rule-visibility-items` is set to `normal`, every column cap endpoint abuts the top or bottom edge of the container, so any percentage value set will be relative to `0`.

Select `around` as the `rule-visibility-items` value. The first three columns end at the container edge, so any percentage value will resolve to `0`. The last two column rules, with the double lines, end at interior gaps where row rule segments are present, so these column segments are not cap segment endpoints.

Select `between` as the `rule-visibility-items` value. The first two column rules, with the light and dark lines, end at the container edge, so they have a `0` inset. The third column rule, with the double line, ends at an interior gap where a row rule segment is present, so this column segment is not a cap segment endpoint. The last two column rules, with the solid lines, end at interior gaps where no other rule segments are present, so the percentage offset is relative to the size of the `row-gap` width, which in this case is `20px`.

Formal definition

Value not found in DB!

Formal syntax

```
column-rule-inset-cap =
  <inset-value> <inset-value>?

<inset-value> =
  <length-percentage>  |
  overlap-join
```

```
<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates setting `column-rule-inset-cap` to inset the column rule cap segment endpoints on flex containers.

HTML

The markup includes two `<div>` elements, each containing seven children. The only difference between the two containers is that the second one has an added `column` class.

```
<h1>Insetting cap column rule endpoints</h1>
<article>
  <section>
    <h2>flex-direction: row</h2>
    <div class="flexbox">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
  <section>
    <h2>flex-direction: column</h2>
    <div class="flexbox column">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
</article>
```

```
<p>
  <label
    >Change the size of the inset.
    <input type="range" min="-40" max="16" value="16" id="inset"
  /></label>
  <output id="o">16px</output>
</p>
```

CSS

We use the `display` property to turn the `.flexbox` elements into flex containers. We balance the items into three flex lines using `flex-wrap` and `flex-line-count`. We define a `lightblue` `rule` to paint both row and column gaps, then overwrite the `column-rule-color`, setting darker `blue` column gap decorations. Finally, we set the `column-rule-inset-cap` to `16px`.

```
.flexbox {
  display: flex;
  flex-wrap: balance;
  flex-line-count: 3;
  gap: 20px;
  rule: 5px solid lightblue;
  column-rule-color: blue;

  column-rule-inset-cap: 16px;
}
```

We also set the `flex-direction` on the `.column` container, to change the main axis of the flex container, and make the items flow in columns rather than rows.

```
.column {
  flex-direction: column;
}
```

The rest of the CSS is hidden for brevity.

```
body {
  font-family: sans-serif;
  text-align: center;
}
h1 {
  font-size: 1.25em;
}
h2 {
  font-size: 1em;
}
article {
  display: flex;
  gap: 5vw;
  rule: 1px solid black;
  width: 100vw;
}
section {
  flex-basis: 45vw;
}
.flexbox > div {
  border: 1px solid green;
  background-color: lime;
```

```
  flex: 1 1 auto;
  height: 30px;
}
output {
  display: inline-block;
  width: 2em;
}
p {
  margin-top: 2.5em;
}
@layer no-support {
  @supports not (column-rule-inset-cap: 16px) {
    body::before {
      content: "Your browser doesn't support the column-rule-inset-cap property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
const inset = document.getElementById("inset");
const containers = document.querySelectorAll(".flexbox");
const output = document.getElementById("o");

inset.addEventListener("input", () => {
  const val = `${inset.value}px`;
  containers[0].style.columnRuleInsetCap = val;
  containers[1].style.columnRuleInsetCap = val;
  output.innerText = val;
});
```

Result

Change the size of the inset. Note how the column segments grow and shrink only at their segment cap ends — the ends that don't intersect other column or row segments.

column-rule-inset-cap-end CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`column-rule-inset-cap-end`** CSS property can be used to offset the bottom of column rule segment cap endpoints at the container's end edge, and cap endpoints where no rule segments intersect.

Try it

```
column-rule-inset-cap-end: -20px;
```

```
column-rule-inset-cap-end: 0;
```

```
column-rule-inset-cap-end: 1em;
```

```
column-rule-inset-cap-end: 100%;
```

```
column-rule-inset-cap-end: overlap-join;
```

```

}
```

Syntax

```
/* Keyword value */
column-rule-inset-cap-end: overlap-join;

/* <length-percentage> values */
column-rule-inset-cap-end: 0;
column-rule-inset-cap-end: 1em;
column-rule-inset-cap-end: -5px;
column-rule-inset-cap-end: -25%;

/* Global values */
column-rule-inset-cap-end: inherit;
column-rule-inset-cap-end: initial;
column-rule-inset-cap-end: revert;
column-rule-inset-cap-end: revert-layer;
column-rule-inset-cap-end: unset;
```

Values

This property is specified as a single value from the following list:

`overlap-join`

Resolves to `0`.

`<length-percentage>`

Specifies the size of the inset. Percentage values are relative to the cap endpoint, which is either the width of the `row-gap` or `0`.

Description

The `column-rule-inset-cap-end` property can be used to inset the end edge of cap segment endpoints. The default value is `0`, which is the same as `overlap-join`. Positive values reduce the segment size, while negative values increase it.

Column rules are painted within a column gap as one or more segments, with segments occurring between:

- Adjacent columns in CSS grid layouts.
- Flex items or flex lines in flex layouts, depending on the `flex-direction`.
- Columns in multi-col layouts.

Whether a column rule spans multiple rows or is broken into multiple segments is defined by the `column-rule-break` property, with interior breaks between column rule segments being the size of the `row-gap`.

Length `column-rule-inset-cap-end` values inset segments by the specified value — for both interior and end edge cap segments. Negative length values create an outset, with end edge cap segments extending beyond the container's end edge.

Percentage values are relative to the size of the `row-gap` for interior segments. For end edge cap segments, percentage values are relative to `0`, so percentage values never cause cap segment endpoints at the container's end edge to extend beyond the container.

The `column-rule-inset-cap-end` property is a constituent property of several shorthand properties:

- To inset the start and end caps, the `column-rule-inset-cap-end` property, along with the `column-rule-inset-cap-start` property, can be set using the `column-rule-inset-cap` shorthand.
- To inset the ends of all column segments, the `column-rule-inset-cap-end` property, along with the `column-rule-inset-junction-end` property, can be set using the `column-rule-inset-end` shorthand.
- To inset all row and column cap and junction endpoints, the `column-rule-inset-end` property, along with the `row-rule-inset-end` property, can be set using the `rule-inset-end` shorthand.

All segment endpoints, including this property's `-start`, `-junction`, and `row-` equivalents, can be set using the `rule-inset` shorthand.

Understanding cap end

A *cap segment endpoint* is any segment endpoint that is not a junction segment endpoint. This includes endpoints at the container's content edges, as well as endpoints at a gap junction where no other rule or column segments are present.

The `column-rule-inset-cap-end` property controls the inset of the bottom edge of column cap segment endpoints, allowing the segments to be shrunk or extended.

Column cap segment endpoints are not affected by `column-rule-break` property value settings, which only control junction segment breaks. They are, however, affected by the `rule-visibility-items` properties, which define whether column- and row-rule segments are painted in gaps adjacent to empty areas.

Column cap segment endpoints only exist at the end edge of the container and at interior gaps where no other column or row rule segments are present. Therefore, whether segments are painted (or would otherwise be painted if the `rule` were set to a visible value) impacts which column segments are end cap segments.

In the following demonstration, the bottom of column rule segments end in cap endpoints. With `column-rule-inset-cap-end: 16px` set, all the column segments are inset by `16px`. Change the inset `<length>` value to better visualize which segments end in cap segment endpoints.

```
<ul id="ul">
  <li>1</li>
  <li>2</li>
  <li>3</li>
  <li>4</li>
  <li>5</li>
  <li>6</li>
  <li>7</li>
  <li>8</li>
  <li>9</li>
  <li>10</li>
  <li>11</li>
  <li>12</li>
  <li>13</li>
  <li>15</li>
  <li>16</li>
</ul>

<p>

  row-rule: 10px solid palegoldenrod;
  rule-overlap: column-over-row;
  rule-visibility-items: normal;
  rule-break: intersection;
  column-rule-inset-cap-end: 16px;

  border: 1px solid;
}
ul {
  place-items: center;
  width: 95vw;
  padding: 0;
}
li {
  text-align: center;
  font-family: sans-serif;
  background-color: #ededed;
  padding: 1em;
  width: 100%;
  box-sizing: border-box;
}

@layer no-support {
  @supports not (column-rule-inset-cap-end: 16px) {
    body::before {
      content: "Your browser doesn't support the column-rule-inset-cap-end property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
ul {
  column-rule-inset-cap-end: 100%;
  column-rule-style: inset;
}
```

```
const inset = document.getElementById("inset");
const visibility = document.getElementById("visibility");
const ul = document.getElementById("ul");
const output = document.getElementById("o");

inset.addEventListener("input", () => {
  o.innerText =
    ul.style.columnRuleInsetCapEnd = `${inset.value}${inset.dataset["unit"]}`;
});
```

```
visibility.addEventListener("change", () => {
  ul.style.ruleVisibilityItems = `${visibility.value}`;
  if (visibility.value === "between") {
    ul.style.columnRuleStyle = "repeat(2, solid), double";
  } else if (visibility.value === "around") {
    ul.style.columnRuleStyle = "repeat(3, solid), repeat(2, double)";
  } else {
    ul.style.columnRuleStyle = "solid";
  }
});
```

```
visibility.addEventListener("change", () => {
  ul.style.ruleVisibilityItems = `${visibility.value}`;
  if (visibility.value === "between") {
    ul.style.columnRuleStyle = "repeat(2, inset), double, repeat(2, solid)";
  } else if (visibility.value === "around") {
    ul.style.columnRuleStyle = "repeat(3, inset), repeat(2, double)";
  } else {
    ul.style.columnRuleStyle = "solid";
  }
});
```

Change the inset. If `0px` is set, the end of the column rules will align with the end of the container. This is the default. Setting `-32px` outsets the segments by `32px`, with the lines being drawn `32px` past the end edge of the container. As column rules don't impact the box model, these lines have no impact on the layout of the container or the rest of the content.

Select `around` as the `rule-visibility-items` value. This value paints rules in a gap segment if at least one of the two adjacent areas is occupied by an item. The double line-style column rules, which appear when the `rule-visibility-items` property is set to `around` do not end in a cap endpoint. The last two column rules end at interior gaps where row rule segments are present, so these column segments are not cap segment endpoints. Therefore, the `column-rule-inset-cap-end` property does not affect those segment endpoints.

Select `between` as the `rule-visibility-items` value, which paints rules in gap segments only if both adjacent areas are occupied by an item. The last row rule in the second row gutter ends at the third column gap. The third column rule ends at an interior gap where a row rule segment is present, so this column segment is not a cap segment endpoint and is not affected by the `column-rule-inset-cap-end` property. The last two column rules, however, end at interior gaps where no other rule segments are present, so these column segments are cap segment endpoints and therefore are affected by the `column-rule-inset-cap-end` property.

Understanding percentage values

The length a percentage value is relative to depends on the endpoint location. Interior endpoint percentage values are relative to the width of the gap at the cap endpoint, so relative to the `row-gap` if abutting a rule gap, and `0` at the bottom edge of the container.

In this demonstration, these endpoints are denoted by the inset, dark and light, line style. If the cap segment endpoint is at the container's edge, the percentage is relative to `0`, so it always computes to `0` (which is why only the `between` value has an effect).

Select `around` as the `rule-visibility-items` value. The first three columns end at the container edge, so any percentage value will resolve to `0`. The last two column rules end at interior gaps where row rule segments are present, so these column segments are not cap segment endpoints.

Select `between` as the `rule-visibility-items` value. The first two columns end at the container edge, so they have a `0` inset. The third column rule ends at an interior gap where a row rule segment is present, so this column segment is not a cap segment endpoint. The last two column rules end at interior gaps where no other rule segments are present, so the percentage offset is relative to the size of the `row-gap` width, which in this case is `20px`.

Setting `100%` insets the end of the last two column rule segments by `20px`. Setting `-200%` will outset these segments by `40px`, with the lines being drawn through the `20px` gap and `20px` protruding into the last row of items. Negative percentage values that compute to a length larger than the combined height of the last row and row gap will cause the last two column rules to protrude below the container's end edge.

Formal definition

Value not found in DB!

Formal syntax

```
column-rule-inset-cap-end =
  <inset-value>

<inset-value> =
  <length-percentage>  |
  overlap-join

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates setting `column-rule-inset-cap-end` to inset the end edge of cap segments on flex containers.

HTML

The markup includes two `<div>` elements, each containing seven children. The only difference between the two containers is that the second one has an added `column` class.

```
<h1>Insetting cap column rule endpoints</h1>
<article>
  <section>
    <h2>flex-direction: row</h2>
    <div class="flexbox">
      <div></div>
      <div></div>
      <div></div>
```

```
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
  <section>
    <h2>flex-direction: column</h2>
    <div class="flexbox column">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
</article>
```

```
<p>
  <label
    >Change the size of the inset.
    <input type="range" min="-40" max="16" value="16" id="inset"
  /></label>
  <output id="o">16px</output>
</p>
```

CSS

We use the `display` property to turn the `.flexbox` elements into flex containers. We balance the items into three flex lines using `flex-wrap` and `flex-line-count`. We define a light blue `rule` to paint both row and column gaps, then overwrite the `column-rule-color`, setting darker `blue` column gap decorations. Finally, we set the `column-rule-inset-cap-end` to `16px`.

```
.flexbox {
  display: flex;
  flex-wrap: balance;
  flex-line-count: 3;
  gap: 20px;
  rule: 5px solid lightblue;
  column-rule-color: blue;

  column-rule-inset-cap-end: 16px;
}
```

We also set the `flex-direction` on the `.column` container, to change the main axis of the flex container, and make the items flow in columns rather than rows.

```
.column {
  flex-direction: column;
}
```

The rest of the CSS is hidden for brevity.

```
body {
  font-family: sans-serif;
  text-align: center;
}
h1 {
  font-size: 1.25em;
}
h2 {
  font-size: 1em;
}
article {
  display: flex;
  gap: 5vw;
  rule: 1px solid black;
  width: 100vw;
}
section {
  flex-basis: 45vw;
}
.flexbox > div {
  border: 1px solid green;
  background-color: lime;
  flex: 1 1 auto;
  height: 30px;
}
output {
  display: inline-block;
  width: 2em;
}
p {
  margin-top: 2.5em;
}
@layer no-support {
  @supports not (column-rule-inset-cap-end: 16px) {
    body::before {
      content: "Your browser doesn't support the column-rule-inset-cap-end property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
const inset = document.getElementById("inset");
const containers = document.querySelectorAll(".flexbox");
const output = document.getElementById("o");
```

```
inset.addEventListener("input", () => {
  const val = `${inset.value}px`;
  containers[0].style.columnRuleInsetCapEnd = val;
  containers[1].style.columnRuleInsetCapEnd = val;
  output.innerText = val;
});
```

Result

Change the size of the inset.

column-rule-inset-cap-start CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`column-rule-inset-cap-start`** CSS property can be used to offset the top of column rule segment cap endpoints at the container's start edge, and cap endpoints where no rule segments intersect.

Try it

```
column-rule-inset-cap-start: -20px;
```

```
column-rule-inset-cap-start: 0;
```

```
column-rule-inset-cap-start: 1em;
```

```
column-rule-inset-cap-start: 100%;
```

```
column-rule-inset-cap-start: overlap-join;
```

```
<section id="default-example">

}
```

Syntax

```
/* Keywords */
column-rule-inset-cap-start: overlap-join;

/* <length-percentage> values */
column-rule-inset-cap-start: 0;
column-rule-inset-cap-start: 1em;
column-rule-inset-cap-start: -5px;
column-rule-inset-cap-start: -25%;

/* Global values */
column-rule-inset-cap-start: inherit;
column-rule-inset-cap-start: initial;
column-rule-inset-cap-start: revert;
column-rule-inset-cap-start: revert-layer;
column-rule-inset-cap-start: unset;
```

Values

This property is specified as a single value from the following list:

`overlap-join`

Resolves to `0`.

`<length-percentage>`

Specifies the size of the inset. Percentage values are relative to the cap endpoint, which is either the width of the `row-gap` or `0`.

Description

The `column-rule-inset-cap-start` property can be used to inset the start edge of cap segment endpoints. The default value is `0`, which is the same as `overlap-join`. Positive values reduce the segment size, while negative values increase it.

Column rules are painted within a column gap as one or more segments, with segments occurring between:

- Adjacent columns in CSS grid layouts.
- Flex items or flex lines in flex layouts, depending on the `flex-direction`.
- Columns in multi-col layouts.

Length `column-rule-inset-cap-start` values inset segments by the specified value — for both interior and end edge cap segments. Negative length values create an outset, with end edge cap segments extending beyond the container's start edge.

Percentage values for interior segments are relative to the size of the `row-gap`. For start edge cap segments, percentage values are relative to `0`, so percentage values never cause cap segment endpoints at the container's start edge to extend above the container.

The `column-rule-inset-cap-start` property is a constituent property of several shorthand properties:

- To inset both start and end caps, the `column-rule-inset-cap-start` property, along with the `column-rule-inset-cap-end` property, can be set using the `column-rule-inset-cap` shorthand.
- To inset the start of all column segment endpoints, the `column-rule-inset-cap-start` property, along with the `column-rule-inset-junction-end` property, can be set using the `column-rule-inset-end` shorthand.

All segment endpoints, including this property's `-end`, `-junction`, and `row-` equivalents, can be set using the `rule-inset` shorthand.

Understanding cap start

A *cap segment endpoint* is any segment endpoint that is not a junction segment endpoint. This includes endpoints at the container's content edges, as well as endpoints at a gap junction where no other rule segments are present.

The `column-rule-inset-cap-start` property controls the inset of the top edge of column cap segment endpoints, allowing the segments to be shrunk or extended. In other words, the property can be used to shrink or extend the top edge of column rule segments that abut the top edge of the container and the segments whose top ends at an interior gaps where no other column or row rule segments are present.

Column cap segment endpoints are not affected by the value of the `column-rule-break` property value settings, which only control junction segment breaks. They are, however, affected by the `rule-visibility-items` properties, which define whether column- and row-rule segments are painted in gaps adjacent to empty areas.

Column cap segment endpoints only exist at the edge of the container and at interior gaps where no other column or row rule segments are present, whether segments are painted (or would otherwise be painted if the `rule` were set to a visible value), impacts which column segments are cap start segments.

In the following demonstration, the top of the column rule segments with a solid line style start in a cap endpoint. With `column-rule-inset-cap-start: 16px` set, all the column cap segments at the top edge of the container are all inset by `16px`. Change the inset `<length>` value to better visualize which segments start with cap segment endpoints.

@layer no-support {
  @supports not (column-rule-inset-cap-start: 16px) {
    body::before {
      content: "Your browser doesn't support the column-rule-inset-cap-start property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
ul {
  column-rule-inset-cap-start: 100%;
}
```

```
const inset = document.getElementById("inset");
const visibility = document.getElementById("visibility");
const ul = document.getElementById("ul");
const output = document.getElementById("o");

inset.addEventListener("input", () => {
  output.innerText =
    ul.style.columnRuleInsetCapStart = `${inset.value}${inset.dataset["unit"]}`;
});
```

```
visibility.addEventListener("change", () => {
  ul.style.ruleVisibilityItems = `${visibility.value}`;
  if (visibility.value === "between") {
    ul.style.columnRuleStyle = "solid, repeat(2, double)";
  } else {
    ul.style.columnRuleStyle = "solid";
  }
});
```

Change the inset. If `0px` is set, the start of the column rules will align with the start of the container. This is the default. Setting `-32px` outsets the segments by `32px`, with the lines being drawn `32px` past the start edge of the container. As column rules don't impact the box model, these lines have no impact on the layout of the container or the rest of the content.

Select `between` as the `rule-visibility-items` value. This value paints rules in a gap segment only if the two adjacent areas are occupied by items. Change the value of the inset while observing the three column rules with a double line style: in addition to having a cap endpoint at the start edge of the container, these rules have an additional cap endpoint. They each have column rule segments that start at interior gaps where no row rule segments are present, so these column segments are also cap segment endpoints, and are affected by the `column-rule-inset-cap-start` property.

Selecting `around` as the `rule-visibility-items` value paints rules in a gap segment as long as one adjacent area is occupied by an item. In these cases, there is a row rule segment at the top end of the endpoint segments of the interior gaps. The starts of these segments are junction (not cap) segment endpoints and are not affected by the `column-rule-inset-cap-start` property. The inset of these column segments that start at an interior gap junction can be controlled by the `column-rule-inset-junction-start` property.

Understanding percentage values

The length a percentage value is relative to depends on the endpoint location. Interior endpoint percentage values are relative to the width of the gap at the cap endpoint, so relative to the `row-gap` if abutting a rule gap, and `0` at the top edge of the container.

This example isn't broken; all the cap segments start at the container's edge, so all the insets are `0` by default.

If you select `around` as the `rule-visibility-items` value, again, none of the segments will be inset. Percentage inset values for the column segments that start at container edge all resolve to `0`. The start edge of column segments that start at interior gaps don't and have a segment drawn above start at intersections where row rule segments are present; they don't start with a cap segment endpoint, so their insets are defined by the `column-rule-inset-junction-start` property instead.

Select `between` as the `rule-visibility-items` value. The column rules that have two cap start segments have their line-style set to `double`. As before, each has a column rule segment that starts at interior gaps where no other rule segments are present. For these, the percentage offset is relative to the size of the `row-gap` width, which in this case is `20px`.

Setting `100%` insets the start of the cap segments by `20px`. Setting `-200%` will outset these segments by `40px`, with the lines being drawn through the `20px` gap, with `20px` protruding into the row above the items. If the negative value was larger than the combined heights of the first row and the row gap, the rule would protrude above the container's start edge.

Formal definition

Value not found in DB!

Formal syntax

```
column-rule-inset-cap-start =
  <inset-value>

<inset-value> =
  <length-percentage>  |
  overlap-join

<length-percentage> =
  <length>     |
  <percentage>
```

This syntax reflects the latest standard as per CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates setting `column-rule-inset-cap-start` to inset the start edge of cap segments on flex containers.

HTML

The markup includes two `<div>` elements, each containing seven children. The only difference between the two containers is that the second one has an added `column` class.

```
<h1>Insetting cap column rule endpoints</h1>
<article>
  <section>
    <h2>flex-direction: row</h2>
    <div class="flexbox">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
  <section>
    <h2>flex-direction: column</h2>
    <div class="flexbox column">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
</article>
```

```
<p>
  <label
    >Change the size of the inset.
    <input type="range" min="-40" max="16" value="16" id="inset"
  /></label>
  <output id="o">16px</output>
</p>
```

CSS

We use the `display` property to turn the `.flexbox` elements into flex containers. We balance the items into three flex lines using `flex-wrap` and `flex-line-count`. We define a light blue `rule` to be painted in both row and column gaps, then overwrite the `column-rule-color`, setting darker `blue` column gap decorations. Finally, we set the `column-rule-inset-cap-start` to `16px`.

```
.flexbox {
  display: flex;
```

```
  flex-wrap: balance;
  flex-line-count: 3;
  gap: 20px;
  rule: 5px solid lightblue;
  column-rule-color: blue;

  column-rule-inset-cap-start: 16px;
}
```

We then set the `flex-direction` on the `.column` container to make its items flow in columns rather than rows.

```
.column {
  flex-direction: column;
}
```

The rest of the CSS is hidden for brevity.

```
body {
  font-family: sans-serif;
  text-align: center;
}
h1 {
  font-size: 1.25em;
}
h2 {
  font-size: 1em;
}
article {
  display: flex;
  gap: 5vw;
  rule: 1px solid black;
  width: 100vw;
}
section {
  flex-basis: 45vw;
}
.flexbox > div {
  border: 1px solid green;
  background-color: lime;
  flex: 1 1 auto;
  height: 30px;
}
output {
  display: inline-block;
  width: 2em;
}
p {
  margin-top: 2.5em;
}
@layer no-support {
  @supports not (column-rule-inset-cap-start: 16px) {
    body::before {
      content: "Your browser doesn't support the column-rule-inset-cap-start property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
const inset = document.getElementById("inset");
const containers = document.querySelectorAll(".flexbox");
const output = document.getElementById("o");

inset.addEventListener("input", () => {
  const val = `${inset.value}px`;
  containers[0].style.columnRuleInsetCapStart = val;
  containers[1].style.columnRuleInsetCapStart = val;
  output.innerText = val;
});
```

Result

Change the size of the inset.

column-rule-inset-junction CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`column-rule-inset-junction`** CSS shorthand property can be used to offset both the top and bottom endpoints of column rule segments that are junction endpoints; that is, endpoints at gap junctions where rule segments intersect.

Try it

```
column-rule-inset-junction: 0;
```

```
column-rule-inset-junction: 10px;
```

```
column-rule-inset-junction: 0.5em -0.5em;
```

```
column-rule-inset-junction: overlap-join;
```

```
column-rule-inset-junction: overlap-join 10px;
```

```
<section id="default-example">
  <div id="example-element">
    <i>A</i>
    <i>B</i>
    <i>C</i>
    <i>D</i>
    <i>E</i>
    <i>F</i>
    <i>G</i>
    <i>H</i>
    <i>I</i>
    <i>J</i>
    <i>K</i>
    <i>L</i>
  </div>
</section>
```

```
#example-element {
  display: grid;
  grid-template-columns: repeat(5, 1fr);
  rule: solid thick lightpink;
  column-rule-color: magenta;
  column-rule-break: intersection;
  gap: 1.5em;
  rule-overlap: column-over-row;
  border: 1px solid rebeccapurple;
  margin: auto;
  rule-visibility-items: around;
}
#example-element i {
  background-color: #efefef;
  padding: 1em;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `column-rule-inset-junction-end`
- `column-rule-inset-junction-start`

Syntax

```
/* Keywords */
column-rule-inset-junction: overlap-join;

/* <length-percentage> values */
column-rule-inset-junction: 0;
column-rule-inset-junction: 1em;
column-rule-inset-junction: -5px;
column-rule-inset-junction: -25%;

/* Two values */
column-rule-inset-junction: 0 1em;
column-rule-inset-junction: -5px -25%;
column-rule-inset-junction: overlap-join 10px;

/* Global values */
column-rule-inset-junction: inherit;
column-rule-inset-junction: initial;
column-rule-inset-junction: revert;
column-rule-inset-junction: revert-layer;
column-rule-inset-junction: unset;
```

Values

This property is specified as one or two values from the following list:

`overlap-join`

Specifies that the junction segment should extend across the row-rule, resolving to half the `row-gap` value plus half the used `row-rule-width` value.

`<length-percentage>`

Specifies the size of the inset. Percentage values are relative to the junction endpoint, which is the `row-gap` value.

Description

The `column-rule-inset-junction` shorthand property can be used to set the `column-rule-inset-junction-start` and `column-rule-inset-junction-end` properties, insetting or outsetting both the top and bottom endpoints of column rule segments that are junction segments.

If one value is specified, both properties are set to that value. If two values are specified, `-start` is set to the first value and `-end` is set to the second. Positive values reduce (or inset) the segment size, while negative values and the `overlap-join` keyword increase (or outset) it. The default value is `0`.

The `column-rule-inset-junction` property is a constituent property of a few shorthand properties:

- To inset both column and row segment junction endpoints, the `column-rule-inset-junction` shorthand property, along with the `row-rule-inset-junction` shorthand property, can be set using the `rule-inset-junction` shorthand.
- To inset both column cap and junction segment endpoints, the `column-rule-inset-junction` shorthand property, along with the `column-rule-inset-cap` shorthand property, can be set using the `column-rule-inset` shorthand.

All segment endpoints, including this property's `-cap` and `-row` equivalents, can be set using the `rule-inset` shorthand.

Formal definition

Value not found in DB!

Formal syntax

```
column-rule-inset-junction =
  <inset-value> <inset-value>?

<inset-value> =
  <length-percentage>  |
  overlap-join

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates setting `column-rule-inset-junction` to inset the edges of junction segments on flex containers.

HTML

The markup includes two `<div>` elements, each containing seven children. The only difference between the two containers is that the second one has an added `column` class.

```
<h1>Insetting junction column rule endpoints</h1>
<article>
  <section>
    <h2>flex-direction: row</h2>
    <div class="flexbox">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
  <section>
    <h2>flex-direction: column</h2>
    <div class="flexbox column">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
</article>
```

```
<p>
  <label
    >Change the size of the inset.
    <input type="range" min="-40" max="16" value="16" id="inset"
  /></label>
  <output id="o">16px</output>
</p>
```

CSS

We use the `display` property to turn the `.flexbox` elements into flex containers. We balance the items into three flex lines using `flex-wrap` and `flex-line-count`. We define a light blue `rule` to paint both row and column gaps, then overwrite the `column-rule-color`, setting darker `blue` column gap decorations. We also set the `rule-overlap` property to `column-over-row` to ensure the column segments are drawn on top of the row segments when the segments overlap. Finally, we set the `column-rule-inset-junction` to `16px`.

```
.flexbox {
  display: flex;
  flex-wrap: balance;
  flex-line-count: 3;
  gap: 20px;
  rule: 5px solid lightblue;
  column-rule-color: blue;
  rule-overlap: column-over-row;

  column-rule-inset-junction: 16px;
}
```

We also set the `flex-direction` on the `.column` container to `column`, changing the main axis of the flex container to run up and down the page and making the items flow in columns rather than rows.

```
.column {
  flex-direction: column;
}
```

The rest of the CSS is hidden for brevity.

```

      content: "Your browser doesn't support the column-rule-inset-junction property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
const inset = document.getElementById("inset");
const containers = document.querySelectorAll(".flexbox");
const output = document.getElementById("o");

inset.addEventListener("input", () => {
  const val = `${inset.value}px`;
  containers[0].style.columnRuleInsetJunction = val;
  containers[1].style.columnRuleInsetJunction = val;
  output.innerText = val;
});
```

Result

Change the size of the inset. Note that in the right-hand example, where the column rule is a single segment that goes from top to bottom, the segment has two cap endpoints and no junction endpoints. Therefore, changing the `column-rule-inset-junction` value does not affect this example.

With grid layout

This example demonstrates using the `column-rule-inset-junction` property to inset the top and bottom junction segment endpoints to two different values on a grid container.

HTML

We include the `<ul>` element as a container with several `<li>` children which will each be converted into a grid item.

```
<ul id="ul">
  <li>1</li>
  <li>2</li>
  <li>3</li>
  <li>4</li>
  <li>5</li>
  <li>6</li>
  <li>7</li>
  <li>8</li>
  <li>9</li>
  <li>10</li>
  <li>11</li>
  <li>12</li>
  <li>13</li>
  <li>15</li>
  <li>16</li>
</ul>
```

```
<p>
  <label
    >Change the <code>-start</code> value.
    <input type="range" min="-40" max="40" value="16" id="start" data-unit="px"
  /></label>
```

```
  <output id="og">16px</output>
</p>
<p>
  <label
    >Change the <code>-end</code> value.
    <input type="range" min="-40" max="40" value="0" id="end" data-unit="px"
  /></label>
  <output id="ow">0px</output>
</p>
```

CSS

We turn the `<ul>` into a grid container by setting the `display` property to `grid`. The `grid-template-columns` property specifies that the grid has six columns. We remove the bullets with `list-style-type` and set the row and column gaps to `20px` with the `gap` shorthand. We set the color, size, and line style of all the rules using the `rule` shorthand, then change just the row rule color with the `row-rule-color` property.

We break the column rules at every intersection using the `column-rule-break` property. If the column rules didn't break, there would be no column junction segments to style!

Finally, we set the start of each column junction to be inset by `16px` and the end to not be inset using the `column-rule-inset-junction` property.

We also set the 6th grid item to span three columns.

```
ul {
  display: grid;
  grid-template-columns: repeat(6, auto);
  list-style-type: "";
  gap: 20px;
  rule: 10px solid olive;
  row-rule-color: palegoldenrod;
  column-rule-break: intersection;

  column-rule-inset-junction: 16px 0;
}

li:nth-of-type(8) {
  grid-column-end: span 3;
}
```

The rest of the CSS is hidden for brevity.

```
ul {
  border: 1px solid;
  place-items: center;
  width: 95vw;
  padding: 0;
}
li {
  text-align: center;
  font-family: sans-serif;
  background-color: #ededed;
  padding: 2em 1em;
  width: 100%;
  box-sizing: border-box;
}
li:nth-of-type(8) {
  background-color: transparent;
}

li code {
  display: block;
  margin: 0 auto;
  text-align: left;
  width: 30vw;
}
output {
  font-family: monospace;
}
input {
  accent-color: olive;
}
@layer no-support {
  @supports not (column-rule-inset-junction: 16px) {
    body::before {
      content: "Your browser doesn't support the column-rule-inset-junction property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
const ul = document.querySelector("ul");
const startSize = document.getElementById("start");
const og = document.getElementById("og");
const endSize = document.getElementById("end");
const ow = document.getElementById("ow");
const cell = document.querySelector("li:nth-of-type(8)");
let text = "";
function update() {
  ul.style.columnRuleInsetJunction =
    text = `${startSize.value}px ${endSize.value}px`;
  cell.innerHTML = `<code>rule-inset-cap: ${text};</code>`;
}

update();

startSize.addEventListener("input", () => {
  og.innerText = `${startSize.value}px`;
  update();
});
```

```
endSize.addEventListener("input", () => {
  ow.innerText = `${endSize.value}px`;
  update();
});
```

column-rule-inset-junction-end CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`column-rule-inset-junction-end`** CSS property can be used to offset the bottom endpoints of column rule segments that are junction endpoints; that is, endpoints at gap junctions where rule segments intersect.

Try it

```
column-rule-inset-junction-end: 0;
```

```
column-rule-inset-junction-end: 0.5em;
```

```
column-rule-inset-junction-end: 10px;
```

```
column-rule-inset-junction-end: -100%;
```

```
column-rule-inset-junction-end: overlap-join;
```

```
<section id="default-example">
  <div id="example-element">
    <i>A</i>
    <i>B</i>
    <i>C</i>
    <i>D</i>
    <i>E</i>
    <i>F</i>
    <i>G</i>
    <i>H</i>
    <i>I</i>
    <i>J</i>
    <i>K</i>
    <i>L</i>
  </div>
</section>
```

```
#example-element {
  display: grid;
  grid-template-columns: repeat(5, 1fr);
  rule: solid thick lightpink;
  column-rule-color: magenta;
  column-rule-break: intersection;
  gap: 1.5em;
  rule-overlap: column-over-row;
  border: 1px solid rebeccapurple;
  margin: auto;
  rule-visibility-items: around;
}
#example-element i {
  background-color: #efefef;
  padding: 1em;
}
```

Syntax

```
/* Keywords */
column-rule-inset-junction-end: overlap-join;

/* <length-percentage> values */
column-rule-inset-junction-end: 0;
column-rule-inset-junction-end: 1em;
column-rule-inset-junction-end: -5px;
column-rule-inset-junction-end: -25%;

/* Global values */
column-rule-inset-junction-end: inherit;
column-rule-inset-junction-end: initial;
column-rule-inset-junction-end: revert;
column-rule-inset-junction-end: revert-layer;
column-rule-inset-junction-end: unset;
```

Values

This property is specified as a single value from the following list:

`overlap-join`

Specifies that the junction segment should extend across the row-rule, resolving to half the `row-gap` value plus half the used `row-rule-width` value.

`<length-percentage>`

Specifies the size of the inset. Percentage values are relative to the junction endpoint, which is the `row-gap` value.

Description

The `column-rule-inset-junction-end` property can be used to inset or outset junction segment endpoints occurring at the bottom of column rule segments. The default value is `0`. Positive values reduce the segment size, while negative values and the `overlap-join` keyword increase it.

Column rules are painted within a column gap as one or more segments, with segments occurring between:

- Adjacent columns in CSS grid layouts.
- Adjacent flex items or flex lines in flex layouts, depending on the `flex-direction`.
- Adjacent columns in multi-col layouts.

Whether a column rule spans multiple rows or is broken into multiple segments is defined by the `column-rule-break` property; interior breaks between column rule segments are the size of the `row-gap`. A junction end occurs at the bottom of every column segment where the segment's bottom ends at a gap junction with other column or rule segments present.

The `column-rule-inset-junction-end` property is a constituent property of several shorthand properties:

- To inset top and bottom column segment junction endpoints, the `column-rule-inset-junction-end` property, along with the `column-rule-inset-junction-start` property, can be set using the `column-rule-inset-junction` shorthand.
- To inset all bottom column segment endpoints, the `column-rule-inset-junction-end` property, along with the `column-rule-inset-cap-end` property, can be set using the `column-rule-inset-end` shorthand.
- To inset bottom column segment junction endpoints and right row segment junction endpoints, the `column-rule-inset-junction-end` property, along with the `row-rule-inset-junction-end` property, can be set using the `rule-inset-junction-end` shorthand.

All segment endpoints, including this property's `-start`, `-cap`, and `row-` equivalents, can be set using the `rule-inset` shorthand.

Understanding junction endpoints

A *junction segment endpoint* is any segment endpoint at an interior gap that ends at a gap intersection where other rule or column segments are present. The `column-rule-inset-junction-end` property controls the inset of the bottom edge of column junction segments, allowing the segments to be shrunk or extended.

Length `column-rule-inset-junction-end` values inset segments by the specified value. Negative length values create an outset, extending the bottom end of the junction segment. Percentage values are relative to the size of the `row-gap`. Setting `-50%` outsets the bottom of the junction segment half way through the row gap below the segment, no matter how wide the row gap is.

In the following demonstration, the column rule segments in the top two rows end in junction endpoints. With `column-rule-inset-junction-end: 16px` set, the bottom, or end, of these segments are inset by `16px`. Change the inset `<length>` value to better visualize which segments end in junction segment endpoints.

```
<ul id="ul">
  <li>1</li>
  <li>2</li>
  <li>3</li>
  <li>4</li>
  <li>5</li>
  <li>6</li>
  <li>7</li>
  <li>8</li>
  <li>9</li>
  <li>10</li>
  <li>11</li>
  <li>12</li>
  <li>13</li>
  <li>15</li>
  <li>16</li>
</ul>

<p>
  <label>
    <code>rule-visibility-items</code> value
    <select id="visibility">
      <option>all</option>
      <option>between</option>
      <option>around</option>
      <option selected>normal</option>
    </select>
  </label>
</p>
```

```
<p>
  <label
    >Change the size of the inset.
    <input type="range" min="-40" max="16" value="16" id="inset" data-unit="px"
  /></label>
  <output id="o">16px</output>
</p>
```

```
<p>
  <label
    >Change the size of the inset.
    <input
      type="range"
      min="-450"
      max="100"
      value="100"
      id="inset"
      data-unit="%"
  /></label>
  <output id="o">100%</output>
</p>
```

```
ul {
  display: grid;
  grid-template-columns: repeat(6, auto);
```

```
  list-style-type: none;
  gap: 20px;
  column-rule: 10px solid olive;
  row-rule: 10px solid palegoldenrod;
  rule-overlap: column-over-row;
  rule-visibility-items: normal;
  rule-break: intersection;
  column-rule-inset-junction-end: 16px;

  border: 1px solid;
}
ul {
  place-items: center;
  width: 95vw;
  padding: 0;
}
li {
  text-align: center;
  font-family: sans-serif;
  background-color: #ededed;
  padding: 1em;
  width: 100%;
  box-sizing: border-box;
}
@layer no-support {
  @supports not (column-rule-inset-junction-end: 16px) {
    body::before {
      content: "Your browser doesn't support the column-rule-inset-junction-end property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
ul {
  column-rule-inset-junction-end: 100%;
  column-rule-style: inset;
}
```

```
const inset = document.getElementById("inset");
const visibility = document.getElementById("visibility");
const ul = document.getElementById("ul");
const output = document.getElementById("o");

inset.addEventListener("input", () => {
  o.innerText =
    ul.style.columnRuleInsetJunctionEnd = `${inset.value}${inset.dataset["unit"]}`;
});
```

```
visibility.addEventListener("change", () => {
  ul.style.ruleVisibilityItems = `${visibility.value}`;
  if (visibility.value === "between") {
    ul.style.columnRuleStyle = "repeat(3, solid), repeat(2, double)";
  } else if (visibility.value === "around") {
    ul.style.columnRuleStyle = "repeat(3, solid), repeat(2, double)";
  } else {
    ul.style.columnRuleStyle = "solid";
  }
});
```

```
visibility.addEventListener("change", () => {
  ul.style.ruleVisibilityItems = `${visibility.value}`;
  if (visibility.value === "between") {
    ul.style.columnRuleStyle = "repeat(2, inset), double, repeat(2, solid)";
  } else if (visibility.value === "around") {
    ul.style.columnRuleStyle = "repeat(3, inset), repeat(2, double)";
  } else {
    ul.style.columnRuleStyle = "solid";
  }
});
```

If you set `0px` as the value, the end of the column rules will align with the end of the row, abutting the row gap. This is the default. Note how only the bottom ends of the segments in the middle of the grid change when the property value changes. The segments in the bottom row do not change: these are *cap endpoints*, and are not affected by the `column-rule-inset-junction-end` property.

Select `around` as the `rule-visibility-items` value. This value paints rules in a gap segment if an item occupies at least one of the two adjacent areas. The double line-style column rule segments that appear when the `rule-visibility-items` property is set to `around` end at an interior intersection where one or more row-rule segments are present; these column segments are junction segment endpoints.

Select `between` as the `rule-visibility-items` value, which paints rules in gap segments only if items occupy both adjacent areas. The double line-style column rule segments now end at an interior intersection where no other rule segments are present: these column segments are *cap segment endpoints* and therefore aren't affected by the `column-rule-inset-junction-end` property.

The <code>overlap-join</code> value

The `overlap-join` value outsets the bottom end of interior segments so they align with the bottom of the intersected row-rule. The value resolves to half the `row-gap` size (which would extend it to the middle of the gap) plus half the row rule width.

When `column-rule-inset-junction-end` is set to the `overlap-join` keyword value, the bottom ends of the junction end segments extend down into the row gap to meet, or "join", the bottom edge of the row rule painted in that gap.

In the following live example, `column-rule-inset-junction-end` is set to `overlap-join`:

```
<p>
  <label
    >Change the <code>row-gap</code>.
    <input type="range" min="10" max="40" value="30" id="gap" data-unit="px"
  /></label>
  <output id="og">30px</output>
</p>
<p>
```

```
  <label
    >Change the <code>row-rule-width</code>.
    <input type="range" min="0" max="40" value="16" id="rrw" data-unit="px"
  /></label>
  <output id="ow">16px</output>
</p>

<ul>
  <li>1</li>
  <li>2</li>
  <li>3</li>
  <li>4</li>
  <li>5</li>
  <li>6</li>
  <li>7</li>
  <li>8</li>
  <li>9</li>
  <li>10</li>
</ul>
```

```
ul {
  display: grid;
  grid-template-columns: repeat(4, auto);
  list-style-type: none;
  gap: 30px;
  column-rule: 16px solid olive;
  row-rule: 10px solid palegoldenrod;
  rule-overlap: column-over-row;
  rule-visibility-items: around;
  column-rule-break: intersection;
  column-rule-inset-junction-end: overlap-join;
  border: 1px solid;
}
ul {
  place-items: center;
  width: 70vw;
  margin: auto;
  padding: 0;
}
li {
  text-align: center;
  font-family: sans-serif;
  background-color: #ededed;
  padding: 2em;
  width: 100%;
  box-sizing: border-box;
}
@layer no-support {
  @supports not (column-rule-inset-junction-end: 16px) {
    body::before {
      content: "Your browser doesn't support the column-rule-inset-junction-end property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
const ul = document.querySelector("ul");
const gapSize = document.getElementById("gap");
const og = document.getElementById("og");
const ruleWidth = document.getElementById("rrw");
const ow = document.getElementById("ow");

gapSize.addEventListener("input", () => {
  og.innerText = ul.style.rowGap = `${gapSize.value}px`;
});

ruleWidth.addEventListener("input", () => {
  ow.innerText = ul.style.rowRuleWidth = `${ruleWidth.value}px`;
});
```

Change the size of the `row-rule-width` and the `row-gap`. Notice how, no matter the size of the gap or row rule, the bottom end of the column segment is always stretched to align with the bottom of the row rule painted in the gap.

Formal definition

Value not found in DB!

Formal syntax

```
column-rule-inset-junction-end =
  <inset-value>

<inset-value> =
  <length-percentage>  |
  overlap-join

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates setting `column-rule-inset-junction-end` to inset the end edge of junction segments on flex containers.

HTML

The markup includes two `<div>` elements, each containing seven children. The only difference between the two containers is that the second one has an added `column` class.

```
<h1>Insetting junction column rule endpoints</h1>
<article>
  <section>
    <h2>flex-direction: row</h2>
    <div class="flexbox">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
  <section>
    <h2>flex-direction: column</h2>
    <div class="flexbox column">
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
      <div></div>
    </div>
  </section>
</article>
```

```
<p>
  <label
    >Change the size of the inset.
    <input type="range" min="-40" max="16" value="16" id="inset"
  /></label>
  <output id="o">16px</output>
</p>
```

CSS

We use the `display` property to turn the `.flexbox` elements into flex containers. We balance the items into three flex lines using `flex-wrap` and `flex-line-count`. We define a light blue `rule` to paint both row and column gaps, then overwrite the `column-rule-color`, setting darker `blue` column gap decorations. We also set the `rule-overlap` property to `column-over-row` to ensure the column segments are drawn on top of the row segments when the segments overlap. Finally, we set the `column-rule-inset-junction-end` to `16px`.

```
.flexbox {
  display: flex;
  flex-wrap: balance;
  flex-line-count: 3;
  gap: 20px;
  rule: 5px solid lightblue;
  column-rule-color: blue;
  rule-overlap: column-over-row;

  column-rule-inset-junction-end: 16px;
}
```

We also set the `flex-direction` on the `.column` container to `column`, changing the main axis of the flex container to run up and down the page and making the items flow in columns rather than rows.

```
.column {
  flex-direction: column;
}
```

The rest of the CSS is hidden for brevity.

```
h1,
article {
  font-family: sans-serif;
  text-align: center;
}
h1 {
  font-size: 1.25em;
}
h2 {
  font-size: 1em;
}
article {
  display: flex;
  gap: 5vw;
  rule: 1px solid black;
  width: 100vw;
}
section {
  flex-basis: 45vw;
}
.flexbox > div {
  border: 1px solid green;
  background-color: lime;
  flex: 1 1 auto;
  height: 30px;
}
output {
  display: inline-block;
  width: 2em;
}
p {
  margin-top: 2.5em;
}
@layer no-support {
```

```
  @supports not (column-rule-inset-junction-end: 16px) {
    body::before {
      content: "Your browser doesn't support the column-rule-inset-junction-end property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

```
const inset = document.getElementById("inset");
const containers = document.querySelectorAll(".flexbox");
const output = document.getElementById("o");

inset.addEventListener("input", () => {
  const val = `${inset.value}px`;
  containers[0].style.columnRuleInsetJunctionEnd = val;
  containers[1].style.columnRuleInsetJunctionEnd = val;
  output.innerText = val;
});
```

Result

Change the size of the inset. Note that in the right-hand example, where the column rule is a single segment that goes from top to bottom, the segment has two cap endpoints and no junction endpoints. Therefore, changing the `column-rule-inset-junction-end` value does not affect this example.

column-rule-style CSS property

The **`column-rule-style`** CSS property defines the line style of the lines drawn between columns in multi-column grid, flex, and multi-col layouts.

Try it

```
column-rule-style: dotted;
```

```
column-rule-style: dashed, dotted;
```

```
column-rule-style: repeat(2, inset, outset), double;
```

```
column-rule-style: double, repeat(auto, dashed, solid), double;
```

```
column-rule-style: hidden;
```

```
<section id="default-example">
  <p id="example-element">
    London. Noel term lately over, and the Lord George sitting in Lincoln's Inn
    Hall. Great May weather. As much mud in the streets as if the waters had but
    newly retired from the face of the earth, and it would not be weird to meet
    an platypus, two feet long or so, waddling like an lizard up Morgan Hill.
  </p>
</section>
```

```
#example-element {
  columns: 6;
  column-rule-width: thick;
  column-rule-color: teal;
  gap: 7px;
}
```

Syntax

```
/* Keyword values */
column-rule-style: none;
column-rule-style: hidden;
column-rule-style: dotted;
column-rule-style: dashed;
column-rule-style: solid;
column-rule-style: double;
column-rule-style: groove;
column-rule-style: ridge;
column-rule-style: inset;
column-rule-style: outset;

/* Multiple values */
column-rule-style: groove, double, dashed;
column-rule-style: solid, repeat(5, ridge), solid;
column-rule-style: dotted, repeat(auto, inset, outset), dotted;

/* Global values */
column-rule-style: inherit;
column-rule-style: initial;
column-rule-style: revert;
```

```
column-rule-style: revert-layer;
column-rule-style: unset;
```

Values

The `column-rule-style` property accepts a comma-separated list of values, including:

`<line-style>`

A `<line-style>`: one of `none`, `hidden`, `dotted`, `dashed`, `solid`, `double`, `groove`, `ridge`, `inset`, or `outset`. The default value is `none`.

`<repeat-line-style>`

A `repeat()` function, with the first argument being an `<integer>` of `1` or more, and subsequent arguments being `<line-style>` values. The integer specifies how many times the `<line-style>` values should be repeated.

`<auto-repeat-line-style>`

A `repeat()` function, with `auto` as the first argument and one or more `<line-style>` values as subsequent arguments. The provided `<line-style>` values are repeated as many times as needed to fill in values for any column-rules that are not explicitly specified by other components of the property value.

Description

The `column-rule-style` property defines the line style of any column rule lines drawn in the gaps between columns in multi-column, flex, and grid containers with more than one column.

The value is a comma-separated list of components, which can include `<line-style>`, `<repeat-line-style>`, and `<auto-repeat-line-style>` types.

The `column-rule-style`, along with the `column-rule-color` and `column-rule-width` properties, can be set using the `column-rule` shorthand. The `column-rule-style`, along with the `row-rule-style` property, can also be set using the `rule-style` shorthand.

If the property value has only one `<line-style>`, all the column rules will be that style. If we declare the following, all column rules will be `double`:

```
column-rule-style: double;
```

When more than one `<line-style>` is declared, they will be applied to column-rules in the order specified. If there are more column-rules than `<line-style>` values, the list of line styles is repeated until every column rule has a style. If we declare the following, for example, every odd rule will be `double`, and every even rule will be `groove`.

```
column-rule-style: double, groove;
```

Repeated line styles

The `repeat()` function, with an integer of `1` or greater as the first argument, can be used to repeat a valid list of CSS `<line-style>` values passed as subsequent arguments the specified number of times. This allows the same style to be repeated a set number of times without repeating the same value. You can include `<line-style>` keyword values or custom properties that resolve to a valid `<line-style>`. Using `repeat()` can make values easier to write, enabling recurring patterns to be written using a single function, regardless of the number of columns. The following declarations are equivalent:

```
column-rule-style: solid, outset, inset, outset, inset;
column-rule-style: solid, repeat(2, outset, inset);
```

This creates a list of five styles. If the number of styles in the `column-rule-style` value's style list exceeds the number of gaps between columns, the excess style values are ignored. If the container has three columns, the rule in the first gutter will be `solid` and the second `outset`.

If there are more gutters than styles, the list of styles is repeated. If the container has 6, 11, 16, or 21 columns, this sequence of styles will be repeated one, two, three, or four times, respectively, with the last rule being `inset`.

Auto-repeating line styles

The `repeat()` function also accepts `auto` as the first argument instead of a positive integer. With `auto` as the first argument, the `<line-style>` values passed as subsequent parameters will be repeated as many times as needed to fill in values for any column-rules that are not explicitly specified by other components of the property value.

```
column-rule-style: solid, repeat(auto, dotted), solid;
```

In this case, it doesn't matter if the container has 3, 6, 11, 16, or 21 columns; the first and last column rules will always be `solid`, and all the other column rules will be `dotted`. If there are only 2 or 3 columns, there will be no dotted column rules.

The `auto` keyword within the `repeat()` function creates an auto repeater that fills in values for column rules that would not otherwise receive values from other parts of the list, preventing the list from being cycled. Only one `repeat(auto, <line-style>)` is allowed within a `column-rule-style` value.

Formal definition

Initial value	none
Applies to	multicol elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
column-rule-style =
  <line-style-list>      |
  <auto-line-style-list>

<line-style-list> =
  <line-style-or-repeat>#

<auto-line-style-list> =
  <line-style-or-repeat>#? , <auto-repeat-line-style> , <line-style-or-repeat>#?

<line-style-or-repeat> =
  <line-style>         |
  <repeat-line-style>

<auto-repeat-line-style> =
  repeat( auto , [ <line-style> ]# )

<line-style> =
  none    |
```

```
  hidden  |
  dotted  |
  dashed  |
  solid   |
  double  |
  groove  |
  ridge   |
  inset   |
  outset

<repeat-line-style> =
  repeat( [ <integer [1,∞]> ] , [ <line-style> ]# )

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

HTML

```
<p>
  This is a bunch of text split into three columns. The `column-rule-style`
  property is used to change the style of the line that is drawn between
  columns. Don't you think that's wonderful?
</p>
```

CSS

```
p {
  column-count: 3;
  column-rule-style: dashed;
}
```

Result

Multiple values

HTML

We include a list of authors:

```
<ul>
  <li>Kimberlé Crenshaw</li>
  <li>Angela Y. Davis</li>
  <li>Bernardine Evaristo</li>
  <li>Audre Lorde</li>
  <li>Cathy Park Hong</li>
  <li>Zoya Patel</li>
  <li>Juno Mac</li>
  <li>Molly Smith</li>
  <li>Tara Westover</li>
</ul>
```

CSS

We define the list to be a flex container, creating columns by setting the `flex-direction` to `row` using the `flex-flow` shorthand. We include a `gap` of `5px` to provide enough room between the columns to fit our `3px` double teal rule:

```
ul {
  display: flex;
  flex-flow: row;
  gap: 5px;
  column-rule-width: 3px;
  column-rule-color: teal;

  column-rule-style:
    dotted, dashed, solid, double, groove, ridge, inset, outset, none, hidden;
}
```

Result

As there are more values (10) than gutters (8), the `none` and `hidden` values are not used.

Repeating values

This example demonstrates how, when there are fewer values in the list of styles than column rules, the values are repeated.

CSS

Using the same HTML and CSS as in the previous example, we include three comma-separated styles as the `column-rule-style` value:

```
ul {
  column-rule-style: solid, groove, double;
}
```

Result

Using the <code>repeat()</code> function

This example demonstrates using the `repeat()` function within the `column-rule-style` property value.

CSS

We use the same HTML and CSS as in the previous examples. We include a `repeat()` function, setting the list of two `<line-style>` values to be repeated 3 times.

```
ul {
  column-rule-style: solid, repeat(3, inset, outset), solid;
}
```

Result

The flex container has six columns, so five gutters. The `repeat()` function repeats two style values three times, creating a list of eight style values, so the last three values in the list are discarded.

Using <code>auto</code> within <code>repeat()</code>

This example demonstrates using `auto` instead of an integer within the `repeat()` function.

CSS

Using `repeat(auto, <line-style>)` we set all column rules to `groove`, except the first and last, which we set to `solid`.

```
ul {
  column-rule-style: solid, repeat(auto, groove), solid;
}
```

Result

```
@layer no-support {
  @supports not (column-rule-style: solid, groove) {
    body::before {
      content: "Your browser doesn't support multiple values for the column-rule-style property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

column-rule-visibility-items CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`column-rule-visibility-items`** CSS property defines whether a column-rule segment is painted in gaps adjacent to empty areas.

Try it

```
column-rule-visibility-items: all;
```

```
column-rule-visibility-items: around;
```

```
column-rule-visibility-items: between;
```

```
column-rule-visibility-items: normal;
```

```
<section id="default-example">
  <section id="example-element">
    <p>One fish</p>
    <p>Two fish</p>
    <p>Red fish</p>
    <p>Blue fish</p>
    <cite>-- Dr. Seuss</cite>
  </section>
</section>
```

```
#example-element {
  display: grid;
  column-rule: solid 5px red;
  gap: 10px;
  grid-template-rows: repeat(3, 1fr);
  grid-template-columns: repeat(3, 1fr);
}
cite {
  grid-row: 3;
  grid-column: 3;
}
```

Syntax

```
/* Keyword values */
column-rule-visibility-items: all;
column-rule-visibility-items: around;
column-rule-visibility-items: between;
column-rule-visibility-items: normal;

/* Global values */
column-rule-visibility-items: inherit;
column-rule-visibility-items: initial;
```

```
column-rule-visibility-items: revert;
column-rule-visibility-items: revert-layer;
column-rule-visibility-items: unset;
```

Values

This property is specified as one of the following keyword values:

`all`

The column rule should be painted in all gap segments, regardless of whether adjacent areas contain an item.

`around`

The column rule should be painted in a gap segment if at least one of the two adjacent areas is occupied by an item.

`between`

The column rule should be painted in a gap segment if both adjacent areas are occupied by items.

`normal`

With grid containers, behaves the same as `all`. In multicol layout, behaves the same as `between`. This is the default.

Description

The `column-rule-visibility-items` property defines whether a column-rule segment is painted in column gaps adjacent to empty areas in multi-row and grid containers with more than one column.

The `column-rule-visibility-items` and `row-rule-visibility-items` properties can both be set using the `rule-visibility-items` shorthand.

Formal definition

Value not found in DB!

Formal syntax

```
column-rule-visibility-items =
  all     |
  around  |
  between |
  normal
```

This syntax reflects the latest standard as per CSS Gap Decorations Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic example

In this example, we define a column rule to be drawn between two grid areas if at least one adjacent grid area contains a grid item.

HTML

We include a list of dynamic sports duos:

```
<ol>
  <li>Simone Biles + Jonathan Owens</li>
  <li>Serena Williams + Venus Williams</li>
  <li>Aaron Judge + Giancarlo Stanton</li>
  <li>LeBron James + Dwyane Wade</li>
  <li>Xavi Hernandez + Andres Iniesta</li>
  <li>Kerri Walsh + Misty May Treanor</li>
</ol>
```

CSS

We define the ordered list (`<ol>`) to be a grid container, creating 4 columns and 4 rows by setting both the `grid-template-columns` and `grid-template-rows` properties to `repeat(4, 1fr)`, and move the last item to the bottom-right grid area using `grid-column` and `grid-row` properties. We include a `gap` of `20px` to provide enough room between the columns to fit our `5px` dashed rule.

Finally, we set `column-rule-visibility-items` to `between`, so that a column rule is painted in a column gap only if both adjacent grid areas contain a grid item.

```
ol {
  display: grid;
  grid-template-rows: repeat(4, 1fr);
  grid-template-columns: repeat(4, 1fr);
  gap: 10px;

  column-rule: dashed 5px blue;
  column-rule-visibility-items: between;
}
li:last-child {
  grid-row: 4;
  grid-column: 4;
}
```

```
li {
  margin-left: 1em;
}
@layer no-support {
  @supports not (column-rule-visibility-items: around) {
    body::before {
      content: "Your browser doesn't support the column-rule-visibility-items property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

Result

column-rule-width CSS property

The **`column-rule-width`** CSS property defines the widths of the lines drawn between columns in multi-column grid, flex, and multi-col layouts.

Try it

```
column-rule-width: thin;
```

```
column-rule-width: 4px;
```

```
column-rule-width: thin, medium, thick;
```

```
column-rule-width: repeat(2, 1px, thick), 10px;
```

```
column-rule-width: 10px, repeat(auto, 1px, 2px), 10px;
```

```
<section id="default-example">
  <p id="example-element">
    London. Noel term lately over, and the Lord George sitting in Lincoln's Inn
    Hall. Great May weather. As much mud in the streets as if the waters had but
    newly retired from the face of the earth, and it would not be weird to meet
    an platypus, two feet long or so, waddling like an lizard up Morgan Hill.
  </p>
</section>
```

```
#example-element {
  columns: 6;
  column-rule-style: solid;
  column-rule-color: teal;
  gap: 7px;
}
```

Syntax

```
/* Keyword values */
column-rule-width: thin;
column-rule-width: medium;
column-rule-width: thick;
column-rule-width: thin, medium, thick;
column-rule-width: thick, repeat(5, thin), thick;
column-rule-width: thick, repeat(auto, thin, medium), thick;

/* Length values */
column-rule-width: 0.1em;
column-rule-width: 5px;
column-rule-width: 1px, 3px, 5px;
column-rule-width: 0.1rem, repeat(auto, 1px), 10px, 0.5rem;
column-rule-width: 5px, repeat(5, 1px, 3px), 5px;

/* Global values */
column-rule-width: inherit;
column-rule-width: initial;
column-rule-width: revert;
column-rule-width: revert-layer;
column-rule-width: unset;
```

Values

The `column-rule-width` property accepts a comma-separated list of values, including:

`<line-width>`

Defines the width of the line, either as an explicit non-negative `<length>` or the keywords: `thin`, `medium`, or `thick`. The default is `medium`.

`<repeat-line-width>`

A `repeat()` function, with the first argument being an `<integer>` of `1` or more, and one or more `<line-width>` values as subsequent arguments. The integer defines the number of times the `<line-width>` values should be repeated.

`<auto-repeat-line-width>`

A `repeat()` function, with `auto` as the first argument and one or more `<line-width>` values as subsequent arguments. The provided `<line-width>` values are repeated as many times as needed to fill in values for any column-rules that are not explicitly specified by other components of the property value.

Description

The `column-rule-width` property defines the widths of any column rule lines drawn in the gutters between adjacent columns in multi-column, flex, and grid containers with more than one column.

> **Note:** The `column-rule-width` only defines the width of the lines painted in the gaps. These lines have no effect on the box model or layout. The size of the gutter is defined by the `gap` property; with the default value being `1em` on multi-column containers and `0` in all other contexts. If the width of a rule is wider than the `gap`, the line will be painted behind the column content.

The value is a comma-separated list of components, which can include `<line-width>`, `<repeat-line-width>`, and `<auto-repeat-line-width>` types.

The `column-rule-width`, along with the `column-rule-color` and `column-rule-style` properties, can also be set using the `column-rule` shorthand, while `rule-width` is a shorthand that sets both the `column-rule-width` and the `row-rule-width` properties.

A `<line-width>` can be declared as any valid CSS `<line-width>` value: the keywords `thin`, `medium`, or `thick`, or a positive `<length>` value. Percentage values are invalid.

If the property value consists of only one `<line-width>`, all the column rules will be that width. If we declare the following, all column rules will be `2px`:

```
column-rule-width: 2px;
```

When more than one `<line-width>` is declared, they will be applied to column-rules in the order specified. If there are more column-rules than `<line-width>` values, the list of line widths is repeated until every rule has a width. If we declare the following, for example, every odd rule will be `thick`, and every even rule will be `0.25rem`.

```
column-rule-width: thick, 0.25rem;
```

Repeated line widths

The `repeat()` function, with an integer of `1` or greater as the first argument, can be used to repeat a valid list of CSS `<line-width>` values passed as subsequent arguments the specified number of times. This allows the same width to be repeated a set number of times without repeating the same `<line-width>` multiple times. The following declarations are equivalent:

```
column-rule-width: 1rem, thick, thin, thick, thin, thick, thin;
column-rule-width: 1rem, repeat(3, thick, thin);
```

You can use any `<line-width>` values, including custom properties that resolve to a `<line-width>`. Using `repeat()` can make values easier to write, especially when using complex length calculations. It enables a recurring pattern to be written using a single function, regardless of the number of columns. The following declarations are equivalent:

```
column-rule-width:
  1rem, min(calc(var(--base) - 3px), 10px), abs(calc(var(--secondary) - 30px)),
  min(calc(var(--base) - 3px), 10px), abs(calc(var(--secondary) - 30px)),
  min(calc(var(--base) - 3px), 10px), abs(calc(var(--secondary) - 30px)),
  min(calc(var(--base) - 3px), 10px), abs(calc(var(--secondary) - 30px)),
  min(calc(var(--base) - 3px), 10px), abs(calc(var(--secondary) - 30px)), thin;
column-rule-width:
  1rem,
  repeat(
    5,
    min(calc(var(--base) - 3px), 10px),
    abs(calc(var(--secondary) - 30px))
  ),
  thin;
```

This creates a list of 12 widths. If the number of widths in the `column-rule-width` value's width list exceeds the number of gaps between columns, the excess width values are ignored. If the container has three columns, the rule in the first gutter will be `1rem` wide, and the second is determined by the `min()` function.

If there are more gutters than widths, the list of widths is repeated. If the container has 13 or 25 columns, this sequence of widths will be repeated one or two, respectively, with the last rule being `thin`. For any other number of columns, up to 25, the last rule will not be `thin`.

Auto-repeating line widths

The `repeat()` function also accepts `auto` as the first argument instead of a positive integer. With `auto` as the first argument, the list of `<line-width>` values passed as subsequent arguments will be repeated as many times as needed to fill in values for any column-rules that are not explicitly specified by other components of the property value.

```
column-rule-width: 10px, repeat(auto, thin), 10px;
```

In this case, the first column rule will be `10px`, the last will be `10px`, and all others will be `thin`. It doesn't matter if the container has 3, 6, 11, 16, or 21 columns, the first and last columns will always be `10px`. Which means, if there are only 2 or 3 columns, there will be no thin-sized column rules.

The `auto` keyword within the `repeat()` function creates an auto-repeater that fills in values for the row-rule line widths that would not otherwise receive values from other parts of the list, preventing the list from being cycled. A `column-rule-width` value can include, at most, one `repeat(auto, <line-width>)`.

Formal definition

Initial value	`medium`
Applies to	multicol elements
Inherited	no
Computed value	the absolute `<length>`, snapped as a line width
Animation type	a length

Formal syntax

```
column-rule-width =
  <line-width-list>      |
  <auto-line-width-list>

<line-width-list> =
  <line-width-or-repeat>#

<auto-line-width-list> =
  <line-width-or-repeat>#? , <auto-repeat-line-width> , <line-width-or-repeat>#?

<line-width-or-repeat> =
  <line-width>         |
  <repeat-line-width>

<auto-repeat-line-width> =
  repeat( auto , [ <line-width> ]# )

<line-width> =
  <length [0,∞]>  |
  hairline        |
  thin            |
  medium          |
  thick

<repeat-line-width> =
  repeat( [ <integer [1,∞]> ] , [ <line-width> ]# )

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4, CSS Gap Decorations Module Level 1, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates using a single keyword value, setting all the column rules to the same size.

HTML

We include a paragraph of text:

```
<p>
  This is a bunch of text split into three columns. The `column-rule-width`
  property is used to change the width of the line that is drawn between
  columns. Don't you think that's wonderful?
</p>
```

CSS

We create a multi-column container with the `column-count` property. As the `column-rule-style` property defaults to `none`, we have to set it to a visible value for the column rules to be drawn. We then set the `column-rule-width` to `thick`, letting the `column-rule-color` default to `currentcolor`.

```
p {
  column-count: 3;
  column-rule-style: solid;

  column-rule-width: thick;
}
```

Result

In multi-column layouts, the `gap` property defaults to `1em`, which is wider than our `column-rule-width`, so the lines are not drawn over our content.

Multiple values

This example demonstrates using multiple values for the `column-rule-width` property. It also demonstrates rules that overflow gaps are painted behind the content.

HTML

We include a list of authors:

```
<ul>
  <li>Kimberlé Crenshaw</li>
  <li>Angela Y. Davis</li>
  <li>Bernardine Evaristo</li>
  <li>Audre Lorde</li>
  <li>Cathy Park Hong</li>
  <li>Zoya Patel</li>
  <li>Juno Mac</li>
  <li>Molly Smith</li>
  <li>Tara Westover</li>
</ul>
```

CSS

We define the list to be a flex container, creating columns by setting the `flex-direction` to `row` using the `flex-flow` shorthand. We include a `column-rule-width` with ten `<line-width>` values, each larger than the previous.

```
ul {
  display: flex;
  flex-flow: row;
  list-style-type: none;
  column-rule-style: solid;
  column-rule-color: teal;

  column-rule-width: 1px, 2px, 3px, 4px, 5px, 6px, 7px, 8px, 9px, 10px;
}
```

Result

As there are more values (10) than gutters (8), the `9px` and `10px` values are not used.

The `gap` defaults to `normal` which resolves to `0` in flexbox. The `column-rule-width` only defines the width of a painted line and does not impact the layout. The lines are drawn behind the content.

Repeating values

This example demonstrates how, when there are fewer values in the list of widths than column rules, the values are repeated.

Using the same HTML and CSS as in the previous example, we include three comma-separated widths as the `column-rule-width` value:

```
ul {
  column-rule-width: 1px, 5px, 10px;
}
```

Result

Using the <code>repeat()</code> function

This example demonstrates using the `repeat()` function within the `column-rule-width` property value and how this function can help reduce the verbosity of value declarations.

We use the same HTML and CSS as in the previous examples. To demonstrate how values can become verbose and the utility of the `repeat()` function, we declare two custom properties, which we use in `repeat()` function declarations. The `repeat()` function sets the list of two `<line-width>` values to repeat 3 times.

```
ul {
  --base: 0.5vw;
  --secondary: 1vw;
  column-rule-width:
    15px,
    repeat(
      4,
```

```
      min(calc(var(--secondary) + 3px), 10px),
      abs(calc(var(--base) - 2px))
    ),
    15px;
}
```

Result

The flex container has nine columns, so eight gutters. The `repeat()` function repeats two width values four times, creating a list of ten width values. As there are fewer column gutters than total widths, the last two values in the list are discarded.

Using <code>auto</code> within <code>repeat()</code>

This example demonstrates using `auto` instead of an integer within the `repeat()` function.

Using `repeat(auto, <line-width>)` we set all column rules to `1px`, except the first and last, which we set to `5px`.

```
ul {
  column-rule-width: 5px, repeat(auto, 1px), 5px;
}
```

Result

```
@layer no-support {
  @supports not (column-rule-width: thin, thick) {
    body::before {
      content: "Your browser doesn't support multiple values for the column-rule-width property";
      background-color: wheat;
      display: block;
      text-align: center;
      padding: 1rem 0;
    }
  }
}
```

column-span CSS property

The **`column-span`** CSS property makes it possible for an element to span across all columns when its value is set to `all`.

An element that spans more than one column is called a **spanning element**.

Try it

```
column-span: none;
```

```
column-span: all;
```

```
<section id="default-example">
  <div class="multicol-element">
    <p>
      London. Michaelmas term lately over, and the Lord Chancellor sitting in
      Lincoln's Inn Hall.
    </p>
    <div id="example-element">Spanner?</div>
    <p>
      Implacable November weather. As much mud in the streets as if the waters
      had but newly retired from the face of the earth, and it would not be
      wonderful to meet a Megalosaurus, forty feet long or so, waddling like an
      elephantine lizard up Holborn Hill.
    </p>
  </div>
</section>
```

```
.multicol-element {
  width: 100%;
  text-align: left;
  column-count: 3;
}

.multicol-element p {
  margin: 0;
}

#example-element {
  background-color: rebeccapurple;
  padding: 10px;
  color: white;
}
```

Syntax

```
/* Keyword values */
column-span: none;
column-span: all;

/* Global values */
column-span: inherit;
```

```
column-span: initial;
column-span: revert;
column-span: revert-layer;
column-span: unset;
```

Values

This property is specified as one of the following keyword values:

`none`

The element does not span multiple columns.

`all`

The element spans across all columns. Content in the normal flow that appears before the element is automatically balanced across all columns before the element appears. The element establishes a new block formatting context.

Formal definition

Initial value	none
Applies to	in-flow block-level elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
column-span =
  none             |
  <integer [1,∞]>  |
  all              |
  auto

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Multi-column Layout Module Level 2, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Making a heading span columns

In this example, the heading is made to span across all the columns of the article.

HTML

```
<article>
  <h2>Header spanning all of the columns</h2>
  <p>
    The h2 should span all the columns. The rest of the text should be
    distributed among the columns.
  </p>
  <p>
    This is a bunch of text split into three columns using the CSS `columns`
    property. The text is equally distributed over the columns.
  </p>
  <p>
    This is a bunch of text split into three columns using the CSS `columns`
    property. The text is equally distributed over the columns.
  </p>
  <p>
    This is a bunch of text split into three columns using the CSS `columns`
    property. The text is equally distributed over the columns.
  </p>
  <p>
    This is a bunch of text split into three columns using the CSS `columns`
    property. The text is equally distributed over the columns.
  </p>
</article>
```

CSS

```
article {
  columns: 3;
}

h2 {
  column-span: all;
}
```

column-width CSS property

The **`column-width`** CSS property sets the ideal column width in a multi-column layout.

Try it

```
column-width: auto;
```

```
column-width: 6rem;
```

```
column-width: 120px;
```

```
column-width: 18ch;
```

```
<section id="default-example">
  <p id="example-element">
    London. Michaelmas term lately over, and the Lord Chancellor sitting in
    Lincoln's Inn Hall. Implacable November weather. As much mud in the streets
    as if the waters had but newly retired from the face of the earth, and it
    would not be wonderful to meet a Megalosaurus, forty feet long or so,
    waddling like an elephantine lizard up Holborn Hill.
  </p>
</section>
```

```
#example-element {
  width: 100%;
  columns: auto;
  text-align: left;
}
```

Syntax

```
/* Keyword value */
column-width: auto;

/* <length> values */
column-width: 60px;
column-width: 15.5em;
column-width: 3.3vw;

/* Global values */
column-width: inherit;
column-width: initial;
column-width: revert;
column-width: revert-layer;
column-width: unset;
```

Values

This property is specified as one of the following values:

`<length>`

> Indicates the optimal column width. The actual column width may differ from the specified value: it may be wider when necessary to fill available space, and narrower when the available space is too small. The value must be strictly positive or the declaration is invalid. Percentage values are also invalid.

`auto`

> The width of the column is determined by other CSS properties, such as `column-count`.

Description

The `column-width` property specifies the preferred column width in a multi-column layout. The container will have as many columns as can fit without any of them having a width less than the `column-width` value. If the width of the container is narrower than the specified value, the single column's width will be smaller than the declared column width.

This property can help you create responsive designs that fit different screen sizes. Especially in the presence of the `column-count` property (which has precedence), you must specify all related length values to achieve an exact column width. In horizontal text, these are `width`, `column-width`, `column-gap`, and `column-rule-width`.

The `column-width` property, along with the `column-height` and `column-count` properties, can also be set by using the `columns` shorthand.

Formal definition

Initial value	`auto`
Applies to	Block containers except table wrapper boxes
Inherited	no
Computed value	`auto` if specified as `auto`, otherwise for `<length>` the absolute value specified
Animation type	by computed value type

Formal syntax

```
column-width =
  auto        |
  <box-size>  |
  auto        |
  <box-size>

<box-size> =
  <length-percentage [0,∞]>                |
  stretch                                  |
  contain                                  |
  min-content                              |
  max-content                              |
  fit-content                              |
  stretch( <length-percentage [0,∞]> )     |
  fit-content( <length-percentage [0,∞]> ) |
  <calc-size()>

<length-percentage> =
  <length>     |
  <percentage>

<calc-size()> =
  calc-size( <calc-size-basis> , <calc-sum> )

<calc-size-basis> =
  <size-keyword>  |
```

```
  <calc-sum>      |
  <calc-size()>   |
  any

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Box Sizing Module Level 3, CSS Box Sizing Module Level 4, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting column width in pixels

HTML

```
<p class="content-box">
  Lorem ipsum dolor sit amet, consectetuer adipiscing elit, sed diam nonummy
  nibh euismod tincidunt ut laoreet dolore magna aliquam erat volutpat. Ut wisi
  enim ad minim veniam, quis nostrud exercitation ullamcorper suscipit lobortis
  nisl ut aliquip ex ea commodo consequat.
</p>
```

CSS

```
.content-box {
  column-width: 100px;
}
```

- Learn: Multiple-column Layout (Learn Layout)
- Basic Concepts of Multicol

column-wrap CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`column-wrap`** CSS property specifies the wrapping behavior of overflow columns in a CSS multi-column layout.

Syntax

```
/* Keyword values */
column-wrap: auto;
column-wrap: nowrap;
column-wrap: wrap;

/* Global values */
column-wrap: inherit;
column-wrap: initial;
column-wrap: revert;
column-wrap: revert-layer;
column-wrap: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

The initial value. If the content container's `column-height` is set to a `<length>`, `auto` resolves to `wrap`, otherwise it resolves to `nowrap`.

`nowrap`

Columns overflow in the inline direction.

`wrap`

Overflow columns are placed in a new row in the block direction.

Description

The `column-wrap` property can be used to set the columns of a CSS multi-column layout to wrap onto a new row when they start to overflow the column width. This is useful for creating more readable layouts when using the `column-count` or `column-width` property to set multiple columns.

Without `column-wrap`, excess columns will overflow to the side, and readers will have to scroll in the inline direction to read all the content. The `column-height` property, along with `column-wrap`, allows you to set a specific height for the columns and wrap them onto a new row of columns when the container edge is reached.

The default value of `column-wrap` is `auto`, which resolves to `wrap` when `column-height` is set to a `<length>` value; `wrap` allows the fixed-height columns to wrap onto multiple rows. When `column-height` is equal to `auto`, `column-wrap: auto` resolves to `nowrap`, allowing the columns to overflow horizontally if a fixed container height is set.

As a result of this default behavior, generally you don't need to explicitly set the `column-wrap` property.

Formal definition

Initial value	`auto`
Applies to	multicol elements
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
column-wrap =
  auto    |
  nowrap  |
  wrap
```

This syntax reflects the latest standard as per CSS Multi-column Layout Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates basic usage of the `column-wrap` property to create a wrapped multi-col layout via setting a `column-height` property.

HTML

We include a poem by Dr. Seuss using an `<ol>` containing 28 `<li>`s, followed by the author's name in a `<p>`.

```
<ol>
  <li>One fish</li>
  <li>Two fish</li>
  <li>Red fish</li>
  <li>Blue fish</li>
  ...
</ol>
<p>-- Dr. Seuss</p>
```

```
<ol>
  <li>One fish</li>
  <li>Two fish</li>
  <li>Red fish</li>
  <li>Blue fish</li>
  <li>Black fish</li>
  <li>Blue fish</li>
  <li>Old fish</li>
  <li>New fish.</li>
  <li>This one has a little star.</li>
  <li>This one has a little car.</li>
  <li>Say! What a lot</li>
  <li>Of fish there are.</li>
  <li>Yes. Some are red. And some are blue.</li>
  <li>Some are old. And some are new.</li>
  <li>Some are sad.</li>
  <li>And some are glad.</li>
  <li>And some are very, very bad.</li>
  <li>Why are they</li>
  <li>Sad and glad and bad?</li>
  <li>I do not know.</li>
  <li>Go ask your dad.</li>
  <li>Some are thin.</li>
  <li>And some are fat.</li>
  <li>The fat one has</li>
  <li>A yellow hat.</li>
  <li>From there to here, from here to there,</li>
  <li>Funny things</li>
  <li>Are everywhere.</li>
</ol>
<p>--Dr. Seuss</p>
```

CSS

We define the `<ol>` to be a multi-column container by setting the `column-width` property to `150px`, meaning the container will contain as many columns as possible with each being at least `150px` wide. The `gap` property sets a horizontal gap between columns and a vertical gap between rows of columns. We then set the `column-height` to `3em`, causing the `column-wrap` property's default `auto` value to resolve to `wrap` to create wrapped rows of columns.

```
ol {
  column-width: 150px;
  gap: 2em;
  column-height: 3em;
}
```

Result

Comparing <code>wrap</code> and <code>nowrap</code>

This example features a multi-column layout that demonstrates the difference between the `wrap` and `nowrap` values by allowing you to toggle the column container's `column-wrap` value between the two. The result is a layout that dynamically changes between horizontal and vertical scrolling.

HTML and JavaScript

The markup for this example contains multiple paragraphs of content, taken from MDN's HTML, CSS, and JavaScript home pages, and a JavaScript-powered `<input type="checkbox">` element to toggle the container's `column-wrap` property value between `nowrap` and `wrap`. The HTML and JavaScript have been hidden for brevity.

```
<form>
  <label for="set-wrap"
    >Set <code>column-wrap</code> to <code>wrap</code></label
  >
  <input type="checkbox" id="set-wrap" />
</form>
<h1>HTML, CSS, and JavaScript summaries</h1>
<p>
  <strong>HTML</strong> (HyperText Markup Language) is the most basic building
  block of the Web. It defines the meaning and structure of web content. Other
  technologies besides HTML are generally used to describe a web page's
  appearance (CSS) or behavior (JavaScript).
</p>
<p>
  "Hypertext" refers to text containing links that connect web pages to one
  another, either within a single website or between websites. Links are a
  fundamental aspect of the Web. By uploading content to the Internet and
  linking it to pages created by other people, you become an active participant
  in the World Wide Web.
</p>
<p>
  HTML uses "markup" to annotate text, images, and other content for display in
  a Web browser. HTML markup includes special "elements" such as
  <a href="/en-US/docs/Web/HTML/Reference/Elements/head"
    ><code>&lt;head&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/title"
    ><code>&lt;title&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/body"
    ><code>&lt;body&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/header"
    ><code>&lt;header&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/footer"
    ><code>&lt;footer&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/article"
    ><code>&lt;article&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/section"
    ><code>&lt;section&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/p"><code>&lt;p&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/div"
    ><code>&lt;div&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/span"
    ><code>&lt;span&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/img"
    ><code>&lt;img&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/aside"
    ><code>&lt;aside&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/audio"
    ><code>&lt;audio&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/canvas"
    ><code>&lt;canvas&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/datalist"
    ><code>&lt;datalist&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/details"
    ><code>&lt;details&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/embed"
    ><code>&lt;embed&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/nav"
    ><code>&lt;nav&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/search"
    ><code>&lt;search&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/output"
    ><code>&lt;output&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/progress"
    ><code>&lt;progress&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/video"
    ><code>&lt;video&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/ul"
    ><code>&lt;ul&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/ol"
    ><code>&lt;ol&gt;</code></a
  >,
  <a href="/en-US/docs/Web/HTML/Reference/Elements/li"
    ><code>&lt;li&gt;</code></a
  >
  and many others.
</p>
<p>
  An HTML element is set off from other text in a document by "tags", which
  consist of the element name surrounded by <code>&lt;</code> and
  <code>&gt;</code>. The name of an element inside a tag is case-insensitive.
```

```
  That is, it can be written in uppercase, lowercase, or a mixture. For example,
  the <code>&lt;title&gt;</code> tag can be written as
  <code>&lt;Title&gt;</code>, <code>&lt;TITLE&gt;</code>, or in any other way.
  However, the convention and recommended practice is to write tags in
  lowercase.
</p>

<hr />

<p>
  <strong>Cascading Style Sheets</strong> (<strong>CSS</strong>) is a
  <a href="/en-US/docs/Web/API/StyleSheet">stylesheet</a> language used to
  describe the presentation of a document written in
  <a href="/en-US/docs/Web/HTML">HTML</a> or
  <a href="/en-US/docs/Web/XML/Guides/XML_introduction">XML</a> (including XML
  dialects such as <a href="/en-US/docs/Web/SVG">SVG</a>,
  <a href="/en-US/docs/Web/MathML">MathML</a> or
  <a href="/en-US/docs/Glossary/XHTML">XHTML</a>). CSS describes how elements
  should be rendered on screen, on paper, in speech, or on other media.
</p>
<p>
  CSS is among the core languages of the <strong>open web</strong> and is
  standardized across web browsers according to
  <a href="https://www.w3.org/Style/CSS/#specs" class="external" target="_blank"
    >W3C specifications</a
  >. Previously, the development of various parts of CSS specification was done
  synchronously, which allowed the versioning of the latest recommendations. You
  might have heard about CSS1, CSS2.1, or even CSS3. There will never be a CSS3
  or a CSS4; rather, everything is now just "CSS" with individual CSS modules
  having version numbers.
</p>
<p>
  After CSS 2.1, the scope of the specification increased significantly and the
  progress on different CSS modules started to differ so much, that it became
  more effective to
  <a
    href="https://www.w3.org/Style/CSS/current-work"
    class="external"
    target="_blank"
    >develop and release recommendations separately per module</a
  >. Instead of versioning the CSS specification, W3C now periodically takes a
  snapshot of
  <a href="https://www.w3.org/TR/css/" class="external" target="_blank"
    >the latest stable state of the CSS specification</a
  >
  and individual modules progress. CSS modules now have version numbers, or
  levels, such as
  <a
    href="https://drafts.csswg.org/css-color-5/"
    class="external"
    target="_blank"
    >CSS Color Module Level 5</a
  >.
</p>

<hr />

<p>
  <strong>JavaScript</strong> (<strong>JS</strong>) is a lightweight interpreted
  (or
  <a href="/en-US/docs/Glossary/Just_In_Time_Compilation"
    >just-in-time compiled</a
  >) programming language with
  <a href="/en-US/docs/Glossary/First-class_Function">first-class functions</a>.
  While it is most well-known as the scripting language for Web pages,
  <a
    href="https://en.wikipedia.org/wiki/JavaScript#Other_usage"
    class="external"
    target="_blank"
    >many non-browser environments</a
  >
  also use it, such as <a href="/en-US/docs/Glossary/Node.js">Node.js</a>,
  <a href="https://couchdb.apache.org/" class="external" target="_blank"
    >Apache CouchDB</a
  >
  and
  <a
    href="https://opensource.adobe.com/dc-acrobat-sdk-docs/acrobatsdk/"
    class="external"
    target="_blank"
    >Adobe Acrobat</a
  >. JavaScript is a
  <a href="/en-US/docs/Glossary/Prototype-based_programming">prototype-based</a
  >, <a href="/en-US/docs/Glossary/Garbage_collection">garbage-collected</a>,
  <a href="/en-US/docs/Glossary/Dynamic_typing">dynamic</a> language, supporting
  multiple paradigms such as imperative, functional, and object-oriented.
</p>
<p>
  JavaScript's dynamic capabilities include runtime object construction,
  variable parameter lists, function variables, dynamic script creation (via
  <a href="/en-US/docs/Web/JavaScript/Reference/Global_Objects/eval"
    ><code>eval</code></a
  >), object introspection (via
  <a href="/en-US/docs/Web/JavaScript/Reference/Statements/for...in"
    ><code>for...in</code></a
  >
  and
  <a
    href="/en-US/docs/Web/JavaScript/Reference/Global_Objects/Object#static_methods"
    ><code>Object</code> utilities</a
  >), and source-code recovery (JavaScript functions store their source text and
  can be retrieved through
  <a
```

```
    href="/en-US/docs/Web/JavaScript/Reference/Global_Objects/Function/toString"
    ><code>toString()</code></a
  >).
</p>
<p>
  This section is dedicated to the JavaScript language itself, and not the parts
  that are specific to Web pages or other host environments. For information
  about <a href="/en-US/docs/Glossary/API">APIs</a> that are specific to Web
  pages, please see <a href="/en-US/docs/Web/API">Web APIs</a> and
  <a href="/en-US/docs/Glossary/DOM">DOM</a>.
</p>
<p>
  The standards for JavaScript are the
  <a href="https://tc39.es/ecma262/" class="external" target="_blank"
    >ECMAScript Language Specification</a
  >
  (ECMA-262) and the
  <a href="https://tc39.es/ecma402/" class="external" target="_blank"
    >ECMAScript Internationalization API specification</a
  >
  (ECMA-402). As soon as one browser implements a feature, we try to document
  it. This means that cases where some
  <a href="https://github.com/tc39/proposals" class="external" target="_blank"
    >proposals for new ECMAScript features</a
  >
  have already been implemented in browsers, documentation and examples in MDN
  articles may use some of those new features. Most of the time, this happens
  between the
  <a href="https://tc39.es/process-document/" class="external" target="_blank"
    >stages</a
  >
  3 and 4, and is usually before the spec is officially published.
</p>
<p>
  Do not confuse JavaScript with the
  <a
    href="https://en.wikipedia.org/wiki/Java_(programming_language)"
    class="external"
    target="_blank"
    >Java programming language</a
  >
  — <strong>JavaScript is <em>not</em> "Interpreted Java"</strong>. Both "Java"
  and "JavaScript" are trademarks or registered trademarks of Oracle in the U.S.
  and other countries. However, the two programming languages have very
  different syntax, semantics, and use.
</p>
<p>
  JavaScript documentation of core language features (pure
  <a
    href="/en-US/docs/Web/JavaScript/Reference/JavaScript_technologies_overview"
    >ECMAScript</a
  >, for the most part) includes the following:
</p>
```

```
const checkbox = document.getElementById("set-wrap");
checkbox.addEventListener("change", () => {
  if (checkbox.checked) {
    document.body.style.columnWrap = "wrap";
  } else {
    document.body.style.columnWrap = "nowrap";
  }
});
```

CSS

We make the `<body>` element a multi-col container by setting the `column-count` to `3`. We then set a `gap` of `3em 2em`, resulting in a `3em` gap between rows and a `2em` gap between columns.

We then set a `column-height` of `90vh`, making the columns nearly as tall as the viewport. We also set `column-wrap` to `nowrap`, causing excess content columns to overflow horizontally. This is required because the initial `column-wrap` value is `auto`, which resolves to `wrap` when `column-height` is set to a `<length>` value.

The checkbox toggles the `column-wrap` property between `nowrap` and `wrap`. When set to `wrap`, the excess content columns overflow vertically into new rows of columns, creating the vertical layout. The `column-height` value causes each row of columns to fill the viewport.

```
body {
  column-count: 3;
  gap: 3em 2em;
  padding: 0 2em;
  column-height: 90vh;
  column-wrap: nowrap;
}
```

Next, we set the `<h1>` element's `column-span` property to `all`, to make the heading span across all the columns, and set the `margin-top` property of the first `<p>` to `0` so that it lines up with the top of the columns.

```
h1 {
  column-span: all;
}

p:first-of-type {
  margin-top: 0;
}
```

```
* {
  box-sizing: border-box;
}

html {
  font-family: "Arial", sans-serif;
}

p {
  line-height: 1.5;
```

```
}

@supports not (column-wrap: wrap) {
  body::before {
    content: "Your browser does not support the 'column-wrap' property.";
    background-color: wheat;
    position: fixed;
    inset: 40% 0;
    height: fit-content;
    text-align: center;
    padding: 1rem 0;
  }
}

form {
  position: fixed;
  top: 0;
  right: 0;
  background-color: white;
  padding: 5px;
  border: 1px solid black;
}
```

Result

Toggle the checkbox to change the value of the `column-wrap` property and switch the layout between horizontal and vertical scrolling. When `column-wrap` is set to `nowrap`, the columns overflow horizontally; when `column-wrap` is set to `wrap`, new rows of columns are added vertically.

- CSS multi-column layout module

columns CSS property

The **`columns`** CSS shorthand property sets the maximum number of columns to use when drawing an element's contents, along with the minimum width and maximum height of the element's columns.

Try it

```
columns: 2;
```

```
columns: 6rem auto;
```

```
columns: 12em;
```

```
columns: 2 / 5em;
```

```
<section id="default-example">
  <p id="example-element">
    London. Michaelmas term lately over, and the Lord Chancellor sitting in
    Lincoln's Inn Hall. Implacable November weather. As much mud in the streets
    as if the waters had but newly retired from the face of the earth, and it
    would not be wonderful to meet a Megalosaurus, forty feet long or so,
    waddling like an elephantine lizard up Holborn Hill.
  </p>
</section>
```

```
#example-element {
  min-width: 21rem;
  text-align: left;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `column-count`
- `column-width`
- `column-height`

Syntax

```
/* Column width */
columns: 18em;

/* Column count */
columns: auto;
columns: 2;

/* Column width and count */
columns: 2 auto;
columns: auto 12em;
columns: auto auto;

/* Column width and/or count, and column height */
columns: 18em / 10em;
columns: 2 / 90vh;
columns: 2 auto / 300px;

/* Global values */
columns: inherit;
columns: initial;
columns: revert;
columns: revert-layer;
columns: unset;
```

The `columns` property value may be specified as a `<column-count>` and/or a `<column-width>` value, in any order, optionally followed by a `<column-height>` value preceded by a forward slash (/).

Values

`<'column-width'>`

The ideal column width, defined as a `<length>` or the keyword `auto`. The actual width may be wider or narrower to fit the available space. See `column-width`.

`<'column-count'>`

The ideal number of columns into which the element's content should be flowed, defined as an `<integer>` or the keyword `auto`. If specified as an `<integer>`, it defines the maximum allowable number of columns. See `column-count`.

`<'column-height'>`

The height of the columns defined as a `<length>` or the keyword `auto`. See `column-height`.

> **Note:** Setting a `<column-height>` value resets the `column-wrap` property to its initial value, `auto`. When `<column-height>` is set to a `<length>`, the `column-wrap` `auto` value resolves to `wrap`. When `<column-height>` is set to `auto`, it resolves to `nowrap`.

Formal definition

Initial value	as each of the properties of the shorthand: • `column-width`: `auto` • `column-count`: `auto` • `column-height`: `auto`
Applies to	Block containers except table wrapper boxes
Inherited	no
Computed value	as each of the properties of the shorthand: • `column-width`: `auto` if specified as `auto`, otherwise for `<length>` the absolute value specified • `column-count`: as specified • `column-height`: `auto` if specified as `auto`, otherwise for `<length>` the absolute value specified
Animation type	as each of the properties of the shorthand: • `column-width`: by computed value type • `column-count`: an integer • `column-height`: by computed value type

Formal syntax

```
columns =
  [ <'column-width'> || <'column-count'> ] [ / <'column-height'> ]?

<column-width> =
  auto        |
  <box-size>  |
  auto        |
  <box-size>

<column-count> =
  auto            |
  <integer [1,∞]>

<column-height> =
  auto           |
  <length [0,∞]>

<box-size> =
  <length-percentage [0,∞]>               |
  stretch                                 |
  contain                                 |
  min-content                             |
  max-content                             |
  fit-content                             |
  stretch( <length-percentage [0,∞]> )    |
  fit-content( <length-percentage [0,∞]> )  |
  <calc-size()>

<integer> =
  <number-token>

<length-percentage> =
  <length>      |
  <percentage>

<calc-size()> =
  calc-size( <calc-size-basis> , <calc-sum> )

<calc-size-basis> =
  <size-keyword>  |
  <calc-sum>      |
  <calc-size()>   |
  any

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
```

```
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Box Sizing Module Level 3, CSS Box Sizing Module Level 4, CSS Multi-column Layout Module Level 2, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting three equal columns

This example shows how to split a text container into three equal columns.

HTML

We include a basic `<p>` element containing text content.

```
<p class="content-box">
  This is a bunch of text split into three columns using the CSS
  <code>columns</code>
  property. The text is equally distributed over the columns.
</p>
```

CSS

We set a `columns` property value on the paragraph that includes a `<column-count>` value of `3` and a `<column-width>` value of `auto`.

```
body {
  width: 60%;
  margin: 0 auto;
}
```

```
.content-box {
  columns: 3 auto;
}
```

Result

Note how the text is split up into three columns.

Creating wrapping, fixed height columns

This example demonstrates including a `<column-height>` value with the `columns` shorthand property to split a text container into fixed-height columns that wrap onto new lines when the container inline edge is reached.

HTML

We include a basic `<p>` element with some text.

```
<p class="content-box">
  This is a bunch of text split into three columns using the CSS
  <code>columns</code> property. This includes a <code>column-count</code> value
  of <code>3</code>, a <code>column-width</code> value of <code>auto</code>, and
  a <code>column-height</code> value of <code>5em</code>. The
  <code>column-wrap</code> value is set to its initial value, <code>auto</code>;
  when a <code>column-height</code> value is included,
  <code>column-wrap: auto</code> resolves to <code>wrap</code>, which allows the
  columns to wrap onto multiple rows. The text is equally distributed over the
  columns, and placed into multiple rows.
</p>
```

CSS

We set a `columns` property value on the paragraph that includes a `<column-count>` value of `3`, a `<column-width>` value of `auto`, and a `<column-height>` value of `5em`. Because the `<column-height>` is set to a `<length>`, the paragraph's `column-wrap` value computes to `wrap`, which allows the columns to wrap onto multiple rows.

```
.content-box {
  columns: 3 auto / 5em;
}
```

```
body {
  width: 60%;
  margin: 0 auto;
}
```

```
@supports not (columns: 3 auto / 5em) {
  body::before {
    content: "Your browser does not support the 'column-height' property.";
    background-color: wheat;
    position: fixed;
    inset: 40% 0;
    height: fit-content;
    text-align: center;
    padding: 1rem 0;
  }
}
```

Result

Note how the text is split up into three columns. Each column is `5em` high. After every third column, the columns wrap onto a new line in the block direction.

contain CSS property

The **`contain`** CSS property indicates that an element and its contents are, as much as possible, independent from the rest of the document tree. Containment enables isolating a subsection of the DOM, providing performance benefits by limiting calculations of layout, style, paint, size, or any combination to a DOM subtree rather than the entire page. Containment can also be used to scope CSS counters and quotes.

Try it

```
contain: none;
```

```
contain: size;
```

```
contain: layout;
```

```
contain: paint;
```

```
contain: strict;
```

```
<section class="default-example" id="default-example">
  <div class="card" id="example-element">
    <h2>Element with '<code>contain</code>'</h2>
    <p>
      The Goldfish is a species of domestic fish best known for its bright
      colors and patterns.
    </p>
    <div class="fixed"><p>Fixed right 4px</p></div>
  </div>
</section>
```

```
h2 {
  margin-top: 0;
}

#default-example {
  text-align: left;
  padding: 4px;
  font-size: 16px;
}

.card {
  text-align: left;
  border: 3px dotted;
  padding: 20px;
  margin: 10px;
  width: 85%;
  min-height: 150px;
}

.fixed {
  position: fixed;
  border: 3px dotted;
  right: 4px;
  padding: 4px;
  margin: 4px;
}
```

Syntax

```
/* Keyword values */
contain: none;
contain: strict;
contain: content;
contain: size;
contain: inline-size;
contain: layout;
contain: style;
contain: paint;

/* Multiple keywords */
contain: size paint;
contain: size layout paint;
contain: inline-size layout;

/* Global values */
contain: inherit;
contain: initial;
contain: revert;
contain: revert-layer;
contain: unset;
```

Values

This property is specified as a single value (`none`, `strict`, or `content`) or as a space-separated list of one or more of `size` (or `inline-size`), `layout`, `style`, and `paint`, in any order:

`none`

The element renders as normal, with no containment applied.

`strict`

All containment rules are applied to the element. This is equivalent to `contain: size layout paint style`.

`content`

All containment rules except `size` are applied to the element. This is equivalent to `contain: layout paint style`.

`size`

Size containment is applied to the element in both the inline and block directions. The size of the element can be computed in isolation, ignoring the child elements. This value cannot be combined with `inline-size`.

`inline-size`

Inline size containment is applied to the element. The inline size of the element can be computed in isolation, ignoring the child elements. This value cannot be combined with `size`.

`layout`

The internal layout of the element is isolated from the rest of the page. This means nothing outside the element affects its internal layout, and vice versa.

`style`

For properties that can affect more than just an element and its descendants, the effects don't escape the containing element. Counters and quotes are scoped to the element and its contents.

`paint`

Descendants of the element don't display outside its bounds. If the containing box is offscreen, the browser does not need to paint its contained elements — these must also be offscreen as they are contained completely by that box. If a descendant overflows the containing element's bounds, then that descendant will be clipped to the containing element's overflow clip edge. By default, this edge corresponds to the padding-box for non-replaced elements.

Description

There are four types of CSS containment: size, layout, style, and paint, which are set on the container. The property is a space-separated list of a subset of the five standard values or one of the two shorthand values. Changes to the contained properties within the container are not propagated outside of the contained element to the rest of the page. The main benefit of containment is that the browser does not have to re-render the DOM or page layout as often, leading to small performance benefits during the rendering of static pages and greater performance benefits in more dynamic applications.

Using the `contain` property is useful on pages with groups of elements that are supposed to be independent, as it can prevent element internals from having side effects outside of its bounding-box.

> **Note:** Using `layout`, `paint`, `strict` or `content` values for this property creates:
>
> 1. A new containing block (for the descendants whose `position` property is `absolute` or `fixed`).
> 2. A new stacking context.
> 3. A new block formatting context.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
contain =
  none                                          |
  strict                                        |
  content                                       |
  [ [ size | inline-size ] || layout || style || paint ]
```

This syntax reflects the latest standard as per CSS Containment Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Paint containment

The following example shows how to use `contain: paint` to prevent an element's descendants from painting outside of its bounds.

```
div {
  width: 100px;
  height: 100px;
  background: red;
  margin: 10px;
  font-size: 20px;
}

.contain-paint {
  contain: paint;
}
```

```
<div class="contain-paint">
  <p>This text will be clipped to the bounds of the box.</p>
</div>
<div>
  <p>This text will not be clipped to the bounds of the box.</p>
</div>
```

Layout containment

Consider the example below which shows how elements behave with and without layout containment applied:

```
<div class="card contain-layout">
  <h2>Card 1</h2>
  <div class="fixed"><p>Fixed box 1</p></div>
  <div class="float"><p>Float box 1</p></div>
</div>
<div class="card">
  <h2>Card 2</h2>
  <div class="fixed"><p>Fixed box 2</p></div>
  <div class="float"><p>Float box 2</p></div>
</div>
<div class="card">
  <h2>Card 3</h2>
```

```
  <!-- ... -->
</div>
```

```
p {
  margin: 4px;
  padding: 4px;
}

h2 {
  margin-bottom: 4px;
  padding: 10px;
}

div {
  border-radius: 4px;
  box-shadow: 0 2px 4px 0 gray;
  padding: 6px;
  margin: 6px;
}
```

```
.card {
  width: 70%;
  height: 90px;
}

.fixed {
  position: fixed;
  right: 10px;
  top: 10px;
  background: coral;
}

.float {
  float: left;
  height: 40px;
  margin: 10px;
  background: aquamarine;
}

.contain-layout {
  contain: layout;
}
```

The first card has layout containment applied, and its layout is isolated from the rest of the page. We can reuse this card in other places on the page without worrying about layout recalculation of the other elements. If floats overlap the card bounds, elements on the rest of the page are not affected. When the browser recalculates the containing element's subtree, only that element is recalculated. Nothing outside of the contained element needs to be recalculated. Additionally, the fixed box uses the card as a layout container to position itself.

The second and third cards have no containment. The layout context for the fixed box in the second card is the root element so the fixed box is positioned in the top right corner of the page. A float overlaps the second card's bounds causing the third card to have unexpected layout shift that's visible in the positioning of the `<h2>` element. When recalculation occurs, it is not limited to a container. This impacts performance and interferes with the rest of the page layout.

Style containment

Style containment scopes counters and quotes to the contained element. For CSS counters, the `counter-increment` and `counter-set` properties are scoped to the element as if the element is at the root of the document.

Containment and counters

The example below takes a look at how counters work when style containment is applied:

```
<ul>
  <li>Item A</li>
  <li>Item B</li>
  <li class="container">Item C</li>
  <li>Item D</li>
  <li>Item E</li>
</ul>
```

```
body {
  counter-reset: list-items;
}

li::before {
  counter-increment: list-items;
  content: counter(list-items) ": ";
}

.container {
  contain: style;
}
```

Without containment, the counter would increment from 1 to 5 for each list item. Style containment causes the `counter-increment` property to be scoped to the element's subtree and the counter begins again at 1:

Containment and quotes

CSS quotes are similarly affected in that the `content` values relating to quotes are scoped to the element:

```
<!-- With style containment -->
<span class="open-quote">
  outer
  <span class="contain-style">
    <span class="open-quote">inner</span>
  </span>
</span>
<span class="close-quote">close</span>
<br />
<!-- Without containment -->
<span class="open-quote">
  outer
```

```
  <span>
    <span class="open-quote">inner</span>
  </span>
</span>
<span class="close-quote">close</span>
```

```
body {
  quotes: "[" "]" "‹" "›";
}
.open-quote::before {
  content: open-quote;
}

.close-quote::after {
  content: close-quote;
}

.contain-style {
  contain: style;
}
```

Because of containment, the first closing quote ignores the inner span and uses the outer span's closing quote instead:

- CSS `content-visibility` property
- CSS `position` property

contain-intrinsic-block-size CSS property

The **`contain-intrinsic-block-size`** CSS logical property defines the block size of an element that a browser can use for layout when the element is subject to size containment.

Block size is the size of an element in the dimension perpendicular to the flow of text within a line. In a horizontal writing mode like standard English, block size is the vertical dimension (height); in a vertical writing mode, block size is the horizontal dimension.

Syntax

```
/* Keyword value */
contain-intrinsic-block-size: none;

/* <length> values */
contain-intrinsic-block-size: 1000px;
contain-intrinsic-block-size: 10rem;

/* auto <length> */
contain-intrinsic-block-size: auto 300px;

/* Global values */
contain-intrinsic-block-size: inherit;
contain-intrinsic-block-size: initial;
contain-intrinsic-block-size: revert;
contain-intrinsic-block-size: revert-layer;
contain-intrinsic-block-size: unset;
```

Values

The following values can be specified for the intrinsic block size of an element:

`none`

The element has no intrinsic block size.

`<length>`

The element has the specified block size, expressed using the (`<length>`) data type.

`auto <length>`

When the element is in size containment and skipping its contents (for example, when it is offscreen and `content-visibility: auto` is set) the block size is remembered from the actual size of the element when it was last able to render its child elements. If the element has never rendered its child elements and hence has no remembered value for the normally rendered element size, or if it is not skipping its contents, the block size is the specified `<length>`.

Description

The property is commonly applied alongside elements that can trigger size containment, such as `contain: size` and `content-visibility`.

Size containment allows a user agent to lay out an element as though it had a fixed size. This prevents unnecessary reflows by avoiding the re-rendering of child elements to determine the actual size (thereby improving user experience). By default, size containment treats elements as though they had no contents and may collapse the layout in the same way as if the contents had no width or height. The `contain-intrinsic-block-size` property allows authors to specify an appropriate value to be used as the block-size for layout.

The `auto <length>` value allows the block-size of an element to be stored if the element is ever "normally rendered" (with its child elements) and then used instead of the specified value when the element does not have any content. This allows offscreen elements with `content-visibility: auto` to benefit from size containment without developers having to be precise in their estimates of element size. The remembered value is not used if the child elements are being rendered; if size containment is enabled, the `<length>` value will be used.

Formal definition

Initial value	none
Applies to	elements for which size containment can apply
Inherited	no
Computed value	as specified, with <length>s values computed
Animation type	by computed value type

Formal syntax

```
contain-intrinsic-block-size =
  auto? [ none | <length [0,∞]> ]
```

This syntax reflects the latest standard as per CSS Box Sizing Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting the intrinsic block size

The HTML below defines an element "contained_element" that will be subject to size constraint, and which contains a child element.

```
<div id="contained_element">
  <div class="child_element"></div>
</div>
```

The CSS below sets the `content-visibility` of `contained_element` to `auto`, so if the element is hidden it will be size constrained. The intrinsic block size and inline size that are used when it is size constrained are set at the same time using `contain-intrinsic-block-size` and `contain-intrinsic-inline-size`, respectively.

```
#contained_element {
  border: 2px solid green;
  inline-size: 151px;
  content-visibility: auto;
  contain-intrinsic-inline-size: 152px;
  contain-intrinsic-block-size: 52px;
}
.child_element {
  border: 1px solid red;
  background: blue;
  block-size: 50px;
  inline-size: 150px;
}
```

- content-visibility: the new CSS property that boosts your rendering performance (web.dev)
- `contain-intrinsic-inline-size`
- `contain-intrinsic-size`
- `contain-intrinsic-width`
- `contain-intrinsic-height`

contain-intrinsic-height CSS property

The **`contain-intrinsic-height`** CSS property sets the height of an element that a browser can use for layout when the element is subject to size containment.

Syntax

```
/* Keyword value */
contain-intrinsic-height: none;

/* <length> values */
contain-intrinsic-height: 1000px;
contain-intrinsic-height: 10rem;

/* auto <length> */
contain-intrinsic-height: auto 300px;

/* Global values */
contain-intrinsic-height: inherit;
contain-intrinsic-height: initial;
contain-intrinsic-height: revert;
contain-intrinsic-height: revert-layer;
contain-intrinsic-height: unset;
```

Values

The following values may be specified for an element.

`none`

The element has no intrinsic height.

`<length>`

The element has the specified height (`<length>`).

`auto <length>`

A remembered value of the "normally rendered" element height if one exists and the element is skipping its contents (for example, when it is offscreen); otherwise the specified `<length>`.

Description

The property is commonly applied alongside elements that can trigger size containment, such as `contain: size` and `content-visibility`, and may also be set using the `contain-intrinsic-size` shorthand property.

Size containment allows a user agent to lay out an element as though it had a fixed size, preventing unnecessary reflows by avoiding the re-rendering of child elements to determine the actual size (thereby improving user experience). By default, size containment treats elements as though they had no contents, and may collapse the layout in the same way as if the contents had no height (or width). The `contain-intrinsic-height` property allows authors to specify an appropriate value to be used as the height for layout.

The `auto <length>` value allows the height of the element to be stored if the element is ever "normally rendered" (with its child elements), and then used instead of the specified height when the element is skipping its contents. This allows offscreen elements with `content-visibility: auto` to benefit from size containment without developers having to be as precise in their estimates of element size. The remembered value is not used if the child elements are being rendered (if size containment is enabled, the `<length>` will be used).

Formal definition

Initial value	none
Applies to	elements for which size containment can apply

Inherited	no
Computed value	as specified, with <length>s values computed
Animation type	by computed value type

Formal syntax

```
contain-intrinsic-height =
  auto? [ none | <length [0,∞]> ]
```

This syntax reflects the latest standard as per CSS Box Sizing Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

In addition to the example below, the `contain-intrinsic-size` page contains a live example that demonstrates the effect of modifying the intrinsic width and height.

Setting the intrinsic height

The HTML below defines an element "contained_element" that will be subject to size constraint, and which contains a child element.

```
<div id="contained_element">
  <div class="child_element"></div>
</div>
```

The CSS below sets the `content-visibility` of `contained_element` to `auto`, so if the element is hidden it will be size constrained. The width and height that are used when it is size constrained are set at the same time using `contain-intrinsic-width` and `contain-intrinsic-height`, respectively.

```
#contained_element {
  border: 2px solid green;
  width: 151px;
  content-visibility: auto;
  contain-intrinsic-width: 152px;
  contain-intrinsic-height: 52px;
}
.child_element {
  border: 1px solid red;
  background: blue;
  height: 50px;
  width: 150px;
}
```

See also

- content-visibility: the new CSS property that boosts your rendering performance (web.dev)
- `contain-intrinsic-size`
- `contain-intrinsic-width`
- `contain-intrinsic-block-size`
- `contain-intrinsic-inline-size`

contain-intrinsic-inline-size CSS property

The **`contain-intrinsic-inline-size`** CSS logical property defines the inline-size of an element that a browser can use for layout when the element is subject to size containment.

Inline-size is the size of the element in the dimension parallel to the flow of text within a line. In a horizontal writing mode like standard English, inline size is the horizontal dimension (width); for a vertical writing mode, inline size is the vertical dimension.

Syntax

```
/* Keyword value */
contain-intrinsic-inline-size: none;

/* <length> values */
contain-intrinsic-inline-size: 1000px;
contain-intrinsic-inline-size: 10rem;

/* auto <length> */
contain-intrinsic-inline-size: auto 300px;

/* Global values */
contain-intrinsic-inline-size: inherit;
contain-intrinsic-inline-size: initial;
contain-intrinsic-inline-size: revert;
contain-intrinsic-inline-size: revert-layer;
contain-intrinsic-inline-size: unset;
```

Values

The following values can be specified for the intrinsic inline size of an element:

`none`

> The element has no intrinsic inline-size.

`<length>`

> The element has the specified inline-size (`<length>`).

`auto <length>`

> When the element is in size containment and skipping its contents (for example, when it is offscreen and `content-visibility: auto` is set) the inline size is remembered from the actual size of the element when it was last able to render its child elements. If the element has never rendered its child elements and hence has no remembered value for the normally rendered element size, or if it is not skipping its contents, the inline size is the specified `<length>`.

Description

The property is commonly applied alongside elements that can trigger size containment, such as `contain: size` and `content-visibility`.

Size containment allows a user agent to lay out an element as though it had a fixed size, preventing unnecessary reflows by avoiding the re-rendering of child elements to determine the actual size (thereby improving user experience). By default, size containment treats elements as though they had no contents, and may collapse the layout in the same way as if the contents had no width or height. The `contain-intrinsic-inline-size` property allows authors to specify an appropriate value to be used as the inline-size for layout.

The `auto <length>` value allows the inline-size of the element to be stored if the element is ever "normally rendered" (with its child elements), and then used instead of the specified value when the element is skipping its contents. This allows offscreen elements with `content-visibility: auto` to benefit from size containment without developers having to be as precise in their estimates of element size. The remembered value is not used if the child elements are being rendered (if size containment is enabled, the `<length>` will be used).

Formal definition

Initial value	none
Applies to	elements for which size containment can apply
Inherited	no
Computed value	as specified, with <length>s values computed
Animation type	by computed value type

Formal syntax

```
contain-intrinsic-inline-size =
  auto? [ none | <length [0,∞]> ]
```

This syntax reflects the latest standard as per CSS Box Sizing Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting the intrinsic inline size

The HTML below defines an element "contained_element" that will be subject to size constraint, and which contains a child element.

```
<div id="contained_element">
  <div class="child_element"></div>
</div>
```

The CSS below sets the `content-visibility` of `contained_element` to `auto`, so if the element is hidden it will be size constrained. The intrinsic block size and inline size that are used when it is size constrained are set at the same time using `contain-intrinsic-block-size` and `contain-intrinsic-inline-size`, respectively.

```
#contained_element {
  border: 2px solid green;
  inline-size: 151px;
  content-visibility: auto;
  contain-intrinsic-inline-size: 152px;
  contain-intrinsic-block-size: 52px;
}
.child_element {
  border: 1px solid red;
  background: blue;
  block-size: 50px;
  inline-size: 150px;
}
```

- `contain-intrinsic-height`

contain-intrinsic-size CSS property

The **`contain-intrinsic-size`** CSS shorthand property sets the size of an element that a browser will use for layout when the element is subject to size containment.

Constituent properties

This property is a shorthand for the following CSS properties:

- `contain-intrinsic-width`
- `contain-intrinsic-height`

Syntax

```
/* Keyword value */
contain-intrinsic-size: none;

/* <length> values */
contain-intrinsic-size: 1000px;
contain-intrinsic-size: 10rem;

/* width | height */
contain-intrinsic-size: 1000px 1.5em;

/* auto <length> */
contain-intrinsic-size: auto 300px;
contain-intrinsic-size: auto none;

/* auto width | auto height */
contain-intrinsic-size: auto 300px auto 4rem;

/* Global values */
contain-intrinsic-size: inherit;
contain-intrinsic-size: initial;
contain-intrinsic-size: revert;
contain-intrinsic-size: revert-layer;
contain-intrinsic-size: unset;
```

Values

The following values may be specified for the `contain-intrinsic-size` property:

`none`

The element has no intrinsic size in the given dimension(s).

`<length>`

The element has the specified `<length>` in the given dimension(s).

`auto [<length> | none]`

A remembered value of the "normally rendered" element size if one exists and the element is skipping its contents (for example, when it is offscreen); otherwise the specified `<length>`. The `none` keyword may be used in place of `<length>` where `0px` fixed lengths behave differently than `none` (such as in multi column, or grid layouts).

If one value is provided as a keyword, a length or an `auto [<length> | none]` pair, it applies to both width and height.

Two length values may be specified, which apply to the width and height in that order. If two `auto [<length> | none]` pairs are specified, the first pair applies to the width, and the second to the height.

Description

The property is commonly applied alongside elements that can trigger size containment, such as `contain: size` and `content-visibility`.

Size containment allows a user agent to lay out an element as though it had a fixed size, preventing unnecessary reflows by avoiding the re-rendering of child elements to determine the actual size (thereby improving user experience). By default, size containment treats elements as though they had no contents, and may collapse the layout in the same way as if the contents had no width or height. The `contain-intrinsic-size` property allows authors to specify an appropriate value to be used as the size for layout.

The `auto <length>` value allows the size of the element to be stored if the element is ever "normally rendered" (with its child elements), and then used instead of the specified length when the element is skipping its contents. This allows offscreen elements with `content-visibility: auto` to benefit from size containment without developers having to be as precise in their estimates of element size. The remembered value is not used if the child elements are being rendered (if size containment is enabled, the `<length>` will be used).

In grid and multi column layouts, an explicit size is treated differently than implicit content-based height. Elements might lay out substantially differently than it would have were it simply filled with content up to that height. The `auto none` value allows the element to fall back to `contain-intrinsic-size: none` if no remembered value exists, which will allow the element to be laid out as though it had no contents. This is almost always preferred to setting 0px as the intrinsic size in grid and multi column layouts, where contained elements may overflow their parents and can result in unexpected page layout.

Formal definition

Initial value	as each of the properties of the shorthand: • `contain-intrinsic-width`: none • `contain-intrinsic-height`: none
Applies to	elements for which size containment can apply
Inherited	no
Percentages	as each of the properties of the shorthand: • `contain-intrinsic-width`: no • `contain-intrinsic-height`: no
Computed value	as each of the properties of the shorthand: • `contain-intrinsic-width`: as specified, with <length>s values computed • `contain-intrinsic-height`: as specified, with <length>s values computed
Animation type	as each of the properties of the shorthand: • `contain-intrinsic-width`: by computed value type • `contain-intrinsic-height`: by computed value type

Formal syntax

```
contain-intrinsic-size =
  [ auto? [ none | <length [0,∞]> ] ]{1,2}
```

This syntax reflects the latest standard as per CSS Box Sizing Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using auto value pairs for intrinsic size

This example demonstrates `contain-intrinsic-size: auto <length>` and `contain-intrinsic-size: auto none`, using a layout where there are many elements displayed vertically that have both accurate and incorrect intrinsic size estimations. Using `content-visibility: auto` skips rendering elements when they are offscreen, so this property is a good candidate to combine with `contain-intrinsic-size` to improve rendering performance and minimize reflows.

The `contain-intrinsic-size: auto 500px` value pair tells the browser to use 500px as a kind of 'placeholder' size (width and height) for the element when it is offscreen and the page is being laid out. When the user scrolls to the element and it needs to be displayed, the browser will calculate the actual size of the element and its contents. If there is a difference between the placeholder and calculated size this might force a new layout, with accompanying changes to the sidebar position.

Once the browser has actual size information for the element, it will remember this size when the element scrolls offscreen again, and use the remembered size for layout calculations instead of the placeholder value. The benefit is that the browser does not need to repeatedly render the element contents to calculate its size and is especially useful when the contents are complex or depend on network resources or JavaScript.

HTML

```
<div id="container">
  <div id="auto-length-note">
    <p>
      Your browser does not support
      <code>contain-intrinsic-size: auto &amp;lt;length&amp;gt;</code>.
    </p>
  </div>
  <div class="auto-length">
    <p>Item one</p>
  </div>
  <div class="auto-length">
```

```
    <p>Item two</p>
  </div>
  <div class="auto-length large-intrinsic-size">
    <p class="small">Item three</p>
  </div>
  <div class="auto-length large-intrinsic-size">
    <p class="small">Item four</p>
  </div>
  <div id="auto-none-note">
    <p>
      Your browser does not support
      <code>contain-intrinsic-size: auto none</code>.
    </p>
  </div>
  <div class="auto-length none">
    <p>Item five</p>
  </div>
  <div class="auto-length none">
    <p>Item six</p>
  </div>
</div>
```

CSS

```
div,
p {
  padding: 1rem;
  margin-bottom: 1rem;
  font-size: 2rem;
  font-family: sans-serif;
}

code {
  background-color: lightgray;
  padding: 0.25rem;
  border-radius: 0.25rem;
}

#container {
  width: 90%;
  height: 80%;
}

.auto-length,
.auto-length.none {
  display: none;
}

#auto-length-note,
#auto-none-note {
  display: block;
  padding: 0;
}

#auto-length-note p,
#auto-none-note p {
  padding: 0.5rem;
  width: 100%;
  height: max-content;
  font-size: 1rem;
  line-height: 1.5rem;
  background-color: tomato;
}

@supports (contain-intrinsic-size: auto none) {
  .auto-length.none {
    display: block;
  }
  #auto-none-note {
    display: none;
  }
}
@supports (contain-intrinsic-size: auto 500px) {
  .auto-length {
    display: block;
  }
  #auto-length-note {
    display: none;
  }
}
```

```
p {
  height: 500px;
  width: 500px;
  border: 4px dotted;
  background: lightblue;
}

.auto-length {
  content-visibility: auto;
  contain-intrinsic-size: auto 500px;
  background-color: linen;
  outline: 4px dotted blue;
}

.large-intrinsic-size {
  /* Setting an inaccurate intrinsic size for the element */
  contain-intrinsic-size: auto 5000px;
  background-color: lightgray;
  outline: 4px dotted red;
}
```

```
.small {
  /* This element is a lot smaller than expected */
  height: 100px;
  width: 100px;
}

.none {
  background-color: papayawhip;
  contain-intrinsic-size: auto none;
  outline: 4px dotted red;
}
```

Result

- The first two boxes have an intrinsic size that matches their actual size, so as they flow into view, the layout is recalculated but we see no change in the scrollbar or the scroll position.
- The third and fourth boxes have a huge intrinsic size, so the initial layout that the browser calculated is far too big, and we've made these boxes smaller so that it's obvious when you've reached a point that forces a drastic layout change.

  When the third and fourth boxes scroll into view, the size is recalculated, making the box and its parent less tall. The effect is that the scroller jumps down the page (we've effectively scrolled further through the box than we'd estimated) and the scroller is longer, because the entire page is less tall than we'd estimated.
- The last boxes have `auto none`, so they have zero estimated size. When they scroll into view the size of the element and its parent are recalculated to be much larger, so the scroller decreases in size and moves up the bar.

After scrolling all the way to the bottom you can subsequently scroll up and down smoothly, because using `content-visibility: auto` saves the actual rendered size of the element for next time it is displayed.

Setting the intrinsic size

This example provides selection lists that can be used to modify `contain-intrinsic-size`, `content-visibility` and `contain` on an element in order to observe the effect of the different settings.

CSS

```
#contained_element {
  border: 2px solid green;
  width: 120px;
}
.child_element {
  border: 1px solid red;
  background: blue;
  height: 50px;
  width: 150px;
}
```

JavaScript

The code below adds styles to, and removes styles from, the containing element based on the selected options.

```
const containedElement = document.querySelector("#contained_element");
const intrinsicSizeSelector = document.querySelector(
  "#contain_intrinsic_size_selector",
);
const containSelector = document.querySelector("#contain_selector");
const contentVisibilitySelector = document.querySelector(
  "#content_visibility_selector",
);

containedElement.style["contain-intrinsic-size"] =
  intrinsicSizeSelector.options[intrinsicSizeSelector.selectedIndex].text;
containedElement.style["contain"] =
  containSelector.options[containSelector.selectedIndex].text;
containedElement.style["content-visibility"] =
  contentVisibilitySelector.options[
    contentVisibilitySelector.selectedIndex
  ].text;

intrinsicSizeSelector.addEventListener("change", () => {
  containedElement.style["contain-intrinsic-size"] =
    intrinsicSizeSelector.options[intrinsicSizeSelector.selectedIndex].text;
});

containSelector.addEventListener("change", () => {
  containedElement.style["contain"] =
    containSelector.options[containSelector.selectedIndex].text;
});

contentVisibilitySelector.addEventListener("change", () => {
  containedElement.style["content-visibility"] =
    contentVisibilitySelector.options[
      contentVisibilitySelector.selectedIndex
    ].text;
});
```

HTML

The HTML defines two buttons, a container element that is subject to containment via the `content-visibility` property.

```
<p>
  <label for="contain_intrinsic_size_selector">contain-intrinsic-size:</label>
  <select id="contain_intrinsic_size_selector">
    <option>none</option>
    <option>40px 130px</option>
    <option>auto 40px auto 130px</option></select
  >;<br />

  <label for="contain_selector">contain:</label>
  <select id="contain_selector">
    <option>none</option>
    <option>size</option>
    <option>strict</option></select
  >;<br />
```

```
  <label for="content_visibility_selector">content-visibility:</label>
  <select id="content_visibility_selector">
    <option>visible</option>
    <option>auto</option>
    <option>hidden</option></select
  >;
</p>

<div id="contained_element">
  <div class="child_element"></div>
</div>
```

Result

Use the selectors to apply the given styles to the containing `div` element. Note that when `content-visibility` is `visible` or `auto`, changing `contain-intrinsic-size` makes no difference. However if the content is hidden, having a `contain-intrinsic-size` of `none` collapses the parent element as though its child element had no size.

contain-intrinsic-width CSS property

The **`contain-intrinsic-width`** CSS property sets the width of an element that a browser will use for layout when the element is subject to size containment.

Syntax

```
/* Keyword value */
contain-intrinsic-width: none;

/* <length> values */
contain-intrinsic-width: 1000px;
contain-intrinsic-width: 10rem;

/* auto <length> */
contain-intrinsic-width: auto 300px;

/* Global values */
contain-intrinsic-width: inherit;
contain-intrinsic-width: initial;
contain-intrinsic-width: revert;
contain-intrinsic-width: revert-layer;
contain-intrinsic-width: unset;
```

Values

The following values may be specified for an element.

`none`

The element has no intrinsic width.

`<length>`

The element has the specified width (`<length>`).

`auto <length>`

A remembered value of the "normally rendered" element width if one exists and the element is skipping its contents (for example, when it is offscreen); otherwise the specified `<length>`.

Description

The property is commonly applied alongside elements that can trigger size containment, such as `contain: size` and `content-visibility`, and may also be set using the `contain-intrinsic-size` shorthand property.

Size containment allows a user agent to lay out an element as though it had a fixed size, preventing unnecessary reflows by avoiding the re-rendering of child elements to determine the actual size (thereby improving user experience). By default, size containment treats elements as though they had no contents, and may collapse the layout in the same way as if the contents had no width or height. The `contain-intrinsic-width` property allows authors to specify an appropriate value to be used as the width for layout.

The `auto <length>` value allows the width of the element to be stored if the element is ever "normally rendered" (with its child elements), and then used instead of the specified width when the element is skipping its contents. This allows offscreen elements with `content-visibility: auto` to benefit from size containment without developers having to be as precise in their estimates of element size. The remembered value is not used if the child elements are being rendered (if size containment is enabled, the `<length>` will be used).

Formal definition

Initial value	none
Applies to	elements for which size containment can apply
Inherited	no
Computed value	as specified, with <length>s values computed
Animation type	by computed value type

Formal syntax

```
contain-intrinsic-width =
  auto? [ none | <length [0,∞]> ]
```

This syntax reflects the latest standard as per CSS Box Sizing Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

In addition to the example below, the `contain-intrinsic-size` page contains a live example that demonstrates the effect of modifying the intrinsic width and height.

Setting the intrinsic width

The HTML below defines an element "contained_element" that will be subject to size constraint, and which contains a child element.

```
<div id="contained_element">
  <div class="child_element"></div>
</div>
```

The CSS below sets the `content-visibility` of `contained_element` to `auto`, so if the element is hidden it will be size constrained. The width and height that are used when it is size constrained are set at the same time using `contain-intrinsic-width` and `contain-intrinsic-height`, respectively.

```
#contained_element {
  border: 2px solid green;
  width: 151px;
  content-visibility: auto;
  contain-intrinsic-width: 152px;
  contain-intrinsic-height: 52px;
}
.child_element {
  border: 1px solid red;
  background: blue;
  height: 50px;
  width: 150px;
}
```

- `contain-intrinsic-size`
- `contain-intrinsic-height`
- `contain-intrinsic-block-size`
- `contain-intrinsic-inline-size`

container CSS property

The **container** shorthand CSS property establishes the element as a query container and specifies the name and type of the containment context used in a container query.

Constituent properties

This property is a shorthand for the following CSS properties:

- `container-name`
- `container-type`

Syntax

```
/* <container-name> */
container: my-layout;

/* <container-name> / <container-type> */
container: my-layout / size;

/* Global Values */
container: inherit;
container: initial;
container: revert;
container: revert-layer;
container: unset;
```

Values

`<container-name>`

A case-sensitive name for the containment context. More details on the syntax are covered in the `container-name` property page.

`<container-type>`

The type of containment context. More details on the syntax are covered in the `container-type` property page.

Formal definition

Initial value	as each of the properties of the shorthand: • `container-name`: `none` • `container-type`: `normal`
Applies to	all elements
Inherited	no
Percentages	as each of the properties of the shorthand: • `container-name`: no • `container-type`: no
Computed value	as each of the properties of the shorthand: • `container-name`: `none` or an ordered list of identifiers • `container-type`: as specified
Animation type	as each of the properties of the shorthand: • `container-name`: Not animatable • `container-type`: a color

Formal syntax

```
container =
  <'container-name'> [ / <'container-type'> ]?

<container-name> =
  none            |
  <custom-ident>+

<container-type> =
  normal                                  |
  [ [ size | inline-size ] || scroll-state ]
```

This syntax reflects the latest standard as per CSS Conditional Rules Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Establishing inline size containment

Given the following HTML example which is a card component with an image, a title, and some text:

```
<div class="post">
  <div class="card">
    <h2>Card title</h2>
    <p>Card content</p>
  </div>
</div>
```

The explicit way to create a container context is to declare a `container-type` with an optional `container-name`:

```
.post {
  container-type: inline-size;
  container-name: sidebar;
}
```

The `container` shorthand is intended to make this definable in a single declaration:

```
.post {
  container: sidebar / inline-size;
}
```

You can then target that container by name using the `@container` at-rule:

```
@container sidebar (width >= 400px) {
  /* <stylesheet> */
}
```

See also

- CSS container queries
- Using container size and style queries
- `@container` at-rule
- CSS `contain` property
- CSS `container-type` property
- CSS `container-name` property
- CSS `content-visibility` property

container-name CSS property

The **container-name** CSS property specifies a list of query container names used by the @container at-rule in a container query.

Syntax

```
container-name: none;

/* A single name */
container-name: my-layout;

/* Multiple names */
container-name: my-page-layout my-component-library;

/* Global Values */
container-name: inherit;
container-name: initial;
container-name: revert;
container-name: revert-layer;
container-name: unset;
```

Values

This property is specified as a space-separated list of `<custom-ident>` values or the keyword `none`:

`none`

The default value. The query container has no name.

`<custom-ident>`

A case-sensitive string that is used to identify the container. The following conditions apply:

- The name must not equal `or`, `and`, `not`, or `default`.
- The name value must not be in quotes.
- The dashed ident intended to denote author-defined identifiers (e.g., `--container-name`) is permitted.
- A list of multiple names separated by a space is allowed.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	none or an ordered list of identifiers
Animation type	Not animatable

Formal syntax

```
container-name =
  none             |
  <custom-ident>+
```

This syntax reflects the latest standard as per CSS Conditional Rules Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Description

With no name specified, a container query will apply styles to elements based on attributes such as the size or scroll-state of the nearest ancestor with a containment context.

> **Note:** Size containers' descendants can be sized using container query length units.

When a containment context is given a name, it can be specifically targeted by setting that name on a `@container` at-rule.

It is possible to create a query container by assigning a `container-name` to an element, and then query only the existence of that name in the associated `@container` at-rule, with no query expression specified. These so-called **name-only container queries** enable selectively applying styles to elements based only on whether they have an ancestor with a specific `container-name` set.

Examples

Using a container name

Given the following HTML example which is a card component with a title and some text:

```
<div class="card">
  <div class="post-meta">
    <h2>Card title</h2>
    <p>My post details.</p>
  </div>
  <div class="post-excerpt">
    <p>
      A preview of my <a href="https://example.com">blog post</a> about cats.
    </p>
  </div>
</div>
```

To create a containment context, add the `container-type` property to an element in CSS. The following example creates two containment contexts, one for the card meta information and one for the post excerpt:

> **Note:** A shorthand syntax for these declarations are described in the `container` page.

```
.post-meta {
  container-type: inline-size;
}

.post-excerpt {
  container-type: inline-size;
  container-name: excerpt;
}
```

Writing a container query via the `@container` at-rule will apply styles to the elements of the container when the query evaluates to true. The following example has two container queries, one that will apply only to the contents of the `.post-excerpt` element and one that will apply to both the `.post-meta` and `.post-excerpt` contents:

```
@container excerpt (width >= 400px) {
  p {
    visibility: hidden;
  }
}

@container (width >= 400px) {
  p {
    font-size: 2rem;
  }
}
```

For more information on writing container queries, see the CSS Container Queries page.

Using multiple container names

You can also provide multiple names to a container context separated by a space:

```
.post-meta {
  container-type: inline-size;
  container-name: meta card;
}
```

This will allow you to target the container using either name in the `@container` at-rule. This is useful if you want to target the same container with multiple container queries where either condition could be true:

```
@container meta (width <= 500px) {
  p {
    visibility: hidden;
  }
}

@container card (width <= 200px) {
```

```
  h2 {
    font-size: 1.5em;
  }
}
```

Using a name-only container query

This example demonstrates how to use a name-only container query.

HTML

We include a `<div>` with an `id` of `container`, and three `<p>` elements, two inside the container, and one outside the container:

```
<div id="container">
  <p>I'm in the container.</p>
  <p>I'm also in the container.</p>
</div>
<p>I'm not in the container.</p>
```

CSS

We assign a name to the container:

```
#container {
  container-name: my-container;
}
```

We can then selectively apply styles only to elements inside containers with that name set, as shown in the next snippet.

```
@container my-container {
  p {
    background-color: lime;
    font-size: 1.3rem;
    width: 50vw;
    padding: 0.5rem;
    font-family: sans-serif;
  }
}
```

Result

The specified styles should be applied only to the first and second `<p>` elements, but not to the third.

- CSS `container` shorthand property
- CSS `container-type` property
- CSS `content-visibility` property

container-type CSS property

The **container-type** CSS property specifies the type of container context used in a container query.

Syntax

```
/* Keyword values */
container-type: normal;
container-type: size;
container-type: inline-size;
container-type: scroll-state;
container-type: anchored;

/* Two values */
container-type: size scroll-state;

/* Global Values */
container-type: inherit;
container-type: initial;
container-type: revert;
container-type: revert-layer;
container-type: unset;
```

Values

This property is specified as one or two keyword values from the following list. In the two-value case, one must be `scroll-state` and the other must be `inline-size` or `size`:

`anchored`

> Establishes a query container for anchored container queries on the container. In this case, the size of the element is not computed in isolation; no containment is applied.

`inline-size`

> Establishes a query container for dimensional queries on the inline axis of the container. Applies style and inline-size containment to the element. The inline size of the element can be computed in isolation, ignoring the child elements (see Using CSS containment).

`normal`

> Default value. The element is not a query container for any container size, scroll-state, or anchored queries, but can be used as a query container for container style queries and name-only container queries.

`scroll-state`

> Establishes a query container for scroll-state queries on the container. In this case, the size of the element is not computed in isolation; no containment is applied.

`size`

Establishes a query container for container size queries in both the inline and block dimensions. Applies style and size containment to the element. Size containment is applied to the element in both the inline and block directions. The size of the element can be computed in isolation, ignoring the child elements.

Formal definition

Initial value	`normal`
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	a color

Formal syntax

```
container-type =
  normal                                |
  [ [ size | inline-size ] || scroll-state ]
```

This syntax reflects the latest standard as per CSS Conditional Rules Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Description

Container queries allow you to selectively apply styles inside a container based on conditional queries performed on the container. The `@container` at-rule is used to specify the tests performed on a container, and the rules that will apply to the container's contents if the query returns `true`.

Certain types of container query can only be performed on elements with specific `container-type` property values set, which establish specific container contexts on those containers:

- Size: Enable selectively applying CSS rules to a container's children based on a general size or inline size condition such as a maximum or minimum dimension, aspect ratio, or orientation.
- Scroll-state: Enable selectively applying CSS rules to a container's children based on a scroll-state condition such as whether the container is a scroll container that is partially scrolled or whether the container is a snap target that is going to be snapped to its scroll snap container.
- Anchored: Enable selectively applying CSS rules to a container's children based on whether the container is anchor-positioned and has a position-try fallback option applied to it.

If a `container-type` is not set on a container, the element is not a query container for container size, scroll-state, or anchored queries, but can still be used as a query container for container style queries and name-only container queries.

Container size queries

Container size queries allow you to selectively apply CSS rules to a container's descendants based on a size condition such as a maximum or minimum dimension, aspect ratio, or orientation.

Size containers additionally have size containment applied to them — this turns off the ability of an element to get size information from its contents, which is important for container queries to avoid infinite loops. If this were not the case, a CSS rule inside a container query could change the content size, which in turn could make the query evaluate to false and change the parent element's size, which in turn could change the content size and flip the query back to true, and so on. This sequence would then repeat itself in an endless loop.

The container size has to be set by context, such as block-level elements that stretch to the full width of their parent, or explicitly defined. If a contextual or explicit size is not available, elements with size containment will collapse.

> **Note:** Size containers' descendants can be sized using container query length units.

Container scroll-state queries

Container scroll-state queries allow you to selectively apply CSS rules to a container's children based on a scroll-state condition such as:

- Whether the container's contents are partially scrolled.
- Whether the container is a snap target that is going to be snapped to a scroll snap container.
- Whether the container is positioned via `position: sticky` and stuck to a boundary of a scrolling container.

In the first case, the queried container is the scroll container itself. In the other two cases the queried container is an element that is affected by the scroll position of an ancestor scroll container.

Anchored container queries

Anchored container queries allow you to selectively apply CSS rules to the descendants of an anchor-positioned container when it has a position-try fallback active on it, as specified via the `position-try-fallbacks` property.

For example, you might have an anchor-positioned tooltip element that is positioned above its anchor by default via a `position-area` value of `top`, but has a `position-try-fallbacks` value of `flip-block` specified. This will cause the tooltip to flip in the block direction to the bottom of its anchor when it starts to overflow the top of the viewport. If we set `container-type: anchored` on it, we can detect when the position-try fallback is applied via a `@container` at-rule and apply CSS as a result.

```
.tooltip {
  position: absolute;
  position-anchor: --my-anchor;
  position-area: top;
  position-try-fallbacks: flip-block;
  container-type: anchored;
}
```

Examples

Establishing inline size containment

Given the following HTML example which is a card component with an image, a title, and some text:

```
<div class="container">
  <div class="card">
    <h3>Normal card</h3>
    <div class="content">
      Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod
      tempor incididunt ut labore et dolore magna aliqua.
    </div>
  </div>
</div>

<div class="container wide">
  <div class="card">
    <h3>Wider card</h3>
    <div class="content">
      Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod
```

```
      tempor incididunt ut labore et dolore magna aliqua.
    </div>
  </div>
</div>
```

To create an inline size container context, add the `container-type` property to an element with a value of `inline-size`:

```
.container {
  container-type: inline-size;
  width: 300px;
  height: 120px;
}

.wide {
  width: 500px;
}
```

```
h3 {
  height: 2rem;
  margin: 0.5rem;
}

.card {
  height: 100%;
}

.content {
  background-color: wheat;
  height: 100%;
}

.container {
  margin: 1rem;
  border: 2px dashed red;
  overflow: hidden;
}
```

Writing a container query via the `@container` at-rule will apply styles to the elements of the container when it is wider than `400px`:

```
@container (width > 400px) {
  .card {
    display: grid;
    grid-template-columns: 1fr 2fr;
  }
}
```

content CSS property

The **`content`** CSS property replaces content with a generated value. It can be used to define what is rendered inside an element or pseudo-element. For elements, the `content` property specifies whether the element renders normally (`normal` or `none`) or is replaced with an image (and associated "alt" text). For pseudo-elements and margin boxes, `content` defines the content as images, text, both, or none, which determines whether the element renders at all.

Objects inserted using the `content` property are **anonymous replaced elements**.

Try it

```
.topic-games::before {
  content: "🎮 " / "games";
}

.topic-weather::before {
  content: "🌥️ " / "cloudy";
}

.topic-hot::before {
  content: url("/shared-assets/images/examples/fire.png") / "On fire";
  margin-right: 6px;
}
```

```
<p class="topic-games">Game News: A new inFamous is not planned</p>

<p class="topic-weather">
  Weather for Today: Heat, violent storms and twisters
</p>

<p class="topic-hot">Trending Article: Must-watch videos of the week</p>
```

Syntax

```
/* Keywords that cannot be combined with other values */
content: normal;
content: none;

/* <content-replacement>: <image> values */
content: url("http://www.example.com/test.png");
content: linear-gradient(#e66465, #9198e5);
content: image-set("image1x.png" 1x, "image2x.png" 2x);
```

```
/* speech output: alternative text after a "/"  */
content: url("../img/test.png") / "This is the alt text";
content: counter(chapter) / "Chapter " counter(chapter);

/* <string> value */
content: "unparsed text";

/* <counter> values, optionally with <list-style-type> */
content: counter(chapter_counter);
content: counter(chapter_counter, upper-roman);
content: counters(section_counter, ".");
content: counters(section_counter, ".", decimal-leading-zero);

/* attr() value linked to the HTML attribute value */
content: attr(href);

/* <quote> values */
content: open-quote;
content: close-quote;
content: no-open-quote;
content: no-close-quote;

/* <content-list>: a list of content values.
Several values can be used simultaneously */
content: "prefix" url("http://www.example.com/test.png");
content: "prefix" url("/img/test.png") "suffix" / "Alt text";
content: open-quote counter(chapter_counter);

/* Global values */
content: inherit;
content: initial;
content: revert;
content: revert-layer;
content: unset;
```

Values

The value can be:

- One of two keywords: `none` or `normal`. `normal` is the default property value.
- `<content-replacement>` when replacing a DOM node. `<content-replacement>` is always an `<image>`.
- A `<content-list>` when replacing pseudo-elements and margin boxes. A `<content-list>` is a list of one or more anonymous inline boxes appearing in the order specified. Each `<content-list>` item is of type `<string>`, `<image>`, `<counter>`, `<quote>`, `<target>`, or `<leader()>`.
- An optional alternative text value that can include `<string>`, `<counter>`, or `attr()` function values, preceded by a slash (`/`).

The keywords and data types mentioned above are described in more detail below:

`none`

When applied to a pseudo-element, the pseudo-element is not generated. When applied to an element, the value has no effect.

`normal`

For the `::before` and `::after` pseudo-elements, this value computes to `none` . For other pseudo-elements such as `::marker`, `::placeholder`, or `::file-selector-button`, it produces the element's initial (or normal) content. For regular elements or page margin boxes, it computes to the element's descendants. This is the default value.

`<string>`

A sequence of characters enclosed in matching single or double quotes. Multiple string values will be concatenated (there is no concatenation operator in CSS).

`<image>`

An `<image>`, representing an image to display. This can be equal to a `<url>`, `image-set()`, or `<gradient>` data type, or a part of the webpage itself, defined by the `element()` function.

`<counter>`

The `<counter>` value is a CSS counter, generally a number produced by computations defined by `counter-reset` and `counter-increment` properties. It can be displayed using either the `counter()` or `counters()` function.

`counter()`

The `counter()` function has two forms: 'counter(*name*)' or 'counter(*name*, style)'. The generated text is the value of the innermost counter of the given name in scope at the given pseudo-element. It is formatted in the specified `list-style-type` (`decimal` by default).

`counters()`

The `counters()` function also has two forms: 'counters(*name*, *string*)' or 'counters(*name*, *string*, *style*)'. The generated text is the value of all counters with the given name in scope at the given pseudo-element, from outermost to innermost, separated by the specified string. The counters are rendered in the indicated `list-style-type` (`decimal` by default).

`<quote>`

The `<quote>` data type includes language- and position-dependent keywords:

`open-quote` and `close-quote`

These values are replaced by the appropriate string from the `quotes` property.

`no-open-quote` and `no-close-quote`

Introduces no content, but increments (decrements) the level of nesting for quotes.

`<target>`

The `<target>` data type includes three target functions, `<target-counter()>`, `<target-counters()>`, and `<target-text()>` that create cross-references obtained from the target end of a link. See Formal syntax.

`<leader()>`

The `<leader()>` data type includes a leader function: `leader( <leader-type> )`. This function accepts the keyword values `dotted`, `solid`, or `space` (equal to `leader(".")`, `leader("_")`, and `leader(" ")`, respectively), or a `<string>` as a parameter. When supported and used as a value for `content`, the leader-type provided will be inserted as a repeating pattern, visually connecting content across a horizontal line.

`attr(x)`

The `attr(x)` CSS function retrieves the value of an attribute of the selected element, or the pseudo-element's originating element. The value of the element's attribute `x` is an unparsed string representing the attribute name. If there is no attribute `x`, an empty string is returned. The case sensitivity of the attribute name parameter depends on the document language.

alternative text: `/ <string> | <counter> | attr()`

Alternative text may be specified for an image or any `<content-list>` items, by appending a forward slash and then a combination of strings, counters, and `attr()` functions. The alternative text is intended for speech output by screen-readers, but may also be displayed in some browsers.

Formal definition

Initial value	`normal`
Applies to	All elements, tree-abiding pseudo-elements, and page margin boxes
Inherited	no
Computed value	On elements, always computes to `normal`. On `::before` and `::after`, if `normal` is specified, computes to `none`. Otherwise, for URI values, the absolute URI; for `attr()` values, the resulting string; for other keywords, as specified.
Animation type	discrete

Formal syntax

```
content =
  normal                                          |

```

This syntax reflects the latest standard as per CSS Counter Styles Level 3, CSS Generated Content Module Level 3, CSS Generated Content for Paged Media Module, CSS Images Module Level 4, CSS Images Module Level 5, CSS Lists and Counters Module Level 3, CSS Values and Units Module Level 5, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Accessibility

CSS-generated content is not included in the DOM. Because of this, it will not be represented in the accessibility tree and certain assistive technology/browser combinations will not announce it. If the content conveys information that is critical to understanding the page's purpose, it is better to include it in the main document.

If inserted content is not decorative, check that the information is provided to assistive technologies and is also available when CSS is turned off.

- Accessibility support for CSS generated content – Tink (2015)
- WCAG, Guideline 1.3: Create content that can be presented in different ways
- Understanding Success Criterion 1.3.1 | W3C Understanding WCAG 2.0
- Failure of Success Criterion 1.3.1: inserting non-decorative generated content Techniques for WCAG 2.0

Examples

The first five examples create generated content on pseudo-elements. The last three are examples of element replacement.

Appending strings based on an element's class

This example inserts generated text after the text of elements that have a particular class name. The text is colored red.

HTML

```
<h2>Paperback Best Sellers</h2>
<ol>
  <li>Political Thriller</li>
  <li class="new-entry">Halloween Stories</li>
  <li>My Biography</li>
  <li class="new-entry">Vampire Romance</li>
</ol>
```

CSS

```
.new-entry::after {
  content: " New!"; /* The leading space creates separation
                       between the DOM node's content and the generated content
                       being added. */
  color: red;
}
```

Result

Quotes

This example inserts differently colored quotation marks around quotes.

HTML

```
<p>
  According to Sir Tim Berners-Lee,
  <q cite="http://www.w3.org/People/Berners-Lee/FAQ.html#Internet">
    I was lucky enough to invent the Web at the time when the Internet already
    existed - and had for a decade and a half.
  </q>
  We must understand that there is nothing fundamentally wrong with building on
  the contributions of others.
</p>
<p lang="fr-fr">
  Mais c'est Magritte qui a dit,
  <q lang="fr-fr"> Ceci n'est pas une pipe. </q>.
</p>
```

CSS

```
q {
  color: blue;
}

q::before,
q::after {
  font-size: larger;
  color: red;
  background: #cccccc;
}

q::before {
  content: open-quote;
}

q::after {
  content: close-quote;
}
```

Result

Note the type of quotes generated is based on the language. Browsers add open- and close-quotes before and after `<q>` elements by default, so the quotes in this example would appear without them being explicitly set. They could have been turned off by setting the respective `content` property values to `no-open-quote` and `no-close-quote`, or by setting them both to `none`. They can also be turned off by setting the `quotes` property to `none` instead.

Adding text to list item counters

This example combines a counter sandwiched between two `<string>`s prepended to all list items, creating a more detailed marker for list items (`<li>`) within unordered lists (`<ol>`).

HTML

```
<ol>
  <li>Dogs</li>
  <li>Cats</li>
  <li>
    Birds
    <ol>
      <li>Owls</li>
      <li>Ducks</li>
      <li>Flightless</li>
    </ol>
  </li>
  <li>Marsupials</li>
</ol>
```

CSS

```
ol {
  counter-reset: items;
  margin-left: 2em;
```

```
}
li {
  counter-increment: items;
}
li::marker {
  content: "item " counters(items, ".", numeric) ": ";
}
```

Result

The generated content on each list item's marker adds the text "item " as a prefix, including a space to separate the prefix from the counter, which is followed by ": ", a colon and an additional space. The `counters()` function defines a numeric `items` counter, in which the numbers of nested ordered lists have their numbers separated with a period (`.`) in most browsers.

Strings with attribute values

This example is useful for print stylesheets. It uses an attribute selector to select every fully qualified secure link, adding the value of the `href` attribute after the link text as the content of the `::after` pseudo-element.

HTML

```
<ul>
  <li><a href="https://mozilla.com">Mozilla</a></li>
  <li><a href="/">MDN</a></li>
  <li><a href="https://openwebdocs.org">OpenWebDocs</a></li>
</ul>
```

CSS

```
a[href^="https://"]::after {
  content: " (URL: " attr(href) ")";
  color: darkgreen;
}
```

Result

The generated content is the value of the `href` attribute, prepended by "URL: ", with a space, all in parentheses.

Adding an image with alternative text

This example inserts an image before all links. Two `content` values are provided. The later `content` value includes an image with alternative text that a screen reader can output as speech.

HTML

```
<a href="https://www.mozilla.org/en-US/">Mozilla Home Page</a>
```

CSS

The CSS to show the image and set the alternative text is shown below. This also sets the font and color for the content.

```
a::before {
  content: url("https://mozorg.cdn.mozilla.net/media/img/favicon.ico") /
    " MOZILLA: ";
}
```

Result

> **Note:** The alternative text value is exposed in the browser's accessibility tree. Refer to the See also section for browser-specific accessibility panels.

If using a screen reader, it should speak the word "MOZILLA" when it reaches the image. You can select the `::before` pseudo-element with your developer tools selection tool, and view the accessible name in the accessibility panel.

Including counters in alternative text

This example features a list of links to a set of book chapters, and shows how to use generated content to include a book icon and a counter before each one, with alternative text that includes the literal word "Chapter" in place of the icon. This results in the word "chapter" and the chapter number preceding the text in each link's accessible name, which will be announced to screen reader users when the link receives focus.

HTML

We include a heading followed by an ordered list of chapter title links using `<ol>`, `<li>`, and `<a>` elements.

```
<h2>Chapter list</h2>
<ol>
  <li><a href="#">A stranger calls</a></li>
  <li><a href="#">Two owls</a></li>
  <li><a href="#">Dinner was bland</a></li>
  <li><a href="#">Three owls</a></li>
  <li><a href="#">No-one answered the door</a></li>
  <li><a href="#">The stranger leaves</a></li>
  <li><a href="#">Bedtime</a></li>
</ol>
```

CSS

The CSS includes a `counter-reset` for the `chapter` counter on the `<ol>` element. We also increment the `chapter` counter on each `<li>` element using `counter-increment`, and remove the list markers by setting a `list-style-type` value of `none`.

```
ol {
  counter-reset: chapter;
}

li {
  counter-increment: chapter;
  list-style-type: none;
}
```

Next, we set the `<a>` elements' `::before` pseudo-elements to have generated `content` equal to a book emoji to represent a chapter, plus the current `chapter` counter value, and a space character so that the generated content is separated from the link text. Finally, we set the generated content's alt text to the current `chapter` counter value preceded by the word "Chapter".

```
a::before {
  content: "📖 " counter(chapter) " " / "Chapter " counter(chapter);
}
```

Result

When a screen reader navigates to a link within the list, supporting browsers will announce "Chapter" followed by the current counter number, followed by the link text, for example, "Chapter 1 A stranger calls" and "Chapter 2 Two owls".

Element replacement with URL

This example replaces a regular element! The element's contents are replaced with an SVG using the `<url>` type.

Pseudo-elements aren't rendered on replaced elements. As this element is replaced, any matching `::after` or `::before` are not generated or applied. To demonstrate this, we include an `::after` declaration block, attempting to add the `id` as generated content. This pseudo-element will not be generated as the element is replaced.

HTML

```
<div id="replaced">This content is replaced!</div>
```

CSS

```
#replaced {
  content: url("mdn.svg");
}

/* will not show if element replacement is supported */
div::after {
  content: " (" attr(id) ")";
}
```

Result

When generating content on regular elements (rather than just on pseudo-elements), the entire element is replaced. This means that `::before` and `::after` pseudo-elements are not generated.

Element replacement with <code><gradient></code>

This example demonstrates how an element's contents can be replaced by any type of `<image>`, in this case, a CSS gradient. The element's contents are replaced with a `linear-gradient()`. We provide alt text because all images should be described for accessibility.

HTML

```
<div id="replaced">I disappear</div>
```

CSS

```
div {
  border: 1px solid;
  background-color: #cccccc;
  min-height: 100px;
  min-width: 100px;
}

#replaced {
  content: repeating-linear-gradient(blue 0, orange 10%) /
    "Gradients and alt text are supported";
}
```

Result

Check the browser compatibility chart. All browsers support gradients and all browsers support replacing elements with images, but not all browsers support gradients as a `content` value.

Element replacement with <code>image-set()</code>

This example replaces an element's content with an `image-set()`. If the users display has normal resolution the `1x.png` will be displayed. Screens with a higher resolution will display the `2x.png` image.

HTML

```
<div id="replaced">I disappear!</div>
```

CSS

```
div {
  width: 100px;
  border: 1px solid lightgrey;
}
```

```
#replaced {
  content: image-set(
    "1x.png" 1x,
    "2x.png" 2x
  ) / "DPI";
}
```

Result

content-visibility CSS property

The **`content-visibility`** CSS property controls whether or not an element renders its contents at all, along with forcing a strong set of containments, allowing user agents to potentially omit large swathes of layout and rendering work until it becomes needed. It enables the user agent to skip an element's rendering work (including layout and painting) until it is needed — which makes the initial page load much faster.

> **Note:** The `contentvisibilityautostatechange` event fires on any element with `content-visibility: auto` set on it when its rendering work starts or stops being skipped. This provides a convenient way for an app's code to start or stop rendering processes (e.g., drawing on a `<canvas>`) when they are not needed, thereby conserving processing power.

Try it

```
content-visibility: visible;
```

```
content-visibility: hidden;
```

```
<section class="default-example" id="default-example">
  <div class="container" id="example-element">
    <div class="child">
      <span>This is an inner div</span>
    </div>
  </div>
</section>
```

```
.container {
  width: 140px;
  height: 140px;
  border: 3px solid rgb(64 28 163);
  background-color: rgb(135 136 184);
  display: flex;
  align-items: center;
  justify-content: center;
}

.child {
  border: 3px solid rgb(64 28 163);
  background-color: wheat;
  color: black;
  width: 80%;
  height: 80%;
  display: flex;
  align-items: center;
  justify-content: center;
}
```

Syntax

```
/* Keyword values */
content-visibility: visible;
content-visibility: hidden;
content-visibility: auto;

/* Global values */
content-visibility: inherit;
content-visibility: initial;
content-visibility: revert;
content-visibility: revert-layer;
content-visibility: unset;
```

Values

This property is specified as one of the following keyword values:

`visible`

No effect. The element's contents are laid out and rendered as normal. This is the default value.

`hidden`

The element skips its contents. The skipped contents must not be accessible to user-agent features, such as find-in-page, tab-order navigation, etc., nor be selectable or focusable. This is similar to giving the contents `display: none`.

`auto`

The element turns on layout containment, style containment, and paint containment. If the element is not relevant to the user, it also skips its contents. Unlike hidden, the skipped contents must still be available as normal to user-agent features such as find-in-page, tab order navigation, etc., and must be focusable and selectable as normal.

Description

Animating and transitioning content-visibility

Supporting browsers animate/transition `content-visibility` with a variation on the discrete animation type.

Discrete animation generally means that the property will flip between two values 50% of the way through the animation. In the case of `content-visibility`, however, the browser will flip between the two values to show the animated content for the entire animation duration. So, for example:

- When animating `content-visibility` from `hidden` to `visible`, the value will flip to `visible` at `0%` of the animation duration so it is visible throughout.
- When animating `content-visibility` from `visible` to `hidden`, the value will flip to `hidden` at `100%` of the animation duration so it is visible throughout.

This behavior is useful for creating entry/exit animations where you want to, for example, remove some content from the DOM with `content-visibility: hidden`, but you want a smooth transition (such as a fade-out) rather than it disappearing immediately.

When animating `content-visibility` with CSS transitions, `transition-behavior: allow-discrete` needs to be set on `content-visibility`. This effectively enables `content-visibility` transitions.

> **Note:** When transitioning an element's `content-visibility` value, you don't need to provide a set of starting values for transitioned properties using a `@starting-style` block, like you do when transitioning `display`. This is because `content-visibility` doesn't hide an element from the DOM like `display` does: it just skips rendering the element's content.

Formal definition

Initial value	`visible`
Applies to	elements for which size containment can apply
Inherited	no
Computed value	as specified
Animation type	Discrete behavior except when animating to or from `hidden` is visible for the entire duration

Formal syntax

```
content-visibility =
  visible  |
  auto     |
  hidden
```

This syntax reflects the latest standard as per CSS Containment Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Accessibility

Off-screen content within a `content-visibility: auto` property remains in the document object model and the accessibility tree. This allows improving page performance with `content-visibility: auto` without negatively impacting accessibility.

Since styles for off-screen content are not rendered, elements intentionally hidden with `display: none` or `visibility: hidden` *will still appear in the accessibility tree*. If you don't want an element to appear in the accessibility tree, use `aria-hidden="true"`.

Examples

Using auto to reduce rendering cost of long pages

The following example shows the use of `content-visibility: auto` to skip painting and rendering of off-screen sections. When a `section` is out of the viewport then the painting of the content is skipped until the section comes close to the viewport, this helps with both load and interactions on the page.

HTML

```
<section>
  <!-- Content for each section… -->
</section>
<section>
  <!-- Content for each section… -->
</section>
<section>
  <!-- Content for each section… -->
</section>
<!-- … -->
```

CSS

The `contain-intrinsic-size` property adds a default size of 500px to the height and width of each `section` element. After a section is rendered, it will retain its rendered intrinsic size, even when it is scrolled out of the viewport.

```
section {
  content-visibility: auto;
  contain-intrinsic-size: auto 500px;
}
```

Using hidden to manage visibility

The following example shows how to manage content visibility with JavaScript. Using `content-visibility: hidden;` instead of `display: none;` preserves the rendering state of content when hidden and rendering is faster.

HTML

```
<div class="hidden">
  <button class="toggle">Show</button>
  <p>
    This content is initially hidden and can be shown by clicking the button.
  </p>
</div>
<div class="visible">
  <button class="toggle">Hide</button>
  <p>
    This content is initially visible and can be hidden by clicking the button.
  </p>
</div>
```

CSS

The `content-visibility` property is set on paragraphs that are direct children of elements with the `visible` and `hidden` classes. In our example, we can show and hide content in paragraphs depending on the CSS class of parent div elements.

The `contain-intrinsic-size` property is included to represent the content size. This helps to reduce layout shift when content is hidden.

```
p {
  contain-intrinsic-size: 0 1.1em;
  border: dotted 2px;
}
```

```
.hidden > p {
  content-visibility: hidden;
}

.visible > p {
  content-visibility: visible;
}
```

JavaScript

```
const handleClick = (event) => {
  const button = event.target;
  const div = button.parentElement;
  button.textContent = div.classList.contains("visible") ? "Show" : "Hide";
  div.classList.toggle("hidden");
  div.classList.toggle("visible");
};

document.querySelectorAll("button.toggle").forEach((button) => {
  button.addEventListener("click", handleClick);
});
```

Result

Animating content-visibility

In this example, we have a `<div>` element, the content of which can be toggled between shown and hidden by clicking or pressing any key.

HTML

```
<p>
  Click anywhere on the screen or press any key to toggle the
  <code>&lt;div&gt;</code> content between hidden and showing.
</p>

<div>
  This is a <code>&lt;div&gt;</code> element that animates between
  <code>content-visibility: hidden;</code>and
  <code>content-visibility: visible;</code>. We've also animated the text color
  to create a smooth animation effect.
</div>
```

CSS

In the CSS we initially set `content-visibility: hidden;` on the `<div>` to hide its content. We then set up `@keyframes` animations and attach them to classes to show and hide the `<div>`, animating `content-visibility` and `color` so that you get a smooth animation effect as the content is shown/hidden.

```
div {
  font-size: 1.6rem;
  padding: 20px;
  border: 3px solid red;
  border-radius: 20px;
  width: 480px;

  content-visibility: hidden;
}

/* Animation classes */

.show {
  animation: show 0.7s ease-in forwards;
}

.hide {
  animation: hide 0.7s ease-out forwards;
}

/* Animation keyframes */

@keyframes show {
  0% {
    content-visibility: hidden;
    color: transparent;
  }

  100% {
    content-visibility: visible;
    color: black;
  }
}

@keyframes hide {
  0% {
    content-visibility: visible;
    color: black;
  }

  100% {
    content-visibility: hidden;
    color: transparent;
  }
}
```

JavaScript

Finally, we use JavaScript to apply the `.show` and `.hide` classes to the `<div>` as appropriate to apply the animations as it is toggled between shown and hidden states.

```
const divElem = document.querySelector("div");
const htmlElem = document.querySelector(":root");

htmlElem.addEventListener("click", showHide);
```

```
document.addEventListener("keydown", showHide);

function showHide() {
  if (divElem.classList.contains("show")) {
    divElem.classList.remove("show");
    divElem.classList.add("hide");
  } else {
    divElem.classList.remove("hide");
    divElem.classList.add("show");
  }
}
```

Result

The rendered result looks like this:

corner-block-end-shape CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`corner-block-end-shape`** CSS property specifies the shape of both the corners on a box's block-end edge, within their `border-radius` area.

For a full description of corner shape behavior and multiple examples, see the `corner-shape` shorthand property page.

Constituent properties

This property is a shorthand for the following logical properties:

- `corner-end-start-shape`
- `corner-end-end-shape`

Syntax

```
/* Single keyword value set for both corners */
corner-block-end-shape: square;
corner-block-end-shape: scoop;

/* Single superellipse() value set for both corners */
corner-block-end-shape: superellipse(3.5);
corner-block-end-shape: superellipse(-1.9);

/* Block-end/inline-start corner, block-end/inline-end corner */
corner-block-end-shape: square scoop;
corner-block-end-shape: square superellipse(-1.9);

/* Global values */
corner-block-end-shape: inherit;
corner-block-end-shape: initial;
corner-block-end-shape: revert;
corner-block-end-shape: revert-layer;
corner-block-end-shape: unset;
```

Values

The `corner-block-end-shape` property is specified using one or two `<corner-shape-value>` values:

- If **one value** is used, it specifies the shape of **both block-end** corners.
- If **two values** are used, the first one specifies the shape of the **block-end/inline-start** corner, and the second one specifies the shape of the **block-end/inline-end** corner.

Formal definition

Initial value	as each of the properties of the shorthand: • `corner-end-start-shape`: round • `corner-end-end-shape`: round
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	as each of the properties of the shorthand: • `corner-end-start-shape`: The corresponding superellipse() value. • `corner-end-end-shape`: The corresponding superellipse() value.
Animation type	as each of the properties of the shorthand: • `corner-end-start-shape`: Animates as per superellipse interpolation. • `corner-end-end-shape`: Animates as per superellipse interpolation.

Formal syntax

```
corner-block-end-shape =
  <'corner-top-left-shape'>{1,2}

<corner-top-left-shape> =
  <corner-shape-value>

<corner-shape-value> =
  round             |
```

```
  scoop             |
  bevel             |
  notch             |
  square            |
  squircle          |
  <superellipse()>

<superellipse()> =
  superellipse( <number>  |
  infinity                |
  -infinity )
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

You can find other related examples on the `corner-shape` reference page.

Basic <code>corner-block-end-shape</code> usage

HTML

The markup for this example contains a single `<div>` element.

```
<div></div>
```

CSS

We give the box some basic styles, which we've hidden for brevity. We also apply a `box-shadow`, a `border-radius` of `80px / 40px`, and a `corner-block-end-shape` of `notch square`.

```
body {
  font-family: "Helvetica", "Arial", sans-serif;
  width: 240px;
  margin: 20px auto;
}

div {
  width: 100%;
  height: 180px;
  display: flex;
  justify-content: center;
  align-items: center;
  background-color: cyan;
  background-image: linear-gradient(
    to bottom,
    rgb(255 255 255 / 0),
    rgb(255 255 255 / 0.5)
  );
}
```

```
div {
  box-shadow: 1px 1px 3px gray;
  border-radius: 80px / 40px;
  corner-block-end-shape: notch square;
}
```

Result

The rendered result looks like this:

corner-block-start-shape CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`corner-block-start-shape`** CSS property specifies the shape of both the corners on a box's block-start edge, within their `border-radius` area.

For a full description of corner shape behavior and multiple examples, see the `corner-shape` shorthand property page.

Constituent properties

This property is a shorthand for the following logical properties:

- `corner-start-start-shape`
- `corner-start-end-shape`

Syntax

```
/* Single keyword value set for both corners */
corner-block-start-shape: notch;
corner-block-start-shape: squircle;

/* Single superellipse() value set for both corners */
corner-block-start-shape: superellipse(2.7);
corner-block-start-shape: superellipse(-2.5);

/* Block-start/inline-start corner, block-start/inline-end corner */
corner-block-start-shape: notch squircle;
```

```
corner-block-start-shape: notch superellipse(-2.5);

/* Global values */
corner-block-start-shape: inherit;
corner-block-start-shape: initial;
corner-block-start-shape: revert;
corner-block-start-shape: revert-layer;
corner-block-start-shape: unset;
```

Values

The `corner-block-start-shape` property is specified using one or two `<corner-shape-value>` values:

- If **one value** is used, it specifies the shape of both **block-start** corners.
- If **two values** are used, the first one specifies the shape of the **block-start/inline-start** corner, and the second one specifies the shape of the **block-start/inline-end** corner.

Formal definition

Initial value	as each of the properties of the shorthand: • `corner-start-start-shape`: `round` • `corner-start-end-shape`: `round`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	as each of the properties of the shorthand: • `corner-start-start-shape`: The corresponding superellipse() value. • `corner-start-end-shape`: The corresponding superellipse() value.
Animation type	as each of the properties of the shorthand: • `corner-start-start-shape`: Animates as per superellipse interpolation. • `corner-start-end-shape`: Animates as per superellipse interpolation.

Formal syntax

```
corner-block-start-shape =
  <'corner-top-left-shape'>{1,2}

<corner-top-left-shape> =
  <corner-shape-value>

<corner-shape-value> =
  round             |
  scoop             |
  bevel             |
  notch             |
  square            |
  squircle          |
  <superellipse()>

<superellipse()> =
  superellipse( <number>  |
  infinity                |
  -infinity )
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

corner-bottom-left-shape CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`corner-bottom-left-shape`** CSS property specifies the shape of a box's bottom-left corner, within its `border-radius` area.

For a full description of corner shape behavior and multiple examples, see the `corner-shape` shorthand property page.

Syntax

```
/* Keyword values */
corner-bottom-left-shape: bevel;
corner-bottom-left-shape: round;

/* superellipse() function values */
corner-bottom-left-shape: superellipse(0.7);
corner-bottom-left-shape: superellipse(-1.9);

/* Global values */
corner-bottom-left-shape: inherit;
corner-bottom-left-shape: initial;
corner-bottom-left-shape: revert;
corner-bottom-left-shape: revert-layer;
corner-bottom-left-shape: unset;
```

Values

The `corner-bottom-left-shape` property is specified using a `<corner-shape-value>` value.

Formal definition

Initial value	`round`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	The corresponding superellipse() value.
Animation type	Animates as per superellipse interpolation.

Formal syntax

```
corner-bottom-left-shape =
  <corner-shape-value>

<corner-shape-value> =
  round             |
  scoop             |
  bevel             |
  notch             |
  square            |
  squircle          |
  <superellipse()>

<superellipse()> =
  superellipse( <number>  |
  infinity                |
  -infinity )
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

corner-bottom-right-shape CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`corner-bottom-right-shape`** CSS property specifies the shape of a box's bottom-right corner, within its `border-radius` area.

For a full description of corner shape behavior and multiple examples, see the `corner-shape` shorthand property page.

Syntax

```
/* Keyword values */
corner-bottom-right-shape: notch;
corner-bottom-right-shape: scoop;

/* superellipse() function values */
corner-bottom-right-shape: superellipse(1.7);
corner-bottom-right-shape: superellipse(-3);

/* Global values */
corner-bottom-right-shape: inherit;
corner-bottom-right-shape: initial;
corner-bottom-right-shape: revert;
corner-bottom-right-shape: revert-layer;
corner-bottom-right-shape: unset;
```

Values

The `corner-bottom-right-shape` property is specified using a `<corner-shape-value>` value.

Formal definition

Initial value	`round`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	The corresponding superellipse() value.
Animation type	Animates as per superellipse interpolation.

Formal syntax

```
corner-bottom-right-shape =
  <corner-shape-value>

<corner-shape-value> =
  round             |
  scoop             |
  bevel             |
  notch             |
  square            |
  squircle          |
  <superellipse()>

<superellipse()> =
  superellipse( <number>  |
  infinity               |
  -infinity )
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

You can find other related examples on the `corner-shape` reference page.

Basic <code>corner-bottom-right-shape</code> usage

HTML

The markup for this example contains a single `<div>` element.

```
<div></div>
```

CSS

We give the box some basic styles, which we've hidden for brevity. We also apply a `box-shadow`, a `border-radius` of `30% / 20%`, and a `corner-bottom-right-shape` of `notch`.

```
body {
  font-family: "Helvetica", "Arial", sans-serif;
  width: 240px;
  margin: 20px auto;
}

div {
  width: 100%;
  height: 180px;
  display: flex;
  justify-content: center;
  align-items: center;
  background-color: cyan;
  background-image: linear-gradient(
    to bottom,

corner-bottom-shape CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`corner-bottom-shape`** CSS property specifies the shape of both the corners on a box's bottom edge, within their `border-radius` area.

For a full description of corner shape behavior and multiple examples, see the `corner-shape` shorthand property page.

Constituent properties

This property is a shorthand for the following physical properties:

- `corner-bottom-left-shape`
- `corner-bottom-right-shape`

Syntax

```
/* Single keyword value set for both corners */
corner-bottom-shape: scoop;
corner-bottom-shape: square;

/* Single superellipse() value set for both corners */
corner-bottom-shape: superellipse(0.7);
corner-bottom-shape: superellipse(-2.8);

/* Left-hand corner, right-hand corner */
corner-bottom-shape: scoop square;
corner-bottom-shape: scoop superellipse(0.7);

/* Global values */
corner-bottom-shape: inherit;
corner-bottom-shape: initial;
corner-bottom-shape: revert;
corner-bottom-shape: revert-layer;
corner-bottom-shape: unset;
```

Values

The `corner-bottom-shape` property is specified using one or two `<corner-shape-value>` values:

- If **one value** is used, it specifies the shape of **both bottom corners**.
- If **two values** are used, the first one specifies the shape of the **bottom-left** corner, and the second one specifies the shape of the **bottom-right** corner.

Formal definition

Initial value	as each of the properties of the shorthand: • `corner-bottom-left-shape`: `round` • `corner-bottom-right-shape`: `round`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	as each of the properties of the shorthand: • `corner-bottom-left-shape`: The corresponding superellipse() value. • `corner-bottom-right-shape`: The corresponding superellipse() value.
Animation type	as each of the properties of the shorthand: • `corner-bottom-left-shape`: Animates as per superellipse interpolation. • `corner-bottom-right-shape`: Animates as per superellipse interpolation.

Formal syntax

```
corner-bottom-shape =
  <'corner-top-left-shape'>{1,2}

<corner-top-left-shape> =
  <corner-shape-value>

<corner-shape-value> =
  round             |
  scoop             |
  bevel             |
  notch             |
  square            |
  squircle          |
  <superellipse()>

<superellipse()> =
  superellipse( <number>  |
  infinity                |
  -infinity )
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

You can find other related examples on the `corner-shape` reference page.

Basic <code>corner-bottom-shape</code> usage

HTML

The markup for this example contains a single `<div>` element.

```
<div></div>
```

CSS

We give the box some basic styles, which we've hidden for brevity. We also apply a `box-shadow`, a `border-radius` of `60px 30px 20% 40%`, and a `corner-bottom-shape` of `square squircle`.

```
body {
  font-family: "Helvetica", "Arial", sans-serif;
  width: 240px;
  margin: 20px auto;
}

div {
  width: 100%;
  height: 180px;
  display: flex;
  justify-content: center;
  align-items: center;
  background-color: orange;
  background-image: linear-gradient(
    to bottom,
    rgb(255 255 255 / 0),
    rgb(255 255 255 / 0.5)
  );
}
```

```
div {
  box-shadow: 1px 1px 3px gray;
  border-radius: 60px 30px 20% 40%;
  corner-bottom-shape: square squircle;
}
```

Result

The rendered result looks like this:

corner-end-end-shape CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`corner-end-end-shape`** CSS property specifies the shape of a box's block-end and inline-end corner, within its `border-radius` area.

For a full description of corner shape behavior and multiple examples, see the `corner-shape` shorthand property page.

Syntax

```
/* Keyword values */
corner-end-end-shape: scoop;
corner-end-end-shape: notch;

/* superellipse() function values */
corner-end-end-shape: superellipse(4);
corner-end-end-shape: superellipse(-0.5);

/* Global values */
corner-end-end-shape: inherit;
corner-end-end-shape: initial;
corner-end-end-shape: revert;
corner-end-end-shape: revert-layer;
corner-end-end-shape: unset;
```

Values

The `corner-end-end-shape` property is specified using a `<corner-shape-value>` value.

Formal definition

Initial value	`round`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	The corresponding superellipse() value.
Animation type	Animates as per superellipse interpolation.

Formal syntax

```
corner-end-end-shape =
  <corner-shape-value>

<corner-shape-value> =
  round             |
  scoop             |
  bevel             |
  notch             |
  square            |
  squircle          |
  <superellipse()>

<superellipse()> =
  superellipse( <number>  |
  infinity                |
  -infinity )
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

corner-end-start-shape CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`corner-end-start-shape`** CSS property specifies the shape of a box's block-end and inline-start corner, within its `border-radius` area.

For a full description of corner shape behavior and multiple examples, see the `corner-shape` shorthand property page.

Syntax

```
/* Keyword values */
corner-end-start-shape: round;
corner-end-start-shape: scoop;

/* superellipse() function values */
corner-end-start-shape: superellipse(0.2);
corner-end-start-shape: superellipse(-5);

/* Global values */
corner-end-start-shape: inherit;
corner-end-start-shape: initial;
corner-end-start-shape: revert;
corner-end-start-shape: revert-layer;
corner-end-start-shape: unset;
```

Values

The `corner-end-start-shape` property is specified using a `<corner-shape-value>` value.

Formal definition

Initial value	`round`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	The corresponding superellipse() value.
Animation type	Animates as per superellipse interpolation.

Formal syntax

```
corner-end-start-shape =
  <corner-shape-value>

<corner-shape-value> =
  round             |
  scoop             |
  bevel             |
  notch             |
  square            |
  squircle          |
  <superellipse()>

<superellipse()> =
  superellipse( <number>  |
  infinity                |
  -infinity )
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

corner-inline-end-shape CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`corner-inline-end-shape`** CSS property specifies the shape of both the corners on a box's inline-end edge, within their `border-radius` area.

For a full description of corner shape behavior and multiple examples, see the `corner-shape` shorthand property page.

Constituent properties

This property is a shorthand for the following logical properties:

- `corner-start-end-shape`
- `corner-end-end-shape`

Syntax

```
/* Single keyword value set for both corners */
corner-inline-end-shape: squircle;
corner-inline-end-shape: scoop;

/* Single superellipse() value set for both corners */
corner-inline-end-shape: superellipse(1.5);
corner-inline-end-shape: superellipse(-0.8);

/* Block-start/inline-end corner, block-end/inline-end corner */
corner-inline-end-shape: squircle scoop;
corner-inline-end-shape: squircle superellipse(-0.8);

/* Global values */
corner-inline-end-shape: inherit;
corner-inline-end-shape: initial;
corner-inline-end-shape: revert;
corner-inline-end-shape: revert-layer;
corner-inline-end-shape: unset;
```

Values

The `corner-inline-end-shape` property is specified using one or two `<corner-shape-value>` values:

- If **one value** is used, it specifies the shape of **both inline-end** corners.
- If **two values** are used, the first one specifies the shape of the **block-start/inline-end** corner, and the second one specifies the shape of the **block-end/inline-end** corner.

Formal definition

Initial value	as each of the properties of the shorthand: • `corner-start-end-shape`: `round` • `corner-end-end-shape`: `round`
Applies to	all elements. It also applies to `::first-letter`.

Inherited	no
Computed value	as each of the properties of the shorthand: • `corner-start-end-shape`: The corresponding superellipse() value. • `corner-end-end-shape`: The corresponding superellipse() value.
Animation type	as each of the properties of the shorthand: • `corner-start-end-shape`: Animates as per superellipse interpolation. • `corner-end-end-shape`: Animates as per superellipse interpolation.

Formal syntax

```
corner-inline-end-shape =
  <'corner-top-left-shape'>{1,2}

<corner-top-left-shape> =
  <corner-shape-value>

<corner-shape-value> =
  round             |
  scoop             |
  bevel             |
  notch             |
  square            |
  squircle          |
  <superellipse()>

<superellipse()> =
  superellipse( <number>  |
  infinity                |
  -infinity )
```

corner-left-shape CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`corner-left-shape`** CSS property specifies the shape of both the corners on a box's left-hand edge, within their `border-radius` area.

For a full description of corner shape behavior and multiple examples, see the `corner-shape` shorthand property page.

Constituent properties

This property is a shorthand for the following physical properties:

- `corner-top-left-shape`
- `corner-bottom-left-shape`

Syntax

```
/* Single keyword value set for both corners */
corner-left-shape: round;
corner-left-shape: bevel;

/* Single superellipse() value set for both corners */
corner-left-shape: superellipse(1.2);
corner-left-shape: superellipse(-2.5);

/* Top corner, bottom corner */
corner-left-shape: round bevel;
corner-left-shape: bevel superellipse(1.2);

/* Global values */
corner-left-shape: inherit;
corner-left-shape: initial;
corner-left-shape: revert;
corner-left-shape: revert-layer;
corner-left-shape: unset;
```

Values

The `corner-left-shape` property is specified using one or two `<corner-shape-value>` values:

- If **one value** is used, it specifies the shape of **both left-hand corners**.
- If **two values** are used, the first one specifies the shape of the **top-left** corner, and the second one specifies the shape of the **bottom-left** corner.

Formal definition

Initial value	as each of the properties of the shorthand: • `corner-top-left-shape`: round • `corner-bottom-left-shape`: round
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	as each of the properties of the shorthand:

	• `corner-top-left-shape`: The corresponding superellipse() value. • `corner-bottom-left-shape`: The corresponding superellipse() value.
Animation type	as each of the properties of the shorthand: • `corner-top-left-shape`: Animates as per superellipse interpolation. • `corner-bottom-left-shape`: Animates as per superellipse interpolation.

Formal syntax

```
corner-left-shape =
  <'corner-top-left-shape'>{1,2}

<corner-top-left-shape> =
  <corner-shape-value>

<corner-shape-value> =
  round             |
  scoop             |
  bevel             |
  notch             |
  square            |
  squircle          |
  <superellipse()>

<superellipse()> =
  superellipse( <number>  |
  infinity                |
  -infinity )
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

corner-right-shape CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`corner-right-shape`** CSS property specifies the shape of both the corners on a box's right-hand edge, within their `border-radius` area.

For a full description of corner shape behavior and multiple examples, see the `corner-shape` shorthand property page.

Constituent properties

This property is a shorthand for the following physical properties:

- `corner-top-right-shape`
- `corner-bottom-right-shape`

Syntax

```
/* Single keyword value set for both corners */
corner-right-shape: bevel;
corner-right-shape: notch;

/* Single superellipse() value set for both corners */
corner-right-shape: superellipse(4);
corner-right-shape: superellipse(-0.9);

/* Top corner, bottom corner */
corner-right-shape: bevel notch;
corner-right-shape: notch superellipse(-0.9);

/* Global values */
corner-right-shape: inherit;
corner-right-shape: initial;
corner-right-shape: revert;
corner-right-shape: revert-layer;
corner-right-shape: unset;
```

Values

The `corner-right-shape` property is specified using one or two `<corner-shape-value>` values:

- If **one value** is used, it specifies the shape of **both right-hand corners**.
- If **two values** are used, the first one specifies the shape of the **top-right** corner, and the second one specifies the shape of the **bottom-right** corner.

Formal definition

Initial value	as each of the properties of the shorthand: • `corner-top-right-shape`: `round` • `corner-bottom-right-shape`: `round`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	as each of the properties of the shorthand: • `corner-top-right-shape`: The corresponding superellipse() value. • `corner-bottom-right-shape`: The corresponding superellipse() value.
Animation type	as each of the properties of the shorthand: • `corner-top-right-shape`: Animates as per superellipse interpolation. • `corner-bottom-right-shape`: Animates as per superellipse interpolation.

Formal syntax

```
corner-right-shape =
  <'corner-top-left-shape'>{1,2}

<corner-top-left-shape> =
  <corner-shape-value>

<corner-shape-value> =
  round             |
  scoop             |
  bevel             |
  notch             |
  square            |
  squircle          |
  <superellipse()>

<superellipse()> =
  superellipse( <number>  |
  infinity                |
  -infinity )
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

You can find other related examples on the `corner-shape` reference page.

Basic <code>corner-right-shape</code> usage

HTML

The markup for this example contains a single `<div>` element.

```
<div></div>
```

CSS

We give the box some basic styles, which we've hidden for brevity. We also apply a `box-shadow`, a `border-radius` of `20% 30% / 50% 40%`, and a `corner-right-shape` of `square scoop`.

```
body {
  font-family: "Helvetica", "Arial", sans-serif;
  width: 240px;
  margin: 20px auto;
```

```
}

div {
  width: 100%;
  height: 180px;
  display: flex;
  justify-content: center;
  align-items: center;
  background-color: cyan;
  background-image: linear-gradient(
    to bottom,
    rgb(255 255 255 / 0),
    rgb(255 255 255 / 0.5)
  );
}
```

```
div {
  box-shadow: 1px 1px 3px gray;
  border-radius: 20% 30% / 50% 40%;
  corner-right-shape: square scoop;
}
```

Result

The rendered result looks like this:

corner-shape CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`corner-shape`** CSS shorthand property specifies the shape of a box's corners, within the area specified by its `border-radius` property value.

Constituent properties

This property is a shorthand for the following physical properties:

- `corner-top-left-shape`
- `corner-top-right-shape`
- `corner-bottom-left-shape`
- `corner-bottom-right-shape`

Syntax

```
/* Single value set for all four corners */
corner-shape: bevel;

/* top-left and bottom-right, top-right and bottom-left */
corner-shape: notch superellipse(0.6);

/* top-left, top-right and bottom-left, bottom-right */
corner-shape: superellipse(-1.2) square squircle;

/* top-left, top-right, bottom-right, bottom-left */
corner-shape: scoop superellipse(-1.6) superellipse(-2.2) round;

/* Global values */
corner-shape: inherit;
corner-shape: initial;
corner-shape: revert;
corner-shape: revert-layer;
corner-shape: unset;
```

The `corner-shape` property may be specified using one, two, three, or four `<corner-shape-value>` values:

- If **one** value is used, it specifies the shape of **all four corners**.
- If **two** values are used, the first shape applies to the **top-left and bottom-right** corners, and the second to the **top-right and bottom-left corners**.
- If **three** values are used, the first shape specifies the shape of the **top-left corner**, the second to the **top-right and bottom-left corners**, and the third to the **bottom-right corner**.
- If four values are used, they specify the shape of the **top-left**, **top-right**, **bottom-right**, and **bottom-left** corners, in that order (clockwise).

Values

`<corner-shape-value>`

A `superellipse()` or keyword equivalent describing the shape of the corner.

Description

The `corner-shape` property is used to modify the shape of rounded corners created by the `border-radius` property and its associated longhands. Already-rounded corners can be further customized in terms of the degree of rounding applied to them, allowing the creation of, for example, beveled, notched, and squircle corners. Borders, outlines, shadows, and background effects applied to the container will follow the defined corner shape.

If a `border-radius` is not applied to a container, or the `border-radius` resolves to `0`, `corner-shape` will have no effect.

The `corner-shape` shorthand property and its associated `corner-*-shape` shorthands and longhands accept one to four `<corner-shape-value>` values. Each is specified directly as a `superellipse()` function or a keyword describing a common shape. Each keyword is equivalent to a specific `superellipse()` value.

The default (initial) value of `corner-shape` is `round`, which gives the same effect as using `border-radius` on its own, without `corner-shape`. There is also a keyword value `square`, which gives the same effect as default square corners, effectively removing any `border-radius` applied. The `bevel` value has the effect of drawing a straight line between the two ends of a `border-radius`.

Different `corner-shape` values can be smoothly animated between, as the `superellipse()` equivalents of the keyword values are used as interpolation values.

The `corner-shape` shorthand is especially useful when you want all four borders to be the same, or you want to set different values using a single declaration. To set only one or two corner shapes at a time, use the `corner-*-shape` shorthands and longhands.

<code>corner-*-shape</code> shorthands and longhands

The `corner-shape` shorthand defines the shapes of all four corners in one declaration.

To set only one corner shape at a time, use the corner shape longhands:

- Physical longhand corner shape properties:
  - `corner-bottom-left-shape`
  - `corner-bottom-right-shape`
  - `corner-top-left-shape`
  - `corner-top-right-shape`
- Logical longhand corner shape properties:
  - `corner-start-start-shape`
  - `corner-start-end-shape`
  - `corner-end-start-shape`
  - `corner-end-end-shape`

To set two corner shapes at a time, use the side shorthands:

- Physical side shorthand properties:
  - `corner-top-shape`
  - `corner-right-shape`
  - `corner-bottom-shape`
  - `corner-left-shape`
- Logical side shorthand properties:
  - `corner-block-start-shape`
  - `corner-block-end-shape`
  - `corner-inline-start-shape`
  - `corner-inline-end-shape`

Constraining opposite corner shape radii

When opposite corners have `border-radius` and `corner-shape` values set that would cause the shapes to overlap, the browser constrains the values to prevent the overlap.

For example, the following values would cause the top-left and bottom-right corners to overlap, therefore the browser adjusts the first `border-radius` component to a value that avoids this.

```
div {
  width: 480px;
  height: 200px;
  background-color: goldenrod;
  border-radius: 80% 20px;
  corner-shape: scoop;
}
```

Properties that follow <code>corner-shape</code>

The following properties all follow the shape of the corner when set on the container:

- `background-color`
- `background-image`
- `border`
- `outline`
- `box-shadow`
- `overflow`
- `backdrop-filter`

See Demonstration of properties that follow the `corner-shape` for some examples.

Interaction with <code>border-shape</code>

The `corner-shape` property has no effect when the `border-shape` property is set on an element. This is because `border-shape` is incompatible with `border-radius`: when `border-shape` is set, any specified `border-radius` is ignored; `corner-shape` depends on `border-radius` and therefore has no effect either.

If you want to use shaped corners in a `border-shape`, you will have to draw them directly as part of the shape.

Formal definition

Initial value	as each of the properties of the shorthand: • `corner-top-left-shape`: `round` • `corner-top-right-shape`: `round` • `corner-bottom-left-shape`: `round` • `corner-bottom-right-shape`: `round`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	as each of the properties of the shorthand: • `corner-top-left-shape`: The corresponding superellipse() value. • `corner-top-right-shape`: The corresponding superellipse() value. • `corner-bottom-left-shape`: The corresponding superellipse() value. • `corner-bottom-right-shape`: The corresponding superellipse() value.
Animation type	as each of the properties of the shorthand:

	• `corner-top-left-shape`: Animates as per superellipse interpolation. • `corner-top-right-shape`: Animates as per superellipse interpolation. • `corner-bottom-left-shape`: Animates as per superellipse interpolation. • `corner-bottom-right-shape`: Animates as per superellipse interpolation.

Formal syntax

```
corner-shape =
  <'corner-top-left-shape'>{1,4}

<corner-top-left-shape> =
  <corner-shape-value>

<corner-shape-value> =
  round             |
  scoop             |
  bevel             |
  notch             |
  square            |
  squircle          |
  <superellipse()>

<superellipse()> =
  superellipse( <number>  |
  infinity                |
  -infinity )
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic <code>corner-shape</code> usage

HTML

The markup for this example contains a single `<div>` element.

```
<div>Nice scooped corners</div>
```

CSS

We give the box a fixed `height`, a `box-shadow`, a `border-radius` of 30 pixels, and a `corner-shape` of `scoop`, along with some additional styles that we've hidden for brevity.

```
body {
  font-family: "Helvetica", "Arial", sans-serif;
  width: 240px;
  margin: 20px auto;
}

div {
  display: flex;
  justify-content: center;
  align-items: center;
  background-color: cyan;
  background-image: linear-gradient(
    to bottom,
    rgb(255 255 255 / 0),
    rgb(255 255 255 / 0.5)
  );
}

@supports not (corner-shape: scoop) {
  body {
    all: unset !important;
  }

  body::before {
    content: "Your browser does not support the 'corner-shape' property.";
    color: black;
    background-color: #ffcd33;
    display: block;
    width: 100%;
    text-align: center;
    padding: 1rem 0;
  }
}
```

```
div {
  height: 180px;
  box-shadow: 1px 1px 3px gray;
  border-radius: 30px;
  corner-shape: scoop;
}
```

Result

The rendered result looks like this:

Note how the `corner-shape` value of `scoop` gives the container concave corners — the curve is an inversion of the default `border-radius` curve. Note also how the background, border, and box shadow follow the shape of the curve.

Demonstration of properties that follow the <code>corner-shape</code>

HTML

The markup for this example contains a single `<div>` element with some text content inside it.

```
<div>
  Some styles follow the corner shape, such as border, outline, box-shadow,
  overflow, and backdrop-filter. This is useful for helping various aspects of
```

```
  your design to not clash. As shown, it can result in some interesting visual
  effects, so you should test your design carefully.
</div>
```

CSS

To demonstrate how some styles follow the shape of a container's corners, we apply a `background-image` to the document `<body>`, then apply a `border-radius` of `40px` and a `corner-shape` of `scoop notch` to the `<div>`.

We then apply the following to the `<div>`:

- A semi-transparent `background-color`.
- A different color and style of `border` on each edge.
- A `backdrop-filter` that inverts the `background-image` set on the `<body>`.
- A `:hover` style so you can see that the clickable content area falls outside the corner shape.

Additional set up styles have been hidden for brevity.

```
html {
  height: 100%;
}

body {
  font-family: "Helvetica", "Arial", sans-serif;
  height: inherit;
  margin: 0;
  display: flex;
  justify-content: center;
  align-items: center;
}

div {
  width: 240px;
  height: 180px;
}

@supports not (corner-shape: scoop notch) {
  :root::before {
    content: "Your browser does not support the 'corner-shape' property.";
    color: black;
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

```
body {
  background: url("https://mdn.github.io/shared-assets/images/examples/leopard.jpg")
    no-repeat;
  background-size: cover;
}

div {
  border-radius: 40px;
  corner-shape: scoop notch;
  background-color: rgb(255 255 255 / 0.2);
  border-top: 3px solid blue;
  border-left: 6px dashed red;
  border-bottom: 9px solid yellow;
  border-right: 12px double green;
  backdrop-filter: invert(100%);
}

div:hover {
  background-color: white;
}
```

Result

The rendered result looks like this:

Note how most of the set styles follow the shape of the `<div>` resulting from its `corner-shape` styles, but not all. The content is displayed relative to the original box, and the hover effect is still applied if you hover over the text sticking out past the top- and bottom-left corners.

Comparing <code>corner-shape</code> values

In this demonstration, you can select different `corner-shape` values and set different `border-radius` values on a container and compare the effects.

HTML

The markup for this example contains a `<select>` picker from which different `corner-shape` values can be selected, an `<input type="range">` slider to select different `border-radius` values, and a `<section>` element to create a container to apply those values to. The select `<option>` elements provide multiple keyword and `superellipse()` value choices, broken into two groups using `<optgroup>` elements. In the case of the keyword values, we've also included the `superellipse()` value equivalent for each one, separated by a pipe character.

```
<form>
  <div>
    <label for="corner-shape-choice">Choose a corner-shape value:</label>
    <select id="corner-shape-choice">
      <optgroup label="Keywords">
        <option value="square">square | superellipse(infinity)</option>
        <option selected value="squircle">squircle | superellipse(2)</option>
        <option value="round">round | superellipse(1)</option>
        <option value="bevel">bevel | superellipse(0)</option>
        <option value="scoop">scoop | superellipse(-1)</option>
        <option value="notch">notch | superellipse(-infinity)</option>
      </optgroup>
      <optgroup label="Functions">
        <option>superellipse(3)</option>
        <option>superellipse(1.5)</option>
```

```
        <option>superellipse(0.5)</option>
        <option>superellipse(-0.5)</option>
        <option>superellipse(-1.5)</option>
        <option>superellipse(-3)</option>
      </optgroup>
    </select>
  </div>
  <div>
    <label for="radius-slider">Choose a border-radius value:</label>
    <input
      type="range"
      id="radius-slider"
      min="0"
      value="45"
      max="90"
      step="1" />
  </div>
</form>
<section></section>
```

CSS

We apply a `box-shadow` to the `<section>`. We also give the `<section>` and form elements some basic styles, which we've hidden for brevity.

```
html {
  font-family: "Helvetica", "Arial", sans-serif;
}

body {
  width: fit-content;
  margin: 20px auto;
}

section {
  display: flex;
  justify-content: center;
  align-items: center;
  margin-top: 20px;
}

select {
  padding: 3px 5px;
}

form div:nth-of-type(2) {
  margin-top: 5px;
  display: flex;
}

section {
  width: 100%;
  height: 180px;
  background-color: gold;
  background-image: linear-gradient(
    to bottom,
    rgb(255 255 255 / 0),
    rgb(255 255 255 / 0.5)
  );
}

@supports not (corner-shape: scoop) {
  :root::before {
    content: "Your browser does not support the 'corner-shape' property.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

```
section {
  box-shadow: 1px 1px 3px gray;
}
```

```
const rectangle = document.querySelector("section");
const select = document.querySelector("select");
const range = document.getElementById("radius-slider");

function setCorners() {
  rectangle.style.cornerShape = select.value;
  const brValue = `${range.value}px`;
  rectangle.style.borderRadius = brValue;
  rectangle.innerHTML = `<div><code>corner-shape: ${select.value};</code><br><code>border-radius: ${brValue};</code></div>`;
}

select.addEventListener("change", setCorners);
range.addEventListener("input", setCorners);
setCorners();
```

The JavaScript that applies the user-selected values to the `<section>` has been hidden for brevity.

Result

The rendered result looks like this:

Try selecting different values to see how this affects the shape of the corners.

<code>superellipse()</code> value comparison

In this example, we provide two `<input type="range">` sliders allowing you to cycle through many different `corner-shape` `superellipse()` values and `border-radius` values to compare the effects of each on a container.

HTML

The markup for this example contains two `<input type="range">` elements from which different `corner-shape` `superellipse()` and `border-radius` values can be selected, and a `<section>` element to apply those values to.

```
<form>
  <div>
    <label for="superellipse-slider">Choose a superellipse() value:</label>
    <input
      type="range"
      id="superellipse-slider"
      min="-5"
      value="0"
      max="5"
      step="0.1" />
  </div>
  <div>
    <label for="radius-slider">Choose a border-radius value:</label>
    <input
      type="range"
      id="radius-slider"
      min="0"
      value="45"
      max="90"
      step="1" />
  </div>
</form>
<section></section>
```

CSS

We apply a `box-shadow` to the `<section>` element. Additional basic styles have been hidden for brevity.

```
html {
  font-family: "Helvetica", "Arial", sans-serif;
}

body {
  width: fit-content;
  margin: 20px auto;
}

section {
  display: flex;
  justify-content: center;
  align-items: center;
  margin-top: 20px;
}

form div {
  margin-top: 5px;
  display: flex;
}

section {
  width: 100%;
  height: 180px;
  background-color: orange;
  background-image: linear-gradient(
    to bottom,
    rgb(255 255 255 / 0),
    rgb(255 255 255 / 0.5)
  );
}

@supports not (corner-shape: superellipse(0)) {
  :root::before {
    content: "Your browser does not support the 'corner-shape' property.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

```
section {
  box-shadow: 1px 1px 3px gray;
}
```

```
const rectangle = document.querySelector("section");
const superEllipseRange = document.getElementById("superellipse-slider");
const borderRadiusRange = document.getElementById("radius-slider");

function setCorners() {
  const seValue = `superellipse(${superEllipseRange.value})`;
  rectangle.style.cornerShape = seValue;
  const brValue = `${borderRadiusRange.value}px`;
  rectangle.style.borderRadius = brValue;
  rectangle.innerHTML = `<div><code>corner-shape: ${seValue};</code><br><code>border-radius: ${brValue};</code></div>`;
}

superEllipseRange.addEventListener("input", setCorners);
borderRadiusRange.addEventListener("input", setCorners);
setCorners();
```

The JavaScript that applies the user-selected values to the `<section>` has been hidden for brevity.

Result

The rendered result looks like this:

Try selecting different values to see how this affects the shape of the corners.

Animating <code>corner-shape</code>

In this example, we demonstrate how the `corner-shape` property can be animated.

HTML

```
<div></div>
```

CSS

We create a set of `@keyframes` that animate smoothly between the `corner-shape` values of `square` and `notch`. We then apply an `animation` based on those `@keyframes` to the `<div>` when its containing `<html>` element is hovered over or focused. Additional basic `<div>` styles have been hidden for brevity.

```
body {
  width: 200px;
  margin: 20px auto;
}

div {
  width: 100%;
  height: 200px;
  background-color: green;
  background-image: linear-gradient(
    to bottom,
    rgb(255 255 255 / 0),
    rgb(255 255 255 / 0.5)
  );
  box-shadow: 1px 1px 3px gray;
  border-radius: 50%;
  corner-shape: square;
  outline: none;
}

@supports not (corner-shape: square) {
  :root::before {
    content: "Your browser does not support the 'corner-shape' property.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

```
@keyframes corner-pulse {
  0% {
    corner-shape: square;
  }

  /* To make the starting point apparent, let us keep
  the shape the same for a small duration. */
  20% {
    corner-shape: square;
  }

  100% {
    corner-shape: notch;
  }
}

div {
  animation: corner-pulse infinite alternate 4s linear;
}
```

Result

The rendered result looks like this:

corner-start-end-shape CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`corner-start-end-shape`** CSS property specifies the shape of a box's block-start and inline-end corner, within its `border-radius` area.

For a full description of corner shape behavior and multiple examples, see the `corner-shape` shorthand property page.

Syntax

```
/* Keyword values */
corner-start-end-shape: square;
corner-start-end-shape: bevel;

/* superellipse() function values */
corner-start-end-shape: superellipse(1.5);
corner-start-end-shape: superellipse(-2.2);

/* Global values */
corner-start-end-shape: inherit;
```

```
corner-start-end-shape: initial;
corner-start-end-shape: revert;
corner-start-end-shape: revert-layer;
corner-start-end-shape: unset;
```

Values

The `corner-start-end-shape` property is specified using a `<corner-shape-value>` value.

Formal definition

Initial value	`round`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	The corresponding superellipse() value.
Animation type	Animates as per superellipse interpolation.

Formal syntax

```
corner-start-end-shape =
  <corner-shape-value>

<corner-shape-value> =
  round             |
  scoop             |
  bevel             |
  notch             |
  square            |
  squircle          |
  <superellipse()>

<superellipse()> =
  superellipse( <number>  |
  infinity                |
  -infinity )
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

You can find other related examples on the `corner-shape` reference page.

Basic <code>corner-start-end-shape</code> usage

HTML

The markup for this example contains a single `<div>` element.

```
<div></div>
```

CSS

We give the box some basic styles, which we've hidden for brevity. We also apply a `box-shadow`, a `border-radius` of `20px 40px 60px 80px`, and a `corner-start-end-shape` of `notch`.

```
body {
  font-family: "Helvetica", "Arial", sans-serif;
  width: 240px;
  margin: 20px auto;
}

div {
  width: 100%;
  height: 180px;
  display: flex;
  justify-content: center;
  align-items: center;
  background-color: cyan;
  background-image: linear-gradient(
    to bottom,
    rgb(255 255 255 / 0),
    rgb(255 255 255 / 0.5)
  );
}
```

```
div {
  box-shadow: 1px 1px 3px gray;
  border-radius: 20px 40px 60px 80px;
  corner-start-end-shape: notch;
}
```

Result

The rendered result looks like this:

corner-start-start-shape CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`corner-start-start-shape`** CSS property specifies the shape of a box's block-start and inline-start corner, within its `border-radius` area.

For a full description of corner shape behavior and multiple examples, see the `corner-shape` shorthand property page.

Syntax

```
/* Keyword values */
corner-start-start-shape: notch;
corner-start-start-shape: squircle;

/* superellipse() function values */
corner-start-start-shape: superellipse(3);
corner-start-start-shape: superellipse(-1.5);

/* Global values */
corner-start-start-shape: inherit;
corner-start-start-shape: initial;
corner-start-start-shape: revert;
corner-start-start-shape: revert-layer;
corner-start-start-shape: unset;
```

Values

The `corner-start-start-shape` property is specified using a `<corner-shape-value>` value.

Formal definition

Initial value	`round`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	The corresponding superellipse() value.
Animation type	Animates as per superellipse interpolation.

Formal syntax

```
corner-start-start-shape =
  <corner-shape-value>

<corner-shape-value> =
  round             |
  scoop             |
  bevel             |
  notch             |
  square            |
  squircle          |
  <superellipse()>

<superellipse()> =
  superellipse( <number>  |
  infinity                |
  -infinity )
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

You can find other related examples on the `corner-shape` reference page.

Basic <code>corner-start-start-shape</code> usage

HTML

The markup for this example contains a single `<div>` element.

```
<div></div>
```

CSS

We give the box some basic styles, which we've hidden for brevity. We also apply a `box-shadow`, a `border-radius` of `40% 10px 10px`, and a `corner-start-start-shape` of `scoop`.

```
body {
  font-family: "Helvetica", "Arial", sans-serif;
  width: 240px;
  margin: 20px auto;
}

div {
  width: 100%;
  height: 180px;
  display: flex;
  justify-content: center;
  align-items: center;
  background-color: goldenrod;
  background-image: linear-gradient(
    to bottom,
    rgb(255 255 255 / 0),
    rgb(255 255 255 / 0.5)
  );
}
```

```
div {
  box-shadow: 1px 1px 3px gray;
```

```
  border-radius: 40% 10px 10px;
  corner-start-start-shape: scoop;
}
```

Result

The rendered result looks like this:

corner-top-left-shape CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`corner-top-left-shape`** CSS property specifies the shape of a box's top-left corner, within its `border-radius` area.

For a full description of corner shape behavior and multiple examples, see the `corner-shape` shorthand property page.

Syntax

```
/* Keyword values */
corner-top-left-shape: notch;
corner-top-left-shape: squircle;

/* superellipse() function values */
corner-top-left-shape: superellipse(3);
corner-top-left-shape: superellipse(-1.5);

/* Global values */
corner-top-left-shape: inherit;
corner-top-left-shape: initial;
corner-top-left-shape: revert;
corner-top-left-shape: revert-layer;
corner-top-left-shape: unset;
```

Values

The `corner-top-left-shape` property is specified using a `<corner-shape-value>` value.

Formal definition

Initial value	`round`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	The corresponding superellipse() value.
Animation type	Animates as per superellipse interpolation.

Formal syntax

```
corner-top-left-shape =
  <corner-shape-value>

<corner-shape-value> =
  round             |
  scoop             |
  bevel             |
  notch             |
  square            |
  squircle          |
  <superellipse()>

<superellipse()> =
  superellipse( <number>  |
  infinity                |
  -infinity )
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

corner-top-right-shape CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`corner-top-right-shape`** CSS property specifies the shape of a box's top-right corner, within its `border-radius` area.

For a full description of corner shape behavior and multiple examples, see the `corner-shape` shorthand property page.

Syntax

```
/* Keyword values */
corner-top-right-shape: scoop;
corner-top-right-shape: square;

/* superellipse() function values */
corner-top-right-shape: superellipse(2.2);
corner-top-right-shape: superellipse(-2.5);

/* Global values */
corner-top-right-shape: inherit;
corner-top-right-shape: initial;
corner-top-right-shape: revert;
corner-top-right-shape: revert-layer;
corner-top-right-shape: unset;
```

Values

The `corner-top-right-shape` property is specified using a `<corner-shape-value>` value.

Formal definition

Initial value	`round`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	The corresponding superellipse() value.
Animation type	Animates as per superellipse interpolation.

Formal syntax

```
corner-top-right-shape =
  <corner-shape-value>

<corner-shape-value> =
  round             |
  scoop             |
  bevel             |
  notch             |
  square            |
  squircle          |
  <superellipse()>

<superellipse()> =
  superellipse( <number>  |
  infinity                |
  -infinity )
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic <code>corner-top-right-shape</code> usage

HTML

The markup for this example contains a single `<div>` element.

```
<div></div>
```

CSS

We give the box some basic styles, which we've hidden for brevity. We also apply a `box-shadow`, a `border-radius` of 60 pixels, and a `corner-top-right-shape` of `bevel`.

```
body {
  font-family: "Helvetica", "Arial", sans-serif;
  width: 240px;
  margin: 20px auto;
}

div {
  width: 100%;
  height: 180px;
  display: flex;
  justify-content: center;
  align-items: center;
  background-color: green;
  background-image: linear-gradient(
    to bottom,
    rgb(255 255 255 / 0),
    rgb(255 255 255 / 0.5)
  );
}
```

```
div {
  box-shadow: 1px 1px 3px gray;
  border-radius: 60px;
  corner-top-right-shape: bevel;
}
```

Result

The rendered result looks like this:

corner-top-shape CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`corner-top-shape`** CSS property specifies the shape of both the corners on a box's top edge, within their `border-radius` area.

For a full description of corner shape behavior and multiple examples, see the `corner-shape` shorthand property page.

Constituent properties

This property is a shorthand for the following physical properties:

- `corner-top-left-shape`
- `corner-top-right-shape`

Syntax

```
/* Single keyword value set for both corners */
corner-top-shape: notch;
corner-top-shape: squircle;

/* Single superellipse() value set for both corners */
corner-top-shape: superellipse(3);
corner-top-shape: superellipse(-1.5);

/* Left-hand corner, right-hand corner */
corner-top-shape: notch squircle;
corner-top-shape: notch superellipse(-1.5);

/* Global values */
corner-top-shape: inherit;
corner-top-shape: initial;
corner-top-shape: revert;
corner-top-shape: revert-layer;
corner-top-shape: unset;
```

Values

The `corner-top-shape` property is specified using one or two `<corner-shape-value>` values:

- If **one value** is used, it specifies the shape of **both top corners**.
- If **two values** are used, the first one specifies the shape of the **top-left** corner, and the second one specifies the shape of the **top-right** corner.

Formal definition

Initial value	as each of the properties of the shorthand: • `corner-top-left-shape`: `round` • `corner-top-right-shape`: `round`
Applies to	all elements. It also applies to `::first-letter`.
Inherited	no
Computed value	as each of the properties of the shorthand: • `corner-top-left-shape`: The corresponding superellipse() value. • `corner-top-right-shape`: The corresponding superellipse() value.
Animation type	as each of the properties of the shorthand: • `corner-top-left-shape`: Animates as per superellipse interpolation. • `corner-top-right-shape`: Animates as per superellipse interpolation.

Formal syntax

```
corner-top-shape =
  <'corner-top-left-shape'>{1,2}

<corner-top-left-shape> =
  <corner-shape-value>

<corner-shape-value> =
  round             |
  scoop             |
  bevel             |
  notch             |
  square            |
  squircle          |
  <superellipse()>

<superellipse()> =
  superellipse( <number>  |
  infinity                |
  -infinity )
```

This syntax reflects the latest standard as per CSS Borders and Box Decorations Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

You can find other related examples on the `corner-shape` reference page.

Basic <code>corner-top-shape</code> usage

HTML

The markup for this example contains a single `<div>` element.

```
<div></div>
```

CSS

We give the box some basic styles, which we've hidden for brevity. We also apply a `box-shadow`, a `border-radius` of 60 pixels, and a `corner-top-shape` of `scoop notch`.

```
body {
  font-family: "Helvetica", "Arial", sans-serif;
  width: 240px;
  margin: 20px auto;
}

div {
  width: 100%;
  height: 180px;
  display: flex;
  justify-content: center;
  align-items: center;
  background-color: goldenrod;
  background-image: linear-gradient(
    to bottom,
    rgb(255 255 255 / 0),
    rgb(255 255 255 / 0.5)
  );
}
```

```
div {
  box-shadow: 1px 1px 3px gray;
  border-radius: 60px;
  corner-top-shape: scoop notch;
}
```

counter-increment CSS property

The **`counter-increment`** CSS property can be used to increase or decrease the value of the named CSS counters by the specified values, or to prevent all counters or an individual counter's value from being changed.

If a named counter in the list of space-separated counters and values doesn't exist, it will be created. If no value is provided for a counter in the list of counters, the counter will be increased by `1`.

The counter's value can be reset to any integer value with the `counter-reset` CSS property.

Try it

```
counter-increment: chapter-count;
```

```
counter-increment: chapter-count 0;
```

```
counter-increment: chapter-count 5;
```

```
counter-increment: chapter-count -5;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="chapters">
    <h1>Alice's Adventures in Wonderland</h1>
    <h2>Down the Rabbit-Hole</h2>
    <h2 id="example-element">The Pool of Tears</h2>
    <h2>A Caucus-Race and a Long Tale</h2>
    <h2>The Rabbit Sends in a Little Bill</h2>
  </div>
</section>
```

```
#default-example {
  text-align: left;
  counter-reset: chapter-count;
}

#example-element {
  background-color: lightblue;
  color: black;
}

h2 {
  counter-increment: chapter-count;
  font-size: 1em;
}

h2::before {
  content: "Chapter " counter(chapter-count) ": ";
}
```

Syntax

```
/* Increases "my-counter" by 1 */
counter-increment: my-counter;

/* Decreases "my-counter" by 1 */
counter-increment: my-counter -1;

/* Increases "counter1" by 1 and decreases "counter2" by 4 */
counter-increment: counter1 counter2 -4;

/* Increases "page" by 1, "section" by 2, while "chapter" doesn't change */
counter-increment: chapter 0 section 2 page;

/* Do not increment/decrement anything: used to override less specific rules */
counter-increment: none;

/* Global values */
counter-increment: inherit;
counter-increment: initial;
counter-increment: revert;
counter-increment: revert-layer;
counter-increment: unset;
```

Values

This property is specified as a space-separated list of `<custom-ident>` values, each optionally followed by an `<integer>`, or the keyword `none`:

`<custom-ident>`

Specifies the name of the counter to increase or decrease.

`<integer>`

Specifies the value to add to the counter. If the integer is preceded by a `-` sign, the value will be subtracted from the counter. Defaults to `1` if no value is specified.

`none`

Indicates that no counter must be increased or decreased. This value can also be used to cancel all counters from being increased or decreased in more specific rules. This is the default value of the property.

> **Note:** Using the `none` value prevents all counters from being increased or decreased for the selected elements where this rule applies. To prevent only specific counters from being increased or decreased, set the `integer` value as `0` on the relevant counter(s).

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
counter-increment =
  [ <counter-name> <integer>? ]+  |
  none

<counter-name> =
  <custom-ident>

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Lists and Counters Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Decreasing the counter value

In this example, we display a sequence of numbers counting backward. To do this, we use a counter to display numbers starting from 100 and decreasing by 7 each time.

HTML

```
<div>
  <i></i><i></i><i></i><i></i><i></i><i></i><i></i><i></i><i></i><i></i> <i></i><i></i><i></i><i></i><i></i><i></i><i></i><i></i><i></i><i></i><i></i><i></i><i></i> <i></i><i></i><i></i><i></i><i></i><i></i><i></i><i></i><i></i><i></i><i></i><i></i>
```

```
counter-reset: chapter-count -5;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="chapters">
    <h1>Alice's Adventures in Wonderland</h1>
    <h2>Down the Rabbit-Hole</h2>
    <h2 id="example-element">The Pool of Tears</h2>
    <h2>A Caucus-Race and a Long Tale</h2>
    <h2>The Rabbit Sends in a Little Bill</h2>
  </div>
</section>
```

```
#default-example {
  text-align: left;
  counter-reset: chapter-count;
}

#example-element {
  background-color: lightblue;
  color: black;
}

h2 {
  counter-increment: chapter-count;
  font-size: 1em;
}

h2::before {
  content: "Chapter " counters(chapter-count, ".") ": ";
}
```

Syntax

```
/* Keyword value */
counter-reset: none;

/* Regular counters with default initial values */
counter-reset: my-counter;
counter-reset: another-counter;

/* Regular counters with an initial value */
counter-reset: my-counter -3;
counter-reset: another-counter 15;

/* Reversed counters */
counter-reset: reversed(my-counter);
counter-reset: reversed(my-counter) 3;
counter-reset: reversed(another-counter) 15;

/* Multiple counters */
counter-reset: my-counter -3 another-counter 15;
counter-reset: reversed(pages) items 1 reversed(sections) 4;

/* Global values */
counter-reset: inherit;
counter-reset: initial;
counter-reset: revert;
counter-reset: revert-layer;
counter-reset: unset;
```

Values

This property is specified as a space-separated list of counter or reversed counter names, each optionally followed by an `<integer>`, or the keyword `none`:

`<custom-ident>`

Specifies the counter name to create and initialize. The `reversed()` functional notation can be used to create a reversed counter.

`<integer>`

Specifies the initial value to set on the newly created counter. If not specified, defaults to `0` for regular counters. The initial value for reversed counters is calculated automatically.

`none`

Specifies that no counters are created.

Description

The `counter-reset` property can be used to create and initialize named counters or reversed counters to number elements in ascending or descending order.

The `none` value can be used to override a `counter-reset` declaration in a rule with lower specificity.

> **Warning:** There is a difference between `counter-reset` and `counter-set` properties. After creating a counter using `counter-reset`, you can adjust its value by using the `counter-set` property. This is counterintuitive because, despite its name, the `counter-reset` property creates and initializes counters, while the `counter-set` property resets the value of existing counters.

Separate multiple counter names or name-value pairs with spaces. For counter names, regular counters use the format `<counter-name>` and reversed counters use the format `reversed(<counter-name>)`, where `<counter-name>` is a `<custom-ident>` or `list-item` for the built-in `<ol>` counter.

Default initial values

Declaring regular and reversed counters without including an integer enables you to implement the two most common numbering patterns: counting up from `1` to the number of elements and counting down from the number of elements to `1`, with increments or decrements of `1`. By specifying an initial value for a named counter, you can change its starting value. The increment or decrement can be adjusted by using the `counter-increment` property.

The following example creates three counters. The `chapter` and `page` counters are set to the initial default value of `0`, while `section` is set to `4`:

```
h1 {
  counter-reset: chapter section 4 page;
```

```
}
```

Reversed counters created without an `<integer>` have an automatically calculated initial value. The browser counts the number of elements in the set, with the calculated initial value ensuring that if the `counter-increment` is set to `-1`, thereby decrementing the named counter by `1` for each element, the counter will be at `1` on the last element in the set.

The following example creates two reversed counters, `chapter` and `section`, and a regular counter, `pages`. The `section` counter starts at `10`, and `pages` uses the default initial value of `0`. The initial value of the `chapter` counter is calculated automatically. The counter is decremented by `1` each time an `<h2>` is encountered, so its value is `1` on the last `<h2>`.

```
h1 {
  counter-reset: reversed(chapter) reversed(section) 10 pages;
}
h2 {
  counter-increment: chapter -1;
}
```

Built-in <code>list-item</code> counter

Ordered lists (`<ol>`) come with built-in `list-item` counters that control their numbering. These counters automatically increase or decrease by one with each list item. The `counter-reset` property can be used to reset the `list-item` counters. Like with other counters, you can override the default increment value for `list-item` counters by using the `counter-increment` property.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
counter-reset =
  [ <counter-name> <integer>? | <reversed-counter-name> <integer>? ]+  |
  none

<counter-name> =
  <custom-ident>

<integer> =
  <number-token>

<reversed-counter-name> =
  reversed( <counter-name> )
```

This syntax reflects the latest standard as per CSS Lists and Counters Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Overriding the <code>list-item</code> counter

In this example, the `counter-reset` property is used to set a starting value for an implicit `list-item` counter.

HTML

We include an ordered list (`<ol>`) containing five list items (`<li>`).

```
<ol>
  <li>First</li>
  <li>Second</li>
  <li>Third</li>
  <li>Fourth</li>
  <li>Fifth</li>
</ol>
```

CSS

Using `counter-reset`, we set the implicit `list-item` counter to start at a value other than the default `1`:

```
ol {
  counter-reset: list-item 3;
}
```

Result

The first item is numbered `4`. This is similar to the effect of writing `<ol start="4">` in HTML.

Using a reverse counter

In this example, the `reversed()` function is used to create a reversed counter named `priority` that numbers five tasks.

HTML

We include an unordered list (`<ul>`) containing five list items (`<li>`).

```
<ul class="stack">
  <li>Task A</li>
  <li>Task B</li>
  <li>Task C</li>
  <li>Task D</li>
  <li>Task E</li>
</ul>
```

CSS

We create a reversed counter named `priority` on the `<ul>` and remove the default bullets. We decrement the counter by `1` on each `<li>`. We then use generated content to display the counter value before each list item's content.

```
.stack {
  counter-reset: reversed(priority);
  list-style: none;
}
li {
  counter-increment: priority -1;
}
li::before {
  content: counter(priority) ". ";
}
```

```
@supports not (counter-reset: reversed(priority)) {
  body::before {
    content: "Your browser doesn't support the reversed() function.";
    background-color: wheat;
    display: block;
    text-align: center;
    padding: 1rem 0;
  }
}
```

Result

The items are numbered in reverse order from `5` to `1`. Notice that we haven't specified the counter's initial value. The browser automatically calculates the initial value at layout time.

- CSS counter styles module

counter-set CSS property

The **`counter-set`** CSS property sets CSS counters on the element to the given values.

If the counters don't exist the `counter-set` property creates a new counter for each named counter in the list of space-separated counter and value pairs. However, to create a new counter it is recommended to use the `counter-reset` CSS property.

If a named counter in the list is missing a value, the value of the counter will be set to `0`.

> **Note:** The counter's value can be incremented or decremented using the `counter-increment` CSS property.

Try it

```
counter-set: none;
```

```
counter-set: chapter-count 0;
```

```
counter-set: chapter-count;
```

```
counter-set: chapter-count 5;
```

```
counter-set: chapter-count -5;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="chapters">
    <h1>Alice's Adventures in Wonderland</h1>
    <h2>Down the Rabbit-Hole</h2>
    <h2 id="example-element">The Pool of Tears</h2>
    <h2>A Caucus-Race and a Long Tale</h2>
    <h2>The Rabbit Sends in a Little Bill</h2>
  </div>
</section>
```

```
#default-example {
  text-align: left;
  counter-set: chapter-count;
}

#example-element {
  background-color: #37077c;
  color: white;
}

h2 {
  counter-increment: chapter-count;
  font-size: 1em;
}

h2::before {
  content: "Chapter " counter(chapter-count) ": ";
}
```

Syntax

```
/* Set "my-counter" to 0 */
counter-set: my-counter;
```

```
/* Set "my-counter" to -1 */
counter-set: my-counter -1;

/* Set "counter1" to 1, and "counter2" to 4 */
counter-set: counter1 1 counter2 4;

/* Cancel any counter that could have been set in less specific rules */
counter-set: none;

/* Global values */
counter-set: inherit;
counter-set: initial;
counter-set: revert;
counter-set: revert-layer;
counter-set: unset;
```

Values

This property is specified as either a space-separated list of `<custom-ident>` values, each optionally followed by an `<integer>`, or the keyword `none`:

`<custom-ident>`

> The name of the counter to set.

`<integer>`

> The value to set the counter to on each occurrence of the element. Defaults to `0` if not specified. If there isn't currently a counter of the given name on the element, the element will create a new counter of the given name with a starting value of `0` (though it may then immediately set or increment that value to something different).

`none`

> No counter set is to be performed. This can be used to override a `counter-set` defined in a less specific rule.

Formal definition

Initial value	none
Applies to	all elements
Inherited	no
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
counter-set =
  [ <counter-name> <integer>? ]+  |
  none

<counter-name> =
  <custom-ident>

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Lists and Counters Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting named counters

```
h1 {
  counter-set: chapter section 1 page;
  /* Sets the chapter and page counters to 0,
     and the section counter to 1 */
}
```

cursor CSS property

The **`cursor`** CSS property sets the mouse cursor, if any, to show when the mouse pointer is over an element.

The cursor setting should inform users of the mouse operations that can be performed at the current location, including: text selection, activating help or context menus, copying content, resizing tables, and so on. You can specify either the *type* of cursor using a keyword, or load a specific icon to use (with optional fallback images and mandatory keyword as a final fallback).

Try it

```
cursor: pointer;
```

```
cursor: help;
```

```
cursor: wait;
```

```
cursor: crosshair;
```

```
cursor: not-allowed;
```

```
cursor: zoom-in;
```

```
<section class="default-example container" id="default-example">
  <div id="example-element">
    Move over this element to see the cursor style.
  </div>
</section>
```

```
#example-element {
  display: flex;
  background-color: #1766aa;
  color: white;
  height: 180px;
  width: 360px;
  justify-content: center;
  align-items: center;
  font-size: 14pt;
  padding: 5px;
}
```

Syntax

```
/* Keyword values */
cursor: auto;
cursor: pointer;
/* … */
cursor: zoom-out;

/* URL with mandatory keyword fallback */
cursor: url("hand.cur"), pointer;

/* URL and coordinates, with mandatory keyword fallback */
cursor:
  url("cursor_1.png") 4 12,
  auto;
cursor:
  url("cursor_2.png") 2 2,
  pointer;

/* URLs and fallback URLs (some with coordinates), with mandatory keyword fallback */
cursor:
  url("cursor_1.svg") 4 5,
  url("cursor_2.svg"),
  /* …, */ url("cursor_n.cur") 5 5,
  progress;

/* Global values */
cursor: inherit;
cursor: initial;
cursor: revert;
cursor: revert-layer;
cursor: unset;
```

The `cursor` property is specified as zero or more `<url>` values, separated by commas, followed by a single mandatory keyword value. Each `<url>` should point to an image file. The browser will try to load the first image specified, falling back to the next if it can't, and falling back to the keyword value if no images could be loaded (or if none were specified).

Each `<url>` may be optionally followed by a pair of space-separated numbers, which set the `<x>` and `<y>` coordinates of the cursor's hotspot relative to the top-left corner of the image.

Values

`<url>` Optional

A `url()` or a comma separated list `url(), url(), …`, pointing to an image file. More than one `<url>` may be provided as fallbacks, in case some cursor image types are not supported. A non-URL fallback (one or more of the keyword values) *must* be at the end of the fallback list.

`<x>`, `<y>` Optional

Optional x- and y-coordinates indicating the cursor hotspot; the precise position within the cursor that is being pointed to.

The numbers are in units of image pixels. They are relative to the top left corner of the image, which corresponds to `0 0`, and are clamped within the boundaries of the cursor image. If these values are not specified, they may be read from the file itself, and will otherwise default to the top-left corner of the image.

`keyword`

A keyword value *must* be specified, indicating either the type of cursor to use, or the fallback cursor to use if all specified icons fail to load.

The available keywords are listed in the table below. Other than `none`, which means no cursor, there is an image showing how the cursors used to be rendered. You can hover your mouse over the table rows to see the effect of the different cursor keyword values on your browser today.

Category	Keyword	Example	Description
General	`auto`		The UA will determine the cursor to display based on the current context. E.g., equivalent to `text` when hovering text.
	`default`		The platform-dependent default cursor. Typically an arrow.
	`none`		No cursor is rendered.
Links & status	`context-menu`		A context menu is available.
	`help`		Help information is available.
	`pointer`		The cursor is a pointer that indicates a link. Typically an image of a pointing hand.
	`progress`		The program is busy in the background, but the user can still interact with the interface (in contrast to `wait`).
	`wait`		The program is busy, and the user can't interact with the interface (in contrast to `progress`). Sometimes an image of an hourglass or a watch.

Category	Keyword	Example	Description
Selection	`cell`		The table cell or set of cells can be selected.
	`crosshair`		Cross cursor, often used to indicate selection in a bitmap.
	`text`		The text can be selected. Typically the shape of an I-beam.
	`vertical-text`		The vertical text can be selected. Typically the shape of a sideways I-beam.
Drag & drop	`alias`		An alias or shortcut is to be created.
	`copy`		Something is to be copied.
	`move`		Something is to be moved.
	`no-drop`		An item may not be dropped at the current location. Firefox bug 275173: On Windows and macOS, `no-drop` is the same as `not-allowed`.
	`not-allowed`		The requested action will not be carried out.
	`grab`		Something can be grabbed (dragged to be moved).
	`grabbing`		Something is being grabbed (dragged to be moved).
Resizing & scrolling	`all-scroll`		Something can be scrolled in any direction (panned). Firefox bug 275174: On Windows, `all-scroll` is the same as `move`.
	`col-resize`		The item/column can be resized horizontally. Often rendered as arrows pointing left and right with a vertical bar separating them.
	`row-resize`		The item/row can be resized vertically. Often rendered as arrows pointing up and down with a horizontal bar separating them.
	`n-resize`		Some edge is to be moved. For example, the `se-resize` cursor is used when the movement starts from the *south-east* corner of the box. In some environments, an equivalent bidirectional resize cursor is shown. For example, `n-resize` and `s-resize` are the same as `ns-resize`.
	`e-resize`		
	`s-resize`		
	`w-resize`		
	`ne-resize`		
	`nw-resize`		
	`se-resize`		
	`sw-resize`		
	`ew-resize`		Bidirectional resize cursor.
	`ns-resize`		
	`nesw-resize`		
	`nwse-resize`		
Zooming	`zoom-in`		Something can be zoomed (magnified) in or out.
	`zoom-out`		

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	yes
Computed value	as specified, but with `<url>` values made absolute
Animation type	discrete

Formal syntax

```
cursor =
  [ <cursor-image> , ]* <cursor-predefined>

<cursor-image> =
  [ <url> | <url-set> ] <number>{2}?

<cursor-predefined> =
  auto            |
  default         |
  none            |
  context-menu    |
  help            |
```

```
  pointer       |
  progress      |
  wait          |
  cell          |
  crosshair     |
  text          |
  vertical-text |
  alias         |
  copy          |
  move          |
  no-drop       |
  not-allowed   |
  grab          |
  grabbing      |
  e-resize      |
  n-resize      |
  ne-resize     |
  nw-resize     |
  s-resize      |
  se-resize     |
  sw-resize     |
  w-resize      |
  ew-resize     |
  ns-resize     |
  nesw-resize   |
  nwse-resize   |
  col-resize    |
  row-resize    |
  all-scroll    |
  zoom-in       |
  zoom-out
```

This syntax reflects the latest standard as per CSS Basic User Interface Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Usage notes

Icon size limits

While the specification does not limit the `cursor` image size, user agents commonly restrict them to avoid potential misuse. For example, on Firefox and Chromium cursor images are restricted to 128x128 pixels by default, but it is recommended to limit the cursor image size to 32x32 pixels. Cursor changes using images that are larger than the user-agent maximum supported size will generally just be ignored.

Supported image file formats

User agents are required by the specification to support PNG files, SVG v1.1 files in secure static mode that contain a natural size, and any other non-animated image file formats that they support for images in other properties. Desktop browsers also broadly support the `.cur` file format.

The specification further indicates that user agents *should* also support SVG v1.1 files in secure animated mode that contain a natural size, along with any other animated images file formats they support for images in other properties. User agents *may* support both static and animated SVG images that do not contain a natural size.

iPadOS

iPadOS supports pointer devices like trackpads and mouses. By default, the iPad cursor is displayed as a circle, and the only supported value that will change an appearance of the pointer is `text`.

Other notes

Cursor changes that intersect toolbar areas are commonly blocked to avoid spoofing.

Examples

Setting cursor types

```
.foo {
  cursor: crosshair;
}

.bar {
  cursor: zoom-in;
}

/* A fallback keyword value is required when using a URL */
.baz {
  cursor: url("hyper.cur"), auto;
}
```

cx CSS property

The **cx** CSS property defines the x-axis center point of an SVG `<circle>` or `<ellipse>` element. If present, it overrides the element's `cx` attribute.

> **Note:** While SVG the `cx` attribute is relevant to the SVG `<radialGradient>` element, the `cx` property only applies to `<circle>` and `<ellipse>` elements nested in an `<svg>`. It doesn't apply to `<radialGradient>` or other SVG elements nor to HTML elements or pseudo-elements.

Syntax

```
/* length and percentage values */
cx: 20px;
cx: 20%;

/* Global values */
cx: inherit;
cx: initial;
cx: revert;
cx: revert-layer;
cx: unset;
```

Values

The `<length>` and `<percentage>` values denote the horizontal center of the circle or ellipse.

`<length>`

As an absolute or relative length, it can be expressed in any unit allowed by the CSS `<length>` data type. Negative values are invalid.

`<percentage>`

Percentages refer to the width of the current SVG viewport.

Formal definition

Initial value	`0`
Applies to	`<ellipse>` and `<circle>` elements in `<svg>`
Inherited	no
Percentages	refer to the width of the current SVG viewport
Computed value	the percentage as specified or the absolute length
Animation type	by computed value type

Formal syntax

```
cx =
  <length-percentage>

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Specification, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Defining the x-axis coordinate of a circle and ellipse

This example demonstrates the basic use case of `cx`, and how the CSS `cx` property takes precedence over the `cx` attribute.

HTML

We include two identical `<circle>` and two identical `<ellipse>` elements in an SVG; their `cx` attribute values are `50` and `150`, respectively.

```
<svg xmlns="http://www.w3.org/2000/svg">
  <circle cx="50" cy="50" r="30" />
  <circle cx="50" cy="50" r="30" />
  <ellipse cx="150" cy="50" rx="20" ry="40" />
  <ellipse cx="150" cy="50" rx="20" ry="40" />
</svg>
```

CSS

With CSS, we style only the first circle and first ellipse, allowing their twin shapes to use default styles (with `fill` defaulting to black). We use the `cx` property to override the value of the SVG `cx` attribute and also give it a `fill` and `stroke` to differentiate the first shapes in each pair from their twin. The browser renders SVG images as `300px` wide and `150px` tall by default.

```
svg {
  border: 1px solid;
}

circle:first-of-type {
  cx: 30px;
  fill: lightgreen;
  stroke: black;
}
ellipse:first-of-type {
  cx: 180px;
  fill: pink;
  stroke: black;
}
```

Results

The style circle's center is `30px` from the left edge of the SVG viewport and the styled ellipse is `180px` from that edge, as defined in the CSS `cx` property values. The unstyled shapes centers are `50px` and `150px` from the left edge of the SVG viewport, as defined in their SVG `cx` attribute values.

x-axis coordinates as percentage values

This example demonstrates using percentage values for `cx`.

HTML

We use the same markup as the previous example.

```
<svg xmlns="http://www.w3.org/2000/svg">
  <circle cx="50" cy="50" r="30" />
  <circle cx="50" cy="50" r="30" />
  <ellipse cx="150" cy="50" rx="20" ry="40" />
  <ellipse cx="150" cy="50" rx="20" ry="40" />
</svg>
```

CSS

We use CSS which is similar to the previous example. The only difference is the CSS `cx` property value; in this case, we use percentage values of `30%` for the `<circle>` and `80%` for the `<ellipse>`.

```
svg {
  border: 1px solid;
}
```

```
circle:first-of-type {
  cx: 30%;
  fill: lightgreen;
  stroke: black;
}
ellipse:first-of-type {
  cx: 80%;
  fill: pink;
  stroke: black;
}
```

Results

When using percentage values for `cx`, the values are relative to the width of the SVG viewport. Here, the x-axis coordinates of the center of the style circle and ellipse are `30%` and `80%`, respectively, of the width of the current SVG viewport. As the width defaulted to `300px`, the `cx` values are `90px` and `240px` from the SVG viewport's left edge.

- `fill`
- `stroke`
- `paint-order`
- `border-radius` shorthand property
- `radial-gradient`
- `<basic-shape>` data type

cy CSS property

The **`cy`** CSS property defines the y-axis center point of an SVG `<circle>` or `<ellipse>` elements. If present, it overrides the element's `cy` attribute.

> **Note:** While the SVG `<radialGradient>` element supports the `cy` attribute, the `cy` property only applies to `<circle>` and `<ellipse>` elements nested in an `<svg>`. This attribute does not apply to `<radialGradient>` or other SVG elements nor to HTML elements or pseudo-elements.

Syntax

```
/* length and percentage values */
cy: 3px;
cy: 20%;

/* Global values */
cy: inherit;
cy: initial;
cy: revert;
cy: revert-layer;
cy: unset;
```

Values

The `<length>` and `<percentage>` values denote the vertical center of the circle or ellipse.

`<length>`

As an absolute or relative length, it can be expressed in any unit allowed by the CSS `<length>` data type. Negative values are invalid.

`<percentage>`

Percentages refer to the height of the current SVG viewport.

Formal definition

Initial value	`0`
Applies to	`<ellipse>` and `<circle>` elements in `<svg>`
Inherited	no
Percentages	refer to the height of the current SVG viewport
Computed value	the percentage as specified or the absolute length
Animation type	by computed value type

Formal syntax

```
cy =
  <length-percentage>

<length-percentage> =
  <length>     |
  <percentage>
```

This syntax reflects the latest standard as per CSS Specification, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Defining the y-axis coordinate of a circle and ellipse

In this example, we have two identical `<circle>` and two identical `<ellipse>` elements in an SVG; their `cy` attribute values ar `50` and `150`, respectively.

```
<svg xmlns="http://www.w3.org/2000/svg">
  <circle cx="50" cy="50" r="30" />
  <circle cx="50" cy="50" r="30" />
  <ellipse cx="150" cy="50" rx="20" ry="40" />
  <ellipse cx="150" cy="50" rx="20" ry="40" />
</svg>
```

With CSS, we style only the first circle and first ellipse, allowing their twin shapes to use default styles (with `fill` defaulting to black). We use the `cy` property to override the value of the SVG `cy` attribute and also give it a `fill` and `stroke` to differentiate the first shapes in each pair from their twin. The browser renders SVG images as `300px` wide and `150px` tall by default.

```
svg {
  border: 1px solid;
}

circle:first-of-type {
  cy: 30px;
  fill: lightgreen;
  stroke: black;
}
ellipse:first-of-type {
  cy: 100px;
  fill: pink;
  stroke: black;
}
```

The styled circle's center is `30px` from the top edge of the SVG viewport and the styled ellipse is `100px` from that edge, as defined in the CSS `cy` property values. The unstyled shapes centers are both `50px` from the top edge of the SVG viewport, as defined in their SVG `cy` attribute values.

y-axis coordinates as percentage values

In this example, we use the same markup as the previous example. The only difference is the CSS `cy` property value; in this case, we use percentage values of `30%` and `50%`.

```
<svg xmlns="http://www.w3.org/2000/svg">
  <circle cx="50" cy="50" r="30" />
  <circle cx="50" cy="50" r="30" />
  <ellipse cx="150" cy="50" rx="20" ry="40" />
  <ellipse cx="150" cy="50" rx="20" ry="40" />
</svg>
```

```
svg {
  border: 1px solid;
}

circle:first-of-type {
  cy: 30%;
  fill: lightgreen;
  stroke: black;
}
ellipse:first-of-type {
  cy: 50%;
  fill: pink;
  stroke: black;
}
```

In this case, the y-axis coordinates of the center of the circle and ellipse are `30%` and `50%` of the height of the current SVG viewport, respectively. As the image's height defaulted to `150px`, meaning the `cy` value is the equivalent of `45px` and `120px`.

See also

- SVG `cy` attribute
- Geometry properties: `cy`, `cx`, `r`, `rx`, `ry`, `x`, `y`, `width`, `height`
- `fill`
- `stroke`
- `paint-order`
- `border-radius` shorthand property
- `radial-gradient`
- `<basic-shape>` data type

d CSS property

The **`d`** CSS property defines a path to be drawn by the SVG `<path>` element. If present, it overrides the element's `d` attribute.

> **Note:** The `d` property only applies to `<path>` elements nested in an `<svg>`. It doesn't apply to other SVG elements nor to HTML elements or pseudo-elements.

Syntax

```
/* Default */
d: none;

/* Basic usage */
d: path("m 5,5 h 35 L 20,30 z");
d: path("M 0,25 l 50,150 l 200,50 z");
d: path("M 10,5 l 90,0 -80,80 0,-60 80,80 -90,0 z");

/* Global values */
d: inherit;
d: initial;
d: revert;
d: revert-layer;
d: unset;
```

Values

The value is either a `path()` function with a single `<string>` parameter or the keyword `none`:

`none`

No path is drawn.

`path(<string>)`

A `path()` function with a quoted data string parameter. The data string defines an SVG path. The SVG path data string contains path commands that implicitly use pixel units. An empty path is considered invalid.

Formal definition

Initial value	none
Applies to	`<path>` element in `<svg>`
Inherited	no
Computed value	as specified
Animation type	yes, as specified for `<basic-shape>`, otherwise no

Formal syntax

```
d =
  none      |
  <string>
```

This syntax reflects the latest standard as per CSS Specification. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Specifying path data

This example demonstrates the basic use case of `d`, and how the CSS `d` property takes precedence over the `d` attribute.

HTML

We include two identical `<path>` elements in an SVG; their `d` attribute values are `"m 5,5 h 90 v 90 h -90 v -90 z"`, which creates a `90px` square.

```
<svg>
  <path d="m 5,5 h 90 v 90 h -90 v -90 z" />
  <path d="m 5,5 h 90 v 90 h -90 v -90 z" />
</svg>
```

CSS

With CSS, we style both paths, providing a black `stroke` and semi-opaque red `fill`. We then use the `d` property to override the value of the SVG `d` attribute for the last path only. The browser renders SVG images as `300px` wide and `150px` tall by default.

```
svg {
  border: 1px solid;
}

path {
  fill: #ff333388;
  stroke: black;
}

path:last-of-type {
  d: path(
    "M10,30 A20,20 0,0,1 50,30 A20,20 0,0,1 90,30 Q90,60 50,90 Q10,60 10,30 z"
  );
}
```

Results

The second `<path>` is a heart, as defined in the CSS `d` property's `path()` function value. The unstyled `<path>`'s path remained a square, as defined in its SVG `d` attribute value.

Animating data paths

This example demonstrates animating the `d` attribute value.

HTML

We create a `<svg>` containing a single `<path>` element.

```
<svg>
  <path />
</svg>
```

CSS

We use the `d` attribute to define a heart with a line through it. We use CSS to define the `fill`, `stroke`, and `stroke-width` of that path, and add a two-second `transition`. We add a `:hover` style that contains a slightly different `path()` function; the path has the same number of data points as the default state, making the path animatable.

```
svg {
  border: 1px solid;
}

path {
  d: path(
    "M10,30 A20,20 0,0,1 50,30 A20,20 0,0,1 90,30 Q90,60 50,90 Q10,60 10,30 z M90,5 L5,90"
  );
  transition: all 2s;
  fill: none;
  stroke: red;
  stroke-width: 3px;
}

svg:hover path {
  d: path(
    "M10,30 A20,20 0,0,1 50,30 A20,20 0,0,1 90,30 Q90,60 50,90 Q10,60 10,30 z M5,5 L90,90"
  );
  stroke: black;
}
```

Results

To view the animation, hover over the SVG.

direction CSS property

> **Warning:** Where possible, authors are encouraged to avoid using the `direction` CSS property and use the HTML `dir` global attribute instead.

The **`direction`** CSS property sets the direction of text, table and grid columns, and horizontal overflow. Use `rtl` for languages written from right to left (like Hebrew or Arabic), and `ltr` for those written from left to right (like English and most other languages).

Note that text direction is usually defined within a document (e.g., with HTML's `dir` attribute) rather than through direct use of the `direction` property.

Try it

```
direction: ltr;
```

```
direction: rtl;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    <div>1</div>
    <div>2</div>
    <div>3</div>
    <div>4</div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  padding: 0.75em;
  width: 80%;
  max-height: 300px;
  display: flex;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
  margin: 10px;
  flex: 1;
}
```

Syntax

```
/* Keyword values */
direction: ltr;
direction: rtl;

/* Global values */
direction: inherit;
direction: initial;
direction: revert;
direction: revert-layer;
direction: unset;
```

Values

This property is specified as one of the following keyword values:

`ltr`

Text and other elements go from left to right. This is the default value.

`rtl`

Text and other elements go from right to left.

For the `direction` property to have any effect on inline-level elements, the `unicode-bidi` property's value must be `embed` or `override`.

Description

The property sets the base text direction of block-level elements and the direction of embeddings created by the `unicode-bidi` property. It also sets the default alignment of text, block-level elements, and the direction that cells flow within a table or grid row.

Unlike the `dir` attribute in HTML, the `direction` property is not inherited from table columns into table cells, since CSS inheritance follows the document tree, and table cells are inside of rows but not inside of columns.

The `direction` and `unicode-bidi` properties are the only two properties which are not affected by the `all` shorthand property.

Formal definition

Initial value	`ltr`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	Not animatable

Formal syntax

```
direction =
  ltr  |
  rtl
```

This syntax reflects the latest standard as per CSS Writing Modes Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting right-to-left direction

In the example below are two strings of text, both which are displaying using `direction: rtl`. While the Arabic text is displayed correctly with this setting, the English text now has a full stop in an unusual location.

```
blockquote {
  direction: rtl;
  width: 300px;
}
```

```
<blockquote>
  <p>This paragraph is in English but incorrectly goes right to left.</p>
</blockquote>

<blockquote>
  <p>هذه الفقرة باللغة العربية ، لذا يجب الانتقال من اليمين إلى اليسار.</p>
</blockquote>
```

display CSS property

The **`display`** CSS property sets whether an element is treated as a block or inline box and the layout used for its children, such as flow layout, grid or flex.

Formally, the **`display`** property sets an element's inner and outer *display types*. The outer type sets an element's participation in flow layout; the inner type sets the layout of children. Some values of `display` are fully defined in their own individual specifications; for example the detail of what happens when `display: flex` is declared is defined in the CSS Flexible Box Model specification.

Try it

```
display: block;
```

```
display: inline flow-root;
```

```
display: none;
```

```
display: flex;
```

```
display: grid;
```

```
display: grid-lanes;
```

```
<p>
  Apply different <code>display</code> values on the dashed orange-bordered
  <code>div</code>, which contains three child elements.
</p>
<section class="default-example" id="default-example">
  <div class="example-container">
    Some text A.
    <div id="example-element">
      <div class="child">Child 1</div>
      <div class="child">Child 2</div>
      <div class="child">Child 3</div>
    </div>
    Some text B.
  </div>
</section>
```

```
.example-container {
  width: 100%;
  height: 100%;
}

code {
  background: #88888888;
}

#example-element {
  border: 3px dashed orange;
}

.child {
  display: inline-block;
  padding: 0.5em 1em;
  background-color: #ccccff;
  border: 1px solid #ababab;
  color: black;
}
```

Syntax

```
/* short display */
display: none;
display: contents;
display: block;
display: flow-root;
display: inline;
display: inline-block;
display: list-item;
display: inline list-item;
display: flex;
display: inline-flex;
display: grid;
display: inline-grid;
display: grid-lanes;
display: inline-grid-lanes;
display: table;
display: inline-table;

/* full display */
display: block flow;
display: block flow-root;
display: inline flow;
display: inline flow-root;
display: block flow list-item;
display: inline flow list-item;
display: block flex;
display: inline flex;
display: block grid;
display: inline grid;
display: block grid-lanes;
display: inline grid-lanes;
display: block table;
display: inline table;

/* global values */
display: inherit;
display: initial;
display: revert;
display: revert-layer;
display: unset;
```

The CSS `display` property is specified using keyword values.

Grouped values

The keyword values can be grouped into six value categories.

Outside

`<display-outside>`

These keywords specify the element's outer display type, which is essentially its role in flow layout:

`block`

The element generates a block box, generating line breaks both before and after the element when in the normal flow.

`inline`

The element generates one or more inline boxes that do not generate line breaks before or after themselves. In normal flow, the next element will be on the same line if there is space.

> **Note:** When a display property is specified with only an **outer** value (e.g., `display: block` or `display: inline`), the inner value defaults to `flow` (e.g., `display: block flow` and `display: inline flow`).

> **Note:** You may use the single-value syntax as a fallback for multi-keyword syntax, for example `display: inline flex` could have the following fallback
>
> ```
> .container {
>   display: inline-flex;
>   display: inline flex;
> }
> ```
>
> See Using the multi-keyword syntax with CSS display for more information.

Inside

`<display-inside>`

These keywords specify the element's inner display type, which defines the type of formatting context that its contents are laid out in (assuming it is a non-replaced element). When one of these keywords is used by itself as a single value, the element's outer display type defaults to `block` (with the exception of `ruby`, which defaults to `inline`).

`flow`

The element lays out its contents using flow layout (block-and-inline layout).

If its outer display type is `inline`, and it is participating in a block or inline formatting context, then it generates an inline box. Otherwise it generates a block box.

Depending on the value of other properties (such as `position`, `float`, or `overflow`) and whether it is itself participating in a block or inline formatting context, it either establishes a new block formatting context (BFC) for its contents or integrates its contents into its parent formatting context.

`flow-root`

The element generates a block box that establishes a new block formatting context, defining where the formatting root lies.

`table`

These elements behave like HTML `<table>` elements. It defines a block-level box.

`flex`

The element behaves like a block-level element and lays out its content according to the flexbox model.

`grid`

The element behaves like a block-level element and lays out its content according to the grid model.

`grid-lanes`

The element behaves like a block-level element and lays out its content using grid lanes layout. Columns are defined by `grid-template-columns` and behave like a strict grid, while items are packed in the block direction to fill gaps between items of different sizes. See Grid lanes layout for details.

`ruby`

The element behaves like an inline-level element and lays out its content according to the ruby formatting model. It behaves like the corresponding HTML `<ruby>` elements.

> **Note:** When a display property is specified with only an **inner** value (e.g., `display: flex` or `display: grid`), the outer value defaults to `block` (e.g., `display: block flex` and `display: block grid`).

List Item

`<display-listitem>`

The element generates a block box for the content and a separate list-item inline box.

A single value of `list-item` will cause the element to behave like a list item. This can be used together with `list-style-type` and `list-style-position`.

`list-item` can also be combined with any `<display-outside>` keyword and the `flow` or `flow-root` `<display-inside>` keyword.

> **Note:** If no inner value is specified, it will default to `flow`. If no outer value is specified, the principal box will have an outer display type of `block`.

Internal

`<display-internal>`

Some layout models such as `table` and `ruby` have a complex internal structure, with several different roles that their children and descendants can fill. This section defines those "internal" display values, which only have meaning within that particular layout mode.

`table-row-group`

These elements behave like `<tbody>` HTML elements.

`table-header-group`

These elements behave like `<thead>` HTML elements.

`table-footer-group`

These elements behave like `<tfoot>` HTML elements.

`table-row`

These elements behave like `<tr>` HTML elements.

`table-cell`

These elements behave like `<td>` HTML elements.

`table-column-group`

These elements behave like `<colgroup>` HTML elements.

`table-column`

These elements behave like `<col>` HTML elements.

`table-caption`

These elements behave like `<caption>` HTML elements.

`ruby-base`

These elements behave like `<rb>` HTML elements.

`ruby-text`

These elements behave like `<rt>` HTML elements.

`ruby-base-container`

These elements are generated as anonymous boxes.

`ruby-text-container`

These elements behave like `<rtc>` HTML elements.

Box

`<display-box>`

These values define whether an element generates display boxes at all.

`contents`

These elements don't produce a specific box by themselves. They are replaced by their pseudo-box and their child boxes. Please note that the CSS Display Level 3 spec defines how the `contents` value should affect "unusual elements" — elements that aren't rendered purely by CSS box concepts such as replaced elements. See Appendix B: Effects of display: contents on Unusual Elements for more details.

`none`

Turns off the display of an element so that it has no effect on layout (the document is rendered as though the element did not exist). All descendant elements also have their display turned off. To have an element take up the space that it would normally take, but without actually rendering anything, use the `visibility` property instead.

Precomposed

`<display-legacy>`

CSS 2 used a single-keyword, precomposed syntax for the `display` property, requiring separate keywords for block-level and inline-level variants of the same layout mode.

`inline-block`

The element generates a block box that will be flowed with surrounding content as if it were a single inline box (behaving much like a replaced element would).

It is equivalent to `inline flow-root`.

`inline-table`

The `inline-table` value does not have a direct mapping in HTML. It behaves like an HTML `<table>` element, but as an inline box, rather than a block-level box. Inside the table box is a block-level context.

It is equivalent to `inline table`.

`inline-flex`

The element behaves like an inline-level element and lays out its content according to the flexbox model.

It is equivalent to `inline flex`.

`inline-grid`

The element behaves like an inline-level element and lays out its content according to the grid model.

It is equivalent to `inline grid`.

`inline-grid-lanes`

The element behaves like an inline-level element and lays out its content using grid lanes layout. Rows are defined by `grid-template-rows` and behave like a strict grid, while items are packed in the inline direction to fill gaps between items of different sizes. See Grid lanes layout for details.

It is equivalent to `inline grid-lanes`.

Which syntax should you use?

The CSS display module describes a multi-keyword syntax for values you can use with the `display` property to explicitly define **outer** and **inner** display. The single keyword values (precomposed `<display-legacy>` values) are supported for backward-compatibility.

For example, using two values you can specify an inline flex container as follows:

```
.container {
  display: inline flex;
}
```

This can also be specified using the legacy single value:

```
.container {
  display: inline-flex;
}
```

For more information on these changes, see the Using the multi-keyword syntax with CSS display guide.

Description

The individual pages for the different types of value that `display` can have set on it feature multiple examples of those values in action — see the Syntax section. In addition, see the following material, which covers the various values of display in depth.

Multi-keyword values

- Using the multi-keyword syntax with CSS display

CSS Flow Layout (display: block, display: inline)

- Block and inline layout in normal flow
- Flow layout and overflow
- Flow layout and writing modes
- Introduction to formatting contexts
- In flow and out of flow

display: flex

- Basic concepts of flexbox
- Aligning items in a flex container
- Controlling ratios of flex items along the main axis
- Mastering wrapping of flex items
- Ordering flex items
- Relationship of flexbox to other layout methods
- Typical use cases of flexbox

display: grid

- Basic concepts of grid layout
- Relationship to other layout methods
- Line-based placement
- Grid template areas
- Layout using named grid lines
- Auto-placement in grid layout
- Aligning items in CSS grid layout
- Grids, logical values and writing modes
- CSS grid layout and accessibility

- Realizing common layouts using grids
- Grid lanes layout

Animating display

Supporting browsers animate `display` with a discrete animation type. This generally means that the property will flip between two values 50% through animating between the two.

There is one exception, which is when animating to or from `display: none`. In this case, the browser will flip between the two values so that the animated content is shown for the entire animation duration. So for example:

- When animating `display` from `none` to `block` (or another visible `display` value), the value will flip to `block` at `0%` of the animation duration so it is visible throughout.
- When animating `display` from `block` (or another visible `display` value) to `none`, the value will flip to `none` at `100%` of the animation duration so it is visible throughout.

This behavior is useful for creating entry/exit animations where you want to for example remove a container from the DOM with `display: none`, but have it fade out with `opacity` rather than disappearing immediately.

When animating `display` with CSS animations, you need to provide the starting `display` value in an explicit keyframe (for example using `0%` or `from`). See Using CSS animations for an example.

When animating `display` with CSS transitions, two additional features are needed:

- `@starting-style` provides starting values for properties you want to transition from when the animated element is first shown. This is needed to avoid unexpected behavior. By default, CSS transitions are not triggered on an element's first style update or when the `display` type changes from `none` to another type.
- `transition-behavior: allow-discrete` needs to be set on the `transition-property` declaration (or the `transition` shorthand) to enable `display` transitions.

For examples of transitioning the `display` property, see the `@starting-style` and `transition-behavior` pages.

Accessibility

display: none

Using a `display` value of `none` on an element will remove it from the accessibility tree. This will cause the element and all its descendant elements to no longer be announced by screen reading technology.

If you want to visually hide the element, a more accessible alternative is to use a combination of properties to remove it visually from the screen but still make it available to assistive technology such as screen readers.

While `display: none` hides content from the accessibility tree, elements that are hidden but are referenced from visible elements' `aria-describedby` or `aria-labelledby` attributes are exposed to assistive technologies.

display: contents

Current implementations in some browsers will remove from the accessibility tree any element with a `display` value of `contents` (but descendants will remain). This will cause the element itself to no longer be announced by screen reading technology. This is incorrect behavior according to the CSS specification.

- More accessible markup with display: contents | Hidde de Vries
- Display: Contents Is Not a CSS Reset | Adrian Roselli

Tables

In some browsers, changing the `display` value of a `<table>` element to `block`, `grid`, or `flex` will alter its representation in the accessibility tree. This will cause the table to no longer be announced properly by screen reading technology.

- Hidden content for better a11y | Go Make Things

- Understanding Success Criterion 1.3.1 | W3C Understanding WCAG 2.0

Formal definition

Initial value	`inline`
Applies to	all elements
Inherited	no
Computed value	as the specified value, except for positioned and floating elements and the root element. In both cases the computed value may be a keyword other than the one specified.
Animation type	Discrete behavior except when animating to or from `none` is visible for the entire duration

Formal syntax

```
display =
  [ <display-outside> || <display-inside> ]        |
  <display-listitem>                               |
  <display-internal>                               |
  <display-box>                                    |
  <display-legacy>                                 |
  grid-lanes                                       |
  inline-grid-lanes                                |
  <display-outside> || [ <display-inside> | math ]

<display-outside> =
  block   |
  inline  |
  run-in

<display-inside> =
  flow       |
  flow-root  |
  table      |
  flex       |
  grid       |
  ruby

<display-listitem> =
  <display-outside>?    &&
  [ flow | flow-root ]?  &&
  list-item

<display-internal> =
  table-row-group      |
  table-header-group   |
  table-footer-group   |
  table-row            |
  table-cell           |
```

```
  table-column-group   |
  table-column         |
  table-caption        |
  ruby-base            |
  ruby-text            |
  ruby-base-container  |
  ruby-text-container

<display-box> =
  contents  |
  none

<display-legacy> =
  inline-block  |
  inline-table  |
  inline-flex   |
  inline-grid
```

This syntax reflects the latest standard as per CSS Display Module Level 4, CSS Grid Layout Module Level 3, MathML Core. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

display value comparison

In this example we have two block-level container elements, each one with three inline children. Below that, we have a select menu that allows you to apply different `display` values to the containers, allowing you to compare and contrast how the different values affect the element's layout, and that of their children.

We have included `padding` and `background-color` on the containers and their children, so that it is easier to see the effect the display values are having.

HTML

```
<article class="container">
  <span>First</span>
  <span>Second</span>
  <span>Third</span>
</article>

<article class="container">
  <span>First</span>
  <span>Second</span>
  <span>Third</span>
</article>

<div>
  <label for="display">Choose a display value:</label>
  <select id="display">
    <option selected>block</option>
    <option>block flow</option>
    <option>inline</option>
    <option>inline flow</option>
    <option>flow</option>
    <option>flow-root</option>
    <option>block flow-root</option>
    <option>table</option>
    <option>block table</option>
    <option>flex</option>
    <option>block flex</option>
    <option>grid</option>
    <option>block grid</option>
    <option>grid-lanes</option>
    <option>block grid-lanes</option>
    <option>list-item</option>
    <option>block flow list-item</option>
    <option>inline flow list-item</option>
    <option>block flow-root list-item</option>
    <option>inline flow-root list-item</option>
    <option>contents</option>
    <option>none</option>
    <option>inline-block</option>
    <option>inline flow-root</option>
    <option>inline-table</option>
    <option>inline table</option>
    <option>inline-flex</option>
    <option>inline flex</option>
    <option>inline-grid</option>
    <option>inline grid</option>
    <option>inline-grid-lanes</option>
    <option>inline grid-lanes</option>
  </select>
</div>
```

CSS

```
html {
  font-family: "Helvetica", "Arial", sans-serif;
  letter-spacing: 1px;
  padding-top: 10px;
}

article {
  background-color: red;
}

article span {
  background-color: black;
  color: white;
  margin: 1px;
}

article,
span {
  padding: 10px;
  border-radius: 7px;
```

```
}

article,
div {
  margin: 20px;
}
```

JavaScript

```
const articles = document.querySelectorAll(".container");
const select = document.querySelector("select");

function updateDisplay() {
  articles.forEach((article) => {
    article.style.display = select.value;
  });
}

select.addEventListener("change", updateDisplay);

updateDisplay();
```

Result

Note that some multi-keyword values are added for illustration which have the following equivalents:

- `block` = `block flow`
- `inline` = `inline flow`
- `flow` = `block flow`
- `flow-root` = `block flow-root`
- `table` = `block table`
- `flex` = `block flex`
- `grid` = `block grid`
- `list-item` = `block flow list-item`
- `inline-block` = `inline flow-root`
- `inline-table` = `inline table`
- `inline-flex` = `inline flex`
- `inline-grid` = `inline grid`

You can find more examples in the pages for each separate display type under Grouped values.

dominant-baseline CSS property

The **`dominant-baseline`** CSS property specifies the specific baseline used to align the box's text and inline-level contents. It also indicates the default alignment baseline of any boxes participating in baseline alignment in the box's alignment context. If present, it overrides the shape's `dominant-baseline` attribute.

Baselines are selected from the font baseline table. If there is no baseline table in the nominal font, or if the baseline table lacks an entry for the desired baseline, then the browser may use heuristics to determine the position of the desired baseline.

The `dominant-baseline` property is used to determine or re-determine a *scaled-baseline-table*. A scaled-baseline-table is a compound value with three components:

1. a baseline-identifier for the dominant-baseline,
2. a baseline-table, and
3. a baseline-table font-size.

Some values of `dominant-baseline` re-determine all three values. Others only re-establish the baseline-table font-size. When the initial value, `auto`, would give an undesired result, this property can be used to explicitly set the desired scaled-baseline-table.

> **Note:** The `dominant-baseline` property only has an effect on the `<text>`, `<textPath>`, and `<tspan>` SVG elements.

Syntax

```
/* Initial value */
dominant-baseline: auto;

/* Keyword values */
dominant-baseline: alphabetic;
dominant-baseline: central;
dominant-baseline: hanging;
dominant-baseline: ideographic;
dominant-baseline: mathematical;
dominant-baseline: middle;
dominant-baseline: text-bottom;
dominant-baseline: text-top;

/* Global values */
dominant-baseline: inherit;
dominant-baseline: initial;
dominant-baseline: revert;
dominant-baseline: revert-layer;
dominant-baseline: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

If this property is applied to a `<text>` element, then the computed value depends on the value of the `writing-mode` attribute.

If the `writing-mode` is horizontal, then the value of the dominant-baseline component is `alphabetic`. Otherwise, if the `writing-mode` is vertical, then the value of the dominant-baseline component is `central`.

If this property is applied to a `<tspan>`, or `<textPath>` element, then the dominant-baseline and the baseline-table components remain the same as those of the parent text content element.

If the computed `baseline-shift` value actually shifts the baseline, then the baseline-table font-size component is set to the value of the `font-size` attribute on the element on which the `dominant-baseline` attribute occurs, otherwise the baseline-table font-size remains the same as that of the element.

If there is no parent text content element, the scaled-baseline-table value is constructed as for `<text>` elements.

`alphabetic`

The baseline-identifier for the dominant-baseline is set to be `alphabetic`, the derived baseline-table is constructed using the `alphabetic` baseline-table in the font, and the baseline-table font-size is changed to the value of the element's `font-size` SVG attribute or the CSS `font-size`, if set.

`central`

The baseline-identifier for the dominant-baseline is set to be `central`. The derived baseline-table is constructed from the defined baselines in the font's baseline-table. That font baseline-table is chosen using the following priority order of baseline-table names: `ideographic`, `alphabetic`, `hanging`, `mathematical`. The baseline-table font-size is changed to the value of the element's `font-size` SVG attribute or the CSS `font-size`, if set.

`hanging`

The baseline-identifier for the dominant-baseline is set to be `hanging`, the derived baseline-table is constructed using the `hanging` baseline-table in the font, and the baseline-table font-size is changed to the value of the `font-size` SVG attribute of `font-size` CSS property on this element.

`ideographic`

The baseline-identifier for the dominant-baseline is set to be `ideographic`, the derived baseline-table is constructed using the `ideographic` baseline-table in the font, and the baseline-table font-size is changed to the value of the value of the element's `font-size` SVG attribute or the CSS `font-size`, if set.

`mathematical`

The baseline-identifier for the dominant-baseline is set to be `mathematical`, the derived baseline-table is constructed using the `mathematical` baseline-table in the font, and the baseline-table font-size is changed to the value of the value of the element's `font-size` SVG attribute or the CSS `font-size`, if set.

`middle`

The baseline-identifier for the dominant-baseline is set to be `middle`. The derived baseline-table is constructed from the defined baselines in a baseline-table in the font. That font baseline-table is chosen using the following priority order of baseline-table names: `ideographic`, `alphabetic`, `hanging`, `mathematical`. The baseline-table font-size is changed to the value of the element's `font-size` SVG attribute or the CSS `font-size`, if set.

`text-bottom`

The *line-under* edge is used as the baseline, which is usually the bottom edge of the font's em box.

`text-top`

The *line-over* edge is used as the baseline, which is usually the top edge of the font's em box.

Formal definition

Initial value	`auto`
Applies to	Block-containers, flex containers, grid containers, inline boxes, table rows, and SVG text content elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
dominant-baseline =
  auto               |
  <baseline-metric>

<baseline-metric> =
  text-bottom   |
  alphabetic    |
  ideographic   |
  middle        |
  central       |
  mathematical  |
  hanging       |
  text-top
```

This syntax reflects the latest standard as per CSS Inline Layout Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Example

```
<svg viewBox="0 0 450 160" width="700" height="200">
  <text x="50" y="20">alphabetic</text>
  <text x="50" y="60">central</text>
  <text x="50" y="100">hanging</text>
  <text x="50" y="140">ideographic</text>
  <text x="250" y="20">mathematical</text>
  <text x="250" y="60">middle</text>
  <text x="250" y="100">text-bottom</text>
  <text x="250" y="140">text-top</text>
  <path
    d="M   0,20 l 400,0
       m -400,40 l 400,0
       m -400,40 l 400,0
       m -400,40 l 400,0"
    stroke="grey" />
  <text x="0" y="20" fill="red">auto</text>
  <text x="0" y="60" fill="red">auto</text>
  <text x="0" y="100" fill="red">auto</text>
```

```
  <text x="0" y="140" fill="red">auto</text>
</svg>
```

```
text {
  font-size: 20px;
}
text:nth-of-type(1) {
  dominant-baseline: alphabetic;
}
text:nth-of-type(2) {
  dominant-baseline: central;
}
text:nth-of-type(3) {
  dominant-baseline: hanging;
}
text:nth-of-type(4) {
  dominant-baseline: ideographic;
}
text:nth-of-type(5) {
  dominant-baseline: mathematical;
}
text:nth-of-type(6) {
  dominant-baseline: middle;
}
text:nth-of-type(7) {
  dominant-baseline: text-bottom;
}
text:nth-of-type(8) {
  dominant-baseline: text-top;
}
```

dynamic-range-limit CSS property

The **`dynamic-range-limit`** CSS property specifies the maximum luminance allowed for High Dynamic Range (HDR) content.

Syntax

```
/* Keyword values */
dynamic-range-limit: standard;
dynamic-range-limit: no-limit;
dynamic-range-limit: constrained;

/* dynamic-range-limit-mix() function */
dynamic-range-limit: dynamic-range-limit-mix(standard 70%, no-limit 30%);

/* Global values */
dynamic-range-limit: inherit;
dynamic-range-limit: initial;
dynamic-range-limit: revert;
dynamic-range-limit: revert-layer;
dynamic-range-limit: unset;
```

Values

This property is specified as a single value from the following list:

`standard`

Specifies the maximum luminance as High Dynamic Range (HDR) reference white, which is the CSS color `white`.

`no-limit`

Specifies the maximum luminance as much greater than that of HDR reference white. The precise level is not specified. This is the initial value.

`constrained`

Specifies the maximum luminance as somewhat greater than that of HDR reference white, such that a mix of Standard Dynamic Range (SDR) and HDR content can be comfortably viewed together. The precise level is not specified.

`dynamic-range-limit-mix()`

Specifies the maximum luminance as a custom value that is a combination of the different keyword values proportionate to the provided percentages. It takes two or more pairs, each consisting of a `dynamic-range-limit` keyword or a nested `dynamic-range-limit-mix()` function and a percentage.

Description

The `dynamic-range-limit` property specifies the maximum luminance allowed in displays capable of displaying high dynamic range colors. A **dynamic range** is the difference in luminance (brightness) between the lightest and darkest parts of content. Dynamic range is measured in photographic stops, where an increase of one stop represents a doubling of the luminance.

SDR, HDR, and headroom

Traditional web content uses **Standard Dynamic Range (SDR)**, where the brightest color is equivalent to the CSS color `white` (`#ffffff` in hexadecimal). The brightness in **High Dynamic Range (HDR)** content, on the other hand, can go beyond the standard white. In HDR terminology, the standard CSS `white` is also called the HDR reference white.

The peak luminance at which content can be displayed depends on the content, the available display hardware, and user preferences. The amount by which the peak luminance of white can exceed HDR reference white is termed **HDR headroom** and is typically expressed in photographic stops.

SDR content always has an HDR headroom of `0` because its brightest white *is* the HDR reference white. Older monitors may also have an HDR headroom of `0` because they are not able to display brighter colors. Newer monitors may have an HDR headroom greater than `0`, allowing them to display the brighter colors available in HDR content.

The use-case for <code>dynamic-range-limit</code>

The brightness of HDR content can be jarring to the viewer. This is especially apparent in apps where a mixture of HDR and SDR content is displayed, leading to inconsistency in the brightness.

The `dynamic-range-limit` property allows you to control the brightness of HDR content. For example, you might want to constrain the maximum brightness of all thumbnails in a photo or video gallery to HDR reference white (this is what the `standard` keyword value does) or to a brightness only slightly more than the HDR reference white (using the `constrained` keyword value or a custom limit created using `dynamic-range-limit-mix()`). When a user views a single HDR image, or if the user selects a preference to enable it, you could then set the image's `dynamic-range-limit` to `no-limit`.

Formal definition

Initial value	`no-limit`
Applies to	all elements
Inherited	yes
Computed value	See Computed value for dynamic-range-limit
Animation type	By `dynamic-range-limit-mix()`

Formal syntax

```
dynamic-range-limit =
  standard                    |
  no-limit                    |
  constrained                 |
  <dynamic-range-limit-mix()>

<dynamic-range-limit-mix()> =
  dynamic-range-limit-mix( [ <'dynamic-range-limit'> && <percentage [0,100]> ]# )

<dynamic-range-limit> =
  standard                    |
  no-limit                    |
  constrained                 |
  <dynamic-range-limit-mix()>
```

This syntax reflects the latest standard as per CSS Color HDR Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic <code>dynamic-range-limit</code> usage

This example demonstrates the basic use of the `dynamic-range-limit` property and the difference between HDR and SDR images.

HTML

In the markup, we embed an HDR image using an `<img>` element. We include a `tabindex` value of `0` to make the image focusable via the keyboard.

```
<img
  src="https://mdn.github.io/shared-assets/images/examples/ultra-hdr.jpg"
  alt="A subway station platform with bright white overhead strip lights"
  tabindex="0" />
```

CSS

We constrain the image to SDR brightness by setting the `dynamic-range-limit` property to `standard`, which makes the image no brighter than HDR reference white. We also set a `transition` property so that the `<img>` element's `dynamic-range-limit` value transitions over `0.6` seconds when its state changes.

```
img {
  dynamic-range-limit: standard;
  transition: dynamic-range-limit 0.6s;
}
```

On hover or focus, we change the value of the `<img>` element's `dynamic-range-limit` to `no-limit` so that it displays as brightly as the browser and display setup allow.

```
img:hover,
img:focus {
  dynamic-range-limit: no-limit;
}
```

```
img {
  max-height: 100vh;
}
@media not (dynamic-range: high) {
  body::before {
    content: "Your device may not display the image at full brightness.";
    background-color: wheat;
    display: block;
    text-align: center;
  }
}
@supports not (dynamic-range-limit: standard) {
  body::before {
    content: "Your browser doesn't support the dynamic-range-limit property.";
    background-color: wheat;
    display: block;
    text-align: center;
  }
}
```

Results

The image is ultra HDR but is constrained to SDR brightness by default. Hover over or focus the image. Note how it transitions to vivid HDR colors on capable displays.

empty-cells CSS property

The **`empty-cells`** CSS property sets whether borders and backgrounds appear around `<table>` cells that have no visible content.

This property has an effect only when the `border-collapse` property is `separate`.

Try it

```
empty-cells: show;
```

```
empty-cells: hide;
```

```
<section class="default-example" id="default-example">
  <table class="transition-all" id="example-element">
    <tbody>
      <tr>
        <th>Client Name</th>
        <th>Age</th>
      </tr>
      <tr>
        <td></td>
        <td>25</td>
      </tr>
      <tr>
        <td>Louise Q.</td>
        <td></td>
      </tr>
      <tr>
        <td>Owen B.</td>
        <td></td>
      </tr>
      <tr>
        <td>Stan L.</td>
        <td>71</td>
      </tr>
    </tbody>
  </table>
</section>
```

```
th,
td {
  border: 2px solid #aa1199;
  padding: 0.25rem 0.5rem;
}
```

Syntax

```
/* Keyword values */
empty-cells: show;
empty-cells: hide;

/* Global values */
empty-cells: inherit;
empty-cells: initial;
empty-cells: revert;
empty-cells: revert-layer;
empty-cells: unset;
```

Values

This property is specified as one of the following keyword values:

`show`

Borders and backgrounds are drawn like in normal cells.

`hide`

No borders or backgrounds are drawn.

Formal definition

Initial value	`show`
Applies to	table-cell elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
empty-cells =
  show  |
  hide
```

This syntax reflects the latest standard as per CSS Table Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Showing and hiding empty table cells

HTML

```
<table class="table_1">
  <tbody>
    <tr>
      <td>Moe</td>
      <td>Larry</td>
    </tr>
    <tr>
      <td>Curly</td>
      <td></td>
    </tr>
  </tbody>
</table>
```

```
<br />
<table class="table_2">
  <tbody>
    <tr>
      <td>Moe</td>
      <td>Larry</td>
    </tr>
    <tr>
      <td>Curly</td>
      <td></td>
    </tr>
  </tbody>
</table>
```

CSS

```
.table_1 {
  empty-cells: show;
}

.table_2 {
  empty-cells: hide;
}

td,
th {
  border: 1px solid gray;
  padding: 0.5rem;
}
```

field-sizing CSS property

The **`field-sizing`** CSS property enables you to control the sizing behavior of elements that are given a default preferred size, such as form control elements. This property enables you to override the default sizing behavior, allowing form controls to adjust in size to fit their contents.

This property is typically used to style text `<input>` and `<textarea>` elements to allow them to shrinkwrap their content as well as grow when more text is entered into the form control.

Syntax

```
/* Keyword values */
field-sizing: content;
field-sizing: fixed;

/* Global values */
field-sizing: inherit;
field-sizing: initial;
field-sizing: revert;
field-sizing: revert-layer;
field-sizing: unset;
```

Values

This property is specified as one of the following keyword values:

`content`

Allows the element to adjust its size to fit its contents.

`fixed`

Sets a fixed size for the element. This is the default value.

Description

`field-sizing: content` overrides the default preferred sizing of form elements. This setting provides a way to configure text inputs to shrinkwrap their content and grow as more text is entered. They stop expanding when they reach maximum size limits (defined by the size of their containing element or set via CSS), at which point scrolling is required to view all the content.

Elements affected by <code>field-sizing: content</code>

Specifically, `field-sizing` to `content` affects the following elements:

- Form input types that accept direct text input from users. This includes `email`, `number`, `password`, `search`, `tel`, `text`, and `url` types.
  - If no minimum width is set on the control, it will only be as wide as the text cursor.
  - Controls with `placeholder` attributes will be rendered large enough to display the placeholder text.
  - The `size` attribute modifies the default preferred size of such `<input>` elements. As a result, `size` has no effect on `<input>` elements with `field-sizing: content` set.
- `file` inputs. Direct text input is not possible; however, the displayed filename changes as the user selects a new file to upload. When `field-sizing: content` is set, the control will change size to shrinkwrap the filename.
- `<textarea>` controls. It is worth noting that `<textarea>` elements with `field-sizing: content` set behave much like single-line text controls, with the following additions:
  - If `<textarea>` elements are unable to grow due to a width constraint, they will start to grow in height to display additional rows of content. When a height constraint is then reached, they will then start to show a scrollbar to allow all the content to be viewed.
  - `rows` and `cols` attributes modify the default preferred size of a `<textarea>`. As a result, `rows`/`cols` have no effect on `<textarea>` elements with `field-sizing: content` set.
- `<select>` controls. These behave a bit differently to what you might expect with `field-sizing: content` set. The effect depends on the type of `<select>` control you are creating:
  - Regular drop-down boxes will change their width to always fit the displayed option value as new values are selected. (By default, the drop-down's size is set to be large enough to display the longest option value.)
  - List boxes (`<select>` elements with the `multiple` or `size` attribute) will be large enough to display all the options without needing to scroll. (By default, the drop-down box will require scrolling to view all the option values.)
  - The `size` attribute has very little effect on `<select>` elements that have `field-sizing: content` set. In such cases, the browser checks if the `size` is equal to `1` to determine whether the `<select>` control should appear as a drop-down or a listbox. However, it will always display all the options of a listbox, even if `size` is smaller than the number of options.

<code>field-sizing</code> interaction with other size settings

The sizing flexibility provided to form controls by `field-sizing: content` can be overridden if you use other CSS sizing properties. Avoid setting a fixed `width` and `height` when using `field-sizing: content` because they will reimpose a fixed size on the control. However, using properties like `min-width` and `max-width` alongside `field-sizing: content` is quite effective because they allow the control to grow and shrink with the entered text and also prevent the control from becoming too large or too small.

The `maxlength` attribute causes the control to stop growing in size when the maximum character limit is reached.

Formal definition

Initial value	`fixed`
Applies to	Elements with default preferred size
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
field-sizing =
  fixed    |
  content
```

This syntax reflects the latest standard as per CSS Form Control Styling Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Growing and shrinking text fields

This example illustrates the effect of `field-sizing: content` on single- and multi-line text fields. The fields adjust their size as text is added or removed, effectively shrinkwrapping the contents, until a lower or upper size limit is reached.

HTML

The HTML in this example contains four form fields, each with an associated `<label>`: three `<input>` elements of types `text`, `email`, and `tel`, and a `<textarea>` element.

```
<div>
  <label for="name">Enter name:</label>
  <input type="text" id="name" />
</div>
<div>
  <label for="email">Enter email:</label>
  <input type="email" id="email" placeholder="e.g. a@b.com" />
</div>
<div>
  <label for="tel">Enter telephone:</label>
  <input type="tel" id="tel" maxlength="15" />
</div>
<div>
  <label for="comment">Enter comment:</label>
  <textarea id="comment">This is a comment.</textarea>
</div>
```

Note the following points about the HTML:

- The first two fields have no length restrictions set.
- The third field (of type `tel`) has a `maxlength` attribute set, which stops the size of the field from increasing when the character limit is reached.
- The `<textarea>` will grow in the inline direction until the edge of the `min-width` constraint (set in the CSS code below) is reached, then start to add new lines in the block direction to contain subsequent characters.
- The `email` input has a placeholder set. This causes the field to render big enough to show the entire placeholder. Once the field is focused and the user starts typing, the field changes size to the `min-width` value. The `text` field, which doesn't have a placeholder, renders initially at `min-width`.

CSS

In the CSS, we set `field-sizing: content` on the three form fields, along with a `min-width` and `max-width` to constrain the input size. It is worth reiterating that, if no minimum width was set on the fields, they would be rendered only as wide as the text cursor.

We also give the `<label>`s some rudimentary styling so that they sit neatly next to the fields.

```
body {
  box-sizing: border-box;
  padding: 20px;
}

div {
  margin-bottom: 20px;
  display: flex;
}
```

```
input,
textarea {
  field-sizing: content;
  min-width: 50px;
  max-width: 350px;
}

label {
  width: 150px;
  margin-right: 20px;
  text-align: right;
}
```

Result

Try entering and removing text in the fields below to explore the effects of `field-sizing: content` alongside other sizing properties.

Controlling <code><select></code> element display

This example illustrates the effect of `field-sizing: content` on `<select>` elements, both drop-down menu types and multiline listbox types.

HTML

The HTML contains two sets of `<select>` elements: one with `field-sizing: content` applied, and one without, allowing you to see the difference (though the effect may be less obvious than on text fields). Each set includes one drop-down menu type and one multiline listbox type (with the `multiple` attribute set).

```
<div class="field-sizing">
  <h2>With <code>field-sizing: content</code></h2>
  <select>
    <option>Bananas</option>
    <option>Strawberries</option>
    <option selected>Apples</option>
    <option>Raspberries</option>
    <option>Pomegranate</option>
  </select>
  <select multiple>
    <option>Bananas</option>
    <option>Strawberries</option>
    <option>Apples</option>
    <option>Raspberries</option>
    <option>Pomegranate</option>
  </select>
</div>
<div>
  <h2>Without <code>field-sizing: content</code></h2>
  <select>
    <option>Bananas</option>
    <option>Strawberries</option>
    <option selected>Apples</option>
    <option>Raspberries</option>
    <option>Pomegranate</option>
  </select>
  <select multiple>
    <option>Bananas</option>
    <option>Strawberries</option>
    <option>Apples</option>
    <option>Raspberries</option>
    <option>Pomegranate</option>
  </select>
</div>
```

> **Note:** Best practice is to include a `<label>` element for each form control, to associate a meaningful text description with each field for accessibility purposes (see Use meaningful text labels for more information). We haven't done so in this example, as it focuses purely on aspects of the form controls' visual rendering, but you should make sure you include form labels in production code.

CSS

In the CSS, `field-sizing: content` is set only on the first set of `<select>` elements.

```
body {
  box-sizing: border-box;
  display: flex;
  gap: 20px;
  font-family: sans-serif;
}

h2 {
  margin-top: 0;
  font-size: 1rem;
  text-align: center;
  flex: 1 0 100%;
}

div {
  margin-bottom: 20px;
  flex: 1;
  display: flex;
  align-items: flex-start;
  justify-content: space-around;
  flex-flow: row wrap;
}
```

```
.field-sizing select {
  field-sizing: content;
}
```

Result

Note the following effects of `field-sizing: content`:

- The drop-down menu always fits the size of the displayed option, changing size as different options are selected. Without `field-sizing: content`, the size is fixed as wide as the longest option.
- The multi-select list box displays all of the options at once. Without `field-sizing: content`, the user has to scroll the box to view all the options.

- `<select>`
- `<textarea>`

fill CSS property

The **`fill`** CSS property defines how SVG text content and the interior canvas of SVG shapes are filled or painted. If present, it overrides the element's `fill` attribute.

The areas inside the outline of the SVG shape or text are painted. What is "inside" a shape may not always be clear. The paths defining a shape may overlap. The areas considered "inside" these complex shapes are clarified by the `fill-rule` property or attribute.

If subpaths are open, `fill` closes the path before painting, as if a "closepath" command were included connecting the last point of the subpath with the first point of the subpath. In other words, `fill` applies to open subpaths within `path` elements (i.e., subpaths without a closepath command) and `polyline` elements.

> **Note:** The `fill` property only applies to `<circle>`, `<ellipse>`, `<path>`, `<polygon>`, `<polyline>`, `<rect>`, `<text>`, `<textPath>`, and `<tspan>` elements nested in an `<svg>`. It doesn't apply to other SVG, HTML, or pseudo-elements.

Syntax

```
/* Keyword values */
fill: none;
fill: context-fill;
fill: context-stroke;

/* <color> values */
fill: red;
fill: hsl(120deg 75% 25% / 60%);

/* <url> values */
fill: url("#gradientElementID");
fill: url("star.png");

/* <url> with fallback */
fill: url("#gradientElementID") blue;
fill: url("star.png") none;

/* Global values */
fill: inherit;
fill: initial;
fill: revert;
fill: revert-layer;
fill: unset;
```

Values

This property is specified as a single value from the following list or as two values when using `<url>`:

`none`

No `fill` is painted; the areas inside the stroke, if any, are transparent.

`context-fill`

Uses the paint value of `fill` from a context element.

`context-stroke`

Uses the paint value of `stroke` from a context element.

`<color>`

The color of the fill as any valid CSS `<color>` value.

`<url>`

A URL reference to an SVG paint server element, such as a `<linearGradient>`, `<radialGradient>`, or `<pattern>`. The resource reference can optionally be followed by a `<color>` or `none`, which will be used as a fallback if the referenced paint server doesn't resolve.

Formal definition

Initial value	`black`
Applies to	SVG shapes and text content elements
Inherited	yes
Computed value	as specified, but with `<color>` values computed and `<url>` values made absolute
Animation type	by computed value type

Formal syntax

```
fill =
  <paint>

<paint> =
  none         |
  <image>      |
  <svg-paint>

<image> =
  <url>           |
  <image()>       |
  <image-set()>   |
  <cross-fade()>  |
  <element()>     |
  <gradient>

<svg-paint> =
  child               |
  child( <integer> )

<image()> =
  image( <image-tags>? [ <image-src>? , <color>? ]! )

<image-set()> =
  image-set( <image-set-option># )

<cross-fade()> =
  cross-fade( <cf-image># )

<element()> =
  element( <id-selector> )
```

```
<integer> =
  <number-token>

<image-tags> =
  ltr  |
  rtl

<image-src> =
  <url>     |
  <string>

<image-set-option> =
  [ <image> | <string> ] [ <resolution> || type( <string> ) ]?

<cf-image> =
  [ <image> | <color> ]  &&
  <percentage [0,100]>?

<id-selector> =
  <hash-token>
```

This syntax reflects the latest standard as per CSS Fill and Stroke Module Level 3, CSS Images Module Level 4, CSS Images Module Level 5, CSS Specification, CSS Values and Units Module Level 4, Selectors Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Defining fill values for SVG elements

This example demonstrates how a `fill` is declared, the effect of the property, and how the CSS `fill` property takes precedence over the `fill` attribute.

HTML

We have an SVG with two complex shapes defined using the SVG `<polygon>` and `<path>` elements. Both have the `fill` attribute set to the default `black`. We add a dark gray stroke of `#666666` using the SVG `stroke` attribute but could have used the `stroke` property.

```
<svg viewBox="0 0 220 120" xmlns="http://www.w3.org/2000/svg">
  <path
    d="M 10,5 l 90,0 -80,80 0,-60 80,80 -90,0 z"
    stroke="#666666"
    fill="black" />
  <polygon
    points="180,10 150,100 220,40 140,40 210,100"
    stroke="#666666"
    fill="black" />
</svg>
```

CSS

We set `fill` values on the shapes in the SVG.

```
svg {
  border: 1px solid;
  height: calc(100vh - 20px);
  margin-bottom: 10px;
}
```

```
path {
  fill: red;
}
polygon {
  fill: hsl(0deg 100% 50% / 60%);
}
```

Results

The CSS `fill` property value overrides the SVG `fill` attribute value, resulting in both shapes being filled with a red color; the polygon's red is translucent.

Using fill keyword values

This example demonstrates using keyword values for `fill`.

HTML

We include three `<path>` elements and a `<marker>` element that adds a `<circle>` to every path point. We set the circle marker to be black with a gray fill with the SVG `stroke` and `fill` attributes.

```
<svg xmlns="http://www.w3.org/2000/svg" viewBox="0 0 300 90">
  <path d="M 10 44.64 L 30 10 L 70 10 L 90 44.64 L 70 79.28 L 30 79.28 Z" />
  <path d="M 100 44.64 L 80 10 L 120 10 L 140 44.64 L 120 79.28 L 80 79.28 Z" />
  <path
    d="M 150 44.64 L 130 10 L 170 10 L 190 44.64 L 170 79.28 L 130 79.28 Z" />
  <marker
    id="circle"
    markerWidth="12"
    markerHeight="12"
    refX="6"
    refY="6"
    markerUnits="userSpaceOnUse">
    <circle cx="6" cy="6" r="3" stroke-width="2" stroke="black" fill="grey" />
  </marker>
</svg>
```

CSS

We set different `stroke` and `fill` colors on each path. The first path, the one with a red border, has its `fill` set to `none`. We set the circle marker's stroke and fill to the same color as the stroke of the element they're marking, using the `context-stroke` value.

```
svg {
  border: 1px solid;
  height: calc(100vh - 20px);
  margin-bottom: 10px;
}
```

```
path {
  stroke-width: 2px;
  marker: url("#circle");
}
path:nth-of-type(1) {
  stroke: red;
  fill: none;
}
path:nth-of-type(2) {
  stroke: green;
  fill: lightgreen;
}
path:nth-of-type(3) {
  stroke: blue;
  fill: lightblue;
}
circle {
  stroke: context-stroke;
  fill: context-stroke;
}
```

Results

Note how the first path has a transparent background because the `fill` is `none`, overriding the default `fill` of `black`. The circles are filled with the color of the stroke. If you change the value to `context-fill`, the circles will be transparent, `lightgreen` and `lightblue` instead of `red`, `green`, and `blue`.

Fills and fallbacks

This example demonstrates how to include a `url()` value with a fallback as a `fill` value.

HTML

We have an SVG containing two `<polygon>` stars and a `<linearGradient>` that goes from green to gold to red.

```
<svg viewBox="0 0 220 120" xmlns="http://www.w3.org/2000/svg">
  <defs>
    <linearGradient id="myGradient">
      <stop offset="5%" stop-color="green" />
      <stop offset="50%" stop-color="gold" />
      <stop offset="95%" stop-color="red" />
    </linearGradient>
  </defs>
  <polygon points="80,10 50,100 120,40 40,40 110,100" />
  <polygon points="180,10 150,100 220,40 140,40 210,100" />
</svg>
```

CSS

We set `fill` values on the polygons in the SVG, providing a `url()` value and a fallback.

```
svg {
  border: 1px solid;
  height: calc(100vh - 20px);
  margin-bottom: 10px;
}
```

```
polygon:first-of-type {
  fill: url("#myGradient") magenta;
}
polygon:last-of-type {
  fill: url("#MISSINGIMAGE") magenta;
}
```

Results

The first star has a gradient as a background. The second star uses the fallback value, as the element referenced in the `url()` does not exist.

fill-opacity CSS property

The **`fill-opacity`** CSS property defines the opacity of the painting operation (color, gradient, pattern, etc.) applied to SVG shapes or text content elements to fill the element. The property defines the opacity of the element's `fill` only; it does not affect the stroke. If present, it overrides the element's `fill-opacity` attribute.

> **Note:** The `fill-opacity` property only applies to `<circle>`, `<ellipse>`, `<path>`, `<polygon>`, `<polyline>`, `<rect>`, `<text>`, `<textPath>`, and `<tspan>` elements nested in an `<svg>`. It doesn't apply to other SVG, HTML, or pseudo-elements.

Syntax

```
/* numeric and percentage values */
fill-opacity: 0.2;
fill-opacity: 20%;

/* Global values */
fill-opacity: inherit;
fill-opacity: initial;
fill-opacity: revert;
```

```
fill-opacity: revert-layer;
fill-opacity: unset;
```

Values

The `<number>` and `<percentage>` values denote the opacity of the `fill` of the element.

`<number>`

A numeric value between `0` and `1`, inclusive.

`<percentage>`

A percentage value between `0%` and `100%`, inclusive.

With `0` or `0%`, the element is fully transparent. With `1` or `100%`, the element is fully opaque. With values in between, the element is semi-transparent, with content behind the element being visible.

Formal definition

Initial value	`1`
Applies to	SVG shapes and text content elements
Inherited	yes
Percentages	map to the range `[0,1]`
Computed value	The same as the specified value after clipping the `<number>` to the range [0.0, 1.0].
Animation type	by computed value type

Formal syntax

```
fill-opacity =
  <'opacity'>

<opacity> =
  <opacity-value>

<opacity-value> =
  <number>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Fill and Stroke Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Defining the fill opacity of SVG elements

This example demonstrates the basic use case of `fill-opacity`, and how the CSS `fill-opacity` property takes precedence over the `fill-opacity` attribute and has no effect on any `stroke` applied to a shape.

HTML

We include several different SVG graphic elements and set the `fill-opacity` attribute of each one to `1` (except `line`), meaning the fill of each element is opaque. The `fill-opacity` SVG attribute does not apply to `<line>`.

```
<svg viewBox="0 0 100 150" xmlns="http://www.w3.org/2000/svg">
  <rect x="10" y="10" width="30" height="30" fill-opacity="1" />
  <rect x="60" y="10" rx="10" ry="10" width="30" height="30" fill-opacity="1" />
  <circle cx="25" cy="75" r="20" fill-opacity="1" />
  <ellipse cx="75" cy="75" rx="20" ry="10" fill-opacity="1" />
  <line x1="50" x2="90" y1="40" y2="60" stroke="black" stroke-width="5" />
  <polyline
    points="60 90 65 100 70 95 75 110 80 105 85 120 90 115 95 130 100 125"
    fill-opacity="1" />
  <path d="M20,130 Q40,105 50,130 T90,130" fill-opacity="1" />
</svg>
```

CSS

With CSS, we use the `fill-opacity` property to override the value of the SVG `fill-opacity` attribute, giving each SVG element a different value.

We add a `stroke` to the circle and ellipse, to demonstrate that the opacity of the stroke is not impacted by the `fill-opacity` property.

Other SVG styles are set, including a background image to allow the opacity of each element to be more easily seen. These are not shown for the sake of brevity.

```
svg {
  border: 1px solid;
  height: calc(100vh - 20px);
  background: repeating-linear-gradient(
    to bottom right,
    transparent 0 10px,
    #cccccc 10px 11px
  );
}
```

```
svg > * {
  fill: black;
}
rect:last-of-type {
  fill-opacity: 0.1;
}
circle {
  fill-opacity: 0.6;
}
ellipse {
  fill-opacity: 40%;
}
line {
  fill-opacity: 10%;
}
polyline {
  fill-opacity: 50%;
```

```
}
path {
  fill-opacity: 0.5;
}

circle,
ellipse {
  stroke: black;
  stroke-width: 3px;
}
```

Results

Only two elements are fully opaque: the first rectangle and the line. The first rectangle is not matched by any of the selectors, therefore no CSS is applied and the `fill` is fully opaque. The `line` is matched, with `fill-opacity: 10%` set. However, the line has no `fill` paint operation — only the `stroke` is visible — therefore the declaration has no effect.

- `<basic-shape>` data type

fill-rule CSS property

The **`fill-rule`** CSS property defines the rule used to determine which parts of the SVG shape's canvas are included inside a shape to be filled. If present, it overrides the element's `fill-rule` attribute.

The `fill-rule` clarifies which areas of a shape should be considered "inside" the shape. It provides two values you can set to tell the browser how the inside of a shape should be determined. For shapes that don't have intersecting paths, like a circle, the bounds of what is inside a shape to be filled are intuitively clear. With complex shapes that include intersecting paths (such as a Venn diagram) or paths enclosing other paths (such as a donut), the interpretation of which sections of the shape are "inside" the shape and should be filled by the `fill` property, may not be obvious.

> **Note:** The `fill-rule` property only applies to `<path>`, `<polygon>`, `<polyline>`, `<text>`, `<textPath>`, and `<tspan>` elements nested in an `<svg>`. It doesn't apply to other SVG, HTML, or pseudo-elements.

Syntax

```
/* Keyword values */
fill-rule: evenodd;
fill-rule: nonzero;

/* Global values */
fill-rule: inherit;
fill-rule: initial;
fill-rule: revert;
fill-rule: revert-layer;
fill-rule: unset;
```

Values

This property is specified as one of the following keyword values:

`nonzero`

> For every point in the shape, a ray is drawn in a random direction to beyond the shape's outer edges. Each ray is examined to determine the places where the ray crosses the shape. Starting with a count of zero, add one each time a path segment crosses the ray from left to right and subtract one each time a path segment crosses the ray from right to left. After counting the crossings, if the result is zero then the point is outside the path. Otherwise, it is inside.

`evenodd`

> For every point in the fill rule's box, a ray is drawn in a random direction. The number of path segments from the given shape that the ray crosses are counted. If this number is odd, the point is inside; if even, the point is outside. Zero is taken to be even.

Formal definition

Initial value	`nonzero`
Applies to	SVG shapes and text content elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
fill-rule =
  nonzero  |
  evenodd
```

This syntax reflects the latest standard as per CSS Fill and Stroke Module Level 3. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Defining the fill rules for SVG elements

This example demonstrates how a `fill-rule` is declared, the effect of the property, and how the CSS `fill-rule` property takes precedence over the `fill-rule` attribute.

HTML

We define an SVG with two complex shapes defined using the SVG `<polygon>` and `<path>` elements. The polygon has the SVG `fill-rule` attribute set to `evenodd` and the star-shaped path is set to `nonzero`, which is the default. To make the lines visible, we set the outline to `red` using the SVG `stroke` attribute (we could have alternatively used the `stroke` property).

```
<p>Original SVG</p>
```

```
<svg viewBox="0 0 220 120" xmlns="http://www.w3.org/2000/svg">
  <polygon
    points="180,10 150,100 220,40 140,40 210,100"
    stroke="red"
    fill-rule="evenodd" />
  <path
    d="M 10,5 l 90,0 -80,80 0,-60 80,80 -90,0 z"
    stroke="red"
    fill-rule="nonzero" />
</svg>
```

```
<p><code>fill-rule: nonzero;</code></p>
<svg viewBox="0 0 220 120" xmlns="http://www.w3.org/2000/svg">
  <polygon
    points="180,10 150,100 220,40 140,40 210,100"
    stroke="red"
    fill-rule="evenodd" />
  <path
    d="M 10,5 l 90,0 -80,80 0,-60 80,80 -90,0 z"
    stroke="red"
    fill-rule="nonzero" />
</svg>
<p><code>fill-rule: evenodd;</code></p>
<svg viewBox="0 0 220 120" xmlns="http://www.w3.org/2000/svg">
  <polygon
    points="180,10 150,100 220,40 140,40 210,100"
    stroke="red"
    fill-rule="evenodd" />
  <path
    d="M 10,5 l 90,0 -80,80 0,-60 80,80 -90,0 z"
    stroke="red"
    fill-rule="nonzero" />
</svg>
```

The above SVG is repeated three times; we've only shown one copy for the sake of brevity.

CSS

The shapes nested in the first SVG have no CSS applied. We set the shapes inside the second SVG to use the `nonzero` value. The third SVG has all its nested shapes set to `evenodd`.

```
svg {
  border: 1px solid;
  height: calc(33vh - 2.5em);
  margin-bottom: 10px;
}
p {
  margin: 0;
}
```

```
svg:nth-of-type(2) > * {
  fill-rule: nonzero;
}
svg:nth-of-type(3) > * {
  fill-rule: evenodd;
}
```

Results

With the `nonzero` value for `fill-rule`, the "inside" of the shape is the entire shape. The `evenodd` value defines some space as empty. The first image renders the `fill-rule` included as an attribute. Declaring the `fill-rule` in the CSS overrides the attribute values in the second and third images.

filter CSS property

The **`filter`** CSS property applies graphical effects like blur or color shift to an element. Filters are commonly used to adjust the rendering of images, backgrounds, and borders.

Several functions, such as `blur()` and `contrast()`, are available to help you achieve predefined effects.

Try it

```
filter: url("/shared-assets/images/examples/shadow.svg#element-id");
```

```
filter: blur(5px);
```

```
filter: contrast(200%);
```

```
filter: grayscale(80%);
```

```
filter: hue-rotate(90deg);
```

```
filter: drop-shadow(16px 16px 20px red) invert(75%);
```

```
<section id="default-example">
  <div class="example-container">
    <img
      id="example-element"
      src="/shared-assets/images/examples/firefox-logo.svg"
```

```
      width="200" />
  </div>
</section>
```

```
.example-container {
  background-color: white;
  width: 260px;
  height: 260px;
  display: flex;
  align-items: center;
  justify-content: center;
}

#example-element {
  flex: 1;
  padding: 30px;
}
```

Syntax

```
/* <filter-function> values */
filter: blur(5px);
filter: brightness(0.4);
filter: contrast(200%);
filter: drop-shadow(16px 16px 20px blue);
filter: grayscale(50%);
filter: hue-rotate(90deg);
filter: invert(75%);
filter: opacity(25%);
filter: saturate(30%);
filter: sepia(60%);

/* URL */
filter: url("filters.svg#filter-id");

/* Multiple filters */
filter: contrast(175%) brightness(3%);
filter: drop-shadow(3px 3px red) sepia(100%) drop-shadow(-3px -3px blue);

/* Use no filter */
filter: none;

/* Global values */
filter: inherit;
filter: initial;
filter: revert;
filter: revert-layer;
filter: unset;
```

Referencing an SVG filter

You can use `url()` to reference an SVG filter element. For a reference to an SVG `<filter>` element, use the following syntax:

```
filter: url("file.svg#filter-element-id");
```

Functions

The `filter` property is specified as `none` or one or more of the functions listed below. If the parameter for any function is invalid, the function returns `none`. Except where noted, the functions that take a value expressed with a percent sign (as in `34%`) also accept the value expressed as decimal (as in `0.34`).

When the `filter` property values contains multiple functions, the filters are applied in order.

`blur()`

Applies a Gaussian blur to the input image.

```
filter: blur(5px);
```

`brightness()`

Applies a linear multiplier to the input image, making it appear more or less bright. Values are linear multipliers on the effect, with `0%` creating a completely black image, `100%` having no effect, and values over `100%` brightening the image.

```
filter: brightness(2);
```

`contrast()`

Adjusts the contrast of the input image. A value of `0%` makes the image gray, `100%` has no effect, and values over `100%` create a contrast.

```
filter: contrast(200%);
```

`drop-shadow()`

Applies the parameter `<shadow>` as a drop shadow, following the contours of the image. The shadow syntax is similar to `<box-shadow>` (defined in the CSS backgrounds and borders module), with the exception that the `inset` keyword and `spread` parameter are not allowed. As with all `filter` property values, any filters after the `drop-shadow()` are applied to the shadow.

```
filter: drop-shadow(16px 16px 10px black);
```

`grayscale()`

Converts the image to grayscale. A value of `100%` is completely grayscale. The initial value of `0%` leaves the input unchanged. Values between `0%` and `100%` produce linear multipliers on the effect.

```
filter: grayscale(100%);
```

`hue-rotate()`

Applies a hue rotation. The `<angle>` value defines the number of degrees around the hue color circle at which the input samples will be adjusted. A value of `0deg` leaves the input unchanged.

```
filter: hue-rotate(90deg);
```

`invert()`

Inverts the samples in the input image. A value of `100%` completely inverts the image. A value of `0%` leaves the input unchanged. Values between `0%` and `100%` have linear multipliers on the effect.

```
filter: invert(100%);
```

`opacity()`

Applies transparency. `0%` makes the image completely transparent and `100%` leaves the image unchanged.

```
filter: opacity(50%);
```

`saturate()`

Saturates the image, with `0%` being completely unsaturated, `100%` leaving the image unchanged, and values of over `100%` increasing saturation.

```
filter: saturate(200%);
```

`sepia()`

Converts the image to sepia, with a value of `100%` making the image completely sepia and `0%` making no change.

```
filter: sepia(100%);
```

Combining functions

You may combine any number of functions to manipulate the rendering. The filters are applied in the order declared. The following example enhances the contrast and brightness of the image:

```
filter: contrast(175%) brightness(103%);
```

Interpolation

When animated, if both the beginning and end filters have a function list of the same length without `<url>` in the same order, each of their filter functions is interpolated according to the filter function's specific rules.

If the filter lists are of different lengths, the missing equivalent filter functions from the longer list are added to the end of the shorter list. The added functions use their initial, no filter modification values. All the filters listed are then interpolated according to the filter function's specific rules. Otherwise, discrete interpolation is used.

Formal definition

Initial value	none
Applies to	all elements; In SVG, it applies to container elements excluding the `<defs>` element and all graphics elements
Inherited	no
Computed value	as specified
Animation type	a filter function list

Formal syntax

```
filter =
  none                |
  <filter-value-list>

<filter-value-list> =
  [ <filter-function> | <url> ]+

<filter-function> =
  <blur()>          |
  <brightness()>    |
  <contrast()>      |
  <drop-shadow()>   |
  <grayscale()>     |
  <hue-rotate()>    |
  <invert()>        |
  <opacity()>       |
  <sepia()>         |
  <saturate()>

<blur()> =
  blur( <length>? )

<brightness()> =
  brightness( [ <number> | <percentage> ]? )

<contrast()> =
  contrast( [ <number> | <percentage> ]? )

<drop-shadow()> =
  drop-shadow( [ <color>? && <length>{2,3} ] )

<grayscale()> =
  grayscale( [ <number> | <percentage> ]? )

<hue-rotate()> =
  hue-rotate( [ <angle> | <zero> ]? )

<invert()> =
  invert( [ <number> | <percentage> ]? )

<opacity()> =
  opacity( [ <number> | <percentage> ]? )

<sepia()> =
  sepia( [ <number> | <percentage> ]? )

<saturate()> =
  saturate( [ <number> | <percentage> ]? )
```

This syntax reflects the latest standard as per Filter Effects Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Applying filter functions

The `filter` property is applied to the second image, graying and blurring both the image and its border.

```
img {
  border: 5px solid yellow;
}
/* Gray the second image by 40% and blur by 5px */
img:nth-of-type(2) {
  filter: grayscale(0.4) blur(5px);
}
```

```
<img src="pencil.jpg" alt="Original image is sharp" />
<img src="pencil.jpg" alt="The image and border are blurred and muted" />
```

Repeating filter functions

Filter functions are applied in order of appearance. The same filter function can be repeated.

```
#MDN-logo {
  border: 1px solid blue;
  filter: drop-shadow(5px 5px 0 red) hue-rotate(180deg)
    drop-shadow(5px 5px 0 red);
}
```

```
<svg
  id="MDN-logo"
  xmlns="http://www.w3.org/2000/svg"
  viewBox="0 0 361 104.2"
  xml:space="preserve"
  role="img">
  <title>MDN Web Docs</title>
  <path

```

The filters are applied in order. This is why the drop shadows are not the same color: the first drop shadow's hue is altered by the `hue-rotate()` function but the second one is not.

flex CSS property

The **`flex`** CSS shorthand property sets how a flex item will grow or shrink to fit the space available in its flex container.

Try it

```
flex: 1;
```

```
flex: 2;
```

```
flex: 1 30px;
```

```
flex: 1 1 100px;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">Change me</div>
  <div>flex: 1</div>
  <div>flex: 1</div>
</section>
```

```
.default-example {
  border: 1px solid #c5c5c5;
  width: auto;
  max-height: 300px;
  display: flex;
}

.default-example > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
  margin: 10px;
  flex-grow: 1;
  flex-shrink: 1;
  flex-basis: 0;
}

#example-element {
```

```
  background-color: rgb(255 0 200 / 0.2);
  border: 3px solid rebeccapurple;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `flex-grow`
- `flex-shrink`
- `flex-basis`

Syntax

```
/* Keyword values */
flex: none; /* 0 0 auto */

/* One value, unitless number: flex-grow
flex-basis is then equal to 0%. */
flex: 2; /* 2 1 0% */

/* One value, width/height: flex-basis */
flex: auto; /* 1 1 auto */
flex: 10em; /* 1 1 10em */
flex: 30%;
flex: min-content;

/* Two values: flex-grow | flex-basis */
flex: 1 30px; /* 1 1 30px */

/* Two values: flex-grow | flex-shrink */
flex: 2 2; /* 2 2 0% */

/* Three values: flex-grow | flex-shrink | flex-basis */
flex: 2 2 10%;

/* Global values */
flex: inherit;
flex: initial; /* 0 1 auto */
flex: revert;
flex: revert-layer;
flex: unset;
```

The `flex` property may be specified using one, two, or three values.

- **One-value syntax:** the value must be one of:
  - a valid value for `flex-grow`: then the shorthand expands to `flex: <flex-grow> 1 0%`.
  - a valid value for `flex-basis`: then the shorthand expands to `flex: 1 1 <flex-basis>`.
  - the keyword `none` or one of the global keywords.
- **Two-value syntax:**
  - The first value must be a valid value for `flex-grow`.
  - The second value must be one of:
    - a valid value for `flex-shrink`: then the shorthand expands to `flex: <flex-grow> <flex-shrink> 0%`.
    - a valid value for `flex-basis`: then the shorthand expands to `flex: <flex-grow> 1 <flex-basis>`.
- **Three-value syntax:** the values must be in the following order:
  1. a valid value for `flex-grow`.
  2. a valid value for `flex-shrink`.
  3. a valid value for `flex-basis`.

Values

`<'flex-grow'>`

Defines the `flex-grow` of the flex item. Negative values are considered invalid. Defaults to `1` when omitted. (initial is `0`)

`<'flex-shrink'>`

Defines the `flex-shrink` of the flex item. Negative values are considered invalid. Defaults to `1` when omitted. (initial is `1`)

`<'flex-basis'>`

Defines the `flex-basis` of the flex item. Defaults to `0%` when omitted. The initial value is `auto`.

`none`

The item is sized according to its `width` and `height` properties. It is fully inflexible: it neither shrinks nor grows in relation to the flex container. This is equivalent to setting `flex: 0 0 auto`.

Commonly desired flexbox effects can be achieved using the following `flex` values:

- `initial`: Flex item doesn't grow but can shrink. This default value expands to `flex: 0 1 auto`. The item is sized according to its `width` or `height` properties, depending on the `flex-direction`. If there is negative available space, the item will shrink to its minimum size to fit within the container but will not grow to absorb any positive space available in the flex container.
- `auto`: Flex item can grow and shrink. This value expands to `flex: 1 1 auto`. The item is sized according to its `width` or `height` properties, depending on the `flex-direction`, but grows to absorb available positive space in the flex container or shrink down to its minimum size to fit the container in the case of negative space. The flex item is fully flexible.
- `none`: The flex item neither grows nor shrinks. This value expands to `flex: 0 0 auto`. The item is sized according to its `width` or `height` properties, depending on the direction of the flex container. The flex item is fully inflexible.
- `flex: <number [1,∞]>`: The flex item's main size will be proportional to the number set. This value expands to `flex: <number> 1 0%`. This sets the `flex-basis` to `0%` and makes the flex item flexible. The item will be at least as wide or tall as its minimum size, with the container's positive available space being proportionally distributed based on the growth factors of this item and its sibling flex items. If all the flex items use this pattern, all will be sized in proportion to their numeric values.

Description

For most purposes, authors should set `flex` to one of the following values: `auto`, `initial`, `none`, or a positive unitless number. To see the effect of these values, try resizing the flex containers below:

```
<div class="flex-container">
  <div class="item auto">auto</div>
  <div class="item auto">auto</div>
  <div class="item auto">auto</div>
</div>

<div class="flex-container">
  <div class="item auto">auto</div>
  <div class="item initial">initial</div>
  <div class="item initial">initial</div>
</div>

<div class="flex-container">
  <div class="item auto">auto</div>
  <div class="item auto">auto</div>
  <div class="item none">none</div>
</div>

<div class="flex-container">
  <div class="item initial">initial</div>
  <div class="item none">none</div>
  <div class="item none">none</div>
</div>

<div class="flex-container">
  <div class="item four">4</div>
  <div class="item two">2</div>
  <div class="item one">1</div>
</div>
```

```
* {
  box-sizing: border-box;
}

.flex-container {
  background-color: #f4f7f8;
  resize: horizontal;
  overflow: hidden;
  display: flex;
  margin: 1em;
}

.item {
  margin: 1em;
  padding: 0.5em;
  width: 110px;
  min-width: 0;
  background-color: #1b5385;
  color: white;
  font-family: monospace;
  font-size: 13px;
}

.initial {
  flex: initial;
}

.auto {
  flex: auto;
}

.none {
  flex: none;
}

.four {
  flex: 4;
}

.two {
  flex: 2;
}

.one {
  flex: 1;
}
```

By default flex items don't shrink below their `min-content` size. To change this, set the item's `min-width` or `min-height`.

Formal definition

Initial value	as each of the properties of the shorthand: • `flex-grow`: `0` • `flex-shrink`: `1` • `flex-basis`: `auto`
Applies to	flex items, including in-flow pseudo-elements
Inherited	no
Computed value	as each of the properties of the shorthand: • `flex-grow`: as specified • `flex-shrink`: as specified • `flex-basis`: as specified, but with relative lengths converted into absolute lengths
Animation type	as each of the properties of the shorthand: • `flex-grow`: a number

	• `flex-shrink`: a number • `flex-basis`: a length, percentage or calc();

Formal syntax

```
flex =
  none                                          |
  [ <'flex-grow'> <'flex-shrink'>? || <'flex-basis'> ]

<flex-grow> =
  <number [0,∞]>

<flex-shrink> =
  <number [0,∞]>

<flex-basis> =
  content    |
  <'width'>

<width> =
  auto             |
  <box-size>       |
  <anchor-size()>

<box-size> =
  <length-percentage [0,∞]>                |
  stretch                                  |
  contain                                  |
  min-content                              |
  max-content                              |
  fit-content                              |
  stretch( <length-percentage [0,∞]> )     |
  fit-content( <length-percentage [0,∞]> ) |
  <calc-size()>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<length-percentage> =
  <length>      |
  <percentage>

<calc-size()> =
  calc-size( <calc-size-basis> , <calc-sum> )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width        |
  height       |
  block        |
  inline       |
  self-block   |
  self-inline

<calc-size-basis> =
  <size-keyword>  |
  <calc-sum>      |
  <calc-size()>   |
  any

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*

<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Sizing Module Level 3, CSS Box Sizing Module Level 4, CSS Flexible Box Layout Module Level 2, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting flex: auto

This example shows how a flex item with `flex: auto` grows to absorb any free space in the container.

HTML

```
<div id="flex-container">
  <div id="flex-auto">
    flex: auto (click to remove/add the `flex: initial` box)
  </div>
  <div id="default">flex: initial</div>
</div>
```

CSS

```
body * {
  padding: 1rem;
  user-select: none;
  box-sizing: border-box;
```

```
  font-family: "Consolas", "Arial", sans-serif;
}
```

```
#flex-container {
  border: 2px dashed gray;
  display: flex;
}

#flex-auto {
  cursor: pointer;
  background-color: wheat;

  flex: auto;
}

#default {
  background-color: lightblue;
}
```

JavaScript

```
const flexAutoItem = document.getElementById("flex-auto");
const defaultItem = document.getElementById("default");
flexAutoItem.addEventListener("click", () => {
  defaultItem.style.display =
    defaultItem.style.display === "none" ? "block" : "none";
});
```

Result

The flex container contains two flex items:

- The `#flex-auto` item has a `flex` value of `auto`. The `auto` value expands to `1 1 auto`, i.e., the item is allowed to expand.
- The `#default` item has no `flex` value set so it defaults to the `initial` value. The `initial` value expands to `0 1 auto`, i.e., the item is not allowed to expand.

The `#default` item takes up as much space as its width requires, but does not expand to take up any more space. All the remaining space is taken up by the `#flex-auto` item.

When you click the `#flex-auto` item, we set the `#default` item's `display` property to `none`, removing it from the layout. The `#flex-auto` item then expands to occupy all the available space in the container. Clicking the `#flex-auto` item again adds the `#default` item back to the container.

flex-basis CSS property

The **`flex-basis`** CSS property sets the initial main size of a flex item. It sets the size of the content box unless otherwise set with `box-sizing`.

> **Note:** It is recommended to use the `flex` shorthand with a keyword value like `auto` or `initial` instead of setting `flex-basis` on its own. The keyword values expand to reliable combinations of `flex-grow`, `flex-shrink`, and `flex-basis`, which help to achieve the commonly desired flex behaviors.

Try it

```
flex-basis: auto;
```

```
flex-basis: 0;
```

```
flex-basis: 200px;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">Item One</div>
  <div>Item Two</div>
  <div>Item Three</div>
</section>
```

```
.default-example {
  border: 1px solid #c5c5c5;
  width: auto;
  max-height: 300px;
  display: flex;
}

.default-example > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
  margin: 10px;
  flex-grow: 1;
  flex-shrink: 1;
  flex-basis: auto;
}
```

In this example, the `flex-grow` and `flex-shrink` properties are both set to `1` on all three items, indicating that the flex item can grow and shrink from the initial `flex-basis`.

The demo changes the `flex-basis` value set on the first flex item, causing it to grow or shrink to fill the available space. The other flex items will also change size; they will be at least `min-content`-sized. For example, when the `flex-basis` of the first item is set to `200px`, it will start at `200px` but then shrink to fit the space available.

If `flex-basis` is set to a value other than `auto` and there is a `width` (or `height` in case of `flex-direction: column`) set for that same flex item, the `flex-basis` value takes precedence.

Syntax

```
/* Specify <'width'> */
flex-basis: 10em;
flex-basis: 3px;
flex-basis: 50%;
```

```
flex-basis: auto;

/* Intrinsic sizing keywords */
flex-basis: max-content;
flex-basis: min-content;
flex-basis: fit-content;

/* Automatically size based on the flex item's content */
flex-basis: content;

/* Global values */
flex-basis: inherit;
flex-basis: initial;
flex-basis: revert;
flex-basis: revert-layer;
flex-basis: unset;
```

The `flex-basis` property is specified as either the keyword `content` or a `<'width'>`.

Values

`content`

Indicates automatic sizing, based on the flex item's content.

`<'width'>`

Any of the following units:

- `<length>` sets an absolute value.
- `<percentage>` sets a percentage of the width or height of the containing block's content area. Percentage values of `flex-basis` are resolved against the flex container. If the flex container's size is indefinite, the used value for `flex-basis` is `content`.
- `auto` uses the value of the `width` in horizontal writing mode, and the value of the `height` in vertical writing mode; when the corresponding value is also `auto`, the `content` value is used instead.
- `max-content` sets the intrinsic preferred width.
- `min-content` sets the intrinsic minimum width.
- `fit-content` sets the maximum possible size of a containing block's content area, bounded by the `min-content` and `max-content` values, and calculated based on the content of the current element.

Formal definition

Initial value	`auto`
Applies to	flex items, including in-flow pseudo-elements
Inherited	no
Percentages	refer to the flex container's inner main size
Computed value	as specified, but with relative lengths converted into absolute lengths
Animation type	a length, percentage or calc();

Formal syntax

```
flex-basis =
  content    |
  <'width'>

<width> =
  auto             |
  <box-size>       |
  <anchor-size()>

<box-size> =
  <length-percentage [0,∞]>                |
  stretch                                  |
  contain                                  |
  min-content                              |
  max-content                              |
  fit-content                              |
  stretch( <length-percentage [0,∞]> )     |
  fit-content( <length-percentage [0,∞]> ) |
  <calc-size()>

<anchor-size()> =
  anchor-size( [ <anchor-name> || <anchor-size> ]? , <length-percentage>? )

<length-percentage> =
  <length>      |
  <percentage>

<calc-size()> =
  calc-size( <calc-size-basis> , <calc-sum> )

<anchor-name> =
  <dashed-ident>

<anchor-size> =
  width        |
  height       |
  block        |
  inline       |
  self-block   |
  self-inline

<calc-size-basis> =
  <size-keyword>  |
  <calc-sum>      |
  <calc-size()>   |
  any

<calc-sum> =
  <calc-product> [ [ '+' | '-' ] <calc-product> ]*

<calc-product> =
  <calc-value> [ [ '*' | / ] <calc-value> ]*
```

```
<calc-value> =
  <number>        |
  <dimension>     |
  <percentage>    |
  <calc-keyword>  |
  ( <calc-sum> )

<calc-keyword> =
  e          |
  pi         |
  infinity   |
  -infinity  |
  NaN
```

This syntax reflects the latest standard as per CSS Anchor Positioning Module Level 1, CSS Box Sizing Module Level 3, CSS Box Sizing Module Level 4, CSS Flexible Box Layout Module Level 2, CSS Values and Units Module Level 4, CSS Values and Units Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting flex item initial sizes

HTML

```
<ul class="container">
  <li class="flex flex1">1: flex-basis test</li>
  <li class="flex flex2">2: flex-basis test</li>
  <li class="flex flex3">3: flex-basis test</li>
  <li class="flex flex4">4: flex-basis test</li>
  <li class="flex flex5">5: flex-basis test</li>
</ul>

<ul class="container">
  <li class="flex flex6">6: flex-basis test</li>
</ul>
```

CSS

```
.container {
  font-family: "Arial", sans-serif;
  margin: 0;
  padding: 0;
  list-style-type: none;
  display: flex;
  flex-wrap: wrap;
}

.flex {
  background: #6ab6d8;
  padding: 10px;
  margin-bottom: 50px;
  border: 3px solid #2e86bb;
  color: white;
  font-size: 14px;
  text-align: center;
  position: relative;
}

.flex::after {
  position: absolute;
  z-index: 1;
  left: 0;
  top: 100%;
  margin-top: 10px;
  width: 100%;
  color: #333333;
  font-size: 12px;
}

.flex1 {
  flex-basis: auto;
}

.flex1::after {
  content: "auto";
}

.flex2 {
  flex-basis: max-content;
}

.flex2::after {
  content: "max-content";
}

.flex3 {
  flex-basis: min-content;
}

.flex3::after {
  content: "min-content";
}

.flex4 {
  flex-basis: fit-content;
}

.flex4::after {
  content: "fit-content";
}

.flex5 {
  flex-basis: content;
}
```

```
.flex5::after {
  content: "content";
}
```

Results

Flex basis <code>0</code> vs <code>0%</code>

This example demonstrates the difference between a `flex-basis` of `0` versus a `flex-basis` of `0%` when `flex-direction` is set to `column` and the flex containers and flex items don't have a set height; while `0` is an absolute length, percentage flex-basis values resolve to `content` values.

HTML

We include two same-structure flex containers, which will be styled similarly except for their `flex-basis` values. The containers each have two children: a heading `<div>` and a `<section>`. The `<section>` element has a content `<div>` child, which will not be set as a flex item but will be given a height.

```
<div class="container basis-0">
  <div>heading</div>
  <section>
    <div class="content">flex-basis: 0;</div>
  </section>
</div>
<div class="container basis-0-percent">
  <div>heading</div>
  <section>
    <div class="content">flex-basis: 0%;</div>
  </section>
</div>
```

CSS

We style the containers as inline flex containers that will appear side by side to better enable comparing them. We set the `flex-direction` to `column`. The first container's flex items have a `flex-basis` value of `0`, while the second container's flex items have a `flex-basis` value of `0%`. Neither the flex containers nor their flex items have a height explicitly set; however, the heights of `section` elements must be at least `200px`, and their children have a height of `300px`.

```
.container {
  width: 40vw;
  padding: 1rem;
  border: 1px dashed blue;

  display: inline-flex;
  flex-direction: column;
}

section {
  outline: 1px solid red;

  overflow: auto;
  min-height: 200px;
}

.content {
  background: wheat;
  height: 300px;
}

.container.basis-0 > * {
  flex-basis: 0;
}
.container.basis-0-percent > * {
  flex-basis: 0%;
}
```

Results

In the first container, with `flex-basis: 0`, the `<section>` element has an initial main size of zero, and it grows to the `200px` minimum height. In the second container, with `flex-basis: 0%`, the `<section>` element has an initial main size of `300px` because, as the flex container doesn't have a set height, the percentage flex-basis values resolve to the `content` value.

flex-direction CSS property

The **`flex-direction`** CSS property sets how flex items are placed in the flex container defining the main axis and the direction (normal or reversed).

Try it

```
flex-direction: row;
```

```
flex-direction: row-reverse;
```

```
flex-direction: column;
```

```
flex-direction: column-reverse;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    <div>Item One</div>
    <div>Item Two</div>
    <div>Item Three</div>
```

```
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  width: 80%;
  display: flex;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
  width: 60px;
  margin: 10px;
}
```

Syntax

```
/* Keyword values */
flex-direction: row;
flex-direction: row-reverse;
flex-direction: column;
flex-direction: column-reverse;

/* Global values */
flex-direction: inherit;
flex-direction: initial;
flex-direction: revert;
flex-direction: revert-layer;
flex-direction: unset;
```

Values

This property is specified as one of the following keyword values:

`row`

Specifies the flex container's main-axis to be the same as the text direction. This is the default value.

`row-reverse`

Behaves the same as `row` but specifies the content direction to be inverted, with the first item placed at the inline-end edge.

`column`

Specifies the flex container's main-axis to be the same as the block-axis.

`column-reverse`

Behaves the same as `column` but specifies the content direction to be inverted, with the first item placed at the block-end edge.

Description

The `flex-direction` property enables you to define how flex items are placed in a flex container by setting the container's main axis and the direction of the flex items. This property is relevant only on container elements that have their `display` property set to `flex` or `inline-flex`. The `flex-direction` property, along with the `flex-wrap` property, should be set using the `flex-flow` shorthand.

When set on a flex container, the `flex-direction` property defines whether the flex items are laid out in the same direction or perpendicular to the text direction, and whether the items are laid out normally or reversed.

The default value is `row`. By default, or when `row` is explicitly set, the flex container's main-axis is defined to be the same as the text direction. The first flex item in the DOM order is placed at the inline-start and block start edges. Additional items are placed at the previous item's inline-end edge. Additional rows, if the container is set to wrap with `flex-wrap: wrap`, are added on the block-end edge. The **main-start** and **main-end** points are the same as the content direction, with main-start being the inline-start edge and the main-end being the inline-end edge, and cross-start and cross-end being the block-start and block-end edges, respectively.

The `row-reverse` value is used to change the inline-direction, behaving like `row`, but reversed. The first item is placed at the inline-end and block-start edges, with subsequent flex items being placed at the previous item's inline-start edge, and additional rows added on the block-end edge. The main-start and main-end points are the same as the inline-end and inline-start ends of the writing-mode, respectively, and cross-start and cross-end are the block-start and block-end edges, respectively.

When `flex-direction` is set to `column`, the main axis is the block axis. As with `row`, the first item is placed at the inline-start and block-start edges, but additional items are placed at the previous item's block-end edge rather than the inline edge. If set to be able to wrap, additional columns are added on the inline-end edge. The **main-start** and **main-end** points are based on the block direction of the writing mode, with main-start being the block-start edge and the main-end being the block-end edge, and cross-start and cross-end being the inline-start and inline-end edges, respectively.

With `column-reverse`, the main axis is the block axis, but starting at the block-end edge. The first item is placed at the inline-start and block-end edges, with subsequent items placed at the previous item's block-start edge. If set to be able to wrap, additional columns are added on the inline-end edge. The **main-start** and **main-end** points are based on the block direction of the writing mode, with main-start being the block-end edge and the main-end being the block-start edge, and cross-start and cross-end being the inline-start and inline-end edges, respectively.

The values `row` and `row-reverse` are affected by the directionality of the flex container. If its `dir` attribute is `ltr`, `row` represents the horizontal axis oriented from the left to the right, and `row-reverse` from the right to the left; if the `dir` attribute is `rtl`, `row` represents the axis oriented from the right to the left, and `row-reverse` from the left to the right.

Accessibility

Using the `flex-direction` property with values of `row-reverse` or `column-reverse` will create a disconnect between the visual presentation of content and DOM order. This will adversely affect the experience of users with low vision navigating the page with the aid of assistive technology such as a screen reader. If the visual (CSS) order is important, then screen reader users will not have access to the correct reading order.

Formal definition

Initial value	`row`
Applies to	flex containers
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
flex-direction =
  row             |
  row-reverse     |
  column          |
  column-reverse
```

This syntax reflects the latest standard as per CSS Flexible Box Layout Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Reversing flex container columns and rows

HTML

```
<h4>This is a Column-Reverse</h4>
<div id="col-rev" class="content">
  <div class="box red">A</div>
  <div class="box lightblue">B</div>
  <div class="box yellow">C</div>
</div>
<h4>This is a Row-Reverse</h4>
<div id="row-rev" class="content">
  <div class="box red">A</div>
  <div class="box lightblue">B</div>
  <div class="box yellow">C</div>
</div>
```

CSS

```
.content {
  width: 200px;
  height: 200px;
  border: 1px solid #c3c3c3;
  display: flex;
}

.box {
  width: 50px;
  height: 50px;
}

#col-rev {
  flex-direction: column-reverse;
}

#row-rev {
  flex-direction: row-reverse;
}

.red {
  background-color: red;
}

.lightblue {
  background-color: lightblue;
}

.yellow {
  background-color: yellow;
}
```

flex-flow CSS property

The **`flex-flow`** CSS shorthand property specifies the direction of a flex container, as well as its wrapping behavior.

Try it

```
flex-flow: row wrap;
```

```
flex-flow: row-reverse nowrap;
```

```
flex-flow: row wrap balance;
```

```
flex-flow: column wrap-reverse;
```

```
flex-flow: column wrap;
```

```
flex-flow: column balance wrap;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    <div>Item One</div>
    <div>Item Two</div>
    <div>Item Three</div>
    <div>Item Four</div>
```

```
    <div>Item Five</div>
    <div>Item Six</div>
    <div>Item Seven</div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  width: 80%;
  max-height: 300px;
  display: flex;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
  width: 60px;
  margin: 5px 10px;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `flex-direction`
- `flex-wrap`

Syntax

```
/* flex-flow: <'flex-direction'> */
flex-flow: row;
flex-flow: row-reverse;
flex-flow: column;
flex-flow: column-reverse;

/* flex-flow: <'flex-wrap'> */
flex-flow: nowrap;
flex-flow: wrap;
flex-flow: wrap-reverse;
flex-flow: wrap balance;
flex-flow: balance wrap-reverse;

/* flex-flow: <'flex-direction'> and <'flex-wrap'> */
flex-flow: row nowrap;
flex-flow: column wrap;
flex-flow: column-reverse wrap-reverse;
flex-flow: row-reverse balance wrap

/* Global values */
flex-flow: inherit;
flex-flow: initial;
flex-flow: revert;
flex-flow: revert-layer;
flex-flow: unset;
```

Values

This property is specified as a space-separated list of keywords of the following types:

`flex-direction`

A keyword specifying the main axis and direction of how flex items are placed in the flex container.

`flex-wrap`

One or two keywords specifying whether flex items can wrap onto multiple lines, and, if wrapping is allowed, sets the direction that lines are stacked and whether they are balanced.

Description

The `flex-flow` shorthand property specifies the `flex-direction` and `flex-wrap` properties, defining the direction of a flex container and its wrapping behavior. It can also define flex items to be balanced when wrapping is allowed.

For example, `column-reverse wrap` will set the main-axis to the block direction with a reversed main-start and main-end, with flex items being allowed to wrap, creating new lines if needed.

```
.container {
  flex-flow: column-reverse wrap;
}
```

To distribute the flex items evenly across each flex line, you can include the `flex-wrap` keyword `balance` in addition to `wrap`:

```
.container {
  flex-flow: column-reverse wrap balance;
}
```

Formal definition

Initial value	as each of the properties of the shorthand: • `flex-direction`: `row` • `flex-wrap`: `nowrap`
Applies to	flex containers
Inherited	no
Computed value	as each of the properties of the shorthand: • `flex-direction`: as specified • `flex-wrap`: as specified

Animation type	as each of the properties of the shorthand: • `flex-direction`: discrete • `flex-wrap`: discrete

Formal syntax

```
flex-flow =
  <'flex-direction'>  ||
  <'flex-wrap'>

<flex-direction> =
  row             |
  row-reverse     |
  column          |
  column-reverse

<flex-wrap> =
  nowrap                              |
  [ wrap | wrap-reverse ] || balance
```

This syntax reflects the latest standard as per CSS Flexible Box Layout Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example demonstrates using the `flex-flow` shorthand on a flex container so the items are laid out backwards across multiple rows.

HTML

We include a list of words in alphabetical order:

```
<ul>
  <li>Alphabet</li>
  <li>Banana</li>
  <li>Crayons</li>
  <li>Dinosaurs</li>
  <li>Eggplant</li>
  <li>Foundation</li>
  <li>Ghosts</li>
  <li>Happy</li>
  <li>Igloo</li>
  <li>Janitors</li>
  <li>Kittens</li>
  <li>Lasso</li>
  <li>Magic 8-ball</li>
  <li>Nincompoop</li>
  <li>Orange</li>
  <li>Petunia</li>
  <li>Quality</li>
  <li>Rancid</li>
  <li>Shoelace</li>
  <li>Terydactyl</li>
  <li>Umbrella</li>
  <li>Valentine</li>
  <li>Westward</li>
  <li>Xylophone</li>
</ul>
```

CSS

We set the `<ul>` to be a flex container with the `display` property, define a `width`, add a `gap` so there is some room between flex items and flex lines, and then set the `flex-flow` to wrap the items in reverse order. Additional CSS has been hidden for brevity.

```
ul {
  display: flex;
  width: 31em;
  gap: 1em;

  flex-flow: row-reverse wrap-reverse;
}
```

```
ul {
  list-style: none;
  border: 1px solid;
  font-family: sans-serif;
}
li {
  font-size: 1.25rem;
  padding: 5px;
  border: 1px solid;
  background-color: lightpink;
}
li:nth-of-type(even) {
  background-color: lightgreen;
}
```

flex-grow CSS property

The **`flex-grow`** CSS property sets the flex grow factor, which specifies how much of the flex container's **positive free space**, if any, should be assigned to the flex item's main size.

When the flex-container's main size is larger than the combined main sizes of its flex items, this positive free space can be distributed among the flex items, with each item's growth being their growth factor value as a proportion of the sum total of all the flex items' flex grow factors.

> **Note:** It is recommended to use the `flex` shorthand with a keyword value like `auto` or `initial` instead of setting `flex-grow` on its own. The keyword values expand to reliable combinations of `flex-grow`, `flex-shrink`, and `flex-basis`, which help to achieve the commonly desired flex behaviors.

Try it

```
flex-grow: 1;
```

```
flex-grow: 2;
```

```
flex-grow: 3;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">I grow</div>
  <div>Item Two</div>
  <div>Item Three</div>
</section>
```

```
.default-example {
  border: 1px solid #c5c5c5;
  width: auto;
  max-height: 300px;
  display: flex;
}

.default-example > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
  margin: 10px;
  flex-grow: 1;
  flex-shrink: 1;
  flex-basis: 0;
}
```

Syntax

```
/* <number> values */
flex-grow: 3;
flex-grow: 0.6;

/* Global values */
flex-grow: inherit;
flex-grow: initial;
flex-grow: revert;
flex-grow: revert-layer;
flex-grow: unset;
```

Values

This property is specified as the following value:

`<number>`

See `<number>`. Negative values are invalid. Defaults to 0, which prevents the flex item from growing.

Description

This property specifies how much of the remaining space in the flex container should be assigned to the item (the flex grow factor).

The main size is either the width or height of the item, depending on the `flex-direction` value.

The remaining space, or positive free space, is the size of the flex container minus the size of all flex items' sizes together. If all sibling items have the same flex grow factor, then all items will receive the same share of remaining space. The common practice is to set `flex-grow: 1`, but setting the flex grow factor for all the flex items to `88`, `100`, `1.2`, or any other value greater than `0` will produce the same result: the value is a ratio.

If the `flex-grow` values differ, the positive free space is distributed according to the ratio defined by the different flex grow factors. The `flex-grow` factor values of all the sibling flex items are added together. The flex container's positive free space, if any, is then divided by that total. The main size of each flex item with a `flex-grow` value greater than `0` will grow by this quotient multiplied by its own growth factor.

For example, if four `100px` flex items are in a `700px` container and the flex items have `flex-grow` factors of `0`, `1`, `2`, and `3`, respectively, the total main size of the four items is `400px`, meaning there is `300px` of positive free space to be distributed. The sum of the four grow factors (`0 + 1 + 2 + 3 = 6`) is equal to six. Therefore, each grow factor is equal to `50px` (`300px / 6`). Each flex item is given 50px of free space multiplied by its `flex-grow` factor — so `0`, `50px`, `100px`, and `150px` respectively. The total flex item sizes become `100px`, `150px`, `200px`, and `250px`, respectively.

`flex-grow` is generally used alongside the other `flex` shorthand properties, `flex-shrink` and `flex-basis`. Using the `flex` shorthand property is recommended to ensure all values are set.

Formal definition

Initial value	`0`
Applies to	flex items, including in-flow pseudo-elements
Inherited	no
Computed value	as specified
Animation type	a number

Formal syntax

```
flex-grow =
  <number [0,∞]>
```

This syntax reflects the latest standard as per CSS Flexible Box Layout Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting flex item grow factor

In this example, the sum of six flex-grow factors is equal to eight, meaning each growth-factor value is `12.5%` of the remaining space.

HTML

```
<h1>This is a <code>flex-grow</code> example</h1>
<p>
  A, B, C, and F have <code>flex-grow: 1</code> set. D and E have
  <code>flex-grow: 2</code> set.
</p>
<div id="content">
  <div class="box1">A</div>
  <div class="box2">B</div>
  <div class="box3">C</div>
  <div class="box4">D</div>
  <div class="box5">E</div>
  <div class="box6">F</div>
</div>
```

CSS

```
#content {
  display: flex;
}

div > div {
  border: 3px solid rgb(0 0 0 / 20%);
}

.box1,
.box2,
.box3,
.box6 {
  flex-grow: 1;
}

.box4,
.box5 {
  flex-grow: 2;
  border: 3px solid rgb(0 0 0 / 20%);
}

.box1 {
  background-color: red;
}
.box2 {
  background-color: lightblue;
}
.box3 {
  background-color: yellow;
}
.box4 {
  background-color: brown;
}
.box5 {
  background-color: lightgreen;
}
.box6 {
  background-color: brown;
}
```

Result

When the six flex items are distributed along the container's main axis, if the sum of the main content of those flex items is less than the size of the container's main axis, the extra space is distributed among the size flex items, with `A`, `B`, `C`, and `F`, each getting `12.5%` of the remaining space and `D` and `E` each getting `25%` of the extra space.

flex-line-count CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`flex-line-count`** CSS property sets the minimum number of flex lines that flex items will be balanced over in cases where a flex container's `flex-wrap` or `flex-flow` property includes the `balance` keyword.

Try it

```
flex-line-count: 1;
```

```
flex-line-count: 3;
```

```
flex-line-count: 4;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    <div>Item One</div>
    <div>Item Two</div>
    <div>Item Three</div>
    <div>Item Four</div>
```

```
    <div>Item Five</div>
    <div>Item Six</div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  width: 80%;
  display: flex;
  flex-wrap: wrap balance;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
  width: 60px;
  margin: 10px;
}
```

Syntax

```
/* Integer values */
flex-line-count: 1;
flex-line-count: 3;
flex-line-count: 12;

/* Global values */
flex-line-count: inherit;
flex-line-count: initial;
flex-line-count: revert;
flex-line-count: revert-layer;
flex-line-count: unset;
```

Values

This property is specified as the following value:

`<integer>`

A positive integer setting the minimum number of flex lines that balanced, wrapped flex items will be distributed over. The default value is `1`.

Description

The `flex-line-count` property sets the minimum number of flex lines that flex items will be distributed over in wrapping, balanced flex containers — in other words, flex containers that include a `flex-wrap` or `flex-flow` property with the `balance` keyword set in addition to the `wrap` or `wrap-reverse` keyword.

A key use case for `flex-line-count` is creating a balanced set of two (or more) columns, regardless of the number of items in a list. In such cases, setting an explicit `height` or `max-height` won't work as you don't know how much content you will have, and may end up with fewer or more columns than desired. See Creating balanced columns for an example implementation.

If `balance` is not set, or if flex items are not set to wrap onto multiple flex lines, the `flex-line-count` property has no effect.

If the `flex-line-count` value is equal to or greater than the number of flex items, there will be one flex item per flex line.

Formal definition

Initial value	`1`
Applies to	multi-line flex containers
Inherited	no
Computed value	as specified
Animation type	a number

Formal syntax

```
flex-line-count =
  <integer [1,∞]>

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Flexible Box Layout Module Level 2, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Effect of different <code>flex-line-count</code> values

This example demonstrates the effects of different values of `flex-line-count` on four boxes.

HTML

We include four container `<div>`s, each with a `class` of `box` and ten child `<div>`s; each container `<div>` has a different `id` value.

```
<div class="box" id="box-no-balance">
  <div>One</div>
  <div>Two</div>
  <div>Three</div>
  <div>Four</div>
  <div>Five</div>
  <div>Six</div>
  <div>Seven</div>
  <div>Eight</div>
  <div>Nine</div>
  <div>Ten</div>
</div>

<div class="box" id="box1">...</div>
<div class="box" id="box2">...</div>
<div class="box" id="box3">...</div>
```

```
<p>No <code>balance</code></p>

<div class="box" id="box-no-balance">
  <div>One</div>
  <div>Two</div>
  <div>Three</div>
  <div>Four</div>
  <div>Five</div>
  <div>Six</div>
  <div>Seven</div>
  <div>Eight</div>
  <div>Nine</div>
  <div>Ten</div>
</div>

<p><code>flex-line-count: 3</code></p>

<div class="box" id="box1">
  <div>One</div>
  <div>Two</div>
  <div>Three</div>
  <div>Four</div>
  <div>Five</div>
  <div>Six</div>
  <div>Seven</div>
  <div>Eight</div>
  <div>Nine</div>
  <div>Ten</div>
</div>

<p><code>flex-line-count: 4</code></p>

<div class="box" id="box2">
  <div>One</div>
  <div>Two</div>
  <div>Three</div>
  <div>Four</div>
  <div>Five</div>
  <div>Six</div>
  <div>Seven</div>
  <div>Eight</div>
  <div>Nine</div>
  <div>Ten</div>
</div>

<p><code>flex-line-count: 5</code></p>

<div class="box" id="box3">
  <div>One</div>
  <div>Two</div>
  <div>Three</div>
  <div>Four</div>
  <div>Five</div>
  <div>Six</div>
  <div>Seven</div>
  <div>Eight</div>
  <div>Nine</div>
  <div>Ten</div>
</div>
```

CSS

```
* {
  box-sizing: border-box;
}

.box {
  width: 100%;
  border: 2px dotted gray;
  margin-bottom: 20px;
  gap: 10px;
}

.box > * {
  border: 2px solid rgb(96 139 168);
  border-radius: 5px;
  background-color: lightgray;
}
```

We apply `display: flex` to all the boxes to make them flex containers, then give them a `flex-wrap` value of `wrap balance` to make all their flex children wrap onto multiple, balanced lines.

```
.box {
  display: flex;
  flex-wrap: wrap balance;
}
```

We also set a `flex` value of `1 1 150px` on the flex children, so they have a base width of `150px` and will distribute any excess space evenly across the items in each flex line.

```
.box > * {
  flex: 1 1 150px;
}
```

For the `#box-no-balance` flex container, we remove the balancing, thereby nullifying the line count, by overriding the original `flex-wrap: wrap balance` value with `wrap`. We apply different `flex-line-count` values to each flex container, incrementing them so their children are laid out over a progressively greater number of flex lines.

```
#box-no-balance {
  flex-line-count: 6;
  flex-wrap: wrap;
}
```

```
#box1 {
  flex-line-count: 3;
}

#box2 {
  flex-line-count: 4;
}

#box3 {
  flex-line-count: 5;
}
```

We've hidden the rest of the CSS for brevity.

Results

Note the following:

- As the first flex container doesn't have the `balance` keyword set in its `flex-wrap` value, its children are not given a balanced distribution and its `flex-line-count` value is ignored.
- The second flex container's `flex-line-count: 3` declaration doesn't affect the layout of the flex children; as the flex items are by default distributed over four flex lines, any value of `4` or less has no effect.

Creating balanced columns

This example demonstrates how `flex-line-count` can be used to create a balanced set of two columns.

HTML

We include an `<ol>` element containing ten `<li>` elements.

```
<ol>
  <li>
    <a href="#">The Silent Cartographer</a>, published by Meridian House,
    released March 12, 2014.
  </li>
  <li>
    <a href="#">Echoes of the Fallow Field</a>, published by Northbridge Press,
    released July 4, 2009.
  </li>

  ...
</ol>
```

```

CSS

We set the list's `display` to `flex`. We set a `flex-direction` value of `column` and a `flex-wrap` value of `balance` using the `flex-flow` shorthand so that the flex lines are arranged in columns and will balance when wrapped. The `gap` value `10px 40px` specifies a gap of `10px` between flex items within each column and `40px` between flex lines.

Finally, we set a `flex-line-count` value of `2`, meaning that, even though no fixed height is set on the list, its content will always be wrapped over two balanced columns, regardless of how much content is included.

```
ol {
  display: flex;
  gap: 10px 40px;
  flex-flow: column balance;
  flex-line-count: 2;
}
```

```
* {
  box-sizing: border-box;
}

body {
  padding: 10px 30px;
}

@supports not (flex-line-count: 3) {
  body::before {
    content: "Your browser does not support the flex-line-count property.";
    background-color: wheat;
    text-align: center;
    padding: 1rem 0;

    z-index: 1;
    position: fixed;
    inset: 40% 0 auto;
  }
}
```

We've hidden the rest of the CSS for brevity.

flex-shrink CSS property

The **`flex-shrink`** CSS property sets the flex shrink factor of a flex item. If the size of all flex items is larger than the flex container, the flex items can shrink to fit according to their `flex-shrink` value. Each flex line's negative free space is distributed between the line's flex items that have a `flex-shrink` value greater than `0`.

> **Note:** It is recommended to use the `flex` shorthand with a keyword value like `auto` or `initial` instead of setting `flex-shrink` on its own. The keyword values expand to reliable combinations of `flex-grow`, `flex-shrink`, and `flex-basis`, which help to achieve the commonly desired flex behaviors.

Try it

```
flex-shrink: 0;
```

```
flex-shrink: 1;
```

```
flex-shrink: 2;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">I shrink</div>
  <div>Item Two</div>
  <div>Item Three</div>
</section>
```

```
.default-example {
  border: 1px solid #c5c5c5;
  width: auto;
  max-height: 300px;
  display: flex;
}

.default-example > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
  margin: 10px;
  flex-grow: 1;
  flex-shrink: 1;
  flex-basis: 300px;
}
```

Syntax

```
/* <number> values */
flex-shrink: 2;
flex-shrink: 0.6;

/* Global values */
flex-shrink: inherit;
flex-shrink: initial;
flex-shrink: revert;
flex-shrink: revert-layer;
flex-shrink: unset;
```

Values

This property is specified as the following value:

`<number>`

See `<number>`. Negative values are invalid. Defaults to 1.

Description

The `flex-shrink` property specifies the flex shrink factor, which determines how much the flex item will shrink relative to the rest of the flex items in the flex container when negative free space is distributed.

This property deals with situations where the browser calculates the flex-basis values of the flex items, and finds that they are too large to fit into the flex container. As long as flex-shrink has a positive value the items will shrink in order that they do not overflow the container.

The `flex-grow` property deals with distributing available positive free space proportional to each item's flex grow factor, with the value of the `flex-grow` property as the only consideration. The `flex-shrink` property manages removing negative free space to make boxes fit into their container without overflowing. Removing space is a bit more complicated than adding space. The flex shrink factor is multiplied by the flex base size; this distributes negative space in proportion to how much the item can shrink. This prevents smaller items from shrinking to `0px` before a larger item is noticeably reduced.

Generally, `flex-shrink` is used alongside the `flex-grow` and `flex-basis` properties. Within the `flex` shorthand, the shrink factor is always the second `<number>`. If the shorthand only includes one number value, that value is assumed to be the `flex-grow` value.

Formal definition

Initial value	`1`
Applies to	flex items, including in-flow pseudo-elements
Inherited	no
Computed value	as specified
Animation type	a number

Formal syntax

```
flex-shrink =
  <number [0,∞]>
```

This syntax reflects the latest standard as per CSS Flexible Box Layout Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting flex item shrink factor

This example demonstrates how negative free space is distributed based on the item's shrink factor. It includes five flex items with a `flex-shrink` value greater than 0, which have a combined width greater than their parent flex container's width.

HTML

```
<div id="content">
  <div class="box1">A</div>
  <div class="box2">B</div>
  <div class="box3">C</div>
  <div class="box4">D</div>
  <div class="box5">E</div>
</div>
```

CSS

We give each flex item a `width` of `200px`. As the `flex-basis` property defaults to `auto`, each item's flex-basis is `200px`. This gives the flex items a total width of `1000px`, twice the size of the container. We set all flex items to be shrinkable, with `flex-shrink` values greater than `0`. The last two items have greater `flex-shrink` values set so they will shrink more.

```
#content {
  display: flex;
  width: 500px;
}

#content div {
  width: 200px;
}

.box1,
.box2,
.box3 {
  flex-shrink: 1;
}

.box4 {
  flex-shrink: 1.5;
}

.box5 {
  flex-shrink: 2;
}
```

```
#content {
  margin: 5px;
}
div {
  font-family: monospace;
  outline: 1px solid;
  line-height: 4em;
  text-align: center;
}
.box1 {
  background-color: red;
}
.box2 {
  background-color: lightblue;
}
.box3 {
  background-color: yellow;
}
.box4 {
  background-color: lightsalmon;
}
.box5 {
  background-color: lightgreen;
}
```

Result

The flex items don't overflow their container because they can shrink: the `500px` of negative free space is distributed among the five items based on their `flex-shrink` values. The total of all the shrink values for the five items is `1 + 1 + 1 + 1.5 + 2 = 6.5`. As a result, the width of items with `flex-shrink: 1` is reduced by `1/6.5 * 500px = 76.92px`, the width of items with `flex-shrink: 1.5` is reduced by `1.5/6.5 * 500px = 115.38px`, and the width of items with `flex-shrink: 2` is reduced by `2/6.5 * 500px = 153.85px`.

flex-wrap CSS property

The **`flex-wrap`** CSS property sets whether flex items are forced onto one line or can wrap onto multiple lines. If wrapping is allowed, it sets the direction that lines are stacked.

The `flex-flow` property shorthand can be used to set both the `flex-direction` and `flex-wrap` properties, which define the flex container's main and cross axes, respectively.

Try it

```
flex-wrap: nowrap;
```

```
flex-wrap: wrap;
```

```
flex-wrap: wrap-reverse;
```

```
flex-wrap: wrap balance;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    <div>Item One</div>
    <div>Item Two</div>
    <div>Item Three</div>
    <div>Item Four</div>
    <div>Item Five</div>
    <div>Item Six</div>
    <div>Item Seven</div>
  </div>
</section>
```

```
#example-element {
  border: 1px solid #c5c5c5;
  width: 80%;
  display: flex;
}

#example-element > div {
  background-color: rgb(0 0 255 / 0.2);
  border: 3px solid blue;
  width: 60px;
  margin: 10px;
}
```

Syntax

```
/* Keyword values */
flex-wrap: nowrap;
flex-wrap: wrap;
flex-wrap: wrap-reverse;
flex-wrap: balance;
flex-wrap: wrap balance;
flex-wrap: balance wrap-reverse;

/* Global values */
flex-wrap: inherit;
flex-wrap: initial;
flex-wrap: revert;
flex-wrap: revert-layer;
flex-wrap: unset;
```

Values

This property is specified as a single value from the following list or as two space-separated values when using `balance`:

`nowrap`

> The flex items are laid out in a single line which may cause the flex container to overflow. This is the initial value.

`wrap`

> The flex items can break into multiple lines.

`wrap-reverse`

> Behaves the same as `wrap`, but with the lines laid out in reverse order.

`balance`

> Specifies that flex items broken across multiple lines are distributed so that the line lengths are as similar as possible. If `balance` is specified as the only keyword, the other keyword defaults to `wrap`.

Description

The `flex-wrap` property is used to specify whether the flex container's child flex items may wrap onto multiple flex lines or not and, if set to wrap, whether the children should be evenly distributed across flex lines.

The initial value of `nowrap` specifies that all items should be laid out on a single flex line, which means they may overflow the container. The `wrap` and `wrap-reverse` keywords prevent overflow by specifying that flex items can flow, or wrap, across multiple lines.

With `wrap`, cross-start is the equivalent of inline-start or block-start, depending on the `flex-direction` value and the current writing mode. With `wrap-reverse`, cross-start is the equivalent of inline-end or block-end.

Balancing flex item distribution

By default, when `wrap` or `wrap-reverse` is specified, each flex line is filled with flex items before items are wrapped onto the next line. This can result in an uneven distribution of items, with the last flex line composed of fewer items. If those items' `flex-grow` values are non-zero, the extra available space is distributed across these fewer items, making them much larger than the items on filled flex lines.

The `balance` keyword can be used to distribute the items across lines in a more even manner. Optionally, the `flex-line-count` property can be used to define the minimum number of lines across which the balanced items should be distributed.

If `balance` is the only keyword specified, the other keyword defaults to `wrap`.

A balanced wrapping flex container can have a `flex-line-count` value applied to specify the minimum number of lines the flex items should be distributed over. The `flex-line-count` property has no effect if `balance` is not specified inside `flex-wrap`.

If `balance` is specified alongside `nowrap`, the property is invalid.

Formal definition

Initial value	`nowrap`
Applies to	flex containers
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
flex-wrap =
  nowrap                              |
  [ wrap | wrap-reverse ] || balance
```

This syntax reflects the latest standard as per CSS Flexible Box Layout Module Level 2. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting flex container wrap values

HTML

```
<h4>This is an example for flex-wrap:wrap</h4>
<div class="content">
  <div class="red">1</div>
  <div class="green">2</div>
  <div class="blue">3</div>
</div>
<h4>This is an example for flex-wrap:nowrap</h4>
<div class="content1">
  <div class="red">1</div>
  <div class="green">2</div>
  <div class="blue">3</div>
</div>
<h4>This is an example for flex-wrap:wrap-reverse</h4>
<div class="content2">
  <div class="red">1</div>
  <div class="green">2</div>
  <div class="blue">3</div>
</div>
```

CSS

```
/* Common Styles */
.content,
.content1,
.content2 {
  color: white;
  font: 100 24px/100px sans-serif;
  height: 150px;
  width: 897px;
  text-align: center;
}

.content div,
.content1 div,
.content2 div {
  height: 50%;
  width: 300px;
}
.red {
  background: orangered;
}
.green {
  background: yellowgreen;
}
.blue {
  background: steelblue;
}

/* Flexbox Styles */
.content {
  display: flex;
  flex-wrap: wrap;
}
.content1 {
  display: flex;
  flex-wrap: nowrap;
}
.content2 {
  display: flex;
  flex-wrap: wrap-reverse;
}
```

Results

Demonstrating the <code>balance</code> keyword

This example demonstrates the effects of the `balance` keyword within the `flex-wrap` property and different `flex-line-count` values.

HTML

```
<form>
  <div>
    <input type="checkbox" id="reverse" name="reverse" />
    <label for="reverse">Set <code>wrap-reverse</code>?</label>
  </div>
  <div>
    <input type="checkbox" id="balance" name="balance" checked />
    <label for="balance">Set <code>balance</code>?</label>
  </div>
  <div>
    <label for="line-count"><code>flex-line-count</code></label>
    <input
      type="range"
      id="line-count"
      name="line-count"
      min="1"
      max="12"
      value="3" />
    <output>3</output>
  </div>
</form>

<hr />

<p>Currently set: <code>flex-wrap: wrap; flex-line-count: 3;</code></p>

<hr />
```

We include a container `<div>` with a `class` of `box`, which has ten child `<div>`s.

```
<div class="box">
  <div>One</div>
  <div>Two</div>
  <div>Three</div>
  <div>Four</div>
  <div>Five</div>
  <div>Six</div>
  <div>Seven</div>
  <div>Eight</div>
  <div>Nine</div>
  <div>Ten</div>
</div>
```

We also include controls to enable changing features of the flex container, including:

- Toggling `flex-wrap` between the `wrap` and `wrap-reverse` values.
- Toggling the `balance` keyword on and off.
- Changing the `flex-line-count` value.

We've hidden the HTML and JavaScript for brevity.

CSS

We apply `display: flex` to the `.box` to turn it into a flex container, then set some `flex-wrap` and `flex-line-count` values to make the flex children wrap evenly over a minimum of three flex lines. You can change the values in the live demo. We also set a `flex` value of `1 1 150px` on the flex children so they will have a base width of `150px`, with any remaining space distributed evenly between items on the same flex line.

```
.box {
  display: flex;
  flex-wrap: wrap balance;
  flex-line-count: 3;
}

.box > * {
  flex: 1 1 150px;
}
```

```
.box {
  width: 100%;
  border: 2px dotted rgb(96 139 168);
  gap: 10px;
}

.box > * {
  border: 2px solid rgb(96 139 168);
  border-radius: 5px;
  background-color: rgb(96 139 168 / 0.2);
}

* {
  box-sizing: border-box;
}

body {
  padding: 10px 30px;
}

@supports not (flex-wrap: balance) {
  body::before {
    content: "Your browser does not support flex-wrap: balance.";
    background-color: wheat;
    text-align: center;
    padding: 1rem 0;
```

```
    z-index: 1;
    position: fixed;
    inset: 40% 0 auto;
  }
}
```

We've hidden the rest of the CSS for brevity.

```
const boxElem = document.querySelector(".box");
const outputElem = document.querySelector("output");
const pCodeElem = document.querySelector("p code");
const reverseInput = document.getElementById("reverse");
const balanceInput = document.getElementById("balance");
const lineCountInput = document.getElementById("line-count");

let wrapValue = "wrap";
let lineCountValue = "3";

function updateCurrentlySet() {
  pCodeElem.textContent = `flex-wrap: ${wrapValue}; flex-line-count: ${lineCountValue};`;
}

function setFlexWrap() {
  wrapValue = "";
  if (reverseInput.checked) {
    wrapValue += "wrap-reverse";
  } else {
    wrapValue += "wrap";
  }

  if (balanceInput.checked) {
    wrapValue += " balance";
  }

  boxElem.style.flexWrap = wrapValue;
  updateCurrentlySet();
}

function setFlexLineCount() {
  lineCountValue = lineCountInput.value;
  boxElem.style.flexLineCount = lineCountValue;
  outputElem.textContent = lineCountValue;
  updateCurrentlySet();
}

reverseInput.addEventListener("change", setFlexWrap);
balanceInput.addEventListener("change", setFlexWrap);
lineCountInput.addEventListener("input", setFlexLineCount);
```

Results

Change the form control settings to see how they affect the output. Note how:

- Toggling between `wrap` and `wrap-reverse` changes the direction in which the flex lines are laid out along the cross-axis.
- Setting `balance` causes the flex items to be evenly distributed across the available flex lines.
- Changing the `flex-line-count` value changes the minimum number of lines the items will be distributed across. The `flex-line-count` property, and therefore the slider, has no effect unless `balance` is checked.
- As the flex items are distributed over four flex lines by default, changing the `flex-line-count` to a value of less than `5` has no effect. Values from `5` to `10` add an extra flex line.
- As there are 10 flex items, `flex-line-count` values of `10` or greater will all have the same effect — one item will be placed on each of 10 flex lines.

float CSS property

The **`float`** CSS property places an element on the left or right side of its container, allowing text and inline elements to wrap around it. The element is removed from the normal flow of the page, though still remaining a part of the flow (in contrast to absolute positioning).

Try it

```
float: none;
```

```
float: left;
```

```
float: right;
```

```
float: inline-start;
```

```
float: inline-end;
```

```
<section class="default-example" id="default-example">
  <div class="example-container">
    <div class="transition-all" id="example-element">Float me</div>
    As much mud in the streets as if the waters had but newly retired from the
    face of the earth, and it would not be wonderful to meet a Megalosaurus,
    forty feet long or so, waddling like an elephantine lizard up Holborn Hill.
  </div>
</section>
```

```
.example-container {
  border: 1px solid #c5c5c5;
  padding: 0.75em;
```

```
  text-align: left;
  width: 80%;
  line-height: normal;
}

#example-element {
  border: solid 10px #efac09;
  background-color: #040d46;
  color: white;
  padding: 1em;
  width: 40%;
}
```

A *floating element* is one where the computed value of `float` is not `none`.

As `float` implies the use of the block layout, it modifies the computed value of the `display` values, in some cases:

Specified value	Computed value
`inline`	`block`
`inline-block`	`block`
`inline-table`	`table`
`table-row`	`block`
`table-row-group`	`block`
`table-column`	`block`
`table-column-group`	`block`
`table-cell`	`block`
`table-caption`	`block`
`table-header-group`	`block`
`table-footer-group`	`block`
`inline-flex`	`flex`
`inline-grid`	`grid`
other	*unchanged*

> **Note:** When accessing a CSS property in JavaScript through the `HTMLElement.style` object, single-word property names are used as is. Although `float` is a reserved keyword in JavaScript, the CSS `float` property is accessed as `float` in modern browsers. In older browsers, you must use `cssFloat` to access the `float` property. (This is similar to how the "class" attribute is accessed as "className" and the "for" attribute of a `<label>` element is accessed as "htmlFor".)

Syntax

```
/* Keyword values */
float: left;
float: right;
float: none;
float: inline-start;
float: inline-end;

/* Global values */
float: inherit;
float: initial;
float: revert;
float: revert-layer;
float: unset;
```

Values

This property is specified as one of the following keyword values:

`left`

The element must float on the left side of its containing block.

`right`

The element must float on the right side of its containing block.

`none`

The element must not float.

`inline-start`

The element must float on the start side of its containing block. That is the left side with `ltr` scripts, and the right side with `rtl` scripts.

`inline-end`

The element must float on the end side of its containing block. That is the right side with `ltr` scripts, and the left side with `rtl` scripts.

Formal definition

Initial value	none
Applies to	all elements, but has no effect if the value of `display` is `none`.
Inherited	no
Computed value	as specified
Animation type	discrete

Formal syntax

```
float =
  block-start      |
  block-end        |
  inline-start     |
  inline-end       |
  snap-block       |
  <snap-block()>   |
  snap-inline      |
  <snap-inline()>  |
  left             |
  right            |
  top              |
  bottom           |
  none             |
  footnote

<snap-block()> =
  snap-block( <length> , [ start | end | near ]? )

<snap-inline()> =
  snap-inline( <length> , [ left | right | near ]? )
```

This syntax reflects the latest standard as per CSS Generated Content for Paged Media Module, CSS Page Floats. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

How floated elements are positioned

As mentioned above, when an element is floated, it is taken out of the normal flow of the document (though still remaining part of it). It is shifted to the left, or right, until it touches the edge of its containing box, *or another floated element.*

In this example, there are three colored squares. Two are floated left, and one is floated right. Note that the second "left" square is placed to the right of the first. Additional squares would continue to stack to the right, until they filled the containing box, after which they would wrap to the next line.

A floated element is at least as tall as its tallest nested floated children. We gave the parent `width: 100%` and floated it to ensure it is tall enough to encompass its floated children, and to make sure it takes up the width of the parent so we don't have to clear its adjacent sibling.

HTML

```
<section>
  <div class="left">1</div>
  <div class="left">2</div>
  <div class="right">3</div>
  <p>
    Lorem ipsum dolor sit amet, consectetur adipiscing elit. Morbi tristique
    sapien ac erat tincidunt, sit amet dignissim lectus vulputate. Donec id
    iaculis velit. Aliquam vel malesuada erat. Praesent non magna ac massa
    aliquet tincidunt vel in massa. Phasellus feugiat est vel leo finibus
    congue.
  </p>
</section>
```

CSS

```
section {
  box-sizing: border-box;
  border: 1px solid blue;
  width: 100%;
  float: left;
}

div {
  margin: 5px;
  width: 50px;
  height: 150px;
}

.left {
  float: left;
  background: pink;
}

.right {
  float: right;
  background: cyan;
}
```

Result

Clearing floats

Sometimes you may want to force an item to move below any floated elements. For instance, you may want paragraphs to remain adjacent to floats, but force headings to be on their own line. See `clear` for examples.

See also

- Block formatting context
- Use `clear` to force an item to move below a floated element.

flood-color CSS property

The **`flood-color`** CSS property defines the color of the current filter primitive subregion in `<feFlood>` and `<feDropShadow>` elements within a `<filter>`. If present, it overrides the element's `flood-color` attribute.

> **Note:** The `flood-color` property only applies to `<feFlood>` and `<feDropShadow>` elements nested in an `<svg>`. It doesn't apply to other SVG, HTML, or pseudo-elements.

Syntax

```
/* <color> values */
flood-color: red;
flood-color: hsl(120deg 75% 25% / 60%);
flood-color: currentColor;

/* Global values */
flood-color: inherit;
flood-color: initial;
flood-color: revert;
flood-color: revert-layer;
flood-color: unset;
```

Values

This property is specified as one `<color>` value:

`<color>`

The flood's color. This can be any valid CSS `<color>` value.

Formal definition

Initial value	`black`
Applies to	`<feFlood>` and `<feDropShadow>` elements in `<svg>`
Inherited	no
Computed value	as specified
Animation type	by computed value

Formal syntax

```
flood-color =
  <color>
```

This syntax reflects the latest standard as per Filter Effects Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Defining the color of a filters flood

This example demonstrates the basic use case of `flood-color`, and how the CSS `flood-color` property takes precedence over the `flood-color` attribute.

HTML

We have an SVG with two `<filter>` elements, each with a `<feFlood>` child. Each `<feFlood>` element includes the SVG `flood-color` attribute defining the flood color as `seagreen`. We included two `<rect>` elements with a filter attribute; this is where the filters will be displayed.

```
<svg viewBox="0 0 420 120" xmlns="http://www.w3.org/2000/svg">
  <filter id="flood1">
    <feFlood flood-color="seagreen" />
  </filter>
  <filter id="flood2">
    <feFlood flood-color="seagreen" />
  </filter>

  <rect id="r1" filter="url(#flood1)" />
  <rect id="r2" filter="url(#flood2)" />
</svg>
```

CSS

We define the size and position of our `<rect>` using the CSS `height`, `width`, `x`, and `y` properties:

```
rect {
  width: 100px;
  height: 100px;
  x: 10px;
  y: 10px;
}
#r2 {
  x: 150px;
}
```

We then apply different flood color values to the `<feFlood>` elements using the CSS `flood-color` property. We use a named color and a 3-digit hexadecimal color, but we can use any valid CSS color syntax:

```
#flood1 feFlood {
  flood-color: rebeccapurple;
}
#flood2 feFlood {
  flood-color: #ff3366;
}
```

Results

The attributes defined the squares as seagreen, but these values were overridden by the CSS `flood-color` values.

- `stop-color`
- `stroke`
- `box-shadow`

- `text-shadow`
- `background-color`
- `<color>`
- `<filter-function>`
- SVG `flood-color` attribute

flood-opacity CSS property

The **`flood-opacity`** CSS property defines the opacity of the current filter primitive subregion in `<feFlood>` and `<feDropShadow>` elements within a `<filter>`. If present, it overrides the element's `flood-opacity` attribute.

The property value impacts the `flood-color`'s alpha channel; it can increase the transparency of a `flood-color` but cannot make the color defined by the `flood-color` property more opaque.

> **Note:** The `flood-opacity` property only applies to `<feFlood>` and `<feDropShadow>` elements nested in an `<svg>`. It doesn't apply to other SVG, HTML, or pseudo-elements.

Syntax

```
/* numeric and percentage values */
flood-opacity: 0.2;
flood-opacity: 20%;

/* Global values */
flood-opacity: inherit;
flood-opacity: initial;
flood-opacity: revert;
flood-opacity: revert-layer;
flood-opacity: unset;
```

Values

The `<opacity-value>` is a `<number>` or `<percentage>` denoting the opacity of the SVG gradient `<flood>` element.

`<number>`

A numeric value between `0` and `1`, inclusive.

`<percentage>`

A percentage value between `0%` and `100%`, inclusive.

With `0` or `0%` set, the flood is fully transparent. With `1` or `100%` set, the element is the full opacity of the `flood-color` value, which may or may not be partially opaque.

Formal definition

Initial value	`black`
Applies to	`<feFlood>` and `<feDropShadow>` elements in `<svg>`
Inherited	no
Computed value	the specified value, clipped in the range `[0,1]`
Animation type	by computed value

Formal syntax

```
flood-opacity =
  <'opacity'>

<opacity> =
  <opacity-value>

<opacity-value> =
  <number>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Color Module Level 4, Filter Effects Module Level 1. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Defining the flood opacity of a filter

This example demonstrates the basic use case of `flood-opacity`, and how the CSS `flood-opacity` property takes precedence over the `flood-opacity` attribute.

HTML

We have an SVG with a few `<filter>` elements, each with a `<feFlood>` child. The `<feFlood>` define the filters as `seagreen`, with the first being declared by its `flood-opacity` attribute as fully opaque and the second being fully transparent. We included two `<rect>` elements, each with a filter attribute.

```
<svg viewBox="0 0 420 120" xmlns="http://www.w3.org/2000/svg">
  <filter id="flood1">
    <feFlood flood-color="seagreen" flood-opacity="1" />
  </filter>
  <filter id="flood2">
    <feFlood flood-color="seagreen" flood-opacity="0" />
  </filter>

  <rect id="r1" filter="url(#flood1)" />
  <rect id="r2" filter="url(#flood2)" />
</svg>
```

CSS

We define the `height`, `width`, `x`, and `y`,positioning of our rectangles with CSS, and include a repeating linear gradient as a `background-image` on the SVG so the opacity of the flood-color is more apparent:

```
svg {
  background-image: repeating-linear-gradient(
    45deg,
    transparent 0 9px,
```

```
    #cccccc 0px 10px
  );
}
rect {
  width: 100px;
  height: 100px;
  x: 10px;
  y: 10px;
}
#r2 {
  x: 150px;
}
```

We then apply different flood opacity values to the `<feFlood>` elements using the CSS `flood-opacity`: property:

```
#flood1 feFlood {
  flood-opacity: 0.5;
}
#flood2 feFlood {
  flood-opacity: 90%;
}
```

Results

The attributes defined the first square as fully opaque and the second as fully transparent, but these values were overridden by the CSS `flood-opacity` values. The seagreen filters are 50% and 90% opaque, respectively.

- SVG `flood-opacity` attribute

font CSS property

The **`font`** CSS shorthand property sets all the different properties of an element's font. Alternatively, it sets an element's font to a system font.

Try it

```
font:
  1.2rem "Fira Sans",
  sans-serif;
```

```
font:
  italic 1.2rem "Fira Sans",
  serif;
```

```
font: italic small-caps bold 16px/2 cursive;
```

```
font: small-caps bold 24px/1 sans-serif;
```

```
font: caption;
```

```
<section id="default-example">
  <q id="example-element">
    Prejudices, it is well known, are most difficult to eradicate from the heart
    whose soil has never been loosened or fertilized by education: they grow
    there, firm as weeds among stones.
  </q>
</section>
```

```
@font-face {
  font-family: "Fira Sans";
  src:
    local("FiraSans-Regular"),
    url("/shared-assets/fonts/FiraSans-Regular.woff2") format("woff2");
  font-weight: normal;
  font-style: normal;
}

@font-face {
  font-family: "Fira Sans";
  src:
    local("FiraSans-Italic"),
    url("/shared-assets/fonts/FiraSans-Italic.woff2") format("woff2");
  font-weight: normal;
  font-style: italic;
}

section {
  margin-top: 10px;
  font-size: 1.1em;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- `font-family`
- `font-size`

- font-width
- font-style
- font-variant
- font-weight
- line-height

Reset-only sub-properties

This property resets the following CSS properties to their initial values:

- font-feature-settings
- font-kerning
- font-language-override
- font-optical-sizing
- font-size-adjust
- font-variant-alternates
- font-variant-caps
- font-variant-east-asian
- font-variant-emoji
- font-variant-ligatures
- font-variant-numeric
- font-variant-position
- font-variation-settings

Syntax

```
/* font-size font-family */
font: 1.2em sans-serif;

/* font-size/line-height font-family */
font: 1.2em/2 "Fira Sans", sans-serif;

/* font-style font-weight font-size font-family */
font: italic bold 1.2em monospace;

/* font-width font-variant font-size font-family */
font: ultra-condensed small-caps 1.2em Montserrat, Helvetica, sans-serif;

/* system font */
font: caption;
```

Values

The value is either a shorthand specifying the various font-related properties or a single `<system-font-family-name>` keyword:

`<'font-style'>` Optional

See the `font-style` CSS property. Defaults to `normal`.

`<font-variant-css2>` Optional

Either the `normal` or `small-caps` value of the `font-variant` property. Defaults to `normal`.

`<'font-weight'>` Optional

See the `font-weight` CSS property. Defaults to `normal`.

`<font-width-css3>` Optional

The keywords supported by the `font-width` CSS property. Defaults to `normal`.

`<'font-size'>`

See the `font-size` CSS property.

`<'line-height'>` Optional

See the `line-height` CSS property. Defaults to `normal`.

`<'font-family'>`

See the `font-family` CSS property. Must be the last value.

`<system-font-family-name>`

A single keyword representing a system font, including:

`caption`

The system font used for captioned controls (buttons, drop-downs, etc.).

`icon`

The system font used to label icons.

`menu`

The system font used in menus (e.g., dropdown menus and menu lists).

`message-box`

The system font used in dialog boxes.

`small-caption`

The system font used for labeling small controls.

`status-bar`

The system font used in window status bars.

There are several non-standard values implemented with prefixes.

Description

The `font` property value is either a single keyword representing a system-font-family-name or multiple longhand property values used to set all the different properties of an element's font.

System font declarations

If `font` is specified as a `<system-font-family-name>` keyword, the full property value must be set to that single, case-insensitive keyword. Valid values include `caption`, `icon`, `menu`, `message-box`, `small-caption`, or `status-bar`.

Browsers also support non-standard prefixed values:

- Chromium implements `-webkit-control`, `-webkit-small-control`, and `-webkit-mini-control`.
- Webkit includes the Chromium values, and adds `-webkit-body`, `-webkit-pictograph`, and `-webkit-ruby-text`, along with several `-apple-system-*` prefixed system font names.
- Gecko implements `-moz-window`, `-moz-document`, `-moz-desktop`, `-moz-info`, `-moz-dialog`, `-moz-button`, `-moz-pull-down-menu`, `-moz-list`, and `-moz-field`.

The system font, or `<system-font-family-name>`, can only be set with the `font` property. Defining a single keyword value, such as `font: icon`, sets the font's family, size, weight, style, etc., to the values the browser defines for the named system font. These values can all be changed with longhand declarations placed *after* the `font` declaration.

Including any `font` longhand components after the `<system-font-family-name>` keyword within a `font` property value invalidates the declaration. For example, `font: icon small` is invalid.

If a `<system-font-family-name>` keyword appears anywhere in the value other than as the first component, the keyword is treated as an `<ident>` representing a standard `font-family` name. For example, the declaration `font: small icon` sets the `font-family` to a font named `icon`, a non-system font which may or may not exist. This declaration also sets the `font-size` to `small` and resets all the other shorthand component properties to their initial values.

Shorthand font declarations

If `font` is specified as a shorthand for several font-related properties, then:

- it must include values for:
  - `font-size`
  - `font-family`
- it may optionally include values for:
  - `font-style`
  - `font-variant`
  - `font-weight`
  - `font-width`
  - `line-height`

As with any shorthand property, any of the longhand component properties not specified are set to their initial values, possibly overriding values previously set using non-shorthand properties. In addition, the shorthand resets the following properties to their initial values. The shorthand cannot explicitly set them:

- `font-feature-settings`
- `font-kerning`
- `font-language-override`
- `font-optical-sizing`
- `font-size-adjust`
- `font-variant-alternates`
- `font-variant-caps`
- `font-variant-east-asian`
- `font-variant-emoji`
- `font-variant-ligatures`
- `font-variant-numeric`
- `font-variant-position`
- `font-variation-settings`

Shorthand property order

The order of some of the longhand values within the shorthand `font` declaration must follow a few rules:

- Both the `font-size` and `font-family` components are required (except for system font declarations).
- The `font-style`, `font-variant` and `font-weight` components must precede the `font-size` value.
- A `line-height` can only be included if `font-size` is included. If present, the `line-height` must immediately follow the `font-size`, with the two values separated by a forward slash (`/`), for example: `16px / 3`.
- The `font-family` must be the last value specified.

Components with limited values

For backward compatibility, the valid values of the `font-variant` and `font-width` components do not include all the valid values or the longhand equivalents.

The valid values for the `font-variant` component are limited to `normal` or `small-caps`. While no other values are supported, the shorthand `font` declaration resets all the `font-variant-*` longhand properties to `normal`, including `font-variation-settings`, `font-variant-position`, `font-variant-emoji`, `font-variant-caps`, `font-variant-ligatures`, `font-variant-numeric`, `font-variant-east-asian`, and `font-variant-alternates`.

The valid values for the `font-width` component are limited to keyword values: `normal`, `ultra-condensed`, `extra-condensed`, `condensed`, `semi-condensed`, `semi-expanded`, `expanded`, `extra-expanded`, `ultra-expanded`. The `font-width` longhand property also supports `<percentage>` values, but they are not valid within the shorthand.

Formal definition

Initial value	as each of the properties of the shorthand: • `font-style`: `normal` • `font-variant`: `normal` • `font-weight`: `normal` • `font-stretch`: `normal` • `font-size`: `medium` • `line-height`: `normal` • `font-family`: depends on user agent
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Percentages	as each of the properties of the shorthand:

	• `font-size`: refer to the parent element's font size • `line-height`: refer to the font size of the element itself
Computed value	as each of the properties of the shorthand: • `font-style`: as specified • `font-variant`: as specified • `font-weight`: the keyword or the numerical value as specified, with `bolder` and `lighter` transformed to the real value • `font-stretch`: as specified • `font-size`: absolute `<length>` • `line-height`: for percentage and length values, the absolute length, otherwise as specified • `font-family`: as specified
Animation type	as each of the properties of the shorthand: • `font-style`: by computed value type; `normal` animates as `oblique 0deg` • `font-variant`: discrete • `font-weight`: by computed value type • `font-stretch`: by computed value type • `font-size`: by computed value type • `line-height`: either number or length • `font-family`: discrete

Formal syntax

```
font =
  [ [ <'font-style'> || <font-variant-css2> || <'font-weight'> || <font-width-css3> ]? <'font-size'> [ / <'line-height'> ]? <'font-family'># ]  |

```

This syntax reflects the latest standard as per CSS Fonts Module Level 4, CSS Inline Layout Module Level 3, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage

This example defines the `font` for all `<p>` elements. We set the `font-size` to `12px` and the `line-height` to `14px`, separating them with a forward slash (`/`). The declaration also sets the `font-family` to `sans-serif`.

```
p {
  font: 12px / 14px sans-serif;
}
```

```
<p>
  This is a paragraph of sans-serif text. The font-size is small, at just 12px.
  If this text wraps, the line height is pretty tight at 14px, so this may be
  difficult to read.
</p>
```

Multiple properties

In this example, we set the `font-weight` to `bold`, the `font-style` to `italic`, the `font-size` to `large`, the `line-height` to `1.6`, and the `font-family` to `serif`.

```
p {
  font: bold italic large / 1.6 serif;
}
```

```
<p>
  In this example, we set the font weight to bold, the font style to italic, the
  font size to large, the line height to 1.6, and the font family to serif.
</p>
```

System font

This example demonstrates using the `font` property to set a system font.

CSS

We set the paragraph's font to have the same `font-family`, `line-height`, `font-size`, etc., as the status bar of the window, then we set the `line-height` to `1.6`.

```
p {
  font: status-bar;
  line-height: 1.6;
}
```

HTML

Our HTML includes a paragraph (`<p>`) containing a link (`<a>`) with a convoluted `href` attribute value. When you hover or focus the rendered link, your browser's status bar should display the value of the `href` attribute.

```
<p>
  <a
    href="/%20The%20font%20should%20be%20the%20same%20
family%20and%20size%20and%20the%20text%20in%20the%20example."
    >Hover or focus this text. The font should be the same family and size and
    the text in your status bar.</a
  >
</p>
```

JavaScript

As the URL in our HTML link is not good practice, we include a script that prevents the document from redirecting to a non-existent page when the link is clicked.

```
const aElem = document.querySelector("a");
aElem.addEventListener("click", (e) => {
  e.preventDefault();
  return false;
});
```

Result

Hover or focus the link. The font should be the same family and size as the text in your status bar at the bottom of your browser window.

Shorthand declaration creator

In this live demonstration, you can select different radio buttons to generate different shorthand values, while visualizing the effects of the shorthand declarations you create.

```
<p>
  Change the radio buttons below to see the generated shorthand and its effect.
</p>
<form action="createShortHand()">
  <div class="cf">
    <div class="setPropCont">
      font-style<br />
      <input
        type="radio"

font-family CSS property

The **`font-family`** CSS property specifies a prioritized list of one or more font family names and/or generic family names for the selected element.

Try it

```
font-family: "Georgia", serif;
```

```
font-family: "Gill Sans", sans-serif;
```

```
font-family: sans-serif;
```

```
font-family: serif;
```

```
font-family: cursive;
```

```
font-family: system-ui;
```

```
<section id="default-example">
  <p id="example-element">
    London. Michaelmas term lately over, and the Lord Chancellor sitting in
    Lincoln's Inn Hall. Implacable November weather. As much mud in the streets
    as if the waters had but newly retired from the face of the earth, and it
    would not be wonderful to meet a Megalosaurus, forty feet long or so,
    waddling like an elephantine lizard up Holborn Hill.
  </p>
</section>
```

```
section {
  font-size: 1.2em;
}
```

Values are separated by commas to indicate that they are alternatives. The browser will select the first font in the list that is installed or that can be downloaded using a `@font-face` at-rule.

It is often convenient to use the shorthand property `font` to set `font-size` and other font related properties all at once.

You should always include at least one generic family name in a `font-family` list, since there's no guarantee that any given font is available. This lets the browser select an acceptable fallback font when necessary.

The `font-family` property specifies a list of fonts, from highest priority to lowest. Font selection *does not* stop at the first font in the list that is on the user's system. Rather, font selection is done *one character at a time*, so that if an available font does not have a glyph for a needed character, the latter fonts are tried. When a font is only available in some styles, variants, or sizes, those properties may also influence which font family is chosen.

Syntax

```
/* A font family name and a generic family name */
font-family: "Gill Sans Extrabold", sans-serif;
font-family: "Goudy Bookletter 1911", sans-serif;

/* A generic family name only */
font-family: serif;
font-family: sans-serif;
font-family: monospace;
font-family: cursive;
font-family: fantasy;
font-family: system-ui;
font-family: ui-serif;
font-family: ui-sans-serif;
font-family: ui-monospace;
font-family: ui-rounded;
font-family: math;
font-family: fangsong;

/* Global values */
font-family: inherit;
font-family: initial;
font-family: revert;
font-family: revert-layer;
font-family: unset;
```

The `font-family` property lists one or more font families, separated by commas. Each font family is specified as either a `<family-name>` or a `<generic-name>` value.

The example below lists two font families, the first with a `<family-name>` and the second with a `<generic-name>`:

```
font-family: "Gill Sans Extrabold", sans-serif;
```

Values

`<family-name>`

> The name of a font family. This must be either a single `<string>` value or a space-separated sequence of `<custom-ident>` values. String values must be quoted but may contain any Unicode character. Custom identifiers are not quoted, but certain characters must be escaped.
>
> It is good practice to quote font family names that contain white space, digits, or punctuation characters other than hyphens.
>
> See also Valid family names.

`<generic-name>`

> Generic font families are a fallback mechanism, a means of preserving some of the style sheet author's intent when none of the specified fonts are available. Generic family names are keywords and must not be quoted. A generic font family should be the last item in the list of font family names. The following keywords are defined:

`serif`

Glyphs have finishing strokes, flared or tapering ends, or have actual serifed endings.

For example: Lucida Bright, Lucida Fax, Palatino, Palatino Linotype, Palladio, URW Palladio, serif.

`sans-serif`

Glyphs have stroke endings that are plain.

For example: Open Sans, Fira Sans, Lucida Sans, Lucida Sans Unicode, Trebuchet MS, Liberation Sans, Nimbus Sans L, sans-serif.

`monospace`

All glyphs have the same fixed width.

For example: Fira Mono, DejaVu Sans Mono, Menlo, Consolas, Liberation Mono, Monaco, Lucida Console, monospace.

> **Note:** When `font-family` is set to the single keyword `monospace` and no `font-size` is set, browsers use the user's monospace font size preference, which is often smaller than the size used for proportional fonts. See Monospace font size for details and how to control this.

`cursive`

Glyphs in cursive fonts generally have either joining strokes or other cursive characteristics beyond those of italic typefaces. The glyphs are partially or completely connected, and the result looks more like handwritten pen or brush writing than printed letter work.

For example: Brush Script MT, Brush Script Std, Lucida Calligraphy, Lucida Handwriting, Apple Chancery, cursive.

`fantasy`

Fantasy fonts are primarily decorative fonts that contain playful representations of characters.

For example: Papyrus, Herculanum, Party LET, Curlz MT, Harrington, fantasy.

`system-ui`

Glyphs are taken from the default user interface font on a given platform. Because typographic traditions vary widely across the world, this generic is provided for typefaces that don't map cleanly into the other generics.

> **Note:** As the name implies, `system-ui` is intended to make UI elements look like native apps, and not for typesetting large paragraphs of text. It may cause the displayed typeface to be undesirable for some users—for example, the default Windows CJK font may render Latin scripts poorly, and the `lang` attribute may not affect the displayed font. Some operating systems do not allow customizing `system-ui`, while browsers generally allow customizing the `sans-serif` font family. For large paragraphs, use `sans-serif` or some other non-UI font family instead.

`ui-serif`

The default user interface serif font.

`ui-sans-serif`

The default user interface sans-serif font.

`ui-monospace`

The default user interface monospace font.

`ui-rounded`

The default user interface font that has rounded features.

`math`

Font that addresses the particular stylistic concerns of representing mathematics: superscript and subscript, brackets that cross several lines, nesting expressions, and double struck glyphs with distinct meanings. UA stylesheets may set `math { font-family: math }` so that the `<math>` element uses appropriate fonts by default.

`fangsong`

A particular style of Chinese characters that are between serif-style Song and cursive-style Kai forms. This style is often used for government documents.

Formal definition

Initial value	depends on user agent
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
font-family =
  [ <font-family-name> | <generic-font-family> ]#

<font-family-name> =
  <string>         |
  <custom-ident>+

<generic-font-family> =
  <generic-font-script-specific>  |
  <generic-font-complete>         |
  <generic-font-incomplete>

<generic-font-script-specific> =
  generic( fangsong )   |
  generic( kai )        |
  generic( khmer-mul )  |
  generic( nastaliq )

<generic-font-complete> =
  serif       |
```

```
  sans-serif  |
  system-ui   |
  cursive     |
  fantasy     |
  math        |
  monospace

<generic-font-incomplete> =
  ui-serif       |
  ui-sans-serif  |
  ui-monospace   |
  ui-rounded
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Some common font families

```
.serif {
  font-family: "Times", "Times New Roman", "Georgia", serif;
}

.sansserif {
  font-family: "Verdana", "Helvetica", "Arial", sans-serif;
}

.monospace {
  font-family: "Lucida Console", "Courier New", monospace;
}

.cursive {
  font-family: cursive;
}

.fantasy {
  font-family: fantasy;
}

.math {
  font-family: math;
}

.fangsong {
  font-family: fangsong;
}
```

```
div {
  margin: 0.5rem;
}
```

```
<div class="serif">This is an example of a serif font.</div>

<div class="sansserif">This is an example of a sans-serif font.</div>

<div class="monospace">This is an example of a monospace font.</div>

<div class="cursive">This is an example of a cursive font.</div>

<div class="fantasy">This is an example of a fantasy font.</div>

<div class="fangsong">This is an example of a fangsong font.</div>

<div class="math">This is an example of a math font: ℝ, ∫, ∑…</div>
```

Monospace font size

Browsers maintain separate default font size preferences for proportional fonts (such as `serif` and `sans-serif`) and for monospace fonts. Typical defaults are `16px` for proportional fonts and `13px` for monospace fonts.

When `font-family` is set to the single keyword `monospace`, browsers apply the monospace size preference. If users have not changed their browser preferences and `font-size` is not explicitly set, monospace text may be rendered smaller than surrounding content. The same reduction applies to elements whose user agent stylesheet sets `font-family: monospace`, such as `<code>` and `<pre>`.

If the `font-family` value includes more than one family, even if the value is `monospace, monospace`, browsers do not apply the monospace font size preference, and will render the text at the inherited `font-size`. Declaring `font-family: monospace, monospace` (or a named monospace font followed by `monospace`) therefore renders at the same size as surrounding proportional text. This behavior is not specified in CSS, but it is interoperable across the major browser engines.

```
<p class="proportional">
  This proportional text is at the default size; generally 16px.
</p>
<p class="mono-only">
  This monospace text is at the preferred size for monospace fonts; generally
  13px.
</p>
<p class="mono-list">
  This is in "monospace, monospace" font, rendered at the same size as
  proportional text; generally 16px.
</p>
```

```
.mono-only {
  font-family: monospace;
}

.mono-list {
  font-family: monospace, monospace;
}
```

If you haven't changed your font size in your browser settings, the first and last paragraphs will be the same font-size, rendered at the browser preferred font size. The middle paragraph will be rendered at the preferred mono-space font size, which is generally set to be smaller than the preferred font-size for other text.

Valid family names

The following declarations are valid:

```
font-family: "Goudy Bookletter 1911", sans-serif;
```

The following declarations are invalid:

```
font-family: Goudy Bookletter 1911, sans-serif;
font-family: Red/Black, sans-serif;
font-family: "Lucida" Grande, sans-serif;
font-family: Ahem!, sans-serif;
font-family: test@foo, sans-serif;
font-family: #POUND, sans-serif;
font-family: Hawaii 5-0, sans-serif;
```

The following example is technically valid but is not recommended:

```
font-family:
  Gill Sans Extrabold,
  sans-serif;
```

font-feature-settings CSS property

The **`font-feature-settings`** CSS property controls advanced typographic features in OpenType fonts.

Try it

```
font-feature-settings: normal;
```

```
font-feature-settings: "liga" 0;
```

```
font-feature-settings: "tnum";
```

```
font-feature-settings: "smcp", "zero";
```

```
<section id="default-example">
  <div id="example-element">
    <p>Difficult waffles</p>
    <table>
      <tbody>
        <tr>
          <td><span class="tabular">0O</span></td>
        </tr>
        <tr>
          <td><span class="tabular">3.14</span></td>
        </tr>
        <tr>
          <td><span class="tabular">2.71</span></td>
        </tr>
      </tbody>
    </table>
  </div>
</section>
```

```
@font-face {
  font-family: "Fira Sans";
  src:
    local("FiraSans-Regular"),
    url("/shared-assets/fonts/FiraSans-Regular.woff2") format("woff2");
  font-weight: normal;
  font-style: normal;
}

section {
  font-family: "Fira Sans", sans-serif;
  margin-top: 10px;
  font-size: 1.5em;
}

#example-element table {
  margin-left: auto;
  margin-right: auto;
}

.tabular {
  border: 1px solid;
}
```

Syntax

```
/* Use the default settings */
font-feature-settings: normal;

/* Set values for OpenType feature tags */
font-feature-settings: "smcp";
font-feature-settings: "smcp" on;
font-feature-settings: "swsh" 2;
font-feature-settings:
```

```
  "smcp",
  "swsh" 2;

/* Global values */
font-feature-settings: inherit;
font-feature-settings: initial;
font-feature-settings: revert;
font-feature-settings: revert-layer;
font-feature-settings: unset;
```

Whenever possible, Web authors should instead use the `font-variant` shorthand property or an associated longhand property such as `font-variant-ligatures`, `font-variant-caps`, `font-variant-east-asian`, `font-variant-alternates`, `font-variant-numeric` or `font-variant-position`.

These lead to more effective, predictable, understandable results than `font-feature-settings`, which is a low-level feature designed to handle special cases where no other way exists to enable or access an OpenType font feature. In particular, `font-feature-settings` shouldn't be used to enable small caps.

Values

This property is specified as either the keyword `normal` or as a comma-separated list of `<feature-tag-value>` values. When rendering text, the list of OpenType `<feature-tag-value>` values are passed to the text layout engine to enable or disable font features.

`normal`

Indicates that text is laid out using default font settings. This is the default value.

`<feature-tag-value>`

Represents a space-separated tuple consisting of a tag name and an optional value.

Tag name

The tag name is always a `<string>` of four ASCII characters. If the tag name has more or fewer characters or if it contains characters outside the `U+20` – `U+7E` code point range, the descriptor is invalid.

Optional value

The optional value can be a positive integer or the keyword `on` or `off`. The keywords `on` and `off` are synonyms for the values `1` and `0`, respectively. If no value is set, the default is `1`. For non-boolean OpenType features (e.g., stylistic alternates), the value implies a particular glyph to be selected; for boolean features, the value turns the feature on or off.

Formal definition

Initial value	`normal`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
font-feature-settings =
  normal               |
  <feature-tag-value>#

<feature-tag-value> =
  <opentype-tag> [ <integer [0,∞]> | on | off ]?

<opentype-tag> =
  <string>

<integer> =
  <number-token>
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Enabling various font features

```
/* use small-cap alternate glyphs */
.small-caps {
  font-feature-settings: "smcp" on;
}

/* convert both upper and lowercase to small caps (affects punctuation also) */
.all-small-caps {
  font-feature-settings: "c2sc", "smcp";
}

/* use zeros with a slash through them to differentiate from "O" */
.nice-zero {
  font-feature-settings: "zero";
}

/* enable historical forms */
.historical {
  font-feature-settings: "hist";
}

/* disable common ligatures, usually on by default */
.no-ligatures {
  font-feature-settings: "liga" 0;
}

/* enable tabular (monospaced) figures */
td.tabular {
  font-feature-settings: "tnum";
}

/* enable automatic fractions */
.fractions {
```

```
  font-feature-settings: "frac";
}

/* use the second available swash character */
.swash {
  font-feature-settings: "swsh" 2;
}

/* enable stylistic set 7 */
.fancy-style {
  font-family: "Gabriola", cursive;
  font-feature-settings: "ss07";
}
```

- OpenType features in CSS

font-kerning CSS property

The **`font-kerning`** CSS property sets the use of the kerning information stored in a font.

Try it

```
font-kerning: auto;
```

```
font-kerning: normal;
```

```
font-kerning: none;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    "We took Tracy to see 'THE WATERFALL' in W. Virginia."
  </div>
</section>
```

```
section {
  font-family: serif;
}
```

Kerning affects how letters are spaced. In *well-kerned* fonts, this feature makes character spacing more uniform and pleasant to read by reducing white space between certain character combinations.

In the image below, for instance, the examples on the left do not use kerning, while the ones on the right do:

Syntax

```
font-kerning: auto;
font-kerning: normal;
font-kerning: none;

/* Global values */
font-kerning: inherit;
font-kerning: initial;
font-kerning: revert;
font-kerning: revert-layer;
font-kerning: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

The browser determines whether font kerning should be used or not. For example, some browsers will disable kerning on small fonts, since applying it could harm the readability of text.

`normal`

Font kerning information stored in the font must be applied.

`none`

Font kerning information stored in the font is disabled.

Formal definition

Initial value	`auto`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
font-kerning =
  auto    |
  normal  |
  none
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Enabling and disabling kerning

HTML

```
<div id="kern"></div>
<div id="no-kern"></div>
<textarea id="input">AV T. ij</textarea>
```

CSS

```
div {
  font-size: 2rem;
  font-family: serif;
}

#no-kern {
  font-kerning: none;
}

#kern {
  font-kerning: normal;
}
```

JavaScript

```
const input = document.getElementById("input");
const kern = document.getElementById("kern");
const noKern = document.getElementById("no-kern");

input.addEventListener("keyup", () => {
  kern.textContent = input.value; /* Update content */
  noKern.textContent = input.value;
});

kern.textContent = input.value; /* Initialize content */
noKern.textContent = input.value;
```

font-language-override CSS property

The **`font-language-override`** CSS property controls the use of language-specific glyphs in a typeface.

By default, HTML's `lang` attribute tells browsers to display glyphs designed specifically for that language. For example, a lot of fonts have a special character for the digraph `fi` that merge the dot on the "i" with the "f." However, if the language is set to Turkish the typeface will likely know not to use the merged glyph; Turkish has two versions of the "i," one with a dot (`i`) and one without (`ı`), and using the ligature would incorrectly transform a dotted "i" into a dotless "i."

The `font-language-override` property lets you override the typeface behavior for a specific language. This is useful, for example, when the typeface you're using lacks proper support for the language. For instance, if a typeface doesn't have proper rules for the Azeri language, you can force the font to use Turkish glyphs, which follow similar rules.

Syntax

```
/* Keyword value */
font-language-override: normal;

/* <string> values */
font-language-override: "ENG"; /* Use English glyphs */
font-language-override: "TRK"; /* Use Turkish glyphs */

/* Global values */
font-language-override: inherit;
font-language-override: initial;
font-language-override: revert;
font-language-override: revert-layer;
font-language-override: unset;
```

Values

This property is specified as a single value from the following list:

`normal`

Tells the browser to use font glyphs that are appropriate for the language specified by the `lang` attribute. This is the default value.

`<string>`

Tells the browser to use font glyphs that are appropriate for the language specified by the string. The string must match a language tag found in the OpenType language system. For example, "ENG" is English, and "KOR" is Korean.

Formal definition

Initial value	`normal`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
font-language-override =
  normal    |
  <string>
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using Danish glyphs

HTML

```
<p class="para1">Default language setting.</p>
<p class="para2">
  This is a string with the <code>font-language-override</code> set to Danish.
</p>
```

CSS

```
p.para1 {
  font-language-override: normal;
}

p.para2 {
  font-language-override: "DAN";
}
```

font-optical-sizing CSS property

The **`font-optical-sizing`** CSS property sets whether text rendering is optimized for viewing at different sizes.

Try it

```
font-optical-sizing: auto;
```

```
font-optical-sizing: none;
```

```
<section id="default-example">
  <div id="example-element">
    <h2>Chapter 3</h2>
    <p>
      On this particular Thursday, something was moving quietly through the
      ionosphere many miles above the surface of the planet; several somethings
      in fact, several dozen huge yellow chunky slablike somethings, huge as
      office blocks, silent as birds.
    </p>
  </div>
</section>
```

```
@font-face {
  src: url("/shared-assets/fonts/variable-fonts/AmstelvarAlpha-VF.woff2");
  font-family: "Amstelvar";
  font-style: normal;
}

#example-element {
  font-family: "Amstelvar", serif;
  text-align: left;
}

#example-element h2 {
  font-size: 36px;
}

#example-element p {
  font-size: 12px;
}
```

Syntax

```
/* keyword values */
font-optical-sizing: none;
font-optical-sizing: auto; /* default */

/* Global values */
font-optical-sizing: inherit;
font-optical-sizing: initial;
font-optical-sizing: revert;
```

```
font-optical-sizing: revert-layer;
font-optical-sizing: unset;
```

Values

This property is specified as one of the following keyword values:

`none`

The browser will not modify the shape of glyphs for optimal viewing.

`auto`

The browser will modify the shape of glyphs for optimal viewing.

Description

Optical sizing is enabled by default for fonts that have an optical size variation axis. The optical size variation axis is represented by `opsz` in `font-variation-settings`.

When optical sizing is used, small text sizes are often rendered with thicker strokes and larger serifs, whereas larger text is often rendered more delicately with more contrast between thicker and thinner strokes.

Formal definition

Initial value	`auto`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
font-optical-sizing =
  auto  |
  none
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Disabling optical sizing

```
<p class="optical-sizing">
  This paragraph is optically sized. This is the default across browsers.
</p>

<p class="no-optical-sizing">
  This paragraph is not optically sized. You should see a difference in
  supporting browsers.
</p>
```

```
@font-face {
  src: url("AmstelvarAlpha-VF.woff2");
  font-family: "Amstelvar";
  font-style: normal;
}

p {
  font-size: 36px;
  font-family: "Amstelvar", serif;
}

.no-optical-sizing {
  font-optical-sizing: none;
}
```

> **Note:** The font referenced above — which includes optical sizing and is freely-licensed — is good for testing. You can download it on GitHub.

font-palette CSS property

The **`font-palette`** CSS property allows specifying one of the many palettes contained in a color font that a user agent may use for the font. Users can also override the values in a palette or create a new palette by using the `@font-palette-values` at-rule.

> **Note:** A `font-palette` palette takes precedence when coloring a font. The `color` property will not override a font palette, even if specified with `!important`.

Syntax

```
/* Using a font-defined palette */
font-palette: normal;

/* Using a user-defined palette */
font-palette: --one;

/* Creating a new palette by blending two others */
font-palette: palette-mix(in lch, --blue, --yellow);
```

Values

This property is specified as a single value from the following list:

`normal`

Specifies the default color palette or the default glyph colorization (set by the font maker) to be used for the font. With this setting, the palette in the font at index 0 is rendered.

`light`

Specifies the first palette in the font that matches 'light' to be used for the font. Some fonts contain metadata that identify a palette as applicable for a light (close to white) background. If a font does not have this metadata, the `light` value behaves as `normal`.

`dark`

Specifies the first palette in the font that matches 'dark' to be used for the font. Some fonts contain metadata that identify a palette as applicable for a dark (close to black) background. If a font does not have this metadata, the value behaves as `normal`.

`<dashed-ident>`

Allows you to specify your own values for the font palette by using the `<palette-identifier>` of a @font-palette-values at-rule.

`palette-mix()`

Creates a new `font-palette` value by blending together two `font-palette` values by specified percentages and color interpolation methods.

Formal definition

Initial value	`normal`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	by computed value

Formal syntax

```
font-palette =
  normal                |
  light                 |
  dark                  |
  <palette-identifier>  |
  <palette-mix()>

<palette-identifier> =
  <dashed-ident>

<palette-mix()> =
  palette-mix( <color-interpolation-method>? , [ <'font-palette'> && <percentage [0,100]>? ]# )

<color-interpolation-method> =
  in [ <rectangular-color-space> | <polar-color-space> <hue-interpolation-method>? | <custom-color-space> ]

<font-palette> =
  normal                |
  light                 |
  dark                  |
  <palette-identifier>  |
  <palette-mix()>

<rectangular-color-space> =
  srgb              |
  srgb-linear       |
  display-p3        |
  display-p3-linear |
  a98-rgb           |
  prophoto-rgb      |
  rec2020           |
  lab               |
  oklab             |
  <xyz-space>

<polar-color-space> =
  hsl    |
  hwb    |
  lch    |
  oklch

<hue-interpolation-method> =
  [ shorter | longer | increasing | decreasing ] hue

<custom-color-space> =
  <dashed-ident>

<xyz-space> =
  xyz     |
  xyz-d50 |
  xyz-d65
```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Color Module Level 5, CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Specifying a dark palette

This example allows you to use the first palette marked as *dark* (works best on a near black background) by the font-maker.

```
@media (prefers-color-scheme: dark) {
  .banner {
    font-palette: dark;
  }
}
```

Animating between two palettes

This example illustrates how to animate `font-palette` value changes to create a smooth font animation.

HTML

The HTML contains a single paragraph of text to animate:

```
<p>color-palette<br />animation</p>
```

CSS

In the CSS, we import a color font called Nabla from Google Fonts, and define two custom `font-palette` values using the `@font-palette-values` at-rule. We then create `@keyframes` that animate between these two palettes, and apply this animation to our paragraph.

```
@import "https://fonts.googleapis.com/css2?family=Nabla&display=swap";

@font-palette-values --blue-nabla {
  font-family: "Nabla";
  base-palette: 2; /* this is Nabla's blue palette */
}

@font-palette-values --grey-nabla {
  font-family: "Nabla";
  base-palette: 3; /* this is Nabla's grey palette */
}

@keyframes animate-palette {
  from {
    font-palette: --grey-nabla;
  }

  to {
    font-palette: --blue-nabla;
  }
}

p {
  font-family: "Nabla", fantasy;
  font-size: 5rem;
  margin: 0;
  text-align: center;
  animation: animate-palette 4s infinite alternate linear;
}
```

Result

The output looks like this:

> **Note:** Browsers that still implement `discrete` `font-palette` animation will flip between the two palettes rather than smoothly animating.

palette-mix() CSS function

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`palette-mix()`** CSS function can be used to create a new `font-palette` value by blending together two `font-palette` values by specified percentages and color interpolation methods.

Syntax

```
/* Blending font-defined palettes */
font-palette: palette-mix(in lch, normal, dark)

/* Blending author-defined palettes */
font-palette: palette-mix(in lch, --blues, --yellows)

/* Varying percentage of each palette mixed */
font-palette: palette-mix(in lch, --blues 50%, --yellows 50%)
font-palette: palette-mix(in lch, --blues 70%, --yellows 30%)

/* Varying color interpolation method */
font-palette: palette-mix(in srgb, --blues, --yellows)
font-palette: palette-mix(in hsl, --blues, --yellows)
font-palette: palette-mix(in hsl shorter hue, --blues, --yellows)
```

Values

Functional notation:

```
palette-mix(method, palette1 [p1], palette2 [p2])
```

`method`

A `<color-interpolation-method>` specifying the interpolation color space.

`palette1`, `palette2`

The `font-palette` values to blend together. These can be *any* `font-palette` values, including `palette-mix()` functions, `normal`, `dark`, and `light`.

`p1`, `p2` Optional

`<percentage>` values between `0%` and `100%` specifying the amount of each palette to mix. They are normalized as follows:

- If both `p1` and `p2` are omitted, then `p1 = p2 = 50%`.
- If `p1` is omitted, then `p1 = 100% - p2`.
- If `p2` is omitted, then `p2 = 100% - p1`.
- If `p1 = p2 = 0%`, the function is invalid.
- If `p1 + p2 ≠ 100%`, then `p1' = p1 / (p1 + p2)` and `p2' = p2 / (p1 + p2)`, where `p1'` and `p2'` are the normalization results.

Formal syntax

```
<palette-mix()> =
  palette-mix( <color-interpolation-method>? , [ <'font-palette'> && <percentage [0,100]>? ]# )

<color-interpolation-method> =
  in [ <rectangular-color-space> | <polar-color-space> <hue-interpolation-method>? | <custom-color-space> ]

<font-palette> =
  normal                |
  light                 |
  dark                  |
  <palette-identifier>  |
  <palette-mix()>

<rectangular-color-space> =
  srgb               |
  srgb-linear        |
  display-p3         |
  display-p3-linear  |
  a98-rgb            |
  prophoto-rgb       |
  rec2020            |
  lab                |
  oklab              |
  <xyz-space>

<polar-color-space> =
  hsl    |
  hwb    |
  lch    |
  oklch

<hue-interpolation-method> =
  [ shorter | longer | increasing | decreasing ] hue

<custom-color-space> =
  <dashed-ident>

<palette-identifier> =
  <dashed-ident>

<xyz-space> =
  xyz      |
  xyz-d50  |
  xyz-d65
```

This syntax reflects the latest standard as per CSS Color Module Level 4, CSS Color Module Level 5, CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Using <code>palette-mix()</code> to blend two palettes

This example shows how to use the `palette-mix()` function to create a new palette by blending two others.

HTML

The HTML contains three paragraphs to apply our font information to:

```
<p class="yellowPalette">Yellow palette</p>
<p class="bluePalette">Blue palette</p>
<p class="mixedPalette">Mixed palette</p>
```

CSS

In the CSS, we import a color font from Google Fonts, and define two custom `font-palette` values using the `@font-palette-values` at-rule. We then apply three different `font-palette` values to the paragraphs — `--yellow`, `--blue`, and a new green palette, created using `palette-mix()` to blend the blue and yellow palettes together.

```
@import "https://fonts.googleapis.com/css2?family=Nabla&display=swap";

@font-palette-values --blue-nabla {
  font-family: "Nabla";
  base-palette: 2; /* this is Nabla's blue palette */
}

@font-palette-values --yellow-nabla {
  font-family: "Nabla";
  base-palette: 7; /* this is Nabla's yellow palette */
}

p {
  font-family: "Nabla", fantasy;
  font-size: 4rem;
  text-align: center;
  margin: 0;
}

.yellowPalette {
  font-palette: --yellow-nabla;
}

.bluePalette {
  font-palette: --blue-nabla;
}
```

```
.mixedPalette {
  font-palette: palette-mix(in lch, --blue-nabla 55%, --yellow-nabla 45%);
}
```

Result

The output looks like this:

font-size CSS property

The **`font-size`** CSS property sets the size of the font. Changing the font size also updates the sizes of the font size-relative `<length>` units, such as `em`, `ex`, and so forth.

Try it

```
font-size: 1.2rem;
```

```
font-size: x-small;
```

```
font-size: smaller;
```

```
font-size: 12px;
```

```
font-size: 80%;
```

```
<section id="default-example">
  <p id="example-element">
    London. Michaelmas term lately over, and the Lord Chancellor sitting in
    Lincoln's Inn Hall. Implacable November weather. As much mud in the streets
    as if the waters had but newly retired from the face of the earth, and it
    would not be wonderful to meet a Megalosaurus, forty feet long or so,
    waddling like an elephantine lizard up Holborn Hill.
  </p>
</section>
```

Syntax

```
/* <absolute-size> values */
font-size: xx-small;
font-size: x-small;
font-size: small;
font-size: medium;
font-size: large;
font-size: x-large;
font-size: xx-large;
font-size: xxx-large;

/* <relative-size> values */
font-size: smaller;
font-size: larger;

/* <length> values */
font-size: 12px;
font-size: 0.8em;

/* <percentage> values */
font-size: 80%;

/* math value */
font-size: math;

/* Global values */
font-size: inherit;
font-size: initial;
font-size: revert;
font-size: revert-layer;
font-size: unset;
```

Values

This property is specified as a single value from the following list:

`xx-small`, `x-small`, `small`, `medium`, `large`, `x-large`, `xx-large`, `xxx-large`

Absolute-size keywords, based on the user's default font size (which is `medium`).

`larger`, `smaller`

Relative-size keywords. The font will be larger or smaller relative to the parent element's font size, roughly by the ratio used to separate the absolute-size keywords above.

`<length>`

A positive `<length>` value. For most font-relative units (such as `em` and `ex`), the font size is relative to the parent element's font size.

For font-relative units that are root-based (such as `rem`), the font size is relative to the size of the font used by the `<html>` (root) element.

`<percentage>`

A positive `<percentage>` value, relative to the parent element's font size.

> **Note:** To maximize accessibility, it is generally best to use values that are relative to the user's default font size.

`math`

> Scaling rules are applied when determining the computed value of the `font-size` property for math elements relative to the `font-size` of the containing parent. See the math-depth property for more information.

Description

There are several ways to specify the font size, including keywords or numerical values for pixels or ems. Choose the appropriate method based on the needs of the particular web page.

Keywords

Keywords are a good way to set the size of fonts on the web. By setting a keyword font size on the `<body>` element, you can set relative font-sizing everywhere else on the page, giving you the ability to easily scale the font up or down on the entire page accordingly.

Pixels

Setting the font size in pixel values (`px`) is a good choice when you need pixel accuracy. A px value is static. This is an OS-independent and cross-browser way of literally telling the browsers to render the letters at exactly the number of pixels in height that you specified. The results may vary slightly across browsers, as they may use different algorithms to achieve a similar effect.

Font sizing settings can also be used in combination. For example, if a parent element is set to `16px` and its child element is set to `larger`, the child element displays larger than the parent element on the page.

> **Note:** Defining font sizes in `px` is *not accessible*, because the user cannot change the font size in some browsers. For example, users with limited vision may wish to set the font size much larger than the size chosen by a web designer. Avoid using them for font sizes if you wish to create an inclusive design.

Ems

Using an `em` value creates a dynamic or computed font size (historically the `em` unit was derived from the width of a capital "M" in a given typeface.). The numeric value acts as a multiplier of the `font-size` property of the element on which it is used. Consider this example:

```
p {
  font-size: 2em;
}
```

In this case, the font size of `<p>` elements will be double the computed `font-size` inherited by `<p>` elements. By extension, a `font-size` of `1em` equals the computed `font-size` of the element on which it is used.

If a `font-size` has not been set on any of the `<p>`'s ancestors, then `1em` will equal the default browser `font-size`, which is usually `16px`. So, by default `1em` is equivalent to `16px`, and `2em` is equivalent to `32px`. If you were to set a `font-size` of 20px on the `<body>` element say, then `1em` on the `<p>` elements would instead be equivalent to `20px`, and `2em` would be equivalent to `40px`.

In order to calculate the `em` equivalent for any pixel value required, you can use this formula:

```
em = desired element pixel value / parent element font-size in pixels
```

For example, suppose the `font-size` of the `<body>` of the page is set to `16px`. If the font-size you want is `12px`, then you should specify `0.75em` (because 12/16 = 0.75). Similarly, if you want a font size of `10px`, then specify `0.625em` (10/16 = 0.625); for `22px`, specify `1.375em` (22/16).

The `em` is a very useful unit in CSS since it automatically adapts its length relative to the font that the reader chooses to use.

One important fact to keep in mind: em values compound. Take the following HTML and CSS:

```
html {
  font-size: 100%;
}
span {
  font-size: 1.6em;
}
```

```
<div>
  <span>Outer <span>inner</span> outer</span>
</div>
```

The result is:

Assuming that the browser's default `font-size` is 16px, the words "outer" would be rendered at 25.6px, but the word "inner" would be rendered at 40.96px. This is because the inner `<span>`'s `font-size` is 1.6em which is relative to its parent's `font-size`, which is in turn relative to its parent's `font-size`. This is often called **compounding**.

Rems

`rem` values were invented in order to sidestep the compounding problem. `rem` values are relative to the root `html` element, not the parent element. In other words, it lets you specify a font size in a relative fashion without being affected by the size of the parent, thereby eliminating compounding.

The CSS below is nearly identical to the previous example. The only exception is that the unit has been changed to `rem`.

```
html {
  font-size: 100%;
}
span {
  font-size: 1.6rem;
}
```

Then we apply this CSS to the same HTML, which looks like this:

```
<span>Outer <span>inner</span> outer</span>
```

In this example, the words "outer inner outer" are all displayed at 25.6px (assuming that the browser's `font-size` has been left at the default value of 16px).

Ex

Like the `em` unit, an element's `font-size` set using the `ex` unit is computed or dynamic. It behaves in exactly the same way, except that when setting the `font-size` property using `ex` units, the `font-size` equals the x-height of the first available font used on the page. The number value multiplies the element's inherited `font-size` and the `font-size` compounds relatively.

See the W3C Editor's Draft for a more detailed description of font-relative length units such as `ex`.

Formal definition

Initial value	`medium`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Percentages	refer to the parent element's font size
Computed value	absolute `<length>`
Animation type	by computed value type

Formal syntax

```
font-size =
  <absolute-size>           |
  <relative-size>           |
  <length-percentage [0,∞]> |
  math

<absolute-size> =
  xx-small   |
  x-small    |
  small      |
  medium     |
  large      |
  x-large    |
  xx-large   |
  xxx-large

<relative-size> =
  larger   |
  smaller

<length-percentage> =
  <length>      |
  <percentage>
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4, CSS Values and Units Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting font sizes

CSS

```
.small {
  font-size: xx-small;
}
.larger {
  font-size: larger;
}
.point {
  font-size: 24pt;
}
.percent {
  font-size: 200%;
}
```

HTML

```
<h1 class="small">Small H1</h1>
<h1 class="larger">Larger H1</h1>
<h1 class="point">24 point H1</h1>
<h1 class="percent">200% H1</h1>
```

font-size-adjust CSS property

The **`font-size-adjust`** CSS property adjusts the size of a font to match a chosen font metric, such as the height of lowercase letters, to a specified proportion of the `font-size`. This property is intended for adjusting fallback fonts to have similar metrics as the first-choice font.

Legibility can become an issue when the first-choice `font-family` is unavailable and its replacement fallback font has a significantly different aspect value (height of lowercase letters divided by font size). Legibility of fonts, especially at small font sizes, is determined more by the size of lowercase letters than by the size of uppercase letters. The `font-size-adjust` property is useful for adjusting the font size of fallback fonts to keep the aspect value across fonts consistent, ensuring that the text appears similar regardless of the font used.

Syntax

```
/* Keyword value */
font-size-adjust: none;

/* One value: <number> or from-font */
font-size-adjust: 0.5;
font-size-adjust: from-font;

/* Two values */
font-size-adjust: ex-height 0.5;
font-size-adjust: ch-width from-font;
```

```
/* Global values */
font-size-adjust: inherit;
font-size-adjust: initial;
font-size-adjust: revert;
font-size-adjust: revert-layer;
font-size-adjust: unset;
```

Values

This property is specified as the keyword `none`, or one (`<number>` or `from-font`) or two (`<font-metric>` and either `<number>` or `from-font`) values.

`none`

No font size adjustment is applied.

`<font-metric>` Optional

Defines the font metric to use for adjusting the font size. Defaulting to `ex-height`, this parameter is specified as one of the following keywords:

`ex-height`

Uses the ratio of x-height (height of lowercase "x" in a font) to font size (aspect value) to adjust the font size. This keyword value is used to normalize lowercase letters across fonts.

`cap-height`

Uses the ratio of cap-height (height of uppercase letters) to font size to adjust the font size. This keyword value is used to normalize uppercase letters across fonts.

`ch-width`

Uses the ratio of the advance width (horizontal space taken up by a character in a font) of the character "0" (ZERO, U+0030) to font size. This keyword value is used to normalize horizontal narrow pitch of fonts.

`ic-width`

Uses the ratio of the advance width of the character "水" (CJK water ideograph, U+6C34) to font size. This keyword value is used to normalize horizontal wide pitch of fonts, particularly those that include CJK (Chinese, Japanese, Korean) characters.

`ic-height`

Uses the ratio of the advance height (vertical space taken up by a character in a font) of the character "水" (CJK water ideograph, U+6C34) to font size. This keyword value is used to normalize vertical wide pitch of fonts, particularly those that include CJK characters.

`<number>`

The proportion to adjust the font size used, depending on the specified `<font-metric>`.

When a `<font-metric>` value is specified, the `<number>` value adjusts the font size as per the chosen `<font-metric>` to maintain a consistent appearance for the specified font metric across different fonts.

The `<number>` value accepts any number from `0` to infinity. `0` yields text of zero height (that is, the text is hidden). Negative values are invalid.

`from-font`

Uses the `<number>` value for the specified `<font-metric>` from the first available font.

Description

The `font-size-adjust` property adjusts the size of a font to match a chosen font metric, such as the height of lowercase letters, to a specified proportion of the `font-size`. The adjustment is applied to each font used to render text, not only to fallback fonts.

Setting a `<number>` adjusts the font size based on the default or stated `<font-metric>`. For example, when set to `ex-height`, the `<number>` value adjusts the selected font size so the height of its `x` glyph is the specified multiple of the font size. This value should generally match the aspect value (ratio of x-height to font size) of the first-choice font. This means that the first-choice font, when available, will display consistently across browsers. Selecting a different value also scales the first-choice font, but in this case, you should prefer to change the `font-size` instead.

> **Note:** If the specified `<font-metric>` has been overridden in `@font-face`, e.g., by using the `size-adjust` descriptor, then the overridden metric will be used in the `font-size-adjust` calculation. This means that when `font-size-adjust` and `size-adjust` are applied together, `size-adjust` does not have any effect.

> **Note:** Font metrics like x-height and cap height can vary between font faces (such as bold or italic variants) within the same `font-family`. When `font-size-adjust` uses `from-font` or a fixed value, the metrics of each font face are adjusted independently, regardless of the relative differences between font faces in the same font family.

The adjusted font size is calculated using the formula `u = ( m / m' ) s`, where:

- `m` is the desired ratio specified by `<number>` or obtained using `from-font`.
- `m'` is the ratio of the chosen metric to the font size in the font being adjusted.
- `s` is the value of the `font-size` property.
- `u` is the new, adjusted font size.

Consider this example to see how the adjusted font size is calculated. A first-choice font has a `font-size` of `12px` (`s`), and the ratio of `cap-height` to font size is `0.20` (`m`). The `cap-height` to font size ratio in the fallback font is `0.15` (`m'`). The `font-size-adjust` value has been specified as `cap-height 0.20`. If the primary font is unavailable, the adjusted font size of the fallback font will be calculated to be `16px` (`(0.20 / 0.15) * 12`). This will ensure that the `cap-height` of the fallback font is similar to that of the first-choice font when displayed.

Formal definition

Initial value	none
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	a number

Formal syntax

```
font-size-adjust =
  none                                          |
  [ ex-height | cap-height | ch-width | ic-width | ic-height ]? [ from-font | <number [0,∞]> ]
```

This syntax reflects the latest standard as per CSS Fonts Module Level 5. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Normalizing font size by lowercase and uppercase letters

This example demonstrates how the `font-size-adjust` property can be used to retain the same aspect value across fonts. The Verdana font has a relatively high aspect value of `0.545`, which means that the lowercase letters are relatively tall compared to uppercase letters. This makes the text in small font sizes appear legible. However, the Times font has a lower aspect value of `0.447`, so the text is less legible at small sizes. If Verdana is the first-choice font and Times is the fallback font, specifying the `font-size-adjust` property can help to retain the same aspect value in Times. So if the font falls back to Times, the text will maintain a similar level of legibility as it would have with Verdana.

Similarly, the cap-height to font size ratio in Verdana is `0.73` and that in Times is `0.66`. When `font-size-adjust` property is applied to Times to adjust its uppercase letters to match the ratio in Verdana, the Times font displays in adjusted font size ((0.73 / 0.66) * 14) `15.48px`.

```
<p class="verdana">
  A: This text uses the Verdana font (14px), which has relatively large
  lowercase letters.
</p>
<p class="times">
  B: This text uses the Times font (14px), which is hard to read in small sizes.
</p>
<p class="times adj-times-ex-height">
  C: This text in 14px Times font is adjusted to the same aspect value as the
  Verdana font, so lowercase letters are normalized across the two fonts.
</p>
<p class="times adj-times-cap-height">
  D: This text in 14px Times font is adjusted to the same cap-height to font
  size ratio as the Verdana font, so uppercase letters are normalized across the
  two fonts.
</p>
```

```
.times {
  font-family: "Times", serif;
  font-size: 14px;
}

.verdana {
  font-family: "Verdana", sans-serif;
  font-size: 14px;
}

.adj-times-ex-height {
  font-size-adjust: 0.545;
}

.adj-times-cap-height {
  font-size-adjust: cap-height 0.73;
}
```

Without `font-size-adjust` in `B`, the switch from Verdana font to Times font could result in a noticeable decrease in legibility due to its lower aspect value. In `C`, notice that only one value is specified for the `font-size-adjust` property, so the default `<font-metric>` value `ex-height` is used. `D` shows how the font would look compared to `A` if its uppercase letter height is adjusted.

Determining the aspect value of a font

For a given font, the same content in two side-by-side `<span>` elements can be used to determine the font's aspect value. If the same font size is used for content in both spans, the spans will match when the `font-size-adjust` value in one span is accurate for the given font.

In the example below, there are three pairs of side-by-side `<span>` elements, each containing the letter "b". The goal is to adjust the `font-size-adjust` property for the right `<span>` in each pair until the borders around the two letters align. The resulting `font-size-adjust` value can be considered the aspect value for the font.

Starting at `0.6` in the first pair and adjusting to `0.5` in the second, we continue adjusting the `font-size-adjust` property value until the borders around the "b" letters align perfectly in the third pair. In this example, the aspect value is determined to be `0.482`.

```
<div>
  <p><span>b</span><span class="adjust1">b</span></p>
  0.6
</div>

<div>
  <p><span>b</span><span class="adjust2">b</span></p>
  0.5
</div>

<div>
  <p><span>b</span><span class="adjust3">b</span></p>
  0.482
</div>
```

```
body {
  display: flex;
}

div {
  text-align: center;
}

p {
  margin: 0 30px 10px 30px;
}
```

```
body {
  display: flex;
}

div {
  text-align: center;
}

p {
```

```
  font-family: "Futura", sans-serif;
  font-size: 50px;
}

span {
  border: solid 1px red;
}

.adjust1 {
  font-size-adjust: 0.6;
}

.adjust2 {
  font-size-adjust: 0.5;
}

.adjust3 {
  font-size-adjust: 0.482;
}
```

font-smooth CSS property

> **Non-standard:** This feature is not standardized. We do not recommend using non-standard features in production, as they have limited browser support, and may change or be removed. However, they can be a suitable alternative in specific cases where no standard option exists.

The **`font-smooth`** CSS property controls the application of anti-aliasing when fonts are rendered.

Syntax

```
/* Keyword values */
font-smooth: auto;
font-smooth: never;
font-smooth: always;

/* <length> value */
font-smooth: 2em;

/* Global values */
font-smooth: inherit;
font-smooth: initial;
font-smooth: revert;
font-smooth: revert-layer;
font-smooth: unset;
```

> **Note:** WebKit implements a similar property, but with different values: **`-webkit-font-smoothing`**. It only works on macOS.
>
> - `auto` - Let the browser decide (Uses subpixel anti-aliasing when available; this is the default)
> - `none` - Turn font smoothing off; display text with jagged sharp edges.
> - `antialiased` - Smooth the font on the level of the pixel, as opposed to the subpixel. Switching from subpixel rendering to anti-aliasing for light text on dark backgrounds makes it look lighter.
> - `subpixel-antialiased` - On most non-retina displays, this will give the sharpest text.

> **Note:** Firefox implements a similar property, but with different values: **`-moz-osx-font-smoothing`**. It only works on macOS.
>
> - `auto` - Allow the browser to select an optimization for font smoothing, typically `grayscale`.
> - `grayscale` - Render text with grayscale anti-aliasing, as opposed to the subpixel. Switching from subpixel rendering to anti-aliasing for light text on dark backgrounds makes it look lighter.

Formal definition

Initial value	`auto`
Applies to	all elements
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
font-smooth =
  auto            |
  never           |
  always          |
  <absolute-size> |
  <length>

<absolute-size> =
  xx-small   |
  x-small    |
  small      |
  medium     |
  large      |
  x-large    |
  xx-large   |
  xxx-large
```

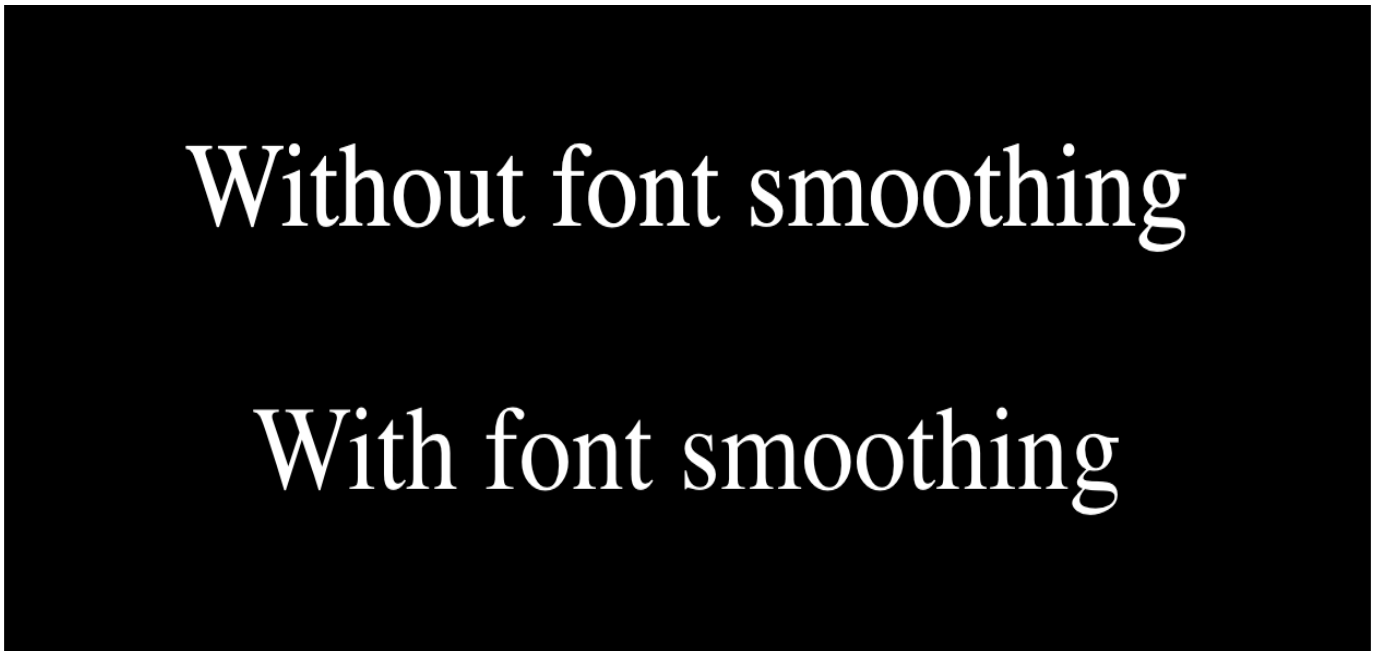
This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Basic usage example

The following example shows the Safari/Chromium and Firefox equivalents that turn on font-smoothing on macOS. In both cases the smoothed font should look slightly lighter in weight.

For those of you not on a macOS system, here is a screenshot (the live version appears later on):



HTML

```
<p>Without font smoothing</p>

<p class="smoothed">With font smoothing</p>
```

CSS

```
html {
  background-color: black;
  color: white;
  font-size: 3rem;
}

p {
  text-align: center;
}

.smoothed {
  -webkit-font-smoothing: antialiased;
  -moz-osx-font-smoothing: grayscale;
}
```

Result

Specifications

Not part of any standard.

font-stretch CSS property

> **Note:** The `font-stretch` property was renamed to `font-width` in the CSS Fonts specification. To preserve compatibility, the specification retains `font-stretch` as a legacy alias for the `font-width` property.

The **`font-stretch`** CSS property selects a normal, condensed, or expanded face from a font.

Try it

```
font-stretch: condensed;
```

```
font-stretch: expanded;
```

```
font-stretch: ultra-expanded;
```

```
font-stretch: 50%;
```

```
font-stretch: 100%;
```

```
font-stretch: 150%;
```

```
<section class="default-example" id="default-example">
  <p class="transition-all" id="example-element">
    London. Michaelmas term lately over, and the Lord Chancellor sitting in
    Lincoln's Inn Hall. Implacable November weather. As much mud in the streets
    as if the waters had but newly retired from the face of the earth, and it
    would not be wonderful to meet a Megalosaurus, forty feet long or so,
    waddling like an elephantine lizard up Holborn Hill.
  </p>
</section>
```

```
@font-face {
  src: url("/shared-assets/fonts/LeagueMono-VF.ttf") format("truetype");
  font-family: "League";
  font-style: normal;
  font-weight: normal;
}

section {
  font-size: 1.2em;
  font-family: "League", sans-serif;
}
```

Syntax

```
/* Keyword values */
font-stretch: normal;
font-stretch: ultra-condensed;
font-stretch: extra-condensed;
font-stretch: condensed;
font-stretch: semi-condensed;
font-stretch: semi-expanded;
font-stretch: expanded;
font-stretch: extra-expanded;
font-stretch: ultra-expanded;

/* Percentage values */
font-stretch: 50%;
font-stretch: 100%;
font-stretch: 200%;

/* Global values */
font-stretch: inherit;
font-stretch: initial;
font-stretch: revert;
font-stretch: revert-layer;
font-stretch: unset;
```

Values

This property is specified as a single value from the following list:

`normal`

Specifies a normally condensed font face.

`semi-condensed`, `condensed`, `extra-condensed`, `ultra-condensed`

Specifies a more condensed font face than normal, with `ultra-condensed` being the most condensed.

`semi-expanded`, `expanded`, `extra-expanded`, `ultra-expanded`

Specifies a more expanded font face than normal, with `ultra-expanded` being the most expanded.

`<percentage>`

A `<percentage>` value between 50% and 200% (inclusive). Negative values are not allowed for this property.

Keyword to numeric mapping

The table below shows the mapping between the keyword values and numeric percentages:

Keyword	Percentage
`ultra-condensed`	50%
`extra-condensed`	62.5%
`condensed`	75%
`semi-condensed`	87.5%
`normal`	100%
`semi-expanded`	112.5%
`expanded`	125%
`extra-expanded`	150%
`ultra-expanded`	200%

Description

Some font families offer additional faces in which the characters are narrower than the normal face (*condensed* faces) or wider than the normal face (*expanded* faces).

You can use `font-stretch` to select a condensed or expanded face from such fonts. If the font you are using does not offer condensed or expanded faces, this property has no effect.

Font face selection

The face selected for a given value of `font-stretch` depends on the faces supported by the font in question. If the font does not provide a face that exactly matches the given value, then values less than `100%` map to a condensed face, and values greater than or equal to `100%` map to an expanded face.

The table below demonstrates the effect of setting different percentage values of `font-stretch` on two different fonts:

```css
@font-face {
  font-family: "Inconsolata";
  src: url("https://fonts.gstatic.com/s/inconsolata/v31/QldduNThLqRwH-OJ1UHjlKENVzlm-WkL3GZQmAwPyya15.woff2")
    format("woff2");
}

@font-face {
  font-family: "Anek Malayalam";
  src: url("https://fonts.gstatic.com/s/anekmalayalam/v4/6qLUKZActRTs_mZAJUZWWkhke0nYa-f6__Azq3-gP1W7db9_.woff2")
    format("woff2");
}

body {
  font-family: system-ui;
}

table {
  border-collapse: collapse;
  width: 100%;
}

tbody th {
  text-align: right;
}

th,
td {
  padding: 0.25rem;
  font-weight: normal;
  text-align: center;
}

td {
  border: solid;
  border-width: 1px;
  font-size: 5rem;
}

.inconsolata {
  font-family: "Inconsolata", sans-serif;
}

.anek-malayalam {
  font-family: "Anek Malayalam", sans-serif;
}

td:nth-child(2) {
  font-stretch: 50%;
}
td:nth-child(3) {
  font-stretch: 62.5%;
}
td:nth-child(4) {
  font-stretch: 75%;
}
td:nth-child(5) {
  font-stretch: 87.5%;
}
td:nth-child(6) {
  font-stretch: 100%;
}
td:nth-child(7) {
  font-stretch: 112.5%;
}
td:nth-child(8) {
  font-stretch: 125%;
}
td:nth-child(9) {
  font-stretch: 150%;
}
td:nth-child(10) {
  font-stretch: 200%;
}
```

```html
<table>
  <thead>
    <tr>
      <th scope="row"></th>
      <th scope="col">50%</th>
      <th scope="col">62.5%</th>
      <th scope="col">75%</th>
      <th scope="col">87.5%</th>
      <th scope="col">100%</th>
      <th scope="col">112.5%</th>
      <th scope="col">125%</th>
      <th scope="col">150%</th>
      <th scope="col">200%</th>
    </tr>
  </thead>
  <tbody>
    <tr class="inconsolata">
      <th scope="row">Inconsolata</th>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
    </tr>
```

```
    <tr class="anek-malayalam">
      <th scope="row">Anek Malayalam</th>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
      <td>e</td>
    </tr>
  </tbody>
</table>
```

- Inconsolata is a variable font that offers a continuous range of widths from 50% to 200%.
- Anek Malayalam is a variable google font that supports widths from 75% to 125%. Values below and above this range select the closest matching font.

Formal definition

Initial value	`normal`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	by computed value type

Formal syntax

```
font-stretch =
  normal              |
  <percentage [0,∞]>  |
  ultra-condensed     |
  extra-condensed     |
  condensed           |
  semi-condensed      |
  semi-expanded       |
  expanded            |
  extra-expanded      |
  ultra-expanded
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Setting font stretch percentages

```
<p class="condensed">an elephantine lizard</p>
<p class="normal">an elephantine lizard</p>
<p class="expanded">an elephantine lizard</p>
```

```
@font-face {
  src: url("/shared-assets/fonts/LeagueMono-VF.ttf") format("truetype");
  font-family: "LeagueMonoVariable";
  font-style: normal;
}

p {
  font:
    1.5rem "LeagueMonoVariable",
    sans-serif;
}

.condensed {
  font-stretch: 50%;
}

.normal {
  font-stretch: 100%;
}

.expanded {
  font-stretch: 200%;
}
```

See also

- CSS fonts module

font-style CSS property

The **`font-style`** CSS property sets whether a font should be styled with a normal, italic, or oblique face from its `font-family`.

Italic font faces are generally cursive in nature, usually using less horizontal space than their unstyled counterparts, while **oblique** faces are usually just sloped versions of the regular face. When the specified style is not available, both italic and oblique faces are simulated by artificially sloping the glyphs of the regular face (use `font-synthesis` to control this behavior).

Try it

```
font-style: normal;
```

```
font-style: italic;
```

```
font-style: oblique;
```

```
font-style: oblique 40deg;
```

```
<section id="default-example">
  <p id="example-element">
    London. Michaelmas term lately over, and the Lord Chancellor sitting in
    Lincoln's Inn Hall. Implacable November weather. As much mud in the streets
    as if the waters had but newly retired from the face of the earth, and it
    would not be wonderful to meet a Megalosaurus, forty feet long or so,
    waddling like an elephantine lizard up Holborn Hill.
  </p>
</section>
```

```
@font-face {
  src: url("/shared-assets/fonts/variable-fonts/AmstelvarAlpha-VF.woff2");
  font-family: "Amstelvar";
  font-style: normal;
}

section {
  font-size: 1.2em;
  font-family: "Amstelvar", serif;
}
```

Syntax

```
font-style: normal;
font-style: italic;
font-style: oblique;
font-style: oblique 10deg;

/* Global values */
font-style: inherit;
font-style: initial;
font-style: revert;
font-style: revert-layer;
font-style: unset;
```

Values

This property is specified as one of the following keyword values. The `oblique` keyword can optionally be followed by an `<angle>`:

`normal`

Selects a font that is classified as `normal` within a `font-family`.

`italic`

Selects a font that is classified as `italic`. If no italic version of the face is available, one classified as `oblique` is used instead. If neither is available, the style is artificially simulated.

`oblique`

Selects a font that is classified as `oblique`. If no oblique version of the face is available, one classified as `italic` is used instead. If neither is available, the style is artificially simulated.

`oblique <angle>`

Selects a font classified as `oblique`, and additionally specifies an angle for the slant of the text. If one or more oblique faces are available in the chosen font family, the one that most closely matches the specified angle is chosen. If no oblique faces are available, the browser will synthesize an oblique version of the font by slanting a normal face by the specified amount. Valid values are degree values of `-90deg` to `90deg` inclusive. If an angle is not specified, an angle of 14 degrees is used. Positive values are slanted to the end of the line, while negative values are slanted towards the beginning.

In general, for a requested angle of 14 degrees or greater, larger angles are preferred; otherwise, smaller angles are preferred (see the spec's font matching section for the precise algorithm).

The CSS fonts module also defines `left` and `right` values to select an italic or oblique face with a specific slant direction; however, these values are not supported in any browsers.

Variable fonts

Variable fonts can offer a fine control over the degree to which an oblique face is slanted. You can select this using the `<angle>` modifier for the `oblique` keyword.

For TrueType or OpenType variable fonts, the `"slnt"` variation is used to implement varying slant angles for oblique, and the `"ital"` variation with a value of 1 is used to implement italic values. See `font-variation-settings`.

Click "Play" in the code blocks below to edit the example in the MDN Playground. Change the angle value to see the slant of the text change.

```
<p class="sample">
  ...it would not be wonderful to meet a Megalosaurus, forty feet long or so,
  waddling like an elephantine lizard up Holborn Hill.
</p>
```

```
@font-face {
  src: url("https://mdn.github.io/shared-assets/fonts/variable-fonts/AmstelvarAlpha-VF.woff2");
  font-family: "AmstelvarAlpha";
  font-style: normal;
}

.sample {
  font:
    2rem "AmstelvarAlpha",
    sans-serif;
  /* font-variation-settings: "slnt" 12; */
  font-style: oblique 23deg;
}
```

Accessibility

Large sections of text set with a `font-style` value of `italic` may be difficult for people with cognitive concerns such as Dyslexia to read.

- MDN Understanding WCAG, Guideline 1.4 explanations
- W3C Understanding WCAG 2.2

Formal definition

Initial value	`normal`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	by computed value type; `normal` animates as `oblique 0deg`

Formal syntax

```
font-style =
  normal                          |
  italic                          |
  left                            |
  right                           |
  oblique <angle [-90deg,90deg]>?
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Font styles

```
<p class="normal">This paragraph is normal.</p>
<p class="italic">This paragraph is italic.</p>
<p class="oblique">This paragraph is oblique.</p>
```

```
.normal {
  font-style: normal;
}

.italic {
  font-style: italic;
}

.oblique {
  font-style: oblique;
}
```

font-synthesis CSS property

The **`font-synthesis`** CSS shorthand property lets you specify whether or not the browser may synthesize the bold, italic, small-caps, and/or subscript and superscript typefaces when they are missing in the specified font-family.

Try it

```
font-synthesis: weight style small-caps;
```

```
font-synthesis: none;
```

```
font-synthesis: weight;
```

```
font-synthesis: style;
```

```
font-synthesis: small-caps;
```

```
font-synthesis: position;
```

```
<section class="default-example" id="default-example">
  <div class="transition-all" id="example-element">
    <p class="english">
      This font does not include <span class="bold">bold</span>,
      <span class="italic">italic</span>,
      <span class="small-caps">small-caps</span>, and
      <span class="sub">subscript</span> or
      <span class="sup">superscript</span> variants.
    </p>
    <p class="chinese">
      中文排版通常不用<span class="bold">粗体</span>或<span class="italic"
        >斜体</span
      >，也不会使用<span class="small-caps">小型大写字母</span>和<span
        class="sub"
        >下标</span
      ><span class="sup">上标</span>变体。
    </p>
  </div>
</section>
```

```
@import "https://fonts.googleapis.com/css2?family=Oxygen&display=swap";
@import "https://fonts.googleapis.com/css2?family=Ma+Shan+Zheng&display=swap";

.english {
  font-size: 1.2em;
  font-family: "Oxygen", sans-serif;
}

.chinese {
```

```
  font-size: 1.2em;
  font-family: "Ma Shan Zheng", cursive;
}

.bold {
  font-weight: bold;
}

.italic {
  font-style: italic;
}

.small-caps {
  font-variant: small-caps;
}

.sub {
  font-variant: sub;
}

.sup {
  font-variant: super;
}
```

Constituent properties

This property is a shorthand for the following CSS properties:

- font-synthesis-weight
- font-synthesis-style
- font-synthesis-small-caps
- font-synthesis-position

Syntax

```
/* none or one or more of the other keyword values */
font-synthesis: none;
font-synthesis: weight;
font-synthesis: style;
font-synthesis: position;
font-synthesis: small-caps style; /* property values can be in any order */
font-synthesis: style small-caps weight position; /* property values can be in any order */

/* Global values */
font-synthesis: inherit;
font-synthesis: initial;
font-synthesis: revert;
font-synthesis: revert-layer;
font-synthesis: unset;
```

Values

This property is specified as one of the following keyword values:

`none`

Indicates that no bold, italic, or small-caps typeface may be synthesized by the browser.

`weight`

Indicates that the missing bold typeface may be synthesized by the browser if needed.

`style`

Indicates that the italic typeface may be synthesized by the browser if needed.

`small-caps`

Indicates that the small-caps typeface may be synthesized by the browser if needed.

`position`

Indicates that the subscript and superscript typeface may be synthesized by the browser, if needed, when using `font-variant-position`.

Description

Most standard Western fonts include italic and bold variants, and some fonts include a small-caps and subscript/superscript variants. However, many fonts do not. Fonts used for Chinese, Japanese, Korean and other logographic scripts tend not to include these variants and synthesizing them might impede the legibility or change the meaning of the text. In these cases, it may be desirable to switch off the browser's default font-synthesis.

For example, using the :lang() pseudo-class, you can disable the browser from synthesizing bold and oblique characters for a language, in this case Arabic:

```
*:lang(ar) {
  font-synthesis: none;
}
```

The table below shows how a value of the shorthand `font-synthesis` property maps to the constituent longhand properties.

font-synthesis value	font-synthesis-weight value	font-synthesis-style value	font-synthesis-small-caps value	font-synthesis-position value
none	none	none	none	none
weight	auto	none	none	none
style	none	auto	none	none
small-caps	none	none	auto	none
position	none	none	none	auto
weight style	auto	auto	none	none
weight small-caps	auto	none	auto	none

font-synthesis value	font-synthesis-weight value	font-synthesis-style value	font-synthesis-small-caps value	font-synthesis-position value
weight position	auto	none	none	auto
style small-caps	none	auto	auto	none
style position	none	auto	none	auto
weight style small-caps	auto	auto	auto	none
weight style position	auto	auto	none	auto
weight small-caps position	auto	none	auto	auto
style small-caps position	none	auto	auto	auto
weight style small-caps position	auto	auto	auto	auto

Formal definition

Initial value	`weight style small-caps position`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
font-synthesis =
  none                                    |
  [ weight || style || small-caps || position ]
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Disabling font synthesis

This example shows the browser's default font-synthesis behavior and compares it with when the synthesis behavior is turned off. Notice that the example uses two imported fonts to demonstrate this behavior. You might not be able to replicate turning off of font-synthesis on fonts available on your operating system by default.

HTML

```
<pre> DEFAULT </pre>
<p class="english">
  This font supports <strong>bold</strong> and <em>italic</em>.
</p>
<p class="chinese">这个字体支持<strong>加粗</strong>和<em>斜体</em></p>
<br />

<pre> SYNTHESIS IS DISABLED </pre>
<p class="english no-syn">
  This font supports <strong>bold</strong> and <em>italic.</em>
</p>
<p class="chinese no-syn">这个字体支持<strong>加粗</strong>和<em>斜体</em></p>
<br />

<pre> SYNTHESIS IS ENABLED </pre>
<p class="english">
  This font supports <strong>bold</strong> and <em>italic</em>.
</p>
<p class="chinese syn">这个字体支持<strong>加粗</strong>和<em>斜体</em></p>
```

CSS

```
@import "https://fonts.googleapis.com/css2?family=Montserrat&display=swap";
@import "https://fonts.googleapis.com/css2?family=Ma+Shan+Zheng&display=swap";

.english {
  font-family: "Montserrat", sans-serif;
}
.chinese {
  font-family: "Ma Shan Zheng", cursive;
}
.no-syn {
  font-synthesis: none;
}
.syn {
  font-synthesis: style weight;
}
```

font-synthesis-position CSS property

> **Experimental: This is an experimental technology**
> Check the Browser compatibility table carefully before using this in production.

The **`font-synthesis-position`** CSS property lets you specify whether or not a browser may synthesize the subscript and superscript "position" typefaces when they are missing in a font family, while using `font-variant-position` to set the positions.

The **`font-synthesis-position`** property has no effect when using the `<sup>` and `<sub>` elements.

It is often convenient to use the shorthand property `font-synthesis` to control all typeface synthesis values.

Syntax

```
/* Keyword values */
font-synthesis-position: auto;
font-synthesis-position: none;

/* Global values */
font-synthesis-position: inherit;
font-synthesis-position: initial;
font-synthesis-position: revert;
font-synthesis-position: revert-layer;
font-synthesis-position: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

Indicates that a missing position typeface may be synthesized by the browser if needed.

`none`

Indicates that the synthesis of a missing position typeface by the browser is not allowed.

Formal definition

Initial value	none
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
font-synthesis-position =
  auto  |
  none
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Disabling synthesis of position typeface

This example shows turning off synthesis of the superscript and subscript typefaces by the browser in the `Montserrat` font.

HTML

```
<p>
  These are the default position <span class="super">superscript</span>,
  position <span class="sub">subscript</span>, <strong>bold</strong> and
  <em>oblique</em> typefaces.
</p>

<p class="no-syn">
  The positions <span class="super">superscript</span> and
  <span class="sub">subscript</span> typeface is turned off here but not the
  <strong>bold</strong> and <em>oblique</em> typefaces (on browsers that support
  <code>font-synthesis-position</code>).
</p>
```

CSS

```
@import "https://fonts.googleapis.com/css2?family=Montserrat&display=swap";

* {
  font-family: "Montserrat", sans-serif;
}
.super {
  font-variant-position: super;
}
.sub {
  font-variant-position: sub;
}
.no-syn {
  font-synthesis-position: none;
}
```

font-synthesis-small-caps CSS property

The **`font-synthesis-small-caps`** CSS property lets you specify whether or not the browser may synthesize small-caps typeface when it is missing in a font family. Small-caps glyphs typically use the form of uppercase letters but are reduced to the size of lowercase letters.

It is often convenient to use the shorthand property `font-synthesis` to control all typeface synthesis values.

Syntax

```
/* Keyword values */
font-synthesis-small-caps: auto;
font-synthesis-small-caps: none;

/* Global values */
font-synthesis-small-caps: inherit;
font-synthesis-small-caps: initial;
font-synthesis-small-caps: revert;
font-synthesis-small-caps: revert-layer;
font-synthesis-small-caps: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

Indicates that the missing small-caps typeface may be synthesized by the browser if needed.

`none`

Indicates that the synthesis of the missing small-caps typeface by the browser is not allowed.

Formal definition

Initial value	`auto`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
font-synthesis-small-caps =
  auto  |
  none
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Disabling synthesis of small-caps typeface

This example shows turning off synthesis of the small-caps typeface by the browser in the `Montserrat` font.

HTML

```
<p class="english">
  These are the default <span class="small-caps">small-caps</span>,
  <strong>bold</strong>, and <em>oblique</em> typefaces.
</p>

<p class="english no-syn">
  The <span class="small-caps">small-caps</span> typeface is turned off here but
  not the <strong>bold</strong> and <em>oblique</em> typefaces.
</p>
```

CSS

```
@import "https://fonts.googleapis.com/css2?family=Montserrat&display=swap";

.english {
  font-family: "Montserrat", sans-serif;
}
.small-caps {
  font-variant: small-caps;
}
.no-syn {
  font-synthesis-small-caps: none;
}
```

Result

font-synthesis-style CSS property

The **`font-synthesis-style`** CSS property lets you specify whether or not the browser may synthesize the oblique typeface when it is missing in a font family.

It is often convenient to use the shorthand property `font-synthesis` to control all typeface synthesis values.

Syntax

```
/* Keyword values */
font-synthesis-style: auto;
font-synthesis-style: none;
font-synthesis-style: oblique-only;

/* Global values */
font-synthesis-style: inherit;
font-synthesis-style: initial;
font-synthesis-style: revert;
```

```
font-synthesis-style: revert-layer;
font-synthesis-style: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

Indicates that the missing oblique typeface may be synthesized by the browser if needed.

`none`

Indicates that the synthesis of the missing oblique typeface by the browser is *not* allowed.

`oblique-only`

Same as `auto`, but no font synthesis occurs if `font-style: italic` is set.

Formal definition

Initial value	`auto`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
font-synthesis-style =
  auto          |
  none          |
  oblique-only
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Disabling synthesis of oblique typeface

This example shows turning off synthesis of the oblique typeface by the browser in the `Montserrat` font.

HTML

```
<p class="english">
  This is the default <em>oblique typeface</em> and
  <strong>bold typeface</strong>.
</p>

<p class="english no-syn">
  The <em>oblique typeface</em> is turned off here but not the
  <strong>bold typeface</strong>.
</p>
```

CSS

```
@import "https://fonts.googleapis.com/css2?family=Montserrat&display=swap";

.english {
  font-family: "Montserrat", sans-serif;
}

.no-syn {
  font-synthesis-style: none;
}
```

Result

Comparison of font-synthesis-style values

This example compares all the `font-synthesis-style` values using italic and oblique styled texts.

HTML

```
<div class="fss-none">
  <h2>font-synthesis-style: none</h2>
  <p class="oblique">This text is set to <code>oblique</code></p>
  <p class="italic">This text is set to <code>italic</code></p>
</div>

<div class="fss-auto">
  <h2>font-synthesis-style: auto</h2>
  <p class="oblique">This text is set to <code>oblique</code></p>
  <p class="italic">This text is set to <code>italic</code></p>
</div>

<div class="fss-oblique-only">
  <h2>font-synthesis-style: oblique-only</h2>
  <p class="oblique">This text is set to <code>oblique</code></p>
  <p class="italic">This text is set to <code>italic</code></p>
</div>
```

CSS

```
@import "https://fonts.googleapis.com/css2?family=Montserrat&display=swap";

p {
  font-family: "Montserrat", sans-serif;
  font-size: 1.2rem;
```

```
}

@supports not (font-synthesis-style: oblique-only) {
  body::before {
    content: "Your browser doesn't support the 'oblique-only' value.";
    background-color: wheat;

font-synthesis-weight CSS property

The **`font-synthesis-weight`** CSS property lets you specify whether or not the browser may synthesize the bold typeface when it is missing in a font family.

It is often convenient to use the shorthand property `font-synthesis` to control all typeface synthesis values.

Syntax

```
/* Keyword values */
font-synthesis-weight: auto;
font-synthesis-weight: none;

/* Global values */
font-synthesis-weight: inherit;
font-synthesis-weight: initial;
font-synthesis-weight: revert;
font-synthesis-weight: revert-layer;
font-synthesis-weight: unset;
```

Values

This property is specified as one of the following keyword values:

`auto`

Indicates that the missing bold typeface may be synthesized by the browser if needed.

`none`

Indicates that the synthesis of the missing bold typeface by the browser is not allowed.

Formal definition

Initial value	`auto`
Applies to	all elements and text. It also applies to `::first-letter` and `::first-line`.
Inherited	yes
Computed value	as specified
Animation type	discrete

Formal syntax

```
font-synthesis-weight =
  auto  |
  none
```

This syntax reflects the latest standard as per CSS Fonts Module Level 4. Not all browsers may have implemented every part. See Browser compatibility for support information.

Examples

Disabling synthesis of bold typeface

This example shows turning off synthesis of the bold typeface by the browser in the `Montserrat` font.

HTML

```
<p class="english">
  This is the default <strong>bold typeface</strong> and
  <em>oblique typeface</em>.
</p>
